5 Configuring MPLS BFD

i The routers and router icons described in this chapter refer to general routers as well as Layer-3 switches running routing protocols. We use "router series" or "switch series" to refer to specific devices.

5.1 Overview

MPLS Bidirectional Forwarding Detection (BFD) is implemented based on *BFD for MPLS LSPs* defined by the IETF. As a part of BFD application, it describes a method of detecting MPLS LSPs.

i For details about BFD, see *BFD-SCG*.

On an MPLS network, the following methods are used to detect LSP failures:

- MPLS Operation Administration and Maintenance (OAM) mechanism: This mechanism can detect, determine, and locate defects or failures of MPLS networks. However, the MPLS OAM mechanism is being standardized, and other OAM mechanisms have been applied to networks for only a short time. Therefore, perhaps not all devices support OAM.
- Hello packet mechanism of the MPLS signaling protocol: It takes a long time (usually several seconds) for this mechanism to detect failures. Therefore, this mechanism will cause massive traffic loss.

With the following features, MPLS BFD can solve the problems:

- Interoperability: MPLS BFD provides a uniform detection mechanism for the entire network.
- Quick detection: MPLS BFD enables light-load quick detection, enables backup forwarding paths quickly, and improves the reliability of MPLS networks.
- BFD can be used to detect failures of the data plane on an MPLS LSP, and BFD packets have fixed formats. Therefore, BFD can be implemented on hardware and traverse firewalls.

5.2 Applications

Application	Description
Detecting Static LSPs by Using BFD	Detects the connectivity of static LSPs by using Bidirectional Forwarding Detection (BFD). Correlates static LSPs with BFD. When a static LSP is in Down state, the LSP is no longer used as a forwarding path.
Detecting LDP LSPs by Using BFD	Detects the connectivity of LDP LSPs by using BFD. Correlates LDP LSPs with BFD. When an LDP LSP is in Down state, the LSP is no longer used as a forwarding path.
Detecting BGP LSPs by Using BFD	Detects the connectivity of BGP LSPs by using BFD. Correlates BGP LSPs with BFD. When a BGP LSP is in Down state, the LSP is no longer used as a forwarding path.

5.2.1 Detecting Static LSPs by Using BFD

Scenario

If static LSPs are used on an MPLS network, you can detect the connectivity of static LSPs by using BFD.

Take PE1 in the following figure as an example. An LSP is unidirectional and BFD is bidirectional, so two LSPs are required for detection. (LSPs in both directions can share one path or use different paths. The following figure shows the latter.)

- When static LSP1 is faulty, BFD for PE2 will perceive the fault and use static LSP2 to inform PE1 of such fault. BFD sessions will be in Down state, and PE1 will delete the Facsimile Transmission Network (FTN) of static LSP1 to avoid selecting LSP1 as a forwarding path.
- When static LSP1 is recovered, the BFD sessions between PE1 and PE2 will return to UP state, and PE1 will reassign an FTN to LSP1 so that LSP1 is available again.

Figure 5-1

Remarks	Static LSP1 is used to transmit data from PE1 to PE2. Static LSP2 is used to transmit data from PE2 to PE1. BFD-based LSP1 detection is configured on PE1. BFD-based LSP2 detection is configured on PE2.
---------	--

Deployment

- Run OSPF on the entire network for unicast routing.
- Enable MPLS forwarding on the entire network to forward MPLS packets.
- Configure the static FTN connected to PE2 on PE1, and set P1 as the next hop. Configure the static ILM connected to PE2 on P1, and establish static LSP1.
- Configure the static FTN connected to PE1 on PE2, and set P2 as the next hop. Configure the static ILM connected to PE1 on P2, and establish static LSP2.
- Configure BFD-based static LSP detection on PE1 and PE2 respectively.

5.2.2 Detecting LDP LSPs by Using BFD

Scenario

If LSPs are established through LDP on an MPLS network, you can detect the connectivity of LDP LSPs by using BFD.

Take PE1 in the following figure as an example (the two LSPs share the same path):

- When LSP1 is faulty, BFD for PE2 will perceive the fault. If LDP LSP2 is available, BFD for PE1 will be informed of such fault; if LSP2 is unavailable, BFD for PE1 will perceive such fault. In both cases, BFD sessions will be in Down state, and PE1 will delete the FTN of LSP1 to avoid selecting LSP1 as a forwarding path.
- When LDP LSP1 is recovered, the BFD sessions between PE1 and PE2 will return to UP state, and PE1 will reassign an FTN to LSP1 so that LSP1 is available again.

Figure 5-2

Remarks	LDP LSP1 is used to transmit data from PE1 to PE2. LDP LSP2 is used to transmit data from PE2 to PE1. BFD-based LDP LSP detection is configured on PE1. BFD-based LDP LSP detection is configured on PE2.
---------	--

Deployment

- Run OSPF on the entire network for unicast routing.
- Enable MPLS forwarding on the entire network to forward MPLS packets.
- Enable LDP on the entire network to establish LDP LSPs.
- Configure BFD-based LDP LSP detection on PE1 and PE2 respectively.

5.2.3 Detecting BGP LSPs by Using BFD

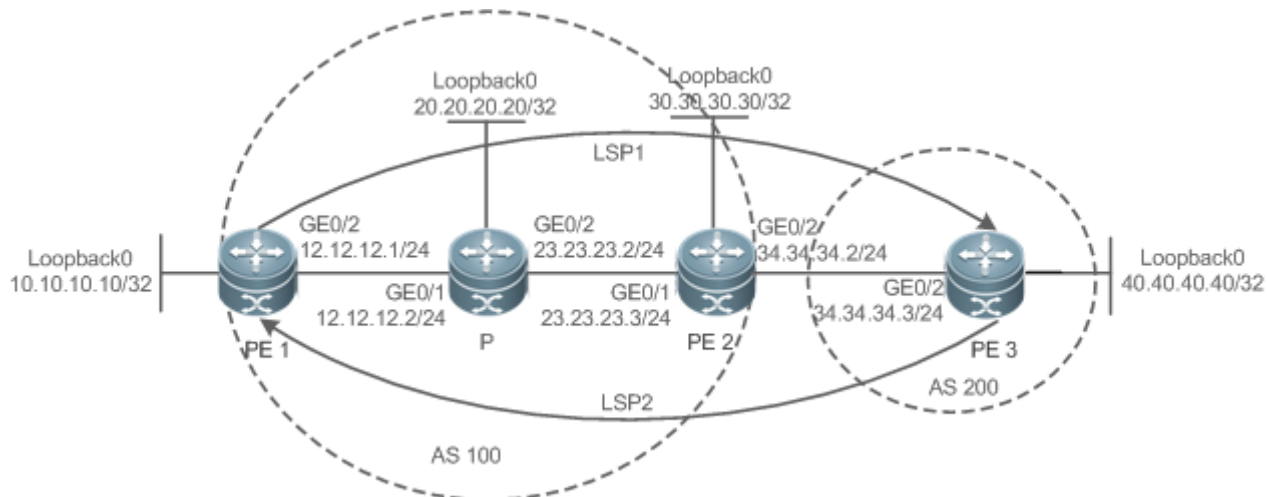

Scenario

If LSPs are established through BGP on an MPLS network, you can detect the connectivity of BGP LSPs by using BFD.

Take PE1 in the following figure as an example (the two LSPs share the same path):

- When BGP LSP1 is faulty, BFD for PE3 will perceive the fault. If BGP LSP2 is available, BFD for PE1 will be informed of such fault; if LSP2 is unavailable, BFD for PE1 will perceive such fault. In both cases, BFD sessions will be in Down state, and PE1 will delete the FTN of LSP1 to avoid selecting LSP1 as a forwarding path.
- When BGP LSP1 is recovered, the BFD sessions between PE1 and PE3 will return to UP state, and PE1 will reassign an FTN to LSP1 so that LSP1 is available again.

Figure 5-3

Remarks	<p>BGP LSP1 is used to transmit data from PE1 to PE3.</p> <p>BGP LSP2 is used to transmit data from PE3 to PE1.</p> <p>BFD-based BGP LSP detection is configured on PE1.</p> <p>BFD-based BGP LSP detection is configured on PE3.</p>
---------	---

Deployment

- Deploy PE1 and PE2 in one Autonomous System (AS), and deploy PE2 and PE3 in the other AS.
- Run OSPF, LDP, and BGP in each AS.
- Run BGP between ASs to assign labels to routes and establish BGP LSPs.
- Enable MPLS forwarding on the entire network to forward MPLS packets.
- Configure BFD-based LSP detection on PE1 and PE3 respectively.

5.3 Features

Basic Concepts

↳ BFD Session

BFD uses local identifier (My Discriminator) and remote identifier (Your Discriminator) to distinguish apart multiple BFD sessions. Identifiers can be configured automatically or manually.

- If identifiers are configured manually, BFD sessions can be established directly.

- If identifiers are automatically configured, before devices establish BFD sessions, local identifiers must be included in LSP Ping echo packets for session negotiation and remote identifiers must be learned.

↘ BFD Mode

Before two devices exchange BFD control packets, they need to establish a BFD session. The control plane and data plane must share the same path. BFD sessions can be operated in two modes:

- Asynchronous mode: Both ends send control packets to each other regularly. If one end fails to receive packets within a specified period of time, it indicates that the session is in Down state.
- Query mode: After a session is established, both ends send control packets to each other only when they need to detect the connectivity. If the recipient does not reply, the sender will consider the session in Down state.

In addition to the preceding modes, BFD defines the echo function. With this function, a device can send customized packets to the peer end. The peer end returns the packets to the sender without processing them. The echo function is applicable to both asynchronous mode and query mode.

 Currently, BFD-LSP correlation supports the asynchronous mode but does not support the query mode or the echo function.

Overview

Feature	Description
Establishing BFD Sessions	Establishes BFD sessions between the devices at both ends of the LSP to be detected.
Correlating BFD with LSPs	When any fault is detected by BFD, the LSP needs to be disabled temporarily and restarted after troubleshooting.

5.3.1 Establishing BFD Sessions

During BFD session initialization, the ingress LSR and egress LSR can be active or passive, which depends on the application scenario. However, at least one of them is active. The following describes two scenarios:

↘ Both Active

As LSPs are unidirectional, the following two scenarios must be considered:

- When packets are sent from the ingress LSR to the egress LSR, the LSP is detected by using BFD; when packets are sent from the egress LSR to the ingress LSR, the other LSP is detected by using BFD.

The ingress LSR sends an LSP Ping echo request packet with a local identifier to the egress LSR. The egress LSR obtains a remote identifier from the received packet. In this way, the egress LSR has both local identifier (generated by the egress LSR) and remote identifier. Then the egress LSR sends a BFD control packet to the ingress LSR. The ingress LSR obtains a remote identifier from the received packet. In this way, the ingress LSR has both local identifier (generated by the ingress LSR) and remote identifier. Then the ingress LSR sends a BFD control packet to the egress LSR. A BFD session is then initialized between both ends.

Note: When receiving an echo request packet, the egress LSR can choose to or not to return an echo reply packet. If the egress LSR returns an echo reply packet, a local identifier (generated by the egress LSR) must be included in the echo reply packet. In this way, the ingress LSR can obtain a remote identifier from both the BFD control packet and the echo reply packet.

i The egress LSR works in a similar way to the ingress LSR.

- When packets are sent from the ingress LSR to the egress LSR, the LSP is detected by using BFD; when packets are sent from the egress LSR to the ingress LSR, the IP address is detected by using BFD (multiple hops exist).

In this case, BFD session can be established only by manually configuring identifiers on the ingress LSR and the egress LSR. That is, after identifiers are configured manually, BFD sessions can be established without identifier negotiation.

📄 One Active, the Other Passive

The active one sends an LSP Ping echo request packet with a local identifier to the passive one. The passive one obtains a remote identifier from the received packet. In this way, the passive one has both local identifier (generated by the passive one) and remote identifier. Then the passive one sends a BFD control packet to the active one. The active one obtains a remote identifier from the received packet. In this way, the active one has both local identifier (generated by the active one) and remote identifier. Then the active one sends a BFD control packet to the passive one. A BFD session is then initialized between both ends.

Note: When receiving an echo request packet, the passive one can choose to or not to return an echo reply packet. If the passive one returns an echo reply packet, a local identifier (generated by the passive one) must be included in the echo reply packet. In this way, the active one can obtain a remote identifier from both the BFD control packet and the echo reply packet.

Before receiving an echo request packet from the active one, the passive one will not send a BFD control packet to the active one.

i Currently, BFD-LSP correlation supports the "both active" mode but does not support the "one active, the other passive" mode.

Working Principle

The following describes the process of BFD session establishment in the first scenario (when packets are sent from the ingress LSR to the egress LSR, the LSP is detected by using BFD; when packets are sent from the egress LSR to the ingress LSR, the other LSP is detected by using BFD) when both ends are active.

Figure 5-4

- Before enabling BFD, both ingress LSR and egress LSR must learn remote identifiers and ensure that LSPs are in Up state. As shown in the figure, the ingress LSR sends an LSP Ping echo request packet with a local identifier to the egress LSR. Upon receipt of the echo request packet, the egress LSR returns an echo reply packet with a local identifier (generated by the egress LSR) to the ingress LSR. The case is similar with the egress LSR. Note: When no identifier is specified, both ends need to learn the identifier of the other through an LSP Ping echo packet. If local and remote identifiers are specified by both ends, the devices will skip to the next step. For information on identifier configuration, see the section "Correlating BFD with LSPs".
- The ingress LSR and egress LSR enable BFD. They are in Down state initially. BFD packets are in Down state.
- The egress LSR receives the BFD packets and locally switches BFD to Init state. The BFD packets are in Init state.
- The egress LSR no longer processes BFD packets that are in Down state.
- The case is similar with the ingress LSR.
- The egress LSR receives BFD packets that are in Init state and locally switches BFD to Up state.
- The case is similar with the ingress LSR.
- The Up state indicates that BFD sessions are established successfully.

Related Configuration

- [Configuring BFD Session Parameters on an Interface](#)

By default, BFD session parameters are not configured on an interface.

By running the **bfd interval** command, you can configure or cancel BFD session parameters on an interface.

The BFD sessions for detecting LSPs can be established only when the **bfd interval** command is configured on the LSP interface, the command for BFD-based LSP detection described in the next section is configured, and the corresponding LSPs exist. The speed of fault detection is determined by the session parameters designated by the **bfd interval** command.

5.3.2 Correlating BFD with LSPs

BFD sessions are distinguished apart through local identifier (My Discriminator) and remote identifier (Your Discriminator). Based on the identifier specification mode, BFD and LSP can be correlated in two modes:

- Manual mode

If identifiers are configured manually, BFD sessions can be established directly.

- Automatic mode

If identifiers are automatically configured, before devices establish BFD sessions, local identifiers must be included in LSP Ping packets for session negotiation and remote identifiers must be learned.

Based on types of LSPs, BFD-LSP correlation includes BFD-based static LSP detection, BFD-based LDP LSP detection, and BFD-based BGP LSP detection.

Working Principle

↘ BFD-based Static LSP Detection

BFD-based static LSP detection can be configured manually or automatically. An LSP is a unidirectional link, while BFD is a bidirectional detection mechanism. Therefore, when detecting unidirectional static LSPs by using BFD, you can select any of the following methods to detect their backward links:

- Detecting backward links with IP
- Detecting backward links with static LSPs

After the detection method is selected, BFD sessions will be established and in UP state. Then, if any fault is detected by BFD, BFD sessions will be in Down state; if the configuration command has the **process-state** parameter, Ingress LSR will delete the FTN of the faulty LSP so that such LSP will not be selected as a forwarding path. If the fault is removed, BFD sessions will return to UP state, and Ingress LSR will re-add the FTN of such LSP so that such LSP will be reused as a forwarding path.

↘ BFD-based LDP LSP Detection

BFD-based LDP LSP detection can be configured manually or automatically. An LSP is a unidirectional link, while BFD is a bidirectional detection mechanism. Therefore, when detecting unidirectional LDP LSPs by using BFD, you can select any of the following methods to detect their backward links:

- Detecting backward links with IP
- Detecting backward links with LDP LSPs

BGP LSPs are used for basic VPN/PW services. Therefore, BFD-based LDP LSP detection detects failures of VPN/PW. By using this function, you can quickly detect various MPLS-based network applications such as VPN Fast Reroute (FRR) and PW FRR, thereby protecting services and improving reliability of MPLS networks. LDP LSPs and static LSPs share the same process of BFD-based fault detection, process of recovery, and relevant processing.

📌 BFD-based BGP LSP Detection

The function can be configured both manually and automatically. An LSP is a unidirectional link, while BFD is a bidirectional detection mechanism. Therefore, when detecting unidirectional BGP LSPs by using BFD, you can select any of the following methods to detect their backward links:

- Detecting backward links with IP
- Detecting backward links with BGP LSPs

BGP LSPs are used for basic VPN/PW services. Therefore, BFD-based BGP LSP detection detects faults of VPN/PW. By using this function, you can quickly detect various MPLS-based network applications such as VPN Fast Reroute (FRR) and PW FRR, thereby protecting services and improving reliability of MPLS networks. LDP LSPs, static LSPs and LDP LSPs share the same process of BFD-based fault detection, process of recovery, and relevant processing.

Related Configuration

📌 Configuring BFD-based Static LSP Detection

By default, BFD-based static LSP detection is disabled.

Run the **bfd bind static-lsp** command to enable BFD-based static LSP detection.

The number of BFD sessions is limited. If the number of BFD sessions submitted by a user exceeds the maximum allowed, the system will generate log information to prompt the user.

📌 Configuring BFD-based LDP LSP Detection

By default, BFD-based LDP LSP detection is disabled.

Run the **bfd bind ldp-lsp** command to enable BFD-based LDP LSP detection.

The number of BFD sessions is limited. If the number of BFD sessions submitted by a user exceeds the maximum allowed, the system will generate log information to prompt the user.

📌 Configuring BFD-based BGP LSP Detection

By default, BFD-based BGP LSP detection is disabled.

Run the **bfd bind bgp-lsp** command to enable BFD-based BGP LSP detection.

The number of BFD sessions is limited. If the number of BFD sessions submitted by a user exceeds the maximum allowed, the system will generate log information to prompt the user.

5.4 Configuration

Configuration items	Description and Command	
Configuring BFD-based Static LSP Detection	 (Mandatory) It is used to detect the connectivity of static LSPs by using BFD.	
	bfd bind static-lsp	Configures BFD-based static LSP detection.
	bfd bind backward-lsp-with-ip	Configures BFD-based detection of backward LSPs with IP.
Configuring BFD-based LDP LSP Detection	 (Mandatory) It is used to detect the connectivity of LDP LSPs by using BFD.	
	bfd bind ldp-lsp	Configures BFD-based LDP LSP detection.
	bfd bind backward-lsp-with-ip	Configures BFD-based detection of backward LSPs with IP.
Detecting BGP LSPs by Using BFD	 (Mandatory) It is used to detect the connectivity of BGP LSPs by using BFD.	
	bfd bind bgp-lsp	Configures BFD-based BGP LSP detection.
	bfd bind backward-lsp-with-ip	Configures BFD-based detection of backward LSPs with IP.

5.4.1 Configuring BFD-based Static LSP Detection

Configuration Effect

The connectivity of static LSPs can be detected by using BFD. Correlating static LSPs with BFD can prevent a private route from using a faulty static LSP as a forwarding path.

Notes

-  Only host-routed static LSPs can be detected by using BFD.
-  In application scenarios where failures need to be detected by using BFD, for example, the BFD-LSP correlation scenario, you need to configure **process-state**.

Before configuring BFD-based static LSP detection, you need to:

- Enable MPLS.
- Configure static LSPs.

Before configuring BFD-based static LSP detection, you need to configure the following:

- Local identifier (My Discriminator) and remote identifier (Your Discriminator) of a BFD session
- Backward link detection
- BFD session parameters: interval for sending BFD control packets, interval for receiving BFD control packets, and BFD control packet detection multiplier

Configuration Steps

Configuring BFD for Ingress LSR

- Mandatory.
- Configure BFD sessions on the outbound interface of an LSP.
- Configure BFD-based static LSP detection and process the BFD session state. If BFD-based static LSP detection is configured manually on the ingress LSR, it must be configured manually on the egress LSR. That is, BFD-based static LSP detection must be configured in the same way at both ends.

 If identifiers are configured manually, local and remote identifiers configured on the ingress LSR must match those configured on the egress LSR.

Configuring BFD for Egress LSR

- Mandatory.
- Configure BFD sessions on the outbound interface of the backward LSP (route if IP is used).
- Configure BFD-based static LSP detection. Do not process the BFD session state. If BFD-based static LSP detection is configured manually on the ingress LSR, it must be configured manually on the egress LSR. That is, BFD-based static LSP detection must be configured in the same way at both ends.

Or:

- Configure BFD-based detection of backward LSPs with IP. If backward LSPs with IP are detected, local and remote identifiers must be configured manually for forward LSPs.

 If identifiers are configured manually, local and remote identifiers configured on the egress LSR must match those configured on the ingress LSR.

Verification

Run the **show bfd neighbors** command to check whether BFD sessions are in Up state.

Configuring BFD-based Static LSP Detection

Command	bfd bind static-lsp peer-ip <i>ip-address</i> source-ip <i>ip-address</i> [local-discriminator <i>discr-value</i> remote-discriminator <i>discr-value</i>] [process-state]
Parameter Description	<p>peer-ip <i>ip-address</i>: Indicates the peer IP address of the static LSP bound with BFD sessions.</p> <p>source-ip <i>ip-address</i>: Indicates the source IP address of BFD packets.</p> <p>local-discriminator <i>discr-value</i>: Configures the local identifier of a BFD session. The value ranges from 1 to 8191.</p> <p>remote-discriminator <i>discr-value</i>: Configures the remote identifier of the BFD session. The value ranges from 1 to 8191.</p> <p>process-state: Processes the BFD session state. In application scenarios where failures need to be detected by using BFD, for example, the BFD-LSP correlation scenario, you need to configure</p>

	process-state.
Command Mode	Global configuration mode
Usage Guide	<ul style="list-style-type: none"> ● This command can be run on the ingress node of the LSP. ● If BFD has been configured, BFD configuration items cannot be established. After BFD is configured, if a static LSP exists, BFD sessions will be immediately created; if no static LSP exists, BFD sessions will not be created until a static LSP exists. ● If a static LSP is deleted, the BFD sessions bound with the LSP will be deleted. However, configuration items of the BFD sessions will be retained. When a static LSP exists, BFD sessions will be re-created. ● You can configure local and remote identifiers for BFD sessions. If no local identifier is configured, the system will automatically elect a local identifier. If backward LSPs with IP are detected, local and remote identifiers must be configured manually for forward LSPs. ● After BFD sessions are established, identifiers cannot be modified. ● The system regularly queries submitted BFD configuration items to establish BFD sessions. ● The number of BFD sessions is limited. If the number of requested BFD sessions exceeds the upper limit, the system will generate a log to prompt you.

📌 **Configuring BFD-based Detection of Backward LSPs with IP**

Command	bfd bind backward-lsp-with-ip peer-ip <i>ip-address</i> [vrf <i>vrf-name</i>] interface <i>interface-type interface-number</i> [source-ip <i>ip-address</i>] { local-discriminator <i>discr-value</i> remote-discriminator <i>discr-value</i> }
Parameter Description	<p>peer-ip <i>ip-address</i>: Indicates the peer IP address of the LSP bound with BFD sessions.</p> <p>vrf <i>vrf-name</i>: Indicates the name of VRF bound with BFD sessions.</p> <p>interface <i>interface-type interface-number</i>: Configures the interface type and number.</p> <p>source-ip <i>ip-address</i>: Indicates the source IP address of BFD packets.</p> <p>local-discriminator <i>discr-value</i>: Configures the local identifier of a BFD session. The value ranges from 1 to 8191.</p> <p>remote-discriminator <i>discr-value</i>: Configures the remote identifier of the BFD session. The value ranges from 1 to 8191.</p>
Command Mode	Global configuration mode
Usage Guide	<p>Configures BFD-based detection of backward LSPs with IP.</p> <p>If backward LSPs with IP are detected, local and remote identifiers must be configured manually for forward LSPs.</p>

Configuration Example

📌 **Detecting the Connectivity of Static LSPs by Using BFD**

Scenario
Figure 5-5

Configuration Steps

- Configure the IP address and OSPF on each node.
- On each node, enable global MPLS forwarding, and enable MPLS labeled packet forwarding on an interface.
- On each node, configure static MPLS routes to enable MPLS traffic forwarding.
- Configure BFD-based static LSP1 detection on PE1.
- Configure BFD-based static LSP2 detection on PE2 (detect backward links with LSPs).

Common Errors

- BFD sessions are not configured on the outbound interface of the LSP.
- The interface on which BFD sessions are configured is not the outbound interface of the LSP.
- Static FTN/ILM entries do not take effect.
- The LSP is incomplete.
- The global **mpls ip** command is not run.
- The **label-switching** command for enabling MPLS forwarding on the interface is not run.
- The source address and destination address of the BFD-detected devices at both ends of an LSP are not matched.
- The identifiers configured (manually) for the BFD-detected devices at both ends of an LSP are not matched.
- Forward Error Correction (FEC) corresponding to the detected LSP is not routed by the host.

5.4.2 Configuring BFD-based LDP LSP Detection

Configuration Effect

- The connectivity of LDP LSPs can be detected by using BFD. Correlating an LDP LSP with BFD can prevent a private route from using the LSP as a forwarding path when it is in Down state.

Notes

- Only host-routed LDP LSPs can be detected by using BFD.
- One LSP can be bound with only one BFD session.

- An LDP LSP must be bound with BFD at its ingress.
- In application scenarios where failures need to be detected by using BFD, for example, the BFD-LSP correlation scenario, you need to configure **process-state**.
- Before configuring BFD-based LDP LSP detection, you need to:
 13. Enable MPLS.
 14. Enable LDP.
- Before configuring BFD-based LDP LSP detection, you need to configure the following:
 15. Local identifier (My Discriminator) and remote identifier (Your Discriminator) of a BFD session
 16. Backward link detection
 17. BFD session parameters: interval for sending BFD control packets, interval for receiving BFD control packets, and BFD control packet detection multiplier

Configuration Steps

▾ Configuring BFD for the Ingress LSR

- Mandatory.
- Configure BFD sessions on the outbound interface of an LSP.
- Configure BFD-based LDP LSP detection and process the BFD session state. If BFD-based LDP LSP detection is configured manually on the ingress LSR, it must be configured manually on the egress LSR. That is, BFD-based LDP LSP detection must be configured in the same way at both ends.

 If identifiers are configured manually, local and remote identifiers configured on the ingress LSR must match those configured on the egress LSR.

▾ Configuring BFD for Egress LSR

- Mandatory.
- Configure BFD sessions on the outbound interface of an LSP.
- Configure BFD-based LDP LSP detection. Do not process the BFD session state. If BFD-based LDP LSP detection is configured manually on the ingress LSR, it must be configured manually on the egress LSR. That is, BFD-based LDP LSP detection must be configured in the same way at both ends.

Or:

- Configures BFD-based detection of backward LSPs with IP. If backward LSPs with IP are detected, local and remote identifiers must be configured manually for forward LSPs.

 If identifiers are configured manually, local and remote identifiers configured on the egress LSR must match those configured on the ingress LSR.

 Only host-routed LDP LSPs can be detected by using BFD.

 One LSP can be bound with only one BFD session.

 An LDP LSP must be bound with BFD at its ingress.

Verification

Run the **show bfd neighbors** command to check whether BFD sessions are in Up state.

```

Common Errors

- BFD sessions are not configured on the outbound interface of an LSP.
- The interface on which BFD sessions are configured is not the outbound interface of an LSP.
- FTN/ILM entries are not assigned through LDP.
- An LSP is incomplete.
- The global **mpls ip** command is not run.
- The **label-switching** command for enabling MPLS forwarding on an interface is not run.
- The source address and destination address of the BFD-detected devices at both ends of an LSP are not matched.
- The identifiers configured (manually) for the BFD-detected devices at both ends of an LSP are not matched.
- The forwarding equivalence class (FEC) corresponding to the detected LSP is not routed by the host.

5.4.3 Configuring BFD-based BGP LSP Detection

Configuration Effect

- The connectivity of BGP LSPs can be detected by using BFD. By correlating a BGP LSP with BFD, you can prevent the private route from using the LSP as a forwarding path when it is in Down state.

Notes

- Only host-routed BGP LSPs can be detected by using BFD.

- One LSP can be bound with only one BFD session.
- A BGP LSP must be bound with BFD at its ingress.
- Before configuring BFD-based BGP LSP detection, you need to:
 18. Enable MPLS.
 19. Assign labels via BGP.
- Before configuring BFD-based BGP LSP detection, you need to configure the following:
 20. Local identifier (My Discriminator) and remote identifier (Your Discriminator) of a BFD session
 21. Backward link detection
 22. BFD session parameters: interval for sending BFD control packets, interval for receiving BFD control packets, and BFD control packet detection multiplier

Configuration Steps

▾ Configuring BFD for the Ingress LSR

- Mandatory.
- Configure BFD sessions on the outbound interface of an LSP.
- Configure BFD-based BGP LSP detection and process the status of BFD sessions. If BFD is configured manually for Ingress LSR, it must be configured manually for Egress LSR. That is to say, configurations at both ends must be consistent.

 If identifiers are configured manually, local and remote identifiers configured on the ingress LSR must match those configured on the egress LSR.

▾ Configuring BFD for the Egress LSR

- Mandatory.
- Configure BFD sessions on the outbound interface of an LSP.
- Configure BFD-based BGP LSP detection. Do not process the BFD session state. If BFD-based BGP LSP detection is configured manually on the ingress LSR, it must be configured manually on the egress LSR. That is, BFD-based BGP LSP detection must be configured in the same way at both ends.

Or:

- Configures BFD-based detection of backward LSPs with IP. If backward LSPs with IP are detected, local and remote identifiers must be configured manually for forward LSPs.

 If identifiers are configured manually, local and remote identifiers configured on the egress LSR must match those configured on the ingress LSR.

 Only host-routed BGP LSPs can be detected by using BFD.

 One LSP can be bound with only one BFD session.

 A BGP LSP must be bound with BFD at its ingress.

Verification

Run the **show bfd neighbors** command to check whether BFD sessions are in Up state.

Related Commands

📌 Detecting the Connectivity of BGP LSPs by Using BFD

Command	bfd bind bgp-lsp peer-ip <i>ip-address</i> source-ip <i>ip-address</i> [local-discriminator <i>discr-value</i> remote-discriminator <i>discr-value</i>]
Parameter Description	peer-ip <i>ip-address</i> : Indicates the sink IP address of the BGP LSP bound with BFD sessions. source-ip <i>ip-address</i> : Indicates the source IP address of BFD packets. local-discriminator <i>discr-value</i> : Configures the local identifier of a BFD session. The value ranges from 1 to 8191. remote-discriminator <i>discr-value</i> : Configures the remote identifier of the BFD session. The value ranges from 1 to 8191.
Command Mode	Global configuration mode
Usage Guide	<ul style="list-style-type: none"> ● Enable global MPLS forwarding on each node, and enable the forwarding of MPLS label packets on the interface. Configure IBGP and assign labels via BGP between PE1 and PE2. Configure EBGP and assign labels via BGP between PE2 and PE3. Configure BFD-based BGP LSP1 detection on PE1. This command can be run on the ingress node of the LSP. ● If BFD has been configured, BFD configuration items cannot be established. After BFD is configured, if a BGP LSP exists, BFD sessions will be immediately created; if no BGP LSP exists, BFD sessions will not be created until an LSP exists. ● If a BGP LSP is deleted, the BFD sessions bound with the LSP will be deleted. However, configuration items of the BFD sessions will be retained. When a BGP LSP exists, BFD sessions will be re-created. ● You can configure local and remote identifiers for BFD sessions. If no local identifier is configured, the system will automatically elect a local identifier. If backward LSPs with IP are detected, local and remote identifiers must be configured manually for forward LSPs. ● After BFD sessions are established, identifiers cannot be modified. ● The system regularly queries submitted BFD configuration items to establish BFD sessions. ● The number of BFD sessions is limited. If the number of requested BFD sessions exceeds the upper limit, the system will generate a log to prompt you.

📌 Configuring BFD-based Detection of Backward LSPs with IP

Command	bfd bind backward-lsp-with-ip peer-ip <i>ip-address</i> [vrf <i>vrf-name</i>] interface <i>interface-type interface-number</i> [source-ip <i>ip-address</i>] local-discriminator <i>discr-value</i> remote-discriminator <i>discr-value</i>
Parameter Description	peer-ip <i>ip-address</i> : Indicates the peer IP address of the LSP bound with BFD sessions. vrf <i>vrf-name</i> : Indicates the name of VRF bound with BFD sessions. interface <i>interface-type interface-number</i> : Configures the interface type and number. source-ip <i>ip-address</i> : Indicates the source IP address of BFD packets.

	<p>local-discriminator <i>discr-value</i>: Configures the local identifier of a BFD session. The value ranges from 1 to 8191.</p> <p>remote-discriminator <i>discr-value</i>: Configures the remote identifier of the BFD session. The value ranges from 1 to 8191.</p>
Command Mode	Global configuration mode
Usage Guide	<p>Configures BFD-based detection of backward LSPs with IP.</p> <p>If backward LSPs with IP are detected, local and remote identifiers must be configured manually for forward LSPs.</p>

Configuration Example

Detecting the Connectivity of BGP LSPs by Using BFD

<p>Scenario Figure 5-7</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure the IP address and loopback address on each node. ● Configure OSPF and LDP between PE1 and PE2. ● On each node, enable global MPLS forwarding, and enable MPLS labeled packet forwarding on an interface. ● Configure IBGP and assign labels via BGP between PE1 and PE2. Configure EBGP and assign labels via BGP between PE2 and PE3. ● Configure BFD-based BGP LSP1 detection on PE1. ● Configure BFD-based BGP LSP2 detection on PE3 (detect backward links with LSPs).

1 Configuring AAA

1.1 Overview

Authentication, authorization, and accounting (AAA) provides a unified framework for configuring the authentication, authorization, and accounting services. Ruijie Networks devices support the AAA application.

AAA provides the following services in a modular way:

Authentication: Refers to the verification of user identities for network access and network services. Authentication is classified into local authentication and authentication through Remote Authentication Dial In User Service (RADIUS) and Terminal Access Controller Access Control System+ (TACACS+).

Authorization: Refers to the granting of specific network services to users according to a series of defined attribute-value (AV) pairs. The pairs describe what operations users are authorized to perform. AV pairs are stored on network access servers (NASs) or remote authentication servers.

Accounting: Refers to the tracking of the resource consumption of users. When accounting is enabled, NASs collect statistics on the network resource usage of users and send them in AV pairs to authentication servers. The records will be stored on authentication servers, and can be read and analyzed by dedicated software to realize the accounting, statistics, and tracking of network resource usage.

AAA is the most fundamental method of access control. Ruijie Networks also provides other simple access control functions, such as local username authentication and online password authentication. Compared to them, AAA offers higher level of network security.

AAA has the following advantages:

- Robust flexibility and controllability
- Scalability
- Standards-compliant authentication
- Multiple standby systems

1.2 Applications

Application	Description
Configuring AAA in a Single-Domain Environment	AAA is performed for all the users in one domain.
Configuring AAA in a Multi-Domain Environment	AAA is performed for the users in different domains by using different methods.

1.2.1 Configuring AAA in a Single-Domain Environment

Scenario

In the network scenario shown, the following application requirements must be satisfied to improve the security management on the NAS:

1. To facilitate account management and avoid information disclosure, each administrator has an individual account with different username and password.
2. Users must pass identity authentication before accessing the NAS. The authentication can be in local or centralized mode. It is recommended to combine the two modes, with centralized mode as active and local mode as standby. As a result, users must undergo authentication by the RADIUS server first. If the RADIUS server does not respond, it turns to local authentication.
3. During the authentication process, users can be classified and limited to access different NASs.
4. Permission management: Users managed are classified into Super User and Common User. Super users have the rights to view and configure the NAS, and common users are only able to view NAS configuration.
5. The AAA records of users are stored on servers and can be viewed and referenced for auditing. (The TACACS+ server in this example performs the accounting.)

Figure 1-1

Remarks	<p>User A, User B, and User C are connected to the NAS in wired or wireless way.</p> <p>The NAS is an access or convergence switch.</p> <p>The RADIUS server can be the Windows 2000/2003 Server (IAS), UNIX system component, and dedicated server software provided by a vendor.</p> <p>The TACACS+ server can be the dedicated server software provided by a vendor.</p>
----------------	---

Deployment

- Enable AAA on the NAS.
- Configure an authentication server on the NAS.
- Configure local users on the NAS.
- Configure the authentication service on the NAS.

- Configure the authorization service on the NAS.
- Configure the accounting service on the NAS.

1.2.2 Configuring AAA in a Multi-Domain Environment

Scenario

Configure the domain-based AAA service on the NAS.

- A user can log in by entering the username PC1@ruijie.net or PC2@ruijie.com.cn and correct password on an 802.1X client.
- Permission management: Users managed are classified into Super User and Common User. Super users have the rights to view and configure the NAS, and common users are only able to view NAS configuration.
- The AAA records of users are stored on servers and can be viewed and referenced for auditing.

Figure 1-2

Remarks	<p>The clients with the usernames PC1@ruijie.net and PC2@ruijie.com.cn are connected to the NAS in wired or wireless way.</p> <p>The NAS is an access or convergence switch.</p> <p>The Security Accounts Manager (SAM) server is a universal RADIUS server provided by Ruijie Networks.</p>
----------------	--

Deployment

- Enable AAA on the NAS.
- Configure an authentication server on the NAS.
- Configure local users on the NAS.
- Define an AAA method list on the NAS.
- Enable domain-based AAA on the NAS.
- Create domains and AV sets on the NAS.

1.3 Features

Basic Concepts

Local Authentication and Remote Server Authentication

Local authentication is the process where the entered passwords are verified by the database on the NAS.

Remote server authentication is the process where the entered passwords are checked by the database on a remote server. It is mainly implemented by the RADIUS server and TACACS+ server.

Method List

AAA is implemented using different security methods. A method list defines a method implementation sequence. The method list can contain one or more security protocols so that a standby method can take over the AAA service when the first method fails. On Ruijie devices, the first method in the list is tried in the beginning and then the next is tried one by one if the previous gives no response. This method selection process continues until a security method responds or all the security methods in the list are tried out. Authentication fails if no method in the list responds.

A method list contains a series of security methods that will be queried in sequence to verify user identities. It allows you to define one or more security protocols used for authentication, so that the standby authentication method takes over services when the active security method fails. On Ruijie devices, the first method in the list is tried in the beginning and then the next is tried one by one if the previous gives no response. This method selection process continues until a method responds or all the methods in the method list are tried out. Authentication fails if no method in the list responds.

! The next authentication method proceeds on Ruijie devices only when the current method does not respond. When a method denies user access, the authentication process ends without trying other methods.

Figure 1-3

Figure 1-3 shows a typical AAA network topology, where two RADIUS servers (R1 and R2) and one NAS are deployed. The NAS can be the client for the RADIUS servers.

Assume that the system administrator defines a method list, where the NAS selects R1 and R2 in sequence to obtain user identity information and then accesses the local username database on the server. For example, when a remote PC user initiates dial-up access, the NAS first queries the user's identity on R1. When the authentication on R1 is completed, R1 returns an Accept response to the NAS. Then the user is permitted to access the Internet. If R1 returns a Reject response, the user is denied Internet access and the connection is terminated. If R1 does not respond, the NAS considers that the R1 method times out and continues to query the user's identity on R2. This process continues as the NAS keeps trying the remaining authentication methods, until the user request is authenticated, rejected, or terminated. If all the authentication methods are responded with Timeout, authentication fails and the connection will be terminated.

i The Reject response is different from the Timeout response. The Reject response indicates that the user does not meet the criteria of the available authentication database and therefore fails in authentication, and the Internet access request is denied. The Timeout response indicates that the authentication server fails to respond to the identity query.

When detecting a timeout event, the AAA service proceeds to the next method in the list to continue the authentication process.

-  This document describes how to configure AAA on the RADIUS server. For details about the configuration on the TACACS+ server, see the *Configuring TACACS+*.

AAA Server Group

You can define an AAA server group to include one or more servers of the same type. If the server group is referenced by a method list, the NAS preferentially sends requests to the servers in the referenced server group when the method list is used to implement AAA.

VRF-Enabled AAA Group

Virtual private networks (VPNs) enable users to share bandwidths securely on the backbone networks of Internet service providers (ISPs). A VPN is a site set consisting of shared routes. An STA site connects to the network of an ISP through one or multiple interfaces. AAA supports assigning a VPN routing forwarding (VRF) table to each user-defined server group.

When AAA is implemented by the server in a group assigned with a VRF table, the NAS sends request packets to the remote servers in the server group. The source IP address of request packets is an address selected from the VRF table according to the IP addresses of the remote servers.

If you run the **ip radius/tacacs+ source-interface** command to specify the source interface for the request packets, the IP address obtained from the source interface takes precedence over the source IP address selected from the VRF table.

Overview

Feature	Description
AAA Authentication	Verifies whether users can access the Internet.
AAA Authorization	Determines what services or permissions users can enjoy.
AAA Accounting	Records the network resource usage of users.
Multi-Domain AAA	Creates domain-specific AAA schemes for 802.1X stations (STAs) in different domains.
RIPT	When Remote Intelligent Perception Technology (RIPT) is enabled, an access controller (AC) can assign the AAA method list settings to the RIPT-enabled access points (APs).

1.3.1 AAA Authentication

Authentication, authorization, and accounting are three independent services. The authentication service verifies whether users can access the Internet. During authentication, the username, password, and other user information are exchanged between devices to complete users' access or service requests. You can use only the authentication service of AAA.

-  To configure AAA authentication, you need to first configure an authentication method list. Applications perform authentication according to the method list. The method list defines the types of authentication and the sequence in which they are performed. Authentication methods are implemented by specified applications. The only exception is the default method list. All applications use the default method list if no method list is configured.

AAA Authentication Scheme

- No authentication (**none**)

The identity of trusted users is not checked. Normally, the no-authentication (None) method is not used.

- Local authentication (**local**)

Authentication is performed on the NAS, which is configured with user information (including usernames, passwords, and AV pairs). Before local authentication is enabled, run the **username password** command to create a local user database.

- Remote server group authentication (**group**)

Authentication is performed jointly by the NAS and a remote server group through RADIUS or TACACS+. A server group consists of one or more servers of the same type. User information is managed centrally on a remote server, thus realizing multi-device centralized and unified authentication with high capacity and reliability. You can configure local authentication as standby to avoid authentication failures when all the servers in the server group fail.

AAA Authentication Types

Ruijie products support the following authentication types:

- Login authentication

Users log in to the command line interface (CLI) of the NAS for authentication through Secure Shell (SSH), Telnet, and File Transfer Protocol (FTP).

- Enable authentication

After users log in to the CLI of the NAS, the users must be authenticated before CLI permission update. This process is called Enable authentication (in Privileged EXEC mode).

- Point-to-Point Protocol (PPP) authentication

PPP authentication is performed for users that initiate dial-up access through PPP.

- Dot1X (IEEE802.1X) authentication

Dot1X (IEEE802.1X) authentication is performed for users that initiate dial-up access through IEEE802.1X.

- Web (second generation portal) authentication

Web authentication is performed by the second generation portal server.

Related Configuration

Enabling AAA

By default, AAA is disabled.

To enable AAA, run the **aaa new-model** command.

Configuring an AAA Authentication Scheme

By default, no AAA authentication scheme is configured.

Before you configure an AAA authentication scheme, determine whether to use local authentication or remote server authentication. If the latter is to be implemented, configure a RADIUS or TACACS+ server in advance. If local authentication is selected, configure the local user database information on the NAS.

↘ [Configuring an AAA Authentication Method List](#)

By default, no AAA authentication method list is configured.

Determine the access mode to be configured in advance. Then configure authentication methods according to the access mode.

1.3.2 AAA Authorization

AAA authorization allows administrators to control the services or permissions of users. After AAA authorization is enabled, the NAS configures the sessions of users according to the user configuration files stored on the NAS or servers. After authorization, users can use only the services or have only the permissions permitted by the configuration files.

↘ [AAA Authorization Scheme](#)

- Direct authorization (**none**)

Direct authorization is intended for highly trusted users, who are assigned with the default permissions specified by the NAS.

- Local authorization (**local**)

Local authorization is performed on the NAS, which authorizes users according to the AV pairs configured for local users.

- Remote server-group authorization (**group**)

Authorization is performed jointly by the NAS and a remote server group. You can configure local or direct authorization as standby to avoid authorization failures when all the servers in the server group fail.

↘ [AAA Authorization Types](#)

- EXEC authorization

After users log in to the CLI of the NAS, the users are assigned with permission levels (0 to 15).

- Config-commands authorization

Users are assigned with the permissions to run specific commands in configuration modes (including the global configuration mode and sub-modes).

- Console authorization

After users log in through consoles, the users are authorized to run commands.

- Command authorization

Authorize users with commands after login to the CLI of the NAS.

- Network authorization

After users access the Internet, the users are authorized to use the specific session services. For example, after users access the Internet through PPP and Serial Line Internet Protocol (SLIP), the users are authorized to use the data service, bandwidth, and timeout service.

[Related Configuration](#)

↘ [Enabling AAA](#)

By default, AAA is disabled.

To enable AAA, run the **aaa new-model** command.

↘ **Configuring an AAA Authorization Scheme**

By default, no AAA authorization scheme is configured.

Before you configure an AAA authorization scheme, determine whether to use local authorization or remote server-group authorization. If remote server-group authorization needs to be implemented, configure a RADIUS or TACACS+ server in advance. If local authorization needs to be implemented, configure the local user database information on the NAS.

↘ **Configuring an AAA Authorization Method List**

By default, no AAA authorization method list is configured.

Determine the access mode to be configured in advance. Then configure authorization methods according to the access mode.

1.3.3 AAA Accounting

In AAA, accounting is an independent process of the same level as authentication and authorization. During the accounting process, start-accounting, update-accounting, and end-accounting requests are sent to the configured accounting server, which records the network resource usage of users and performs accounting, audit, and tracking of users' activities.

In AAA configuration, accounting scheme configuration is optional.

↘ **AAA Accounting Schemes**

- No accounting (**none**)

Accounting is not performed on users.

- Local accounting (**local**)

Accounting is completed on the NAS, which collects statistics on and limits the number of local user connections. Billing is not performed.

- Remote server-group accounting (**group**)

Accounting is performed jointly by the NAS and a remote server group. You can configure local accounting as standby to avoid accounting failures when all the servers in the server group fail.

↘ **AAA Accounting Types**

- EXEC accounting

Accounting is performed when users log in to and out of the CLI of the NAS.

- Command accounting

Records are kept on the commands that users run on the CLI of the NAS.

- Network accounting

Records are kept on the sessions that users set up after completing 802.1X and Web authentication to access the Internet.

Related Configuration

↳ Enabling AAA

By default, AAA is disabled.

To enable AAA, run the **aaa new-model** command.

↳ Configuring an AAA Accounting Scheme

By default, no AAA accounting method is configured.

Before you configure an AAA accounting scheme, determine whether to use local accounting or remote server-group accounting. If remote server-group accounting needs to be implemented, configure a RADIUS or TACACS+ server in advance. If local accounting needs to be implemented, configure the local user database information on the NAS.

↳ Configuring an AAA Accounting Method List

By default, no AAA accounting method list is configured.

Determine the access mode to be configured in advance. Then configure accounting methods according to the access mode.

1.3.4 Multi-Domain AAA

In a multi-domain environment, the NAS can provide the AAA services to users in different domains. The user AVs (such as usernames and passwords, service types, and permissions) may vary with different domains. It is necessary to configure domains to differentiate the user AVs in different domains and configure an AV set (including an AAA service method list, for example, RADIUS) for each domain.

Our products support the following username formats:

1. userid@domain-name
2. domain-name\userid
3. userid.domain-name
4. userid

The fourth format (userid) does not contain a domain name, and it is considered to use the **default** domain name.

The NAS provides the domain-based AAA service based on the following principles:

- Resolves the domain name carried by a user.
- Searches for the user domain according to the domain name.
- Searches for the corresponding AAA method list name according to the domain configuration information on the NAS.
- Searches for the corresponding method list according to the method list name.
- Provides the AAA services based on the method list.

 If any of the preceding procedures fails, the AAA services cannot be provided.

Figure 1-4 shows the typical multi-domain topology.

Figure 1-4

Related Configuration

↳ Enabling AAA

By default, AAA is disabled.

To enable AAA, run the **aaa new-model** command.

↳ Configuring an AAA Method List

By default, no AAA method list is configured.

For details, see section 5.2.1, section 5.2.2, and section 5.2.3.

↳ Enabling the Domain-Based AAA Service

By default, the domain-based AAA service is disabled.

To enable the domain-based AAA service, run the **aaa domain enable** command.

↳ Creating a Domain

By default, no domain is configured.

To configure a domain, run the **aaa domain domain-name** command.

↳ Configuring an AV Set for a Domain

By default, no domain AV set is configured.

A domain AV set contains the following elements: AAA method lists, the maximum number of online users, whether to remove the domain name from the username, and whether the domain name takes effect.

↳ Displaying Domain Configuration

To display domain configuration, run the **show aaa domain** command.

i The system supports a maximum of 32 domains.

1.4 Configuration

Configuration	Description and Command
---------------	-------------------------

Configuration	Description and Command	
Configuring AAA Authentication	 Mandatory if user identities need to be verified.	
	aaa new-model	Enables AAA.
	aaa authentication login	Defines a method list of login authentication.
	aaa authentication enable	Defines a method list of Enable authentication.
	aaa authentication dot1x	Defines a method list of 802.1X authentication.
	aaa authentication ppp	Defines a method list of PPP authentication.
	aaa authentication sslvpn	Defines a method list of SSL VPN authentication.
	aaa authentication web-auth	Configures a method list of Web authentication.
	aaa local authentication attempts	Sets the maximum number of login attempts.
aaa local authentication lockout-time	Sets the maximum lockout time after a login failure.	
Configuring AAA Authorization	 Mandatory if different permissions and services need to be assigned to users.	
	aaa new-model	Enables AAA.
	aaa authorization exec	Defines a method list of EXEC authorization.
	aaa authorization commands	Defines a method list of command authorization.
	aaa authorization network	Configures a method list of network authorization.
	authorization exec	Applies EXEC authorization methods to a specified VTY line.
authorization commands	Applies command authorization methods to a specified VTY line.	
Configuring AAA Accounting	 Mandatory if accounting, statistics, and tracking need to be performed on the network resource usage of users.	
	aaa new-model	Enables AAA.
	aaa accounting exec	Defines a method list of EXEC accounting.
	aaa accounting commands	Defines a method list of command accounting.
	aaa accounting network	Defines a method list of network accounting.
accounting exec	Applies EXEC accounting methods to a specified VTY line.	

Configuration	Description and Command	
	accounting commands	Applies command accounting methods to a specified VTY line.
	aaa accounting update	Enables accounting update.
	aaa accounting update periodic	Configures the accounting update interval.
Configuring an AAA Server Group	 Recommended if a server group needs to be configured to handle AAA through different servers in the group.	
	aaa group server	Creates a user-defined AAA server group.
	server	Adds an AAA server group member.
	ip vrf forwarding	Configures the VRF attribute of an AAA server group.
Configuring the Domain-Based AAA Service	 Mandatory if AAA management of 802.1X access STAs needs to be performed according to domains.	
	aaa new-model	Enables AAA.
	aaa domain enable	Enables the domain-based AAA service.
	aaa domain	Creates a domain and enters domain configuration mode.
	authentication dot1x	Associates the domain with an 802.1X authentication method list.
	accounting network	Associates the domain with a network accounting method list.
	authorization network	Associates the domain with a network authorization method list.
	state	Configures the domain status.
	username-format	Configures whether to contain the domain name in usernames.
access-limit	Configures the maximum number of domain users.	

1.4.1 Configuring AAA Authentication

Configuration Effect

Verify whether users are able to obtain access permission.

Notes

- If an authentication scheme contains multiple authentication methods, these methods are executed according to the configured sequence.
- The next authentication method is executed only when the current method does not respond. If the current method fails, the next method will be not tried.

- When the **none** method is used, users can get access even when no authentication method gets response. Therefore, the **none** method is used only as standby.
-
- i** Normally, do not use None authentication. You can use the **none** method as the last optional authentication method in special cases. For example, all the users who may request access are trusted users and the users' work must not be delayed by system faults. Then you can use the **none** method to assign access permissions to these users when the authentication server does not respond. It is recommended that the local authentication method be added before the **none** method.
-
- If AAA authentication is enabled but no authentication method is configured and the default authentication method does not exist, users can directly log in to the Console without being authenticated. If users log in by other means, the users must pass local authentication.
 - When a user enters the CLI after passing login authentication (the **none** method is not used), the username is recorded. When the user performs Enable authentication, the user is not prompted to enter the username again, because the username that the user entered during login authentication is automatically filled in. However, the user must enter the password previously used for login authentication.
 - The username is not recorded if the user does not perform login authentication when entering the CLI or the **none** method is used during login authentication. Then, a user is required to enter the username each time when performing Enable authentication.

Configuration Steps

↳ Enabling AAA

- Mandatory.
- Run the **aaa new-model** command to enable AAA.
- By default, AAA is disabled.

↳ Defining a Method List of Login Authentication

- Run the **aaa authentication login** command to configure a method list of login authentication.
- This configuration is mandatory if you need to configure a login authentication method list (including the configuration of the default method list).
- By default, no method list of login authentication is configured.

↳ Defining a Method List of Enable Authentication

- Run the **aaa authentication enable** command to configure a method list of Enable authentication.
- This configuration is mandatory if you need to configure an Enable authentication method list. (You can configure only the default method list.)
- By default, no method list of Enable authentication is configured.

↳ Defining a Method List of 802.1X Authentication

- Run the **aaa authentication dot1x** command to configure a method list of 802.1X authentication.

- This configuration is mandatory if you need to configure an 802.1X authentication method list (including the configuration of the default method list).
- By default, no method list of 802.1X authentication is configured.

↘ Defining a Method List of PPP Authentication

- Run the **aaa authentication ppp** command to configure a method list of PPP authentication.
- This configuration is mandatory if you need to configure an authentication method list for PPP dial-up access.
- By default, no method list of PPP authentication is configured.

↘ Defining a Method List of Web Authentication

- Run the **aaa authentication web-auth** command to configure a method list of Web authentication.
- This configuration is mandatory if you need to configure a Web authentication method list (including the configuration of the default method list).
- By default, no method list of Web authentication is configured.

↘ Defining a Method List of SSL VPN Authentication

- Run the **aaa authentication sslvpn** command to configure a method list of SSL VPN authentication.
- This configuration is mandatory if you need to configure an SSL VPN authentication method list (including the configuration of the default method list).
- By default, no method list of SSL VPN authentication is configured.

↘ Setting the Maximum Number of Login Attempts

- Optional.
- By default, a user is allowed to enter passwords up to three times during login.

↘ Setting the Maximum Lockout Time After a Login Failure

- Optional.
- By default, a user is locked for 15 minutes after entering wrong passwords three times.

Verification

- Run the **show aaa method-list** command to display the configured method lists.
- Run the **show aaa lockout** command to display the settings of the maximum number of login attempts and the maximum lockout time after a login failure.
- Run the **show running-config** command to display the authentication method lists associated with login authentication and 802.1X authentication.

Related Commands

↘ Enabling AAA

Command	aaa new-model
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	To enable the AAA services, run this command. None of the rest of AAA commands can be effective if AAA is not enabled.

↘ Defining a Method List of Login Authentication

Command	aaa authentication login { default list-name } method1 [method2...]
Parameter	default: With this parameter used, the configured method list will be defaulted.
Description	<p><i>list-name:</i> Indicates the name of a login authentication method list in characters.</p> <p><i>method:</i> Indicates authentication methods from local, none, group, and subs. A method list contains up to four methods.</p> <p>local: Indicates that the local user database is used for authentication.</p> <p>none: Indicates that authentication is not performed.</p> <p>group: Indicates that a server group is used for authentication. Currently, the RADIUS and TACACS+ server groups are supported.</p> <p>subs: Indicates that the subs database is used for authentication.</p>
Command Mode	Global configuration mode
Usage Guide	<p>If the AAA login authentication service is enabled on the NAS, users must perform login authentication negotiation through AAA. Run the aaa authentication login command to configure the default or optional method lists for login authentication.</p> <p>In a method list, the next method is executed only when the current method does not receive response.</p> <p>After you configure login authentication methods, apply the methods to the VTY lines that require login authentication; otherwise, the methods will not take effect.</p>

↘ Defining a Method List of Enable Authentication

Command	aaa authentication enable default method1 [method2...]
Parameter	default: With this parameter used, the configured method list will be defaulted.
Description	<p><i>list-name:</i> Indicates the name of an Enable authentication method list in characters.</p> <p><i>method:</i> Indicates authentication methods from enable, local, none, and group. A method list contains up to four methods.</p> <p>enable: Indicates that the password that is configured using the enable command is used for authentication.</p> <p>local: Indicates that the local user database is used for authentication.</p> <p>none: Indicates that authentication is not performed.</p> <p>group: Indicates that a server group is used for authentication. Currently, the RADIUS and TACACS+ server groups are supported.</p>
Command Mode	Global configuration mode

Usage Guide	<p>If the AAA login authentication service is enabled on the NAS, users must perform Enable authentication negotiation through AAA. Run the aaa authentication enable command to configure the default or optional method lists for Enable authentication.</p> <p>In a method list, the next method is executed only when the current method does not receive response.</p>
--------------------	--

▾ Defining a Method List of 802.1X Authentication

Command	aaa authentication dot1x { default <i>list-name</i> } <i>method1</i> [<i>method2...</i>]
Parameter Description	<p>default: With this parameter used, the configured method list will be defaulted.</p> <p><i>list-name</i>: Indicates the name of an 802.1X authentication method list in characters.</p> <p><i>method</i>: Indicates authentication methods from local, none, and group. A method list contains up to four methods.</p> <p>local: Indicates that the local user database is used for authentication.</p> <p>none: Indicates that authentication is not performed.</p> <p>group: Indicates that a server group is used for authentication. Currently, the RADIUS server group is supported.</p>
Command Mode	Global configuration mode
Usage Guide	<p>If the AAA 802.1X authentication service is enabled on the NAS, users must perform 802.1X authentication negotiation through AAA. Run the aaa authentication dot1x command to configure the default or optional method lists for 802.1X authentication.</p> <p>In a method list, the next method is executed only when the current method does not receive response.</p>

▾ Defining a Method List of PPP, Web, iPortal or SSL VPN Authentication

Command	aaa authentication { ppp web-auth sslvpn } { default <i>list-name</i> } <i>method1</i> [<i>method2...</i>]
Parameter Description	<p>ppp: Configures a method list of PPP authentication.</p> <p>web-auth: Configures a method list of Web authentication.</p> <p>sslvpn: Configures a method list of SSL VPN authentication.</p> <p>default: With this parameter used, the configured method list will be defaulted.</p> <p><i>list-name</i>: Indicates the name of a PPP authentication method list in characters.</p> <p><i>method</i>: Indicates authentication methods from local, none, group, and subs. A method list contains up to four methods.</p> <p>local: Indicates that the local user database is used for authentication.</p> <p>none: Indicates that authentication is not performed.</p> <p>group: Indicates that a server group is used for authentication. Currently, the RADIUS and TACACS+ server groups are supported.</p> <p>subs: Specifies the SUBS authentication method using the SUBS database.</p>
Command Mode	Global configuration mode
Usage Guide	<p>If the AAA PPP authentication service is enabled on the NAS, users must perform PPP authentication negotiation through AAA. Run the aaa authentication ppp command to configure the default or optional method lists for PPP authentication.</p>

	In a method list, the next method is executed only when the current method does not receive response.
--	---

Setting the Maximum Number of Login Attempts

Command	aaa local authentication attempts <i>max-attempts</i>
Parameter Description	<i>max-attempts</i> : Indicates the maximum number of login attempts. The value ranges from 1 to 2,147,483,647.
Command Mode	Global configuration mode
Usage Guide	Use this command to set the maximum number of times a user can attempt to login.

Setting the Maximum Lockout Time After a Login Failure

Command	aaa local authentication lockout-time <i>lockout-time</i>
Parameter Description	<i>lockout-time</i> : Indicates the time during which a user is locked after entering wrong passwords up to the specified times. The value ranges from 1 to 2,147,483,647, in the unit of minutes.
Command Mode	Global configuration mode
Usage Guide	Use this command to set the maximum time during which a user is locked after entering wrong passwords up to the specified times.

Configuration Example

Configuring AAA Login Authentication

Configure a login authentication method list on the NAS containing **group** *radius* and **local** methods in order.

Scenario Figure 1-5	 <p>The diagram illustrates a network setup for AAA login authentication. On the left, a laptop labeled 'User' is connected to a Network Access Server (NAS) via interface Gi 0/1. The NAS is then connected to a Server via interface Gi 0/2. The Server's IP address is shown as 10.1.1.1.</p>
Configuration Steps	<p>Step 1: Enable AAA.</p> <p>Step 2: Configure a RADIUS or TACACS+ server in advance if group-server authentication needs to be implemented. Configure the local user database information on the NAS if local authentication needs to be implemented. (This example requires the configuration of a RADIUS server and local database information.)</p> <p>Step 3: Configure an AAA authentication method list for login authentication users. (This example uses group <i>radius</i> and local in order.)</p> <p>Step 4: Apply the configured method list to an interface or line. Skip this step if the default authentication method is used.</p>
NAS	<pre>Ruijie#configure terminal Ruijie(config)#username user password pass Ruijie(config)#aaa new-model</pre>

	<pre>Ruijie(config)#radius-server host 10.1.1.1 Ruijie(config)#radius-server key ruijie Ruijie(config)#aaa authentication login list1 group radius local Ruijie(config)#line vty 0 20 Ruijie(config-line)#login authentication list1 Ruijie(config-line)#exit</pre>
Verification	Run the show aaa method-list command on the NAS to display the configuration.
NAS	<pre>Ruijie#show aaa method-list Authentication method-list: aaa authentication login list1 group radius local Accounting method-list: Authorization method-list:</pre>
	<p>Assume that a user remotely logs in to the NAS through Telnet. The user is prompted to enter the username and password on the CLI.</p> <p>The user must enter the correct username and password to access the NAS.</p>
User	<pre>User Access Verification Username:user Password:pass</pre>

▾ Configuring AAA Enable Authentication

Configure an Enable authentication method list on the NAS containing **group** *radius*, **local**, and then **enable** methods in order.

Scenario Figure 1-6	 <pre> graph LR User[User] --- Gi01[Gi 0/1] --- NAS[NAS] NAS --- Gi02[Gi 0/2] --- Server[Server] Server --- IP[10.1.1.1] </pre>
Configuration Steps	<p>Step 1: Enable AAA.</p> <p>Step 2: Configure a RADIUS or TACACS+ server in advance if group-server authentication needs to be implemented. Configure the local user database information on the NAS if local authentication needs to be</p>

	<p>implemented. Configure Enable authentication passwords on the NAS if you use Enable password authentication.</p> <p>Step 3: Configure an AAA authentication method list for Enable authentication users.</p> <p> You can define only one Enable authentication method list globally. You do not need to define the list name but just default it. After that, it will be applied automatically.</p>
NAS	<pre>Ruijie#configure terminal Ruijie(config)#username user privilege 15 password pass Ruijie(config)#enable secret w Ruijie(config)#aaa new-model Ruijie(config)#radius-server host 10.1.1.1 Ruijie(config)#radius-server key ruijie Ruijie(config)#aaa authentication enable default group radius local enable</pre>
Verification	Run the show aaa method-list command on the NAS to display the configuration.
NAS	<pre>Ruijie#show aaa method-list Authentication method-list: aaa authentication enable default group radius local enable Accounting method-list: Authorization method-list:</pre>
	The CLI displays an authentication prompt when the user level is updated to level 15. The user must enter the correct username and password to access the NAS.
NAS	<pre>Ruijie>enable Username:user Password:pass Ruijie#</pre>

📌 Configuring AAA 802.1X Authentication

Configure an 802.1X authentication method list on the NAS containing **group radius**, and then **local** methods in order.

Scenario Figure 1-7	
Configuration Steps	<p>Step 1: Enable AAA.</p> <p>Step 2: Configure a RADIUS server in advance if group-server authentication needs to be implemented. Configure the local user database information on the NAS if local authentication needs to be implemented. (This example requires the configuration of a RADIUS server and local database information.) Currently, 802.1X authentication does not support TACACS+.</p> <p>Step 3: Configure an AAA authentication method list for 802.1X authentication users. (This example uses group radius and local in order.)</p> <p>Step 4: Apply the AAA authentication method list. Skip this step if the default authentication method is used.</p> <p>Step 5: Enable 802.1X authentication on an interface.</p>
NAS	<pre>Ruijie#configure terminal Ruijie(config)#username user1 password pass1 Ruijie(config)#username user2 password pass2 Ruijie(config)#aaa new-model Ruijie(config)#radius-server host 10.1.1.1 Ruijie(config)#radius-server key ruijie Ruijie(config)#aaa authentication dot1x default group radius local Ruijie(config)#interface gigabitEthernet 0/1 Ruijie(config-if-gigabitEthernet 0/1)#dot1x port-control auto Ruijie(config-if-gigabitEthernet 0/1)#exit</pre>
Verification	<p>Run the show aaa method-list command on the NAS to display the configuration.</p>
NAS	<pre>Ruijie#show aaa method-list Authentication method-list: aaa authentication dot1x default group radius local Accounting method-list: Authorization method-list:</pre>

Common Errors

- No RADIUS server or TACACS+ server is configured.
- Usernames and passwords are not configured in the local database.

1.4.2 Configuring AAA Authorization

Configuration Effect

- Determine what services or permissions authenticated users can enjoy.

Notes

- EXEC authorization is often used with login authentication, which can be implemented on the same line. Authorization and authentication can be performed using different methods and servers. Therefore, the results of the same user may be different. If a user passes login authentication but fails in EXEC authorization, the user cannot enter the CLI.
- The authorization methods in an authorization scheme are executed in accordance with the method configuration sequence. The next authorization method is executed only when the current method does not receive response. If authorization fails using a method, the next method will be not tried.
- Command authorization is supported only by TACACS+.
- Console authorization: The RGOS can differentiate between the users who log in through the Console and the users who log in through other types of clients. You can enable or disable command authorization for the users who log in through the Console. If command authorization is disabled for these users, the command authorization method list applied to the Console line no longer takes effect.

Configuration Steps

↳ Enabling AAA

- Mandatory.
- Run the **aaa new-model** command to enable AAA.
- By default, AAA is disabled.

↳ Defining a Method List of EXEC Authorization

- Run the **aaa authorization exec** command to configure a method list of EXEC authorization.
- This configuration is mandatory if you need to configure an EXEC authorization method list (including the configuration of the default method list).
- By default, no EXEC authorization method list is configured.

i The default access permission level of EXEC users is the lowest. (Console users can connect to the NAS through the Console port or Telnet. Each connection is counted as an EXEC user, for example, a Telnet user and SSH user.)

↳ Defining a Method List of Command Authorization

- Run the **aaa authorization commands** command to configure a method list of command authorization.
- This configuration is mandatory if you need to configure a command authorization method list (including the configuration of the default method list).
- By default, no command authorization method list is configured.

↘ **Configuring a Method List of Network Authorization**

- Run the **aaa authorization network** command to configure a method list of network authorization.
- This configuration is mandatory if you need to configure a network authorization method list (including the configuration of the default method list).
- By default, no authorization method is configured.

↘ **Applying EXEC Authorization Methods to a Specified VTY Line**

- Run the **authorization exec** command in line configuration mode to apply EXEC authorization methods to a specified VTY line.
- This configuration is mandatory if you need to apply an EXEC authorization method list to a specified VTY line.
- By default, all VTY lines are associated with the default authorization method list.

↘ **Applying Command Authorization Methods to a Specified VTY Line**

- Run the **authorization commands** command in line configuration mode to apply command authorization methods to a specified VTY line.
- This configuration is mandatory if you need to apply a command authorization method list to a specified VTY line.
- By default, all VTY lines are associated with the default authorization method list.

↘ **Enabling Authorization for Commands in Configuration Modes**

- Run the **aaa authorization config-commands** command to enable authorization for commands in configuration modes.
- By default, authorization is disabled for commands in configuration modes.

↘ **Enabling Authorization for the Console to Run Commands**

- Run the **aaa authorization console** command to enable authorization for console users to run commands.
- By default, authorization is disabled for the Console to run commands.

Verification

Run the **show running-config** command to verify the configuration.

Related Commands

↘ **Enabling AAA**

Command	aaa new-model
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	To enable the AAA services, run this command. None of the rest of AAA commands can be effective if AAA is not enabled.

↘ Defining a Method List of EXEC Authorization

Command	aaa authorization exec { default list-name } method1 [method2...]
Parameter	default: With this parameter used, the configured method list will be defaulted.
Description	<p><i>list-name:</i> Indicates the name of an EXEC authorization method list in characters.</p> <p><i>method:</i> Specifies authentication methods from local, none, and group. A method list contains up to four methods.</p> <p>local: Indicates that the local user database is used for EXEC authorization.</p> <p>none: Indicates that EXEC authorization is not performed.</p> <p>group: Indicates that a server group is used for EXEC authorization. Currently, the RADIUS and TACACS+ server groups are supported.</p>
Command Mode	Global configuration mode
Usage Guide	<p>The RGOS supports authorization of the users who log in to the CLI of the NAS to assign the users CLI operation permission levels (0 to 15). Currently, EXEC authorization is performed only on the users who have passed login authentication. If a user fails in EXEC authorization, the user cannot enter the CLI.</p> <p>After you configure EXEC authorization methods, apply the methods to the VTY lines that require EXEC authorization; otherwise, the methods will not take effect.</p>

↘ Defining a Method List of Command Authorization

Command	aaa authorization commands level { default list-name } method1 [method2...]
Parameter	default: With this parameter used, the configured method list will be defaulted.
Description	<p><i>list-name:</i> Indicates the name of a command authorization method list in characters.</p> <p><i>method:</i> Indicates authentication methods from none and group. A method list contains up to four methods.</p> <p>none: Indicates that command authorization is not performed.</p> <p>group: Indicates that a server group is used for command authorization. Currently, the TACACS+ server group is supported.</p>
Command Mode	Global configuration mode
Usage Guide	<p>The RGOS supports authorization of the commands executable by users. When a user enters a command, AAA sends the command to the authentication server. If the authentication server permits the execution, the command is executed. If the authentication server forbids the execution, the command is not executed and a message is displayed showing that the execution is rejected.</p>

	<p>When you configure command authorization, specify the command level, which is used as the default level. (For example, if a command above Level 14 is visible to users, the default level of the command is 14.)</p> <p>After you configure command authorization methods, apply the methods to the VTY lines that require command authorization; otherwise, the methods will not take effect.</p>
--	---

↘ Configuring a Method List of Network Authorization

Command	aaa authorization network { default list-name } method1 [method2...]
Parameter Description	<p>default: With this parameter used, the configured method list will be defaulted.</p> <p><i>list-name:</i> Indicates the name of a network authorization method list in characters.</p> <p><i>method:</i> Indicates authentication methods from none and group. A method list contains up to four methods.</p> <p>none: Indicates that authentication is not performed.</p> <p>group: Indicates that a server group is used for network authorization. Currently, the RADIUS and TACACS+ server groups are supported.</p>
Command Mode	Global configuration mode
Usage Guide	<p>The RGOS supports authorization of network-related service requests such as PPP and SLIP requests. After authorization is configured, all authenticated users or interfaces are authorized automatically.</p> <p>You can configure three different authorization methods. The next authorization method is executed only when the current method does not receive response. If authorization fails using a method, the next method will be not tried.</p> <p>RADIUS or TACACS+ servers return a series of AV pairs to authorize authenticated users. Network authorization is based on authentication. Only authenticated users can perform network authorization.</p>

↘ Enabling Authorization for Commands in Configuration Modes (Including the Global Configuration Mode and Sub-Modes)

Command	aaa authorization config-commands
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	If you need to enable authorization for commands only in non-configuration modes (for example, privileged EXEC mode), disable authorization in configuration modes by using the no form of this command. Then users can run commands in configuration mode and sub-modes without authorization.

↘ Enabling Authorization for the Console to Run Commands

Command	aaa authorization console
Parameter Description	N/A
Command Mode	Global configuration mode

Usage Guide	The RGOS can differentiate between the users who log in through the Console and the users who log in through other types of clients. You can enable or disable command authorization for the users who log in through the Console. If command authorization is disabled for these users, the command authorization method list applied to the Console line no longer takes effect.
--------------------	--

Configuration Example

Configuring AAA EXEC Authorization

Configure login authentication and EXEC authorization for users on VTY lines 0 to 4. Login authentication is performed in local mode, and EXEC authorization is performed on a RADIUS server. If the RADIUS server does not respond, users are redirected to the local authorization.

Scenario Figure 1-8	
Configuration Steps	<p>Step 1: Enable AAA.</p> <p>Step 2: Configure a RADIUS or TACACS+ server in advance if remote server-group authorization needs to be implemented. If local authorization needs to be implemented, configure the local user database information on the NAS.</p> <p>Step 3: Configure an AAA authorization method list according to different access modes and service types.</p> <p>Step 4: Apply the configured method list to an interface or line. Skip this step if the default authorization method is used.</p> <p>EXEC authorization is often used with login authentication, which can be implemented on the same line.</p>
NAS	<pre>Ruijie#configure terminal Ruijie(config)#username user password pass Ruijie(config)#username user privilege 6 Ruijie(config)#aaa new-model Ruijie(config)#radius-server host 10.1.1.1 Ruijie(config)#radius-server key test Ruijie(config)#aaa authentication login list1 group local Ruijie(config)#aaa authorization exec list2 group radius local Ruijie(config)#line vty 0 4 Ruijie(config-line)#login authentication list1 Ruijie(config-line)# authorization exec list2 Ruijie(config-line)#exit</pre>

Verification	Run the show run and show aaa method-list commands on the NAS to display the configuration.
NAS	<pre>Ruijie#show aaa method-list Authentication method-list: aaa authentication login list1 group local Accounting method-list: Authorization method-list: aaa authorization exec list2 group radius local</pre>
	<pre>Ruijie# show running-config aaa new-model ! aaa authorization exec list2 group local aaa authentication login list1 group radius local ! username user password pass username user privilege 6 ! radius-server host 10.1.1.1 radius-server key 7 093b100133 ! line con 0 line vty 0 4 authorization exec list2 login authentication list1 ! End</pre>

📌 Configuring AAA Command Authorization

Provide command authorization for login users according to the following default authorization method: Authorize level-15 commands first by using a TACACS+ server. If the TACACS+ server does not respond, local authorization is performed. Authorization is applied to the users who log in through the Console and the users who log in through other types of clients.

Scenario Figure 1-9	
Configuration Steps	<p>Step 1: Enable AAA.</p> <p>Step 2: Configure a RADIUS or TACACS+ server in advance if remote server-group authorization needs to be implemented. If local authorization needs to be implemented, configure the local user database information on the NAS.</p> <p>Step 3: Configure an AAA authorization method list according to different access modes and service types.</p> <p>Step 4: Apply the configured method list to an interface or line. Skip this step if the default authorization method is used.</p>
NAS	<pre>Ruijie#configure terminal Ruijie(config)#username user1 password pass1 Ruijie(config)#username user1 privilege 15 Ruijie(config)#aaa new-model Ruijie(config)#tacacs-server host 192.168.217.10 Ruijie(config)#tacacs-server key aaa Ruijie(config)#aaa authentication login default local Ruijie(config)#aaa authorization commands 15 default group tacacs+ local Ruijie(config)#aaa authorization console</pre>
Verification	<p>Run the show run and show aaa method-list commands on the NAS to display the configuration.</p>
NAS	<pre>Ruijie#show aaa method-list Authentication method-list: aaa authentication login default local Accounting method-list: Authorization method-list: aaa authorization commands 15 default group tacacs+ local</pre>
	<pre>Ruijie#show run ! aaa new-model</pre>

```

↘ Configuring AAA Network Authorization

Scenario Figure 1-10	
Configuration Steps	<p>Step 1: Enable AAA.</p> <p>Step 2: Configure a RADIUS or TACACS+ server in advance if remote server-group authorization needs to be implemented. If local authorization needs to be implemented, configure the local user database information on the NAS.</p> <p>Step 3: Configure an AAA authorization method list according to different access modes and service types.</p>

	Step 4: Apply the configured method list to an interface or line. Skip this step if the default authorization method is used.
NAS	<pre>Ruijie#configure terminal Ruijie(config)#aaa new-model Ruijie(config)#radius-server host 10.1.1.1 Ruijie(config)#radius-server key test Ruijie(config)#aaa authorization network default group radius none Ruijie(config)# end</pre>
Verification	Run the show aaa method-list command on the NAS to display the configuration.
NAS	<pre>Ruijie#show aaa method-list Authentication method-list: Accounting method-list: Authorization method-list: aaa authorization network default group radius none</pre>

Common Errors

N/A

1.4.3 Configuring AAA Accounting

Configuration Effect

- Record the network resource usage of users.
- Record the user login and logout processes and the commands executed by users during device management.

Notes

About accounting methods:

- If an accounting scheme contains multiple accounting methods, these methods are executed according to the method configuration sequence. The next accounting method is executed only when the current method does not receive response. If accounting fails using a method, the next method will be not tried.
- After the default accounting method list is configured, it is applied to all VTY lines automatically. If a non-default accounting method list is applied to a line, it will replace the default one. If you apply an undefined method list to a line,

the system will display a message indicating that accounting on this line is ineffective. Accounting will take effect only when a defined method list is applied.

EXEC accounting:

- EXEC accounting is performed only when login authentication on the NAS is completed. EXEC accounting is not performed if login authentication is not configured or the **none** method is used for authentication. If Start accounting is not performed for a user upon login, Stop accounting will not be performed when the user logs out.

Command accounting

- Only the TACACS+ protocol supports command accounting.

Configuration Steps

↳ Enabling AAA

- Mandatory.
- Run the **aaa new-model** command to enable AAA.
- By default, AAA is disabled.

↳ Defining a Method List of EXEC Accounting

- Run the **aaa accounting exec** command to configure a method list of EXEC accounting.
- This configuration is mandatory if you need to configure an EXEC accounting method list (including the configuration of the default method list).
- The default access permission level of EXEC users is the lowest. (Console users can connect to the NAS through the Console port or Telnet. Each connection is counted as an EXEC user, for example, a Telnet user and SSH user.)
- By default, no EXEC accounting method list is configured.

↳ Defining a Method List of Command Accounting

- Run the **aaa accounting commands** command to configure a method list of command accounting.
- This configuration is mandatory if you need to configure a command accounting method list (including the configuration of the default method list).
- By default, no command accounting method list is configured. Only the TACACS+ protocol supports command accounting.

↳ Defining a Method List of Network Accounting

- Run the **aaa accounting network** command to configure a method list of network accounting.
- This configuration is mandatory if you need to configure a network accounting method list (including the configuration of the default method list).
- By default, no network accounting method list is configured.

↳ Applying EXEC Accounting Methods to a Specified VTY Line

- Run the **accounting exec** command in line configuration mode to apply EXEC accounting methods to a specified VTY line.
- This configuration is mandatory if you need to apply an EXEC accounting method list to a specified VTY line.
- You do not need to run this command if you apply the default method list.
- By default, all VTY lines are associated with the default accounting method list.

▾ Applying Command Accounting Methods to a Specified VTY Line

- Run the **accounting commands** command in line configuration mode to apply command accounting methods to a specified VTY line.
- This configuration is mandatory if you need to apply a command accounting method list to a specified VTY line.
- You do not need to run this command if you apply the default method list.
- By default, all VTY lines are associated with the default accounting method list.

▾ Applying 802.1X Network Accounting Methods

- Run the **dot1x accounting network** command to configure 802.1X network accounting methods.
- This configuration is mandatory if you need to specify 802.1X network accounting methods.
- You do not need to run this command if you apply the default method list.
- By default, all VTY lines are associated with the default accounting method list.

▾ Enabling Accounting Update

- Optional.
- It is recommended that accounting update be configured for improved accounting accuracy.
- By default, accounting update is disabled.

▾ Configuring the Accounting Update Interval

- Optional.
- It is recommended that the accounting update interval not be configured unless otherwise specified.

Verification

Run the **show running-config** command to verify the configuration.

Related Commands

▾ Enabling AAA

Command	aaa new-model
Parameter	N/A
Description	
Command	Global configuration mode

Mode	
Usage Guide	To enable the AAA services, run this command. None of the rest of AAA commands can be effective if AAA is not enabled.

▾ Defining a Method List of EXEC Accounting

Command	aaa accounting exec { default <i>list-name</i> } start-stop <i>method1</i> [<i>method2...</i>]
Parameter Description	<p>default: With this parameter used, the configured method list will be defaulted.</p> <p><i>list-name:</i> Indicates the name of an EXEC accounting method list in characters.</p> <p><i>method:</i> Indicates authentication methods from none and group. A method list contains up to four methods.</p> <p>none: Indicates that EXEC accounting is not performed.</p> <p>group: Indicates that a server group is used for EXEC accounting. Currently, the RADIUS and TACACS+ server groups are supported.</p>
Command Mode	Global configuration mode
Usage Guide	<p>The RGOS enables EXEC accounting only when login authentication is completed. EXEC accounting is not performed if login authentication is not performed or the none authentication method is used.</p> <p>After accounting is enabled, when a user logs in to the CLI of the NAS, the NAS sends a start-accounting message to the authentication server. When the user logs out, the NAS sends a stop-accounting message to the authentication server. If the NAS does not send a start-accounting message when the user logs in, the NAS will not send a stop-accounting message when the user logs out.</p> <p>After you configure EXEC accounting methods, apply the methods to the VTY lines that require EXEC accounting; otherwise, the methods will not take effect.</p>

▾ Defining a Method List of Command Accounting

Command	aaa accounting commands <i>level</i> { default <i>list-name</i> } start-stop <i>method1</i> [<i>method2...</i>]
Parameter Description	<p><i>level:</i> Indicates the command level for which accounting will be performed. The value ranges from 0 to 15.</p> <p>After a command of the configured level is executed, the accounting server records related information based on the received accounting packet.</p> <p>default: With this parameter used, the configured method list will be defaulted.</p> <p><i>list-name:</i> Indicates the name of a command accounting method list in characters.</p> <p><i>method:</i> Indicates authentication methods from none and group. A method list contains up to four methods.</p> <p>none: Indicates that command accounting is not performed.</p> <p>group: Indicates that a server group is used for command accounting. Currently, the TACACS+ server group is supported.</p>
Command Mode	Global configuration mode
Usage Guide	<p>The RGOS enables command accounting only when login authentication is completed. Command accounting is not performed if login authentication is not performed or the none authentication method is used. After accounting is enabled, the NAS records information about the commands of the configured level that users run and sends the information to the authentication server.</p> <p>After you configure command accounting methods, apply the methods to the VTY lines that require</p>

	command accounting; otherwise, the methods will not take effect.
--	--

↘ Defining a Method List of Network Accounting

Command	aaa accounting network { default <i>list-name</i> } start-stop <i>method1</i> [<i>method2...</i>]
Parameter	default: With this parameter used, the configured method list will be defaulted.
Description	<p><i>list-name:</i> Indicates the name of a network accounting method list in characters.</p> <p>start-stop: Indicates that a start-accounting message and a stop-accounting message are sent when a user accesses a network and when the user disconnects from the network respectively. The start-accounting message indicates that the user is allowed to access the network, regardless of whether accounting is successfully enabled.</p> <p><i>method:</i> Indicates authentication methods from none and group. A method list contains up to four methods.</p> <p>none: Indicates that network accounting is not performed.</p> <p>group: Indicates that a server group is used for network accounting. Currently, the RADIUS and TACACS+ server groups are supported.</p>
Command Mode	Global configuration mode
Usage Guide	The RGOS sends record attributes to the authentication server to perform accounting of user activities. The start-stop keyword is used to configure user accounting options.

↘ Enabling Accounting Update

Command	aaa accounting update
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	Accounting update cannot be used if the AAA services are not enabled. After the AAA services are enabled, run this command to enable accounting update.

↘ Configuring the Accounting Update Interval

Command	aaa accounting update periodic <i>interval</i>
Parameter	<i>Interval:</i> Indicates the accounting update interval, in the unit of minutes. The shortest is 1 minute.
Description	
Command Mode	Global configuration mode
Usage Guide	Accounting update cannot be used if the AAA services are not enabled. After the AAA services are enabled, run this command to configure the accounting update interval.

Configuration Example

↘ Configuring AAA EXEC Accounting

Configure login authentication and EXEC accounting for users on VTY lines 0 to 4. Login authentication is performed in local mode, and EXEC accounting is performed on a RADIUS server.

Scenario Figure 1-11	
Configuration Steps	<p>Step 1: Enable AAA.</p> <p>If remote server-group accounting needs to be implemented, configure a RADIUS or TACACS+ server in advance.</p> <p>Step 2: Configure an AAA accounting method list according to different access modes and service types.</p> <p>Step 3: Apply the configured method list to an interface or line. Skip this step if the default accounting method is used.</p>
NAS	<pre>Ruijie#configure terminal Ruijie(config)#username user password pass Ruijie(config)#aaa new-model Ruijie(config)#radius-server host 10.1.1.1 Ruijie(config)#radius-server key test Ruijie(config)#aaa authentication login list1 group local Ruijie(config)#aaa accounting exec list3 start-stop group radius Ruijie(config)#line vty 0 4 Ruijie(config-line)#login authentication list1 Ruijie(config-line)# accounting exec list3 Ruijie(config-line)#exit</pre>

NAS	<pre>Ruijie#show aaa method-list Authentication method-list: aaa authentication dotlx autlx group radius local Accounting method-list: aaa accounting network acclx start-stop group radius Authorization method-list:</pre>

Common Errors

N/A

1.4.4 Configuring an AAA Server Group

Configuration Effect

- Create a user-defined server group and add one or more servers to the group.
- When you configure authentication, authorization, and accounting method lists, name the methods after the server group name so that the servers in the group are used to handle authentication, authorization, and accounting requests.
- Use self-defined server groups to separate authentication, authorization, and accounting.

Notes

In a user-defined server group, you can specify and apply only the servers in the default server group.

Configuration Steps

📌 Creating a User-Defined AAA Server Group

- Mandatory.
- Assign a meaningful name to the user-defined server group. Do not use the predefined **radius** and **tacacs+** keywords in naming.

✚ Adding an AAA Server Group Member

- Mandatory.
- Run the **server** command to add AAA server group members.
- By default, a user-defined server group does not have servers.

✚ Configuring the VRF Attribute of an AAA Server Group

- Optional.
- Run the **ip vrf forwarding** command to configure the VRF attribute of an AAA server group.
- By default, the AAA server group belongs to the global VRF table.

Verification

Run the **show aaa group** command to verify the configuration.

Related Commands

✚ Creating a User-Defined AAA Server Group

Command	aaa group server {radius tacacs+} name
Parameter Description	<i>name</i> : Indicates the name of the server group to be created. The name must not contain the radius and tacacs+ keywords because they are the names of the default RADIUS and TACACS+ server groups.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure an AAA server group. Currently, the RADIUS and TACACS+ server groups are supported.

✚ Adding an AAA Server Group Member

Command	server ip-addr [auth-port port1] [acct-port port2]
Parameter Description	<i>ip-addr</i> : Indicates the IP address of a server. <i>port1</i> : Indicates the authentication port of a server. (This parameter is supported only by the RADIUS server group.) <i>port2</i> : Indicates the accounting port of a server. (This parameter is supported only by the RADIUS server group.)
Command Mode	Server group configuration mode
Usage Guide	When you add servers to a server group, the default ports are used if you do not specify ports.

✚ Configuring the VRF Attribute of an AAA Server Group

Command	ip vrf forwarding vrf_name
Parameter Description	<i>vrf_name</i> : Indicates the name of a VRF table.

Command Mode	Server group configuration mode
Usage Guide	Use this command to assign a VRF table to the specified server group.

Configuration Example

Creating an AAA Server Group

Create RADIUS server groups named g1 and g2. The IP addresses of the servers in g1 are 10.1.1.1 and 10.1.1.2, and the IP addresses of the servers in g2 are 10.1.1.3 and 10.1.1.4.

Scenario Figure 1-14	
Prerequisites	<ol style="list-style-type: none"> The required interfaces, IP addresses, and VLANs have been configured on the network, network connections have been set up, and the routes from the NAS to servers are reachable. Enable AAA.
Configuration Steps	<p>Step 1: Configure a server (which belongs to the default server group).</p> <p>Step 2: Create user-defined AAA server groups.</p> <p>Step 3: Add servers to the AAA server groups.</p>
NAS	<pre>Ruijie#configure terminal Ruijie(config)#radius-server host 10.1.1.1 Ruijie(config)#radius-server host 10.1.1.2 Ruijie(config)#radius-server host 10.1.1.3 Ruijie(config)#radius-server host 10.1.1.4 Ruijie(config)#radius-server key secret Ruijie(config)#aaa group server radius g1 Ruijie(config-gs-radius)#server 10.1.1.1 Ruijie(config-gs-radius)#server 10.1.1.2</pre>

	<pre>Ruijie(config-gs-radius)#exit Ruijie(config)#aaa group server radius g2 Ruijie(config-gs-radius)#server 10.1.1.3 Ruijie(config-gs-radius)#server 10.1.1.4 Ruijie(config-gs-radius)#exit</pre>
Verification	Run the show aaa group and show run commands on the NAS to display the configuration.
NAS	<pre>Ruijie#show aaa group Type Reference Name ----- radius 1 radius tacacs+ 1 tacacs+ radius 1 g1 radius 1 g2</pre>
	<pre>Ruijie#show run ! radius-server host 10.1.1.1 radius-server host 10.1.1.2 radius-server host 10.1.1.3 radius-server host 10.1.1.4 radius-server key secret ! aaa group server radius g1 server 10.1.1.1 server 10.1.1.2 ! aaa group server radius g2 server 10.1.1.3 server 10.1.1.4 ! !</pre>

Common Errors

- For RADIUS servers that use non-default authentication and accounting ports, when you run the **server** command to add servers, specify the authentication or accounting port.
- Only the RADIUS server group can be configured with the VRF attribute.

1.4.5 Configuring the Domain-Based AAA Service

Configuration Effect

Create AAA schemes for 802.1X users in different domains.

Notes

About referencing method lists in domains:

- The AAA method lists that you select in domain configuration mode should be defined in advance. If the method lists are not defined in advance, when you select them in domain configuration mode, the system prompts that the configurations do not exist.
- The names of the AAA method lists selected in domain configuration mode must be consistent with those of the method lists defined for the AAA service. If they are inconsistent, the AAA service cannot be properly provided to the users in the domain.

About the default domain:

- Default domain: After the domain-based AAA service is enabled, if a username does not carry domain information, the AAA service is provided to the user based on the default domain. If the domain information carried by the username is not configured in the system, the system determines that the user is unauthorized and will not provide the AAA service to the user. If the default domain is not configured initially, it must be created manually.
- When the domain-based AAA service is enabled, the default domain is not configured by default and needs to be created manually. The default domain name is **default**. It is used to provide the AAA service to the users whose usernames do not carry domain information. If the default domain is not configured, the AAA service is not available for the users whose usernames do not carry domain information.

About domain names:

- The domain names carried by usernames and those configured on the NAS are matched in the longest matching principle. For example, if two domains, **domain.com** and **domain.com.cn** are configured on a NAS and a user sends a request carrying **aaa@domain.com**, the NAS determines that the user belongs to **domain.com**, instead of **domain.com.cn**.
- If the username of an authenticated user carries domain information but the domain is not configured on the NAS, the AAA service is not provided to the user.

Configuration Steps

▾ Enabling AAA

- Mandatory.
- Run the **aaa new-model** command to enable AAA.
- By default, AAA is disabled.

▾ Enabling the Domain-Based AAA Service

- Mandatory.
- Run the **aaa domain enable** command to enable the domain-based AAA service.
- By default, the domain-based AAA service is disabled.

▾ Creating a Domain and Entering Domain Configuration Mode

- Mandatory.
- Run the **aaa domain** command to create a domain or enter the configured domain.
- By default, no domain is configured.

▾ Associating the Domain with an 802.1X Authentication Method List

- Run the **authentication dot1x** command to associate the domain with an 802.1X authentication method list.
- This configuration is mandatory if you need to apply a specified 802.1X authentication method list to the domain.
- Currently, the domain-based AAA service is applicable only to 802.1X access.

▾ Associating the Domain with a Network Accounting Method List

- Run the **accounting network** command to associate the domain with a network accounting method.
- This configuration is mandatory if you need to apply a specified network accounting method list to the domain.
- If a domain is not associated with a network accounting method list, by default, the global default method list is used for accounting.

▾ Associating the Domain with a Network Authorization Method List

- Run the **authorization network** command to associate the domain with a network authorization method list.
- This configuration is mandatory if you need to apply a specified network authorization method list to the domain.
- If a domain is not associated with a network authorization method list, by default, the global default method list is used for authorization.

▾ Configuring the Domain Status

- Optional.
- When a domain is in Block state, the users in the domain cannot log in.
- By default, after a domain is created, its state is Active, indicating that all the users in the domain are allowed to request network services.

▾ Configuring Whether to Contain the Domain Name in Usernames

- Optional.
- By default, the usernames exchanged between the NAS and an authentication server carry domain information.

↘ Configuring the Maximum Number of Domain Users

- Optional.
- By default, the maximum number of access users allowed in a domain is not limited.

Verification

Run the **show aaa domain** command to verify the configuration.

Related Commands

↘ Enabling AAA

Command	aaa new-model
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	To enable the AAA services, run this command. None of the rest of AAA commands can be effective if AAA is not enabled.

↘ Enabling the Domain-Based AAA Service

Command	aaa domain enable
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	Use this command to enable the domain-based AAA service.

↘ Creating a Domain and Entering Domain Configuration Mode

Command	aaa domain { default domain-name }
Parameter	default: Uses this parameter to configure the default domain.
Description	domain-name: Indicates the name of the domain to be created.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure a domain to provide the domain-based AAA service. The default parameter specifies the default domain. If a username does not carry domain information, the NAS uses the method list associated with the default domain to provide the AAA service to the user. The domain-name parameter specifies the name of the domain to be created. If the domain name carried by a username matches the configured domain name, the NAS uses the method list associated with this domain to provide the AAA

	service to the user. The system supports a maximum of 32 domains.
--	---

↘ Associating the Domain with an 802.1X Authentication Method List

Command	authentication dot1x { default <i>list-name</i> }
Parameter	default: Indicates that the default method list is used.
Description	<i>list-name:</i> Indicates the name of the method list to be associated.
Command Mode	Domain configuration mode
Usage Guide	Use this command to associate the domain with a 802.1X authentication method list.

↘ Associating the Domain with a Web Authentication Method List

Command	authentication web-auth { default <i>list-name</i> }
Parameter	default: Indicates that the default method list is used.
Description	<i>list-name:</i> Indicates the name of the method list to be associated.
Command Mode	Domain configuration mode
Usage Guide	Use this command to associate the domain with a Web authentication method list.

↘ Associating the Domain with a Network Accounting Method List

Command	accounting network { default <i>list-name</i> }
Parameter	default: Indicates that the default method list is used.
Description	<i>list-name:</i> Indicates the name of the method list to be associated.
Command Mode	Domain configuration mode
Usage Guide	Use this command to associate the domain with a network accounting method list.

↘ Associating the Domain with a Network Authorization Method List

Command	authorization network { default <i>list-name</i> }
Parameter	default: Indicates that the default method list is used.
Description	<i>list-name:</i> Indicates the name of the method list to be associated.
Command Mode	Domain configuration mode
Usage Guide	

↘ Configuring the Domain Status

Command	state { block active }
Parameter	block: Indicates that the configured domain is invalid.
Description	active: Indicates that the configured domain is valid.
Command Mode	Domain configuration mode

Usage Guide	Use this command to make the configured domain valid or invalid.
--------------------	--

↘ Configuring Whether to Contain the Domain Name in Usernames

Command	<code>username-format { without-domain with-domain }</code>
Parameter	without-domain: Indicates to remove domain information from usernames.
Description	with-domain: Indicates to keep domain information in usernames.
Command Mode	Domain configuration mode
Usage Guide	Use this command in domain configuration mode to determine whether to include domain information in usernames when the NAS interacts with authentication servers in a specified domain.

↘ Configuring the Maximum Number of Domain Users

Command	<code>access-limit num</code>
Parameter	<i>num</i> : Indicates the maximum number of access users allowed in a domain. This limit is applicable only to 802.1X STAs.
Description	
Command Mode	Domain configuration mode
Usage Guide	Use this command to limit the number of access users in a domain.

Configuration Example

↘ Configuring the Domain-Based AAA Services

Configure authentication and accounting through a RADIUS server to 802.1X users (username: *user@domain.com*) that access the NAS. The usernames that the NAS sends to the RADIUS server do not carry domain information, and the number of access users is not limited.

Scenario Figure 1-15	 <pre> graph LR User[User] --- Gi01[Gi 0/1] --- NAS[NAS] NAS --- Gi02[Gi 0/2] --- Server[Server] Server --- IP[10.1.1.1] </pre>
Configuration Steps	<p>The following example shows how to configure RADIUS authentication and accounting, which requires the configuration of a RADIUS server in advance.</p> <p>Step 1: Enable AAA.</p> <p>Step 2: Define an AAA method list.</p> <p>Step 3: Enable the domain-based AAA service.</p> <p>Step 4: Create a domain.</p> <p>Step 5: Associate the domain with the AAA method list.</p> <p>Step 6: Configure the domain attribute.</p>

2 Configuring RADIUS

2.1 Overview

The Remote Authentication Dial-In User Service (RADIUS) is a distributed client/server system.

RADIUS works with the Authentication, Authorization, and Accounting (AAA) to conduct identity authentication on users who attempt to access a network, to prevent unauthorized access. In RGOS implementation, a RADIUS client runs on a device or Network Access Server (NAS) and transmits identity authentication requests to the central RADIUS server, where all user identity authentication information and network service information are stored. In addition to the authentication service, the RADIUS server provides authorization and accounting services for access users.

RADIUS is often applied in network environments that have high security requirements and allow the access of remote users. RADIUS is a completely open protocol and the RADIUS server is installed on many operating systems as a component, for example, on UNIX, Windows 2000, and Windows 2008. Therefore, RADIUS is the most widely applied security server currently.

The Dynamic Authorization Extensions to Remote Authentication Dial In User Service is defined in the IETF RFC3576. This protocol defines a user offline management method. Devices communicate with the RADIUS server through the Disconnect-Messages (DMs) to bring authenticated users offline. This protocol implements compatibility between devices of different vendors and the RADIUS server in terms of user offline processing.

In the DM mechanism, the RADIUS server actively initiates a user offline request to a device, the device locates a user according to the user session information, user name, and other information carried in the request and brings the user offline. Then, the device returns a response packet that carries the processing result to the RADIUS server, thereby implementing user offline management of the RADIUS server.

Protocols and Standards

- RFC2865: Remote Authentication Dial In User Service (RADIUS)
- RFC2866: RADIUS Accounting
- RFC2867: RADIUS Accounting Modifications for Tunnel Protocol Support
- RFC2868: RADIUS Attributes for Tunnel Protocol Support
- RFC2869: RADIUS Extensions
- RFC3576: Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS)

2.2 Applications

Application	Description
Providing Authentication, Authorization, and Accounting	Authentication, authorization, and accounting are conducted on access users on a network, to prevent unauthorized access or operations.

Application	Description
Services for Access Users	
Forcing Users to Go Offline	The server forces an authenticated user to go offline.

2.2.1 Providing Authentication, Authorization, and Accounting Services for Access Users

Scenario

RADIUS is typically applied in the authentication, authorization, and accounting of access users. A network device serves as a RADIUS client and transmits user information to a RADIUS server. After completing processing, the RADIUS server returns the authentication acceptance/authentication rejection/accounting response information to the RADIUS client. The RADIUS client performs processing on the access user according to the response from the RADIUS server.

Figure 2-1 Typical RADIUS Networking Topology

Remarks	<p>PC 1 and PC 2 are connected to the RADIUS client as access users in wired mode, and initiate authentication and accounting requests.</p> <p>The RADIUS client is usually an access switch or aggregate switch.</p> <p>The RADIUS server can be a component built in the Windows 2000/2003, Server (IAS), or UNIX operating system or dedicated server software provided by vendors.</p>
----------------	--

Deployment

- Configure access device information on the RADIUS server, including the IP address and shared key of the access devices.
- Configure the AAA method list on the RADIUS client.
- Configure the RADIUS server information on the RADIUS client, including the IP address and shared key.
- Enable access control on the access port of the RADIUS client.
- Configure the network so that the RADIUS client communicates with the RADIUS server successfully.

2.2.2 Forcing Users to Go Offline

Scenario

The RADIUS server forces authenticated online users to go offline for the sake of management.

See Figure 2-1 for the networking topology.

Deployment

- Add the following deployment on the basis of 1.2.1 "Deployment".
- Enable the RADIUS dynamic authorization extension function on the RADIUS client.

2.3 Features

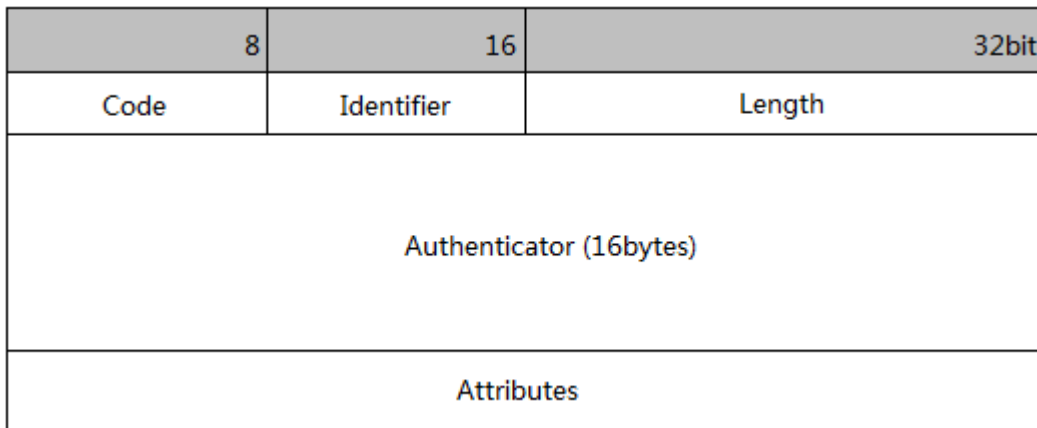

Basic Concepts

Client/Server Mode

- Client: A RADIUS client initiates RADIUS requests and usually runs on a device or NAS. It transmits user information to the RADIUS server, receives responses from the RADIUS server, and performs processing accordingly. The processing includes accepting user access, rejecting user access, or collecting more user information for the RADIUS server.
- Server: Multiple RADIUS clients map to one RADIUS server. The RADIUS server maintains the IP addresses and shared keys of all RADIUS clients as well as information on all authenticated users. It receives requests from a RADIUS client, conducts authentication, authorization, and accounting, and returns processing information to the RADIUS client.

Structure of RADIUS Packets

The following figure shows the structure of RADIUS packets.

- Code: Identifies the type of RADIUS packets, which occupies one byte. The following table lists the values and meanings.

Code	Packet Type	Code	Packet Type
1	Access-Request	4	Accounting-Request
2	Access-Accept	5	Accounting-Response
3	Access-Reject	11	Access-Challenge

- Identifier: Indicates the identifier for matching request packets and response packets, which occupies one byte. The identifier values of request packets and response packets of the same type are the same.

- **Length:** Identifies the length of a whole RADIUS packet, which includes **Code, Identifier, Length, Authenticator,** and **Attributes**. It occupies two bytes. Bytes that are beyond the **Length** field will be truncated. If the length of a received packet is smaller than the value of **Length**, the packet is discarded.
- **Authenticator:** Verifies response packets of the RADIUS server by a RADIUS client, which occupies 16 bytes. This field is also used for encryption/decryption of user passwords.
- **Attributes:** Carries authentication, authorization, and accounting information, with the length unfixed. The **Attributes** field usually contains multiple attributes. Each attribute is represented in the Type, Length, Value (TLV) format. Type occupies one byte and indicates the attribute type. The following table lists common attributes of RADIUS authentication, authorization, and accounting. Length occupies one byte and indicates the attribute length, with the unit of bytes. Value indicates the attribute information.

Attribute No.	Attribute Name	Attribute No.	Attribute Name
1	User-Name	43	Acct-Output-Octets
2	User-Password	44	Acct-Session-Id
3	CHAP-Password	45	Acct-Authentic
4	NAS-IP-Address	46	Acct-Session-Time

41	Acct-Delay-Time	86	Acct-Tunnel-Packets-Lost
42	Acct-Input-Octets	87	NAS-Port-Id

Shared Key

A RADIUS client and a RADIUS server mutually confirm their identities by using a shared key during communication. The shared key cannot be transmitted over a network. In addition, user passwords are encrypted for transmission for the sake of security.

RADIUS Server Group

The RADIUS security protocol, also called RADIUS method, is configured in the form of a RADIUS server group. Each RADIUS method corresponds to one RADIUS server group and one or more RADIUS servers can be added to one RADIUS server group. For details about the RADIUS method, see the *Configuring AAA*. If you add multiple RADIUS servers to one RADIUS server group, when the communication between a device and the first RADIUS server in this group fails or the first RADIUS server becomes unreachable, the device automatically attempts to communicate with the next RADIUS server till the communication is successful or the communication with all the RADIUS servers fails.

RADIUS Attribute Type

- Standard attributes

The RFC standards specify the RADIUS attribute numbers and attribute content but do not specify the format of some attribute types. Therefore, the format of attribute contents needs to be configured to adapt to different RADIUS server requirements. Currently, the format of the RADIUS Calling-Station-ID attribute (attribute No.: 31) can be configured.

The RADIUS Calling-Station-ID attribute is used to identify user identities when a network device transmits request packets to the RADIUS server. The RADIUS Calling-Station-ID attribute is a string, which can adopt multiple formats. It needs to uniquely identify a user. Therefore, it is often set to the MAC address of a user. For example, when IEEE 802.1X authentication is used, the Calling-Station-ID attribute is set to the MAC address of the device where the IEEE 802.1X client is installed. The following table describes the format of MAC addresses.

Format	Description
ietf	Indicates the standard format specified in the IETF standard (RFC3580), which is separated by the separator (-). Example: 00-D0-F8-33-22-AC
Normal	Indicates the common format that represents a MAC address (dotted hexadecimal format), which is separated by the separator (.). Example: 00d0.f833.22ac
Unformatted	Indicates the format without separators. This format is used by default. Example: 00d0f83322ac

- Private attributes

RADIUS is an extensible protocol. According to RFC2865, the Vendor-Specific attribute (attribute No.: 26) is used by device vendors to extend the RADIUS protocol to implement private functions or functions that are not defined in the standard RADIUS protocol. Table 1-3 lists private attributes supported by Ruijie products. The **TYPE** column indicates the default configuration of private attributes of Ruijie products and the **Extended TYPE** column indicates the default configuration of private attributes of other non-Ruijie products.

ID	Function	TYPE	Extended TYPE
1	max-down-rate	1	76
2	port-priority	2	77
3	user-ip	3	3
4	vlan-id	4	4
5	last-supPLICANT-version	5	5
6	net-ip	6	6
7	user-name	7	7
8	password	8	8
9	file-directory	9	9
10	file-count	10	10
11	file-name-0	11	11
12	file-name-1	12	12
13	file-name-2	13	13

Overview

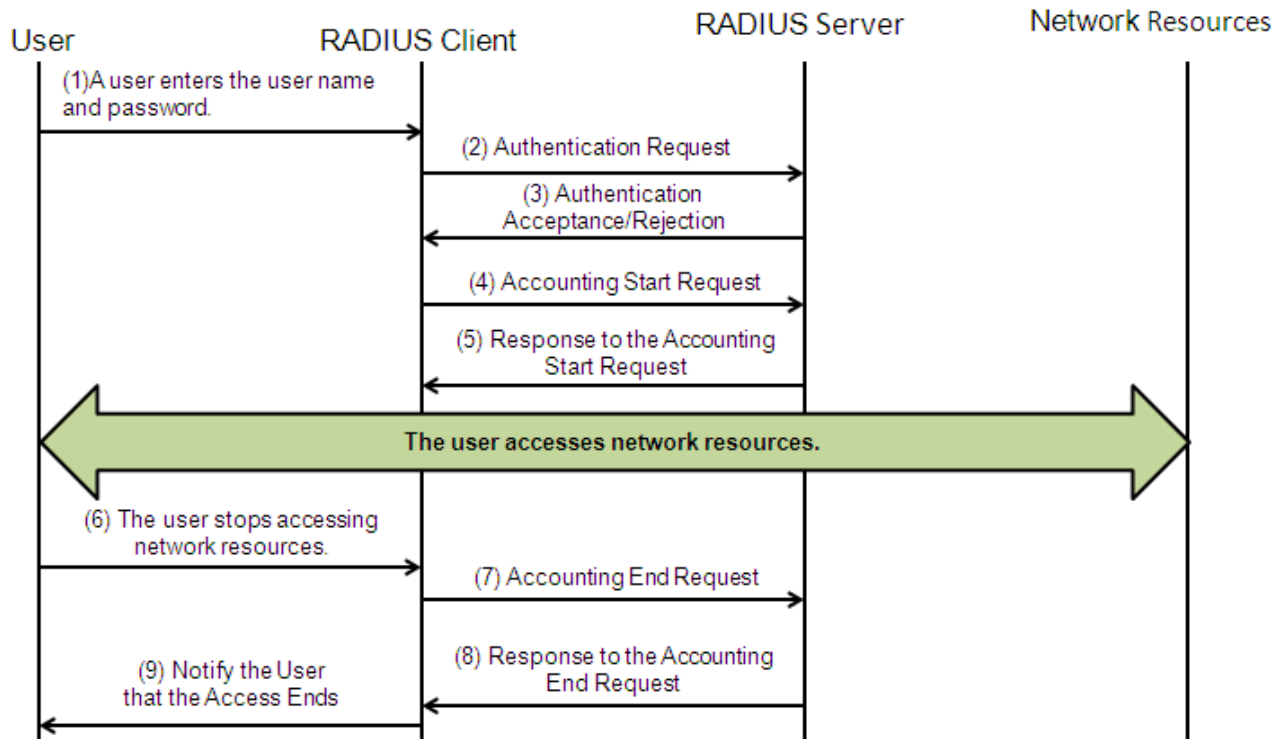

Feature	Description
RADIUS Authentication, Authorization, and Accounting	Conducts identity authentication and accounting on access users, safeguards network security, and facilitates management for network administrators.
Source Address of RADIUS Packets	Specifies the source IP address used by a RADIUS client to transmit packets to a RADIUS server.
RADIUS Timeout Retransmission	Specifies the packet retransmission parameter for a RADIUS client when a RADIUS server does not respond to packets transmitted from the RADIUS client within a period of time.
RADIUS Server Accessibility Detection	Enables a RADIUS client to actively detect whether a RADIUS server is reachable and maintain the accessibility of each RADIUS server. A reachable RADIUS server is selected preferentially to improve the handling performance of RADIUS services.
RADIUS Forced Offline	Enables a RADIUS server to actively force authenticated users to go offline.

2.3.1 RADIUS Authentication, Authorization, and Accounting

Conduct identity authentication and accounting on access users, safeguard network security, and facilitate management for network administrators.

Working Principle

Figure 2-2

The RADIUS authentication and authorization process is described as follows:

1. A user enters the user name and password and transmits them to the RADIUS client.
2. After receiving the user name and password, the RADIUS client transmits an authentication request packet to the RADIUS server. The password is encrypted for transmission. For the encryption method, see RFC2865.
3. The RADIUS server accepts or rejects the authentication request according to the user name and password. When accepting the authentication request, the RADIUS server also issues authorization information apart from the authentication acceptance information. The authorization information varies with the type of access users.

The RADIUS accounting process is described as follows:

1. If the RADIUS server returns authentication acceptance information in Step (3), the RADIUS client sends an accounting start request packet to the RADIUS server immediately.
2. The RADIUS server returns the accounting start response packet, indicating accounting start.
3. The user stops accessing network resources and requests the RADIUS client to disconnect the network connection.
4. The RADIUS client transmits the accounting end request packet to the RADIUS server.
5. The RADIUS server returns the accounting end response packet, indicating accounting end.
6. The user is disconnected and cannot access network resources.

Related Configuration

↘ [Configuring RADIUS Server Parameters](#)

No RADIUS server is configured by default.

You can run the **radius-server host** command to configure a RADIUS server.

At least one RADIUS server must be configured so that RADIUS services run normally.

↘ [Configuring the AAA Authentication Method List](#)

No AAA authentication method list is configured by default.

You can run the **aaa authentication** command to configure a method list for different user types and select **group radius** when setting the authentication method.

The RADIUS authentication can be conducted only after the AAA authentication method list of relevant user types is configured.

↘ [Configuring the AAA Authorization Method List](#)

No AAA authorization method list is configured by default.

You can run the **aaa authorization** command to configure an authorization method list for different user types and select **group radius** when setting the authorization method.

The RADIUS authorization can be conducted only after the AAA authorization method list of relevant user types is configured.

↘ [Configuring the AAA Accounting Method List](#)

No AAA accounting method list is configured by default.

You can run the **aaa accounting** command to configure an accounting method list for different user types and select **group radius** when setting the accounting method.

The RADIUS accounting can be conducted only after the AAA accounting method list of relevant user types is configured.

2.3.2 Source Address of RADIUS Packets

Specify the source IP address used by a RADIUS client to transmit packets to a RADIUS server.

Working Principle

When configuring RADIUS, specify the source IP address to be used by a RADIUS client to transmit RADIUS packets to a RADIUS server, in an effort to reduce the workload of maintaining a large amount of NAS information on the RADIUS server.

Related Configuration

The global routing is used to determine the source address for transmitting RADIUS packets by default.

Run the **ip radius source-interface** command to specify the source interface for transmitting RADIUS packets. The device uses the first IP address of the specified interface as the source address of RADIUS packets.

2.3.3 RADIUS Timeout Retransmission

Working Principle

After a RADIUS client transmits a packet to a RADIUS server, a timer is started to detect the response of the RADIUS server. If the RADIUS server does not respond within a certain period of time, the RADIUS client retransmits the packet.

Related Configuration

↘ [Configuring the RADIUS Server Timeout Time](#)

The default timeout time is 5 seconds.

You can run the **radius-server timeout** command to configure the timeout time. The value ranges from 1 second to 1,000 seconds.

The response time of a RADIUS server is relevant to its performance and the network environment. Set an appropriate timeout time according to actual conditions.

↘ [Configuring the Retransmission Count](#)

The default retransmission count is 3.

You can run the **radius-server retransmit** command to configure the retransmission count. The value ranges from 1 to 100.

↘ [Configuring Whether to Retransmit Accounting Update Packets](#)

Accounting update packets are not retransmitted by default.

You can run the **radius-server account update retransmit** command to configure retransmission of accounting update packets for authenticated users.

2.3.4 RADIUS Server Accessibility Detection

Working Principle

A RADIUS client actively detects whether a RADIUS server is reachable and maintains the accessibility of each RADIUS server. A reachable RADIUS server is selected preferentially to improve the handling performance of RADIUS services.

Related Configuration

↘ [Configuring the Criteria for the Device to Judge That a RADIUS Server Is Unreachable](#)

The default criteria configured for judging that a RADIUS server is unreachable meet the two conditions simultaneously: 1. The device does not receive a correct response packet from the RADIUS security server within 60 seconds. 2. The device transmits the request packet to the same RADIUS security server for consecutive 10 times.

You can run the **radius-server dead-criteria** command to configure the criteria for the device to judge that the RADIUS security server is unreachable.

↘ [Configuring the Test User Name for Actively Detecting the RADIUS Security Server](#)

No test user name is specified for actively detecting the RADIUS security server by default.

You can run the `radius-server host x.x.x.testusername xxx` command to configure the test user name.

2.3.5 RADIUS Forced Offline

Working Principle

Figure 2-3 DM Message Exchange of the RADIUS Dynamic Authorization Extension Protocol

The preceding figure shows the exchange of DM messages between the RADIUS server and the device. The RADIUS server transmits the Disconnect-Request message to UDP Port 3799 of the device. After processing, the device returns the Disconnect-Response message that carries the processing result to the RADIUS server.

Related Configuration

N/A

2.4 Configuration

Configuration	Description and Command
RADIUS Basic Configuration	(Mandatory) It is used to configure RADIUS authentication, authorization, and accounting.
	<code>radius-serverhost</code> Configures the IP address of the remote RADIUS security server.
	<code>radius-serverkey</code> Configures the shared key for communication between the device and the RADIUS server.
	<code>radius-serverretransmit</code> Configures the request transmission count, after which the device confirms that a RADIUS server is unreachable.
	<code>radius-servertimeout</code> Configures the waiting time, after which the device retransmits a request.
	<code>radius-server account update retransmit</code> Configures retransmission of accounting update packets for authenticated users.
	<code>ip radius source-interface</code> Configures the source address of RADIUS packets.
Configuring the RADIUS Attribute Type	(Optional) It is used to define attribute processing adopted when the device encapsulates and parses RADIUS packets.

Configuration	Description and Command	
	radius-serverattribute31	Configures the MAC address format of RADIUS attribute No. 31 (Calling-Station-ID).
	radius-server attribute class	Configures the parsing mode of the RADIUS Class attribute.
	radius attribute	Configures the RADIUS private attribute type.
	radius set qoscos	Sets the private attribute port-priority issued by the server to the COS value of an interface. For COS-relevant concepts, see the <i>Configuring QoS</i> .
	radius support cui	Configures the device to support the CUI attribute.
Configuring RADIUS Accessibility Detection	 (Optional) It is used to detect whether a RADIUS server is reachable and maintain the accessibility of the RADIUS server.	
	radius-server dead-criteria	Configures the global criteria for judging that a RADIUS security server is unreachable.
	radius-server deadtime	Configures the duration for the device to stop transmitting request packets to an unreachable RADIUS server.
	radius-server host	Configures the IP address of the remote RADIUS security server, authentication port, accounting port, and active detection parameters.

2.4.1 RADIUS Basic Configuration

Configuration Effect

- RADIUS authentication, authorization, and accounting can be conducted after RADIUS basic configuration is complete.

Notes

- Before configuring RADIUS on the device, ensure that the network communication of the RADIUS server is in good condition.
- When running the **ip radius source-interface** command to configure the source address of RADIUS packets, ensure that the device of the source IP address communicates with the RADIUS server successfully.
- When conducting RADIUS IPv6 authentication, ensure that the RADIUS server supports RADIUS IPv6 authentication.

Configuration Steps

▾ Configuring the Remote RADIUS Security Server

- Mandatory.
- Configure the IP address, authentication port, accounting port, and shard key of the RADIUS security server.

▾ Configuring the Shared Key for Communication Between the Device and the RADIUS Server

- Optional.
- Configure a shared key in global configuration mode for servers without a shared key.

 The shared key on the device must be consistent with that on the RADIUS server.

▾ Configuring the Request Transmission Count, After Which the Device Confirms That a RADIUS Server Is Unreachable

- Optional.
- Configure the request transmission count, after which the device confirms that a RADIUS server is unreachable, according to the actual network environment.

▾ Configuring the Waiting Time, After which the Device Retransmits a Request

- Optional.
- Configure the waiting time, after which the device retransmits a request, according to the actual network environment.

 In an 802.1X authentication environment that uses the RADIUS security protocol, if a network device serves as the 802.1X authenticator and Ruijie SU is used as the 802.1X client software, it is recommended that **radius-server timeout** be set to 3 seconds (the default value is 5 seconds) and **radius-server retransmit** be set to 2 (the default value is 3) on the network device.

▾ Configuring Retransmission of Accounting Update Packets for Authenticated Users

- Optional.
- Determine whether to enable the function of retransmitting accounting update packets of authenticated users according to actual requirements.

▾ Configuring the Source Address of RADIUS Packets

- Optional.
- Configure the source address of RADIUS packets according to the actual network environment.

Verification

- Configure the AAA method list that specifies to conduct authentication, authorization, and accounting on users by using RADIUS.
- Enable the device to interact with the RADIUS server. Conduct packet capture to confirm that the device communicates with the RADIUS server over the RADIUS protocol.

Related Commands

▾ Configuring the Remote RADIUS Security Server

Command	<code>radius-server host [oob] { ipv4-address ipv6-address } [auth-portport-number] [acct-portport-number][test username name [idle-time time] [ignore-auth-port] [ignore-acct-port]] [key [0 7] text-string]</code>
---------	--

Parameter Description	<p>oob: Indicates oob authentication, that is, the source interface for transmitting packets to the RADIUS server is an mgmt port.</p> <p><i>ipv4-address</i>: Indicates the IPv4 address of the RADIUS security server.</p> <p><i>ipv6-address</i>: Indicates the IPv6 address of the RADIUS security server.</p> <p>auth-port <i>port-number</i>: Indicates the UDP port for RADIUS identity authentication. The value ranges from 0 to 65,535. If it is set to 0, the host does not conduct identity authentication.</p> <p>acct-port <i>port-number</i>: Indicates the UDP port for RADIUS accounting. The value ranges from 0 to 65,535. If it is set to 0, the host does not conduct accounting.</p> <p>test username <i>name</i>: Enables the function of actively detecting the RADIUS security server and specifies the user name used for active detection.</p> <p>idle-time <i>time</i>: Indicates the interval for the device to transmit test packets to a reachable RADIUS security server. The default value is 60 minutes. The value ranges from 1 minute to 1,440 minutes (24 hours).</p> <p>ignore-auth-port: Disables the function of detecting the authentication port of the RADIUS security server. It is enabled by default.</p> <p>ignore-acct-port: Disables the function of detecting the accounting port of the RADIUS security server. It is enabled by default.</p> <p>key [0 7] <i>text-string</i> : Configures the shared key of the server. The global shared key is used if it is not configured.</p>
Command Mode	Global configuration mode
Usage Guide	A RADIUS security server must be defined to implement the AAA security service by using RADIUS. You can run the radius-server host command to define one or more RADIUS security servers. If a RADIUS security server is not added to a RADIUS server group, the device uses the global routing table when transmitting RADIUS packets to the RADIUS server. Otherwise, the device uses the VRF routing table of the RADIUS server group.

✚ Configuring the Shared Key for Communication Between the Device and the RADIUS Server

Command	radius-server key [0 7] <i>text-string</i>
Parameter Description	<p><i>text-string</i>: Indicates the text of the shared key.</p> <p>0 7: Indicates the encryption type of the key. The value 0 indicates no encryption and 7 indicates simple encryption. The default value is 0.</p>
Command Mode	Global configuration mode
Usage Guide	A shared key is the basis for correct communication between the device and the RADIUS security server. The same shared key must be configured on the device and RADIUS security server so that they can communicate with each other successfully.

✚ Configuring the Request Transmission Count, After Which the Device Confirms That a RADIUS Server Is Unreachable

Command	radius-server retransmit <i>retries</i>
Parameter	<i>retries</i> : Indicates the RADIUS retransmission count. The value ranges from 1 to 100.

Description	
Command Mode	Global configuration mode
Usage Guide	The prerequisite for AAA to use the next user authentication method is that the current security server used for authentication does not respond. The criteria for the device to judge that a security server does not respond are that the security server does not respond within the RADIUS packet retransmission duration of the specified retransmission count. There is an interval between consecutive two retransmissions.

↘ **Configuring the Waiting Time, After which the Device Retransmits a Request**

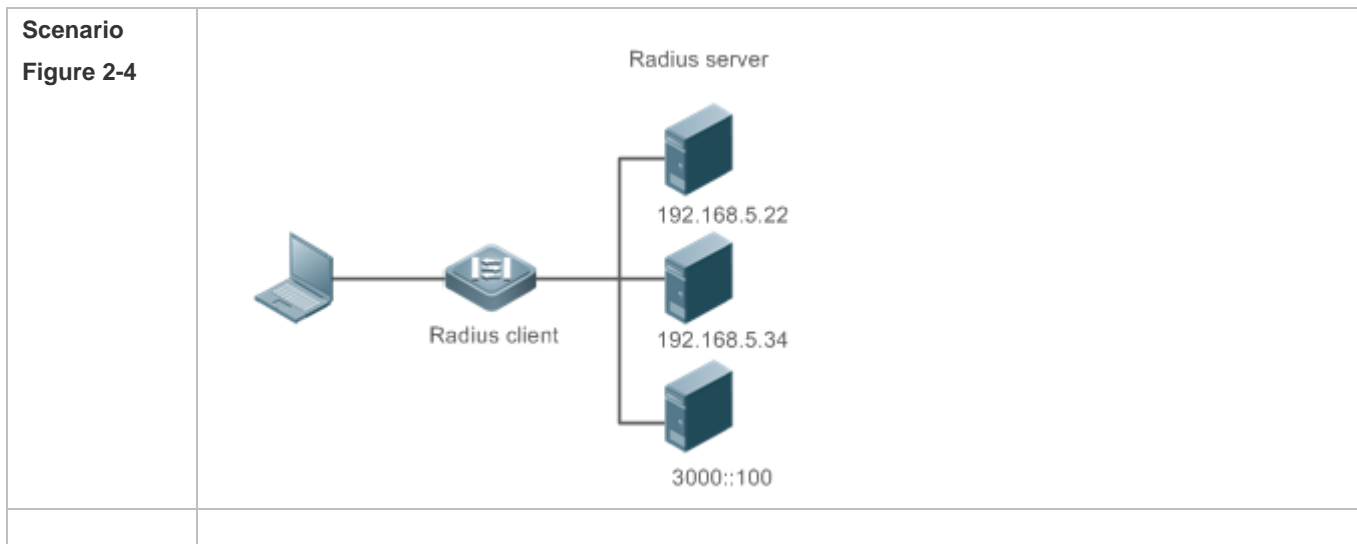

Command	radius-server timeout <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the timeout time, with the unit of seconds. The value ranges from 1 second to 1,000 seconds.
Command Mode	Global configuration mode
Usage Guide	Use this command to adjust the packet retransmission timeout time.

↘ **Configuring Retransmission of Accounting Update Packets for Authenticated Users**

Command	radius-server account update retransmit
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Configure retransmission of accounting update packets for authenticated users. Accounting update packets are not retransmitted by default. The configuration does not affect users of other types.

Configuration Example

↘ **Using RADIUS Authentication, Authorization, and Accounting for Login Users**

Configuration Steps	<ul style="list-style-type: none"> ● Enable AAA. ● Configure the RADIUS server information. ● Configure to use the RADIUS authentication, authorization, and accounting methods. ● Apply the configured authentication method on the interface.
RADIUS Client	<pre>Ruijie#configure terminal Ruijie (config)#aaa new-model Ruijie (config)# radius-server host 192.168.5.22 Ruijie (config)#radius-server host 3000::100 Ruijie (config)# radius-server key aaa Ruijie (config)#aaa authentication login test group radius Ruijie (config)#aaa authorizationexec test group radius Ruijie (config)#aaa accountingexec test start-stop group radius Ruijie (config)# line vty 0 4 Ruijie (config-line)#login authentication test Ruijie (config-line)# authorization exec test Ruijie (config-line)# accounting exec test</pre>
Verification	<p>Telnet to a device from a PC. The screen requesting the user name and password is displayed. Enter the correct user name and password to log in to the device. After obtaining a certain access level granted by the server, only run commands under this access level. Display the authentication log of the user on the RADIUS server. Perform management operations on the device as the user and then log out. Display the accounting information on the user on the RADIUS server.</p>
	<pre>Ruijie#show running-config ! radius-server host 192.168.5.22 radius-server host 3000::100 radius-server key aaa aaa new-model aaa accounting exec test start-stop group radius aaa authorization exec test group radius aaa authentication login test group radius no service password-encryption iptcp not-send-rst</pre>

```
!  
vlan 1  
!  
line con 0  
line vty 0 4  
accounting exec test  
authorization exec test  
login authentication test  
!
```

Common Errors

- The key configured on the device is inconsistent with that configured on the server.
- No method list is configured.

2.4.2 Configuring the RADIUS Attribute Type

Configuration Effect

- Define the attribute processing adopted when the device encapsulates and parses RADIUS packets.

Notes

- Private attributes involved in "Configuring the RADIUS Attribute Type" refer to Ruijie private attributes.

Configuration Steps

↘ **Configuring the MAC Address Format of RADIUS Attribute No. 31 (Calling-Station-ID)**

- Optional.
- Set the MAC address format of **Calling-Station-Id** to a type supported by the server.

↘ **Configuring the Parsing Mode of the RADIUS Class Attribute**

- Optional.
- Configure the parsing mode of the Class attribute according to the server type.

↘ **Configuring the RADIUS Private Attribute Type**

- Optional.
- If the server is a Ruijie application server, the RADIUS private attribute type needs to be configured.

↘ **Setting the Private Attribute port-priority Issued by the Server to the COS Value of an Interface**

- Optional.
- Set the private attribute **port-priority** issued by the server to the COS value of an interface as required.
- ↳ **Configures the Device to Support the CUI Attribute**
- Optional.
- Configure whether the device supports the RADIUS CUI attribute as required.
- ↳ **Configuring the Mode of Parsing Private Attributes by the Device**
- Optional.
- Configure the index of a Ruijie private attribute parsed by the device as required.
- ↳ **Configuring Whether RADIUS Authentication Request Packets Carry a Specified Attribute**
- Optional.
- Configure whether to specify the attribute type for RADIUS authentication request packets as required.
- ↳ **Configuring Whether RADIUS Accounting Request Packets Carry a Specified Attribute**
- Optional.
- Configure whether to specify the attribute type for RADIUS accounting request packets as required.
- ↳ **Configuring Whether RADIUS Authentication Request Packets Carry the Private Attribute of a Specified Vendor**
- Optional.
- Configure whether RADIUS authentication request packets carry the private attribute of a specified vendor as required.
- ↳ **Configuring Whether RADIUS Accounting Request Packets Carry the Private Attribute of a Specified Vendor**
- Optional.
- Configure whether RADIUS accounting request packets carry the private attribute of a specified vendor as required.
- ↳ **Configuring Whether RADIUS Server Parses the Private Attribute of Cisco, Huawei or Microsoft**
- Optional.
- Configure whether RADIUS server parses the private attribute of Cisco, Huawei or Microsoft.
- ↳ **Configuring the Nas-Port-Id Encapsulation Format for RADIUS Packets**
- Optional.
- In either QINQ or non-QINQ scenarios, configure the nas-port-id encapsulation format for RADIUS packets. By default, the packets are encapsulated in the normal format.

Verification

- Configure the AAA method list that specifies to conduct authentication, authorization, and accounting on users by using RADIUS.

- Enable the device to interact with the RADIUS server. Conduct packet capture to display the MAC address format of Calling-Station-Id.
- Enable the device to interact with the RADIUS server. Display the debug information of the device to check that Ruijie private attributes are correctly parsed by the device.
- Enable the device to interact with the RADIUS server. Display the debug information of the device to check that the CUI attribute is correctly parsed by the device.

Related Commands

▾ Configuring the MAC Address Format of RADIUS Attribute No. 31 (Calling-Station-ID)

Command	radius-server attribute 31 mac format {ietf normal unformatted }
Parameter Description	<p>ietf: Indicates the standard format specified in the IETF standard (RFC3580), which is separated by the separator (-). Example: 00-D0-F8-33-22-AC.</p> <p>normal: Indicates the common format that represents a MAC address (dotted hexadecimal format), which is separated by the separator (.). Example: 00d0.f833.22ac.</p> <p>unformatted: Indicates the format without separators. This format is used by default. Example: 00d0f83322ac.</p>
Command Mode	Global configuration mode
Usage Guide	Some RADIUS security servers (mainly used for 802.1X authentication) can identify only MAC addresses in the IETF format. In this case, set the MAC address format of Calling-Station-ID to IETF.

▾ Setting the Private Attribute port-priority Issued by the Server to the COS Value of an Interface

Command	radius set qos cos
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Configure this command to use the issued QoS value as the CoS value. The QoS value is used as the DSCP value by default.

▾ Configures the Device to Support the CUI Attribute

Command	radius support cui
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Configure this command to enable the RADIUS-compliant device to support the CUI attribute.

Configuration Example

▾ Configuring the RADIUS Attribute Type

Scenario	One authentication device
Configuration Steps	<ul style="list-style-type: none"> ● Configure the MAC address format of RADIUS Calling-Station-Id. ● Configure the RADIUS private attribute type. ● Set the QoS value issued by the RADIUS server as the COS value of the interface. ● Configure the RADIUS function to support the CUI attribute. ● Configure the device to support private attributes of other vendors. ● Configure authentication requests not to carry the NAS-PORT-ID attribute. ● Configure accounting requests to carry the CMCC private attribute. ● Configure the RADIUS server not to parse Cisco's private attributes contained in packets. ● Configure application of the nas-port-id encapsulation format in a QINQ scenario.
	<pre>Ruijie(config)#radius-server attribute 31 mac format ietf Ruijie(config)#radius attribute 16 vendor-type 211 Ruijie(config)#radius set qos cos Ruijie(config)#radius support cui Ruijie(config)# radius-server attribute nas-port-id format qinq</pre>
Verification	Conduct packet capture or display debug information of the device to check whether the RADIUS standard attributes and private attributes are encapsulated/parsed correctly.

2.4.3 Configuring RADIUS Accessibility Detection

Configuration Effect

The device maintains the accessibility status of each configured RADIUS server: reachable or unreachable. The device will not transmit authentication, authorization, and accounting requests of access users to an unreachable RADIUS server unless all the other servers in the same RADIUS server group as the unreachable server are all unreachable.

The device actively detects a specified RADIUS server. The active detection function is disabled by default. If the active detection function is enabled for a specified RADIUS server, the device will, according to the configuration, periodically transmits detection requests (authentication requests or accounting requests) to the RADIUS server. The transmission interval is as follows:

- For a reachable RADIUS server, the interval is the active detection interval of the reachable RADIUS server (the default value is 60 minutes).
- For an unreachable RADIUS server, the interval is always 1 minute.

Notes

All the following conditions need to be met before the active detection function is enabled for a specified RADIUS server:

- The test user name of the RADIUS server is configured on the device.

- At least one tested port (authentication port or accounting port) of the RADIUS server is configured on the device.

If the following two conditions are all met, it is deemed that a reachable RADIUS server becomes unreachable:

- After the previous correct response is received from the RADIUS server, the time set in **radius-server dead-criteria time seconds** has elapsed.
- After the previous correct response is received from the RADIUS server, the count that the device transmits requests to the RADIUS server but fails to receive correct responses (including retransmission) reaches the value set in **radius-server dead-criteria tries number**.

If any of the following conditions is met, it is deemed that an unreachable RADIUS server becomes reachable:

- The device receives correct responses from the RADIUS server.
- The duration that the RADIUS server is in the unreachable state exceeds the time set in **radius-server deadtime** and the active detection function is disabled for the RADIUS server.
- The authentication port or accounting port of the RADIUS server is updated on the device.

Configuration Steps

✚ Configuring the Global Criteria for Judging That a RADIUS Security Server Is Unreachable

- Mandatory.
- Configuring the global criteria for judging that a RADIUS security server is unreachable is a prerequisite for enabling the active detection function.

✚ Configuring the IP Address of the Remote RADIUS Security Server, Authentication Port, Accounting Port, and Active Detection Parameters

- Mandatory.
- Configuring active detection parameters of the RADIUS server is a prerequisite for enabling the active detection function.

✚ Configuring the Duration for the Device to Stop Transmitting Request Packets to an Unreachable RADIUS Server

- Optional.
- The configured duration for the device to stop transmitting request packets to an unreachable RADIUS server takes effect only when the active detection function is disabled for the RADIUS server.

Verification

- Run the **show radius server** command to display the accessibility information of each RADIUS server.

Related Commands

✚ Configuring the Global Criteria for Judging That a RADIUS Security Server Is Unreachable

Command	<code>radius-server dead-criteria { timeseconds [triesnumber] triesnumber }</code>

Parameter Description	<p>timeseconds: Indicates the time condition parameter. If the device fails to receive a correct response packet from a RADIUS security server within the specified time, it is deemed that the RADIUS security server meets the inaccessibility duration condition. The value ranges from 1 second to 120 seconds.</p> <p>triesnumber: Indicates the consecutive request timeout count. If the timeout count of request packets transmitted by the device to the same RADIUS security server reaches the preset count, it is deemed that the RADIUS security server meets the consecutive timeout count condition of inaccessibility. The value ranges from 1 to 100.</p>
Command Mode	Global configuration mode
Usage Guide	If a RADIUS security server meets both the duration condition and the consecutive request timeout count condition, it is deemed that the RADIUS security server is unreachable. Users can use this command to adjust parameter values in the duration condition and consecutive request timeout count condition.

↘ **Configuring the Duration for the Device to Stop Transmitting Request Packets to an Unreachable RADIUS Server**

Command	Radius-server deadtime <i>minutes</i>
Parameter Description	<i>minutes:</i> Indicates the duration for the device to stop transmitting requests to an unreachable RADIUS security server, with the unit of minutes. The value ranges from 1 minute to 1,440 minutes (24 hours).
Command Mode	Global configuration mode
Usage Guide	If the active detection function is enabled for a RADIUS security server on the device, the time parameter in radius-server deadtime does not take effect on the RADIUS server. If the active detection function is disabled for a RADIUS security server, the device automatically restores the RADIUS security server to the reachable state when the duration that the RADIUS security server is in the unreachable state exceeds the time specified in radius-server deadtime .

Configuration Example

↘ **Configuring Accessibility Detection on the RADIUS Server**

Scenario Figure 2-5	<p>The diagram illustrates a network connection between a Radius client (represented by a laptop icon) and a Radius server (represented by a server rack icon). The IP address 192.168.5.22 is shown above the server rack. The connection is represented by a horizontal line with a central node containing a cube icon.</p>
Configuration Steps	<ul style="list-style-type: none"> ● Configure the global criteria for judging that a RADIUS security server is unreachable. ● Configure the IP address of the remote RADIUS security server, authentication port, accounting port, and active detection parameters.
RADIUS Client	<pre>Ruijie(config)#radius-server dead-criteria time120 tries 5 Ruijie(config)# radius-server host 192.168.5.22 test username test ignore-acct-port idle-time 90</pre>

Verification	Disconnect the network communication between the device and the server with the IP address of 192.168.5.22. Conduct RADIUS authentication through the device. After 120 seconds, run the show radius server command to check that the server state is dead .
	<pre>Ruijie#show running-config ... radius-server host 192.168.5.22 test username test ignore-acct-port idle-time 90 radius-server dead-criteria time 120 tries 5 ...</pre>

2.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears statistics of the RADIUS dynamic authorization extension function and restarts statistics.	clear radius dynamic-authorization-extension statistics

Displaying

Description	Command
Displays global parameters of the RADIUS server.	show radius parameter
Displays the configuration of the RADIUS server.	show radius server
Displays statistics relevant to the RADIUS dynamic authorization extension function.	show radius dynamic-authorization-extension statistics
Displays statistics relevant to RADIUS authentication.	show radius auth statistics
Displays statistics relevant to RADIUS accounting.	show radius acct statistics
Displays configuration of RADIUS server groups.	show radius group

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the RADIUS event.	debugradiusevent
Debugs RADIUS packet printing.	debugradiusdetail
Debugs the RADIUS dynamic authorization extension function.	debug radiusextension event
Debugs the RADIUS dynamic authorization extension packet printing.	debug radius extension detail

3 Configuring TACACS+

3.1 Overview

TACACS+ is a security protocol enhanced in functions based on the Terminal Access Controller Access Control System (TACACS) protocol. It is used to implement the authentication, authorization, and accounting (AAA) of multiple users.

Protocols and Standards

- RFC 1492 Terminal Access Controller Access Control System

3.2 Applications

Application	Description
Managing and Controlling Login of End Users	Password verification and authorization need to be conducted on end users.

3.2.1 Managing and Controlling Login of End Users

Scenario

TACACS+ is typically applied in the login management and control of end users. A network device serves as the TACACS+ client and sends a user name and password to the TACACS+ server for verification. The user is allowed to log in to the network device and perform operations after passing the verification and obtaining authorization. See the following figure.

Figure 3-1

Remarks	<ul style="list-style-type: none"> ● A is a client that initiates TACACS+ requests. ● B, C, and D are servers that process TACACS+ requests.
----------------	--

Deployment

- Start the TACACS+ server on Server B, Server C, and Server D, and configure information on the access device (Device A) so that the servers provide TACACS+-based AAA function for the access device. Enable the AAA function on Device A to start authentication for the user login.
- Enable the TACACS+ client function on Device A, add the IP addresses of the TACACS+ servers (Server B, Server C, and Server D) and the shared key so that Device A communicates with the TACACS+ servers over TACACS+ to implement the AAA function.

3.3 Features

Basic Concepts

Format of TACACS+ Packets

Figure 3-2

4	8	16	24	32 bit
Major	Minor	Packet type	Sequence no.	Flags
Session ID				
Length				

- Major Version: Indicates the major TACACS+ version number.
- Minor Version: Indicates the minor TACACS+ version number.
- Packet Type: Indicates the type of packets, with the options including:
 TAC_PLUS_AUTHEN: = 0x01 (authentication);
 TAC_PLUS_AUTHOR: = 0x02 (authorization);
 TAC_PLUS_ACCT: = 0x03 (accounting)
- Sequence Number: Indicates the sequence number of a data packet in the current session. The sequence number of the first TACACS+ data packet in a session must be 1 and the sequence number of subsequent each data packet increases by one. Therefore, the client sends data packets only with an odd sequence number and TACACS+ Daemon sends packets only with an even sequence number.
- Flags: Contains various bitmap format flags. One of the bits in the value specifies whether data packets need to be encrypted.
- Session ID: Indicates the ID of a TACACS+ session.
- Length: Indicates the body length of a TACACS+ data packet (excluding the header). Packets are encrypted for transmission on a network.

Overview

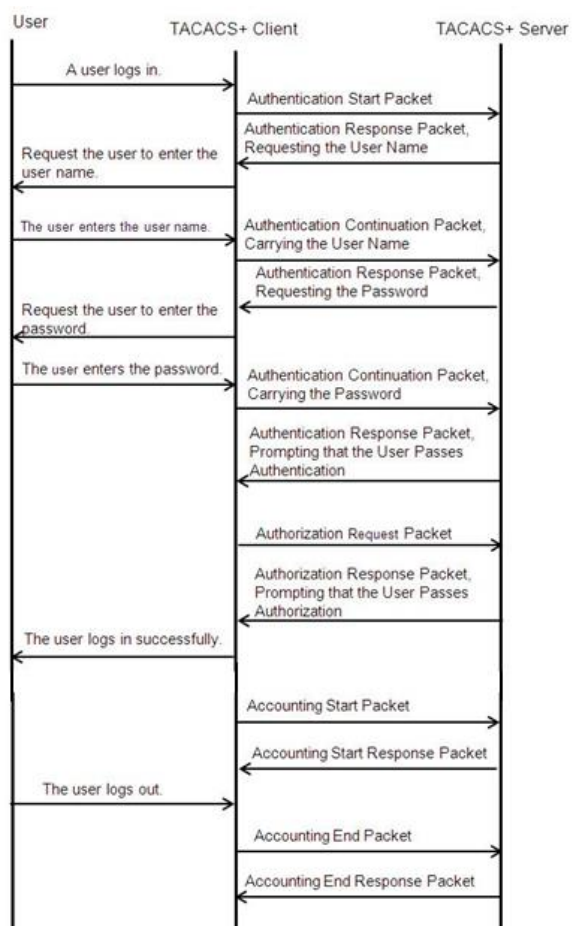

Feature	Description
TACACS+ Authentication, Authorization, and Accounting	Conducts authentication, authorization, and accounting on end users.

3.3.1 TACACS+ Authentication, Authorization, and Accounting

Working Principle

The following figure uses basic authentication, authorization, and accounting of user login to describe interaction of TACACS+ data packets.

Figure 3-3

The entire basic message interaction process includes three sections:

1. The authentication process is described as follows:
 - 1) A user requests to log in to a network device.
 - 2) After receiving the request, the TACACS+ client sends an authentication start packet to the TACACS+ server.
 - 3) The TACACS+ server returns an authentication response packet, requesting the user name.

- 4) The TACACS+ client requests the user to enter the user name.
- 5) The user enters the login user name.
- 6) After receiving the user name, the TACACS+ client sends an authentication continuation packet that carries the user name to the TACACS+ server.
- 7) The TACACS+ server returns an authentication response packet, requesting the login password.
- 8) The TACACS+ client requests the user to enter the login password.
- 9) The user enters the login password.
- 10) After receiving the login password, the TACACS+ client sends an authentication continuation packet that carries the login password to the TACACS+ server.
- 11) The TACACS+ server returns an authentication response packet, prompting that the user passes authentication.

Configuration	Description and Command	
Configuring TACACS+ Basic Functions	 (Mandatory) It is used to enable the TACACS+ security service.	
	tacacs-server host	Configures the TACACS+ server.
	tacacs-server key	Specifies the key shared by the server and network device.
	tacacs-server timeout	Configures the global waiting timeout time of the TACACS+ server for communication between a network device and the TACACS+ server.
Configuring Separate Processing of Authentication, Authorization, and Accounting of TACACS+	 (Optional) It is used to separately process authentication, authorization, and accounting requests.	
	aaa group server tacacs+	Configures TACACS+ server groups and divides TACACS+ servers into different groups.
	server	Adds servers to TACACS+ server groups.

2. The user authorization starts after successful authentication:
 - 1) The TACACS+ client sends an authorization request packet to the TACACS+ server.
 - 2) The TACACS+ server returns an authorization response packet, prompting that the user passes authorization.
 - 3) After receiving the authorization success packet, the TACACS+ client outputs the network device configuration screen for the user.
3. Accounting and audit need to be conducted on the login user after successful authorization:
 - 1) The TACACS+ client sends an accounting start packet to the TACACS+ server.
 - 2) The TACACS+ server returns an accounting response packet, prompting that the accounting start packet has been received.

- 3) The user logs out.
- 4) The TACACS+ client sends an accounting end packet to the TACACS+ server.
- 5) The TACACS+ server returns an accounting response packet, prompting that the accounting end packet has been received.

3.4 Configuration

3.4.1 Configuring TACACS+ Basic Functions

Configuration Effect

- The TACACS+ basic functions are available after the configuration is complete. When configuring the AAA method list, specify the method of using TACACS+ to implement TACACS+ authentication, authorization, and accounting.
- When authentication, authorization, and accounting operations are performed, TACACS+ initiates the authentication, authorization, and accounting requests to configured TACACS+ servers according to the configured sequence. If response timeout occurs on a TACACS+ server, TACACS+ traverses the TACACS+ server list in sequence.

Notes

- The TACACS+ security service is a type of AAA service. You need to run the **aaa new-model** command to enable the security service.
- Only one security service is provided after TACACS+ basic functions are configured. To make the TACACS+ functions take effect, specify the TACACS+ service when configuring the AAA method list.

Configuration Steps

↳ Enabling AAA

- Mandatory. The AAA method list can be configured only after AAA is enabled. TACACS+ provides services according to the AAA method list.

Command	aaa new-model
Parameter	N/A
Description	
Defaults	The AAA function is disabled.
Command Mode	Global configuration mode
Usage Guide	The AAA method list can be configured only after AAA is enabled. TACACS+ provides services according to the AAA method list.

↳ Configuring the IP Address of the TACACS+ Server

- Mandatory. Otherwise, a device cannot communicate with the TACACS+ server to implement the AAA function.

Command	tacacs-server host [oob via <i>mgmt_name</i>] { <i>ipv4-address</i> <i>ipv6-address</i> } [port <i>integer</i>] [timeout <i>integer</i>] [key [0 7] <i>text-string</i>]
Parameter Description	<p><i>ipv4-address</i>: Indicates the IPv4 address of the TACACS+ server.</p> <p><i>ipv6-address</i>: Indicates the IPv6 address of the TACACS+ server.</p> <p>oob: Uses an MGMT port as the source interface for communicating with the TACACS+ server. A non-MGMT port is used for communication by default.</p> <p>via <i>mgmt_name</i>: Specifies a specific MGMT port when oob supports multiple MGMT ports.</p> <p>port<i>integer</i>: Indicates the TCP port used for TACACS+ communication. The default TCP port is 49.</p> <p>timeout <i>integer</i>: Indicates the timeout time of the communication with the TACACS+ server. The global timeout time is used by default.</p> <p>key [0 7] <i>text-string</i>: Indicates the shared key of the server. The global key is used if it is not configured. An encryption type can be specified for the configured key. The value 0 indicates no encryption and 7 indicates simple encryption. The default value is 0.</p>
Defaults	No TACACS+ server is configured.
Command Mode	Global configuration mode
Usage Guide	<ol style="list-style-type: none"> You can specify the shared key of the server when configuring the IP address of the server. If no shared key is specified, the global key configured using the tacacs-server key command is used as the shared key of the server. The shared key must be completely the same as that configured on the server. You can specify the communication port of the server when configuring the IP address. You can specify the communication timeout time of the server when configuring the IP address.

▾ Configuring the Shared Key of the TACACS+ Server

- Optional.
- If no global communication protocol is configured using this command, set **key** to specify the shared key of the server when running the **tacacs-server host** command to add server information. Otherwise, a device cannot communicate with the TACACS+ server.
- If no shared key is specified by using **key** when you run the **tacacs-server host** command to add server information, the global key is used.

Command	tacacs-server [key [0 7] <i>text-string</i>]
Parameter Description	<p><i>text-string</i>: Indicates the text of the shared key.</p> <p>0 7: Indicates the encryption type of the key. The value 0 indicates no encryption and 7 indicates simple encryption.</p>
Defaults	No shared key is configured for any TACACS+ server.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure a global shared key for servers. To specify a different key for each server, set key when running the tacacs-server host command.

▾ Configuring the Timeout Time of the TACACS+ Server

- Optional.
- You can set the timeout time to a large value when the link between the device and the server is unstable.

Command	tacacs-server timeout <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the timeout time, with the unit of seconds. The value ranges from 1 second to 1,000 seconds.
Defaults	The default value is 5 seconds.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the global server response timeout time. To set different timeout time for each server, set timeout when running the tacacs-server host command.

Verification

Configure the AAA method list that specifies to conduct authentication, authorization, and accounting on users by using TACACS+.

- Enable the device to interact with the TACACS+ server and conduct packet capture to check the TACACS+ interaction process between the device and the TACACS+ server.
- View server logs to check whether the authentication, authorization, and accounting are normal.

Configuration Example

Using TACACS+ for Login Authentication

Scenario Figure 3-4	<p>The diagram illustrates a network topology for TACACS+ authentication. On the left, a laptop icon represents the 'User'. A horizontal line connects the laptop to a central device labeled 'A', which is identified as the 'TACACS+ Client'. Another horizontal line connects device 'A' to a server rack icon labeled 'B', identified as the 'TACACS+ Server' with the IP address '192.168.5.22'.</p>
Remarks	<ul style="list-style-type: none"> ● A is a client that initiates TACACS+ requests. ● B is a server that processes TACACS+ requests.
Configuration Steps	<ul style="list-style-type: none"> ● Enable AAA. ● Configure the TACACS+ server information. ● Configure the method of using TACACS+ for authentication. ● Apply the configured authentication method on an interface.
A	<pre>Ruijie# configure terminal Ruijie(config)# aaa new-model</pre>

	<pre>Ruijie(config)# tacacs-server host 192.168.5.22 Ruijie(config)# tacacs-server key aaa Ruijie(config)# aaa authentication login test group tacacs+ Ruijie(config)# line vty 0 4 Ruijie(config-line)# login authentication test</pre>
Verification	Telnet to a device from a PC. The screen requesting the user name and password is displayed. Enter the correct user name and password to log in to the device. View the authentication log of the user on the TACACS+ server.

Common Errors

- The AAA security service is disabled.
- The key configured on the device is inconsistent with the key configured on the server.
- No method list is configured.

3.4.2 Configuring Separate Processing of Authentication, Authorization, and Accounting of TACACS+

Configuration Effect

- The authentication, authorization, and accounting in the security service are processed by different TACACS+ servers, which improves security and achieves load balancing to a certain extent.

Notes

- The TACACS+ security service is a type of AAA service. You need to run the **aaa new-model** command to enable the security service.
- Only one security service is provided after TACACS+ basic functions are configured. To make the TACACS+ functions take effect, specify the TACACS+ service when configuring the AAA method list.

Configuration Steps

▾ Configuring TACACS+ Server Groups

- Mandatory. There is only one TACACS+ server group by default, which cannot implement separate processing of authentication, authorization, and accounting.
- Three TACACS+ server groups need to be configured for separately processing authentication, authorization, and accounting.

Command	aaa group server tacacs+group-name
Parameter	<i>group-name</i> : Indicates the name of a group. A group name cannot be radius or tacacs+, which are the names of embedded groups.
Description	

Defaults	No TACACS+ server group is configured.
Command Mode	Global configuration mode
Usage Guide	Group TACACS+ servers so that authentication, authorization, and accounting are completed by different server groups.

▾ Adding Servers to TACACS+ Server Groups

- Mandatory. If no server is added to a server group, a device cannot communicate with TACACS+ servers.
- In server group configuration mode, add the servers that are configured using the **tacacs-server host** command.

Command	server { <i>ipv4-address</i> <i>ipv6-address</i> }
Parameter Description	<i>ipv4-address</i> : Indicates the IPv4 address of the TACACS+ server. <i>ipv6-address</i> : Indicates the IPv6 address of the TACACS+ server.
Defaults	No server is configured.
Command Mode	TACACS+ server group configuration mode
Usage Guide	Before configuring this command, you must run the aaa group server tacacs+ command to enter the TACACS+ server group configuration mode. For the address of a server configured in a TACACS+ server group, the server must be configured using the tacacs-server host command in global configuration mode. If multiple servers are added to one server group, when one server does not respond, the device continues to send a TACACS+ request to another server in the server group.

▾ Configuring VRF of a TACACS+ Server Group

- Optional. Configure Virtual Routing and Forwarding (VRF) if a device needs to send TACACS+ packets through a specified address.
- In server group configuration mode, use a configured VRF name to specify the routing for the communication of servers in this group.

Command	ip vrf forwarding <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Indicates the VRF name.
Defaults	No VRF is specified by default.
Command Mode	TACACS+ server group configuration mode
Usage Guide	Before configuring this command, you must run the aaa group server tacacs+ command to enter the TACACS+ server group configuration mode. For VRF configured in a TACACS+ server group, a valid name must be configured for VRF by using the vrf definition command in global configuration mode.

▾ Configuring oob of a TACACS+ Server Group

- Optional. Configure oob if a device needs to send TACACS+ packets through a specified MGMT port.
- In server group configuration mode, specify routing for the communication of servers in the group.

Command	<code>ip oob via <i>mgmt_name</i></code>
Parameter Description	<i>mgmt-name</i> : Indicates the name of a management port.
Defaults	No oob is specified by default.
Command Mode	TACACS+ server group configuration mode
Usage Guide	Before configuring this command, you must run the <code>aaa group server tacacs+</code> command to enter the TACACS+ server group configuration mode. If no MGMT port is specified, the MGMT0 port is used by default.

Verification

Configure the AAA method list that specifies to conduct authentication, authorization, and accounting on users by using TACACS+.

- Enable a device to interact with TACACS+ servers. Conduct packet capture, check that the authentication, authorization, and accounting packets are interacted with different servers, and check the source addresses in packets.

Configuration Example

Configuring Different TACACS+ Server Groups for Separately Processing Authentication, Authorization, and Accounting

Scenario Figure 3-5	<p>The diagram illustrates a TACACS+ network setup. On the left, a 'User' (represented by a laptop icon) is connected to a 'TACACS+ Client' (represented by a server rack icon labeled 'A'). This client is then connected to a central line that branches out to three separate 'TACACS+ Server' units (represented by server rack icons). These servers are labeled B, C, and D, with their respective IP addresses: B (192.168.5.22), C (192.168.5.34), and D (192.168.5.44).</p>
Remarks	<ul style="list-style-type: none"> ● A is a client that initiates TACACS+ requests. ● B is a server that processes TACACS+ authentication requests. ● C is a server that processes TACACS+ authorization requests. ● D is a server that processes TACACS+ accounting requests.
Configuration Steps	<ul style="list-style-type: none"> ● Enable AAA.

- Configure the TACACS+ server information.
- Configure TACACS+ server groups.
- Add servers to TACACS+ server groups.
- Configure the method of using TACACS+ for authentication.
- Configure the method of using TACACS+ for authorization.
- Configure the method of using TACACS+ for accounting.
- Apply the configured authentication method on an interface.
- Apply the configured authorization method on an interface.
- Apply the configured accounting method on an interface.

```
Ruijie# configure terminal
Ruijie(Ruijie(config)# aaa new-model
Ruijie(config)# tacacs-server host 192.168.5.22
Ruijie(config)# tacacs-server host 192.168.5.34
Ruijie(config)# tacacs-server host 192.168.5.44
Ruijie(config)# tacacs-server key aaa
Ruijie(config)# aaa group server tacacs+ tacgrp1
Ruijie(config-gs-tacacs)# server 192.168.5.22
Ruijie(config-gs-tacacs)# exit
Ruijie(config)# aaa group server tacacs+ tacgrp2
Ruijie(config-gs-tacacs)# server 192.168.5.34
Ruijie(config-gs-tacacs)# exit
Ruijie(config)# aaa group server tacacs+ tacgrp3
Ruijie(config-gs-tacacs)# server 192.168.5.44
Ruijie(config-gs-tacacs)# exit
Ruijie(config)# aaa authentication login test1 group tacacs+
Ruijie(config)# aaa authentication enable default group tacgrp1
Ruijie(config)# aaa authorization exec test2 group tacgrp2
Ruijie(config)# aaa accounting commands 15 test3 start-stop group tacgrp3
Ruijie(config)# line vty 0 4
Ruijie(config-line)# login authentication test1
Ruijie(config-line)# authorization exec test2
Ruijie(config-line)# accounting commands 15 test3
```

Verification	<p>Telnet to a device from a PC. The screen requesting the user name and password is displayed. Enter the correct user name and password to log in to the device. Enter the enable command and enter the correct enable password to initiate enable authentication. Enter the privilege EXEC mode after passing the authentication. Perform operations on the device and then exit the device.</p> <p>View the authentication log of the user on the server with the IP address of 192.168.5.22.</p> <p>View the enable authentication log of the user on the server with the IP address of 192.168.5.22.</p> <p>View the exec authorization log of the user on the server with the IP address of 192.168.5.34.</p> <p>View the command accounting log of the user on the server with the IP address of 192.168.5.44.</p>
---------------------	--

Common Errors

- The AAA security service is disabled.
- The key configured on the device is inconsistent with the key configured on the server.
- Undefined servers are added to a server group.
- No method list is configured.

3.5 Monitoring

Displaying

Description	Command
Displays interaction with each TACACS+ server.	show tacacs

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs TACACS+.	debug tacacs+

4 Configuring 802.1X

4.1 Overview

IEEE 802.1X is a standard for port-based network access control that provides secure access service for local area networks (LANs).

In IEEE 802-compliant LANs, users connecting to the network access devices (NASs) can access network resources without authentication and authorization, bringing security risks to the network. IEEE 802.1X was proposed to resolve security problems of such LANs.

802.1X supports three security applications: authentication, authorization, and accounting, which are called AAA.

- Authentication: Checks whether to allow user access and restricts unauthorized users.
- Authorization: Grants specified services to users and controls permissions of authorized users.
- Accounting: Records network resource status of users to provide statistics for charges.

802.1X can be deployed in a network to realize user authentication, authorization and other functions.

Protocols and Standards

- IEEE 802.1X: Port-Based Network Access Control

4.2 Applications

Application	Description
Wired 802.1X Authentication	To ensure secure admission on the campus network, 802.1X authentication is deployed on access switches.

4.2.1 Wired 802.1X Authentication

Scenario

The campus network is deployed at the access, convergence, and core layers. 802.1X is deployed on access switches connected to dormitories to perform secure admission. Dormitory users must pass 802.1X authentication before accessing the campus network.

As shown in Figure 4-1:

- User ends must be installed with 802.1X clients (which can come with the operating system, or others like Ruijie Supplicant).
- Access switches support 802.1X.

- One or multiple Remote Authentication Dial-In User Service (RADIUS) servers perform authentication.

Figure 4-1

Remarks	The supplicant software installed on the user ends (or software coming with the operating system) performs 802.1X authentication. 802.1X authentication is deployed on access switches, convergence switches, or core switches. The RADIUS server runs the RADIUS server software to perform identity verification.
----------------	---

Deployment

- Enable 802.1X authentication on ports between access switches and users to make ports controllable. Only authenticated users on one port can access the network.
- Configure an AAA authentication method list so that 802.1X can adopt the appropriate method and authentication server.
- Configure RADIUS parameters to ensure proper communication between a switch and the RADIUS server. For details, see the *Configuring RDS*.
- If a Ruijie RADIUS server is used, configure SNMP parameters to allow the RADIUS server to manage devices, such as querying and setting.
- Configure the port between the access switch and the RADIUS server as an uncontrolled port to ensure proper communication between them.
- Create an account on the RADIUS server, register the IP address of an access switch, and configure RADIUS-related parameters. Only in this case, can the RADIUS server respond to the requests of the switch.

4.2.2 MAB Auto Authentication

Scenario

MAC address bypass (MAB) auto authentication indicates that MAB authentication is performed together with Web authentication. In the original wireless Web authentication scenario, it is complained that the ease-to-use performance of Web authentication is poor. During each Web authentication, a user needs to associate the STA with an SSID, open the browser, and enter the user name and password. In addition, if the STA drops out of the network, the STA cannot automatically access the network again. To ensure that all Web authenticated STAs are always online and access the network imperceptibly, MAB auto authentication is proposed. After a STA passes Web authentication, the STA can access the network again imperceptibly without Web authentication.

As shown in Figure 4-2

- Only the browser is mandatory on the client.
- The AC supports Web authentication and MAB authentication.
- One or multiple RADIUS servers provide authentication. In addition, the authentication server supports the authentication mode of using the MAC address as the user name and password.

Figure 4-2

Remarks	Wireless MAB authentication is triggered by a STA advertisement. When a STA is already online, MAB authentication will not be triggered again. If MAB authentication fails, it can be triggered again only after the STA
----------------	--

goes offline and reconnects to the network.

Deployment

- Enable Web authentication, DOT1X authentication, and MAB authentication on the interface of the AC. MAB authentication can be performed only after DOT1X authentication is enabled. (For details about MAB authentication, see section 4.4.5 “Configuring MAB Auto Authentication”. For details about Web authentication, see the WEB-AUTH-SCG document.)
- Configure an AAA authentication method list, so that a correct method and authentication server can be used for MAB/Web authentication. (For details about the AAA authentication method list configuration, see the AAA-SCG document.)
- Configure RADIUS parameters to ensure proper communication between the AC and the RADIUS server. In addition, configure the RADIUS server to support the authentication mode of using the MAC address as the user name and password. For details about the RADIUS configuration, see the corresponding configuration guide.
- If a Ruijie RADIUS server is used, configure SNMP parameters to allow the RADIUS server to perform operations such as querying and setting on the AP.
- Create an account on the RADIUS server, register the IP address of the AC, and configure RADIUS-related parameters. The RADIUS server can respond to the requests of the AP and AC only after the foregoing settings are completed.

4.3 Features

Basic Concepts

↘ User

In wired environment, 802.1X is a LAN-based protocol. It identifies users based on physical information but not accounts. In a LAN, a user is identified by the MAC address and VLAN ID (VID). Except them, all other information such as the account ID and IP address can be changed

↘ RADIUS

RADIUS is a remote authentication protocol defined in RFC2865, which get wide practice. Using this protocol, the authentication server can remotely deploy and perform authentication. During 802.1X deployment, the authentication server is remotely deployed, and 802.1X authentication information between the NAS and the authentication server is transmitted through RADIUS.

↘ Timeout

During authentication, an NAS needs to communicate with the authentication client and server. If the authentication client or server times out, not responding within the time specified by 802.1X, authentication will fail. During deployment, ensure that the timeout specified by 802.1X is longer than that specified by RADIUS.

↘ MAB

MAC address bypass (MAB) authentication means that the MAC address is used as the user name and password for authentication. Since Ruijie Supplicant cannot be installed on some dumb ends such as network printers, use MAB to perform security control.

↘ EAP

802.1X uses Extensible Authentication Protocol (EAP) to carry authentication information. Defined in RFC3748, EAP provides a universal authentication framework, in which multiple authentication modes are embedded, including Message Digest Algorithm 5 (MD5), Challenge Handshake Authentication Protocol (CHAP), Password Authentication Protocol (PAP), and Transport Layer Security (TLS). Ruijie 802.1X authentication supports various modes including MD5, CHAP, PAP, PEAP-MSCHAP, and TLS.

↘ Authorization

Authorization means to bind specified services to authenticated users, such as IP address, VLAN, Access Control List (ACL), and Quality of Service (QoS).

↘ Accounting

Accounting performs network audit on network usage duration and traffic for users, which facilitates network operation, maintenance, and management.

i Some RADIUS servers such as RG-SAM\RG-SMP servers need to check the online/offline status based on accounting packets. Therefore, accounting must be enabled on these RADIUS servers.

Overview

Feature	Description
Authentication	Provides secure admission for users. Only authenticated users can access the network.
Authorization	Grants network access rights to authenticated users, such as IP address binding and ACL binding
Accounting	Provides online record audit, such as online duration and traffic.

4.3.1 Authentication

Authentication aims to check whether users are authorized and prevent unauthorized users from accessing the network. Users must pass authentication to obtain the network access permission. They can access the network only after the authentication server verifies the account. Before user authentication succeeds, only EAPOL packets (Extensible Authentication Protocol over LAN, 802.1X packets) can be transmitted over the network for authentication.

Working Principle

802.1X authentication is very simple. After a user submits its account information, the NAS sends the account information to the remote RADIUS server for identity authentication. If the authentication succeeds, the user can access the network.

↘ Roles in Authentication

802.1X authentication involves three roles: supplicant, authenticator, and server. In real applications, their respective roles are client, network access server (NAS), and authentication server (mostly RADIUS server).

Figure 4-3

- Supplicant

The supplicant is the role of end users, usually a PC. It requests to access network services and replies to the request packets of the authenticator. The supplicant must run software compliant with the 802.1X standard. Except the typical 802.1X client support embedded in the operating system, Ruijie has launched a Ruijie Supplicant compliant with the 802.1X standard.

- Authenticator

The authenticator is usually an NAS such as a switch access hotspot. It controls the network connection of a client based on the client's authentication status. As a proxy between the client and the authentication server, the authenticator requests the user name from the client, verifies the authentication information from the authentication server, and forwards it to the client. Except as the 802.1X authenticator, the so-called NAS also acts as a RADIUS Client. It encapsulates the replies of the client into the RADIUS-format packets and forwards the packets to the RADIUS server. After receiving the information from the RADIUS server, it interprets the information and forwards it to the client.

The authenticator has two types of ports: controlled port and uncontrolled port. Users connected to controlled ports can access network resources only when authenticated. Users connected to uncontrolled ports can directly access network resources without authentication. We can connect users to controlled ports to control users. Uncontrolled ports are mainly used to connect the authentication server to ensure proper communication between the authentication server and the NAS.

- Authentication server

The authenticator server is usually an RADIUS server. It cooperates with the authenticator to provide authentication service for users. The authentication server saves the user names, passwords, and related authorization information. One server can provides authentication service for multiple authenticators to achieve centralized user management. The authentication server also manages accounting data received from authenticators. Ruijie RADIUS servers compliant with 802.1X standard include Microsoft IAS/NPS, Free RADIUS Server, and Cisco ACS.

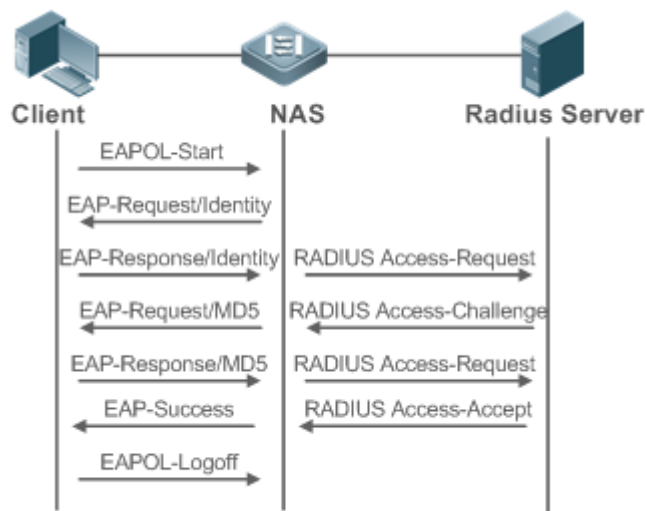

↘ Authentication Process and Packet Exchange

The supplicant exchanges information with the authenticator through EAPOL while exchanges information with the authentication server through RADIUS. EAPOL is encapsulated on the MAC layer, with the type number of 0x888E. IEEE

assigned a multicast MAC address 01-80-C2-00-00-03 for EAPOL to exchange packets during initial authentication. Ruijie Supplicant may also use 01-D0-F8-00-00-03 to for initial authentication packets.

Figure 4-4 shows the typical authentication process of a wired user.

Figure 4-4

This is a typical authentication process initiated by a user. In special cases, the NAS, may take place of the user to initiate an authentication request.

Authenticating User Status

802.1X determines whether a user on a port can access the network based on the authentication status of the port. Ruijie products extend the 802.1X and realizes access control based on users (identify a wired user by the MAC address and VLAN ID) by default. Ruijie 802.1X can also be enabled in interface configuration mode. For details, see the chapter "Configuration."

All users on an uncontrolled port can access network resources, while users on a controlled port can access network resources only after authorized. When a user initiates authentication, its status remains Unauthorized and cannot access the network yet. After it passes authentication, its status changes to Authorized and can access network resources.

If the user connected to a controlled port does not support 802.1X, it will not respond to the NAS requesting the user name of the user. That means, the user remains Unauthorized and cannot access network resources.

In the case of 802.1X-enabled user and 802.1X-disabled NAS, if the user does not receive any responses after sending a specified number of EAPOL-Start packets, it regards the connected port uncontrolled and directly accesses network resources.

On 802.1X-enabled devices, all ports are uncontrolled by default. We can configure a port as controlled so that all users on this port have to be authorized.

If a user passes authentication (that is, the NAS receives a success packet from the RADIUS server), the user becomes Authorized and can freely access network resources. If the user fails in authentication, it remains Unauthorized and

re-initiates authentication. If the communication between the NAS and the RADIUS server fails, the user remains Unauthorized and cannot access network resources.

When a user sends an EAPOL-LOGOFF packet, the user's status changes from Authorized to Unauthorized.

When a port of the NAS goes down, all users on this port will become Unauthorized.

When the NAS restarts, all users on it become Unauthorized.

📌 Deploying the Authentication Server

802.1X authentication uses the RADIUS server as the authentication server. Therefore, when 802.1X secure admission is deployed, the RADIUS server also needs to be deployed. Common RADIUS servers include Microsoft IAS/NPS, Cisco ACS, and RG-SAM/SMP. For details about the deployment procedure, see related software description.

📌 Configuring Authentication Parameters

To use 802.1X authentication, enable 802.1X authentication on the access port and configure AAA authentication method list and RADIUS server parameters. To ensure the accessibility between the NAS and RADIUS server, the 802.1X server timeout should be longer than the RADIUS server timeout.

📌 Supplicant

A user should start Ruijie Supplicant to enter the user name and initiate authentication. If the operating system brings an own authentication client and the network is available, a dialog box will be displayed, asking the user to enter the user name. Different clients may have different implementation processes and Graphical User Interfaces (GUIs). It is recommended to use Ruijie Supplicant as the authentication client. If other software is used, see related software description.

📌 Offline

If a user does not want to access the network, it can choose to go offline by multiple approaches, such as powering off the device, connecting the port to the network, and offline function provided by some supplicants.

4.3.2 Authorization

After a user passes authentication, the NAS restricts the accessible network resources of the user in multiple approaches, such as binding the IP address and the MAC address, and specifying the maximum online time or period, accessible VLANs, and bandwidth limit.

Working Principle

Authorization means to bind the permissions with the users. A user is identified based on the MAC address and VLAN ID, as mentioned before. Besides MAC-VID binding, some other information such as the IP address and VLAN ID are bound with a user to implement authorization.

📌 IP Authorization

802.1X does not support IP address identification. Ruijie 802.1X authentication extends 802.1X to support IP-MAC binding, which is called IP authorization. IP authorization supports four modes:

Supplicant authorization: The IP address is provided by Ruijie Supplicant.

RADIUS authorization: After successful authentication, the RADIUS server delivers the IP address to the NAS.

DHCP authorization: In such case, an authenticated user will initiate a DHCP request to obtain an IP address, and then bind the IP address with the MAC address of the client.

Mixed authorization: IP-MAC binding is configured for users in the following sequence: Supplicant authorization -> RADIUS authorization -> DHCP authorization. That is, the IP address provided by Ruijie Supplicant preferred, then the IP address provided by the RADIUS server, and finally the IP address provided by DHCP.

↳ Kickoff

Used with RG-SAM/SMP, Ruijie 802.1X server can kick off online users who will be disconnected with the network. This function applies to the environment where the maximum online period and real-time accounting check function are configured.

4.3.3 Accounting

Accounting allows the network operators to audit the network access or fees of accessed users, including the online time and traffic.

Working Principle

Accounting is enabled on the NAS. The RADIUS server supports RFC2869-based accounting. When a user goes online, the NAS sends an accounting start packet to the RADIUS server which then starts accounting. When the user goes offline, the NAS sends an accounting end packet to the RADIUS server which then completes the accounting and generates a network fee accounting list. Different servers may perform accounting in different ways. Moreover, not all servers support accounting. Therefore, refer to the usage guide of the authentication server during actual deployment and accounting.

↳ Accounting Start

After a user passes authentication, the accounting-enabled switch sends the RADIUS server an accounting start packet carrying user accounting attributes such as user name and accounting ID. After receiving the packet, the RADIUS server starts accounting.

↳ Accounting Update

The NAS periodically sends Accounting Update packets to the RADIUS server, making the accounting more real-time. The accounting update interval can be provided by the RADIUS server or configured on the NAS.

↳ Accounting End

After a user goes offline, the NAS sends the RADIUS server an accounting end packet carrying the online period and traffic of the user. The RADIUS server generates online records based on the information carried in this packet.

4.4 Configuration

Configuration	Description and Command
---------------	-------------------------

Configuring 802.1X Basic Functions	 (Mandatory) It is used to configure basic authentication and accounting.	
	aaa new-model	Enables AAA.
	aaa authentication dot1x	Configures an AAA authentication method list.
	aaa accounting network	Configures an AAA accounting method list.
	radius-server host	Configures the RADIUS server parameters.
	radius-server key	Configures the preshared key for communication between the NAS and the RADIUS server.
	dot1x port-control auto	Enables 802.1X authentication on a port.
Configuring 802.1X Parameters	 (Optional) It is used to configure 802.1X parameters.	
	 Ensure that the 802.1X server timeout is longer than the RADIUS server timeout.	
	 Online Ruijie client detection applies only to Ruijie Supplicant.	
	dot1x re-authentication	Enables re-authentication.
	dot1x timeout re-authperiod	Configures the re-authentication interval.
	dot1x timeout tx-period	Configures the interval of EAP-Request/Identity packet retransmission.
	dot1x reauth-max	Configures the maximum times of EAP-Request/Identity packet retransmission.
	dot1x timeout supp-timeout	Configures the interval of EAP-Request/Challenge packet retransmission.
	dot1x max-req	Configures the maximum times of EAP-Request/Challenge packet retransmission.
	dot1x timeout server-timeout	Configures the authentication server timeout.
	dot1x timeout quiet-period	Configures the quiet period after authentication fails.
	dot1x auth-mode	Specifies the authentication mode (EAP/CHAP/PAP).
	dot1x client-probe enable	Enables online Ruijie client detection.
dot1x probe-timer interval	Configures the interval of online Ruijie client detection.	
dot1x probe-timer alive	Configures the duration of online Ruijie client detection.	

Configuring Authorization	<p> (Optional) It is used to configure authorization.</p> <p> Ruijie Supplicant should be used to perform supplicant authorization in IP authorization mode.</p>	
	aaa authorization ip-auth-mode	Specifies the IP authorization mode.
	dot1x private-supplicant-only	Filters non-Ruijie clients.
	dot1x redirect	Enables Web Redirection for 2G Ruijie Supplicant Deployment.
	snmp	Configures SNMP parameters. RG-SAM/SMP can implement functions for 802.1X online users through SNMP. SNMP parameters should be configured to implement such functions.
Configuring MAB	<p> (Optional) It is used to configure MAC Authentication Bypass (MAB).</p> <p> 802.1X authentication takes priority over MAB.</p> <p> MAB does not support IP authorization.</p> <p> Single-user MAB and multi-user MAB cannot be enabled at the same time.</p> <p> MAB adopts the PAP authentication mode. Ensure correct server configurations during deployment.</p>	
	dot1x mac-auth-bypass	Enables single-user MAB.
	dot1x mac-auth-bypass multi-user	Enables multi-user MAB.
	dot1x multi-mab quiet-period	Configures the quiet period after multi-user MAB fails.
	dot1x mac-auth-bypass timeout-activity	Configures the timeout of MAB users.
	dot1x mac-auth-bypass violation	Enables MAB violation mode.
	dot1x mac-auth-bypass vlan	Configures VLAN-based MAB.
	dot1x mac-auth-bypass valid-ip-auth	Enables IP address-based MAB.
	dot1x mab-username upper	Enables uppercase letters in MAB user names.
Configuring IAB	<p> (Optional) It is used to configure Inaccessible Authentication Bypass (IAB).</p>	
	dot1x critical	Enables IAB.
	dot1x critical recovery action reinitialize	Enables IAB recovery.

Configuring Extended Functions	 (Optional) It is used to configure active authentication requests on a port.	
	 (Optional) It is used to configure the authenticated client list.	
	 (Optional) It is used to enable 802.1X packet sending with the pseudo source MAC address.	
	 (Optional) It is used to configure multiple accounts for the same MAC address.	
	dot1x auto-req	Enables active authentication.
	dot1x auto-req packet-num	Configures the number of active authentication requests.
	dot1x auto-req user-detect	Enables user detection for active authentication.
	dot1x auto-req req-interval	Configures the interval of active authentication request.
	dot1x auth-address-table address	Configures the authenticatable client list.
	dot1x pseudo source-mac	Enables 802.1X packets sending with the pseudo source MAC address.
dot1x multi-account enable	Enables multi-account authentication with one MAC address.	
dot1x valid-ip-acct enable	Enables IP-triggered accounting.	
dot1x valid-ip-acct timeout	Configures the timeout of obtaining IP addresses after users get authenticated. If timeout is reached, they will be kicked off.	
dot1x user-name compatible	Configures compatibility for H3C 802.1X authentication clients and authentication servers.	

4.4.1 Configuring 802.1X Basic Functions

Configuration Effect

- Enable basic authentication and accounting services.
- On a wired network, run the **dot1x port-control auto** command in interface configuration mode to enable 802.1X authentication on a port.
- Run the **radius-server host ip-address** command to configure the IP address and port information of the RADIUS server and the **radius-server key** command to configure the RADIUS communication key between the NAS and the RADIUS server to ensure secure communication.
- Run the **aaa accounting update** command in global configuration mode to enable accounting update and the **aaa accounting update interval** command on the NAS to configure the accounting update interval. If the RADIUS server supports accounting update, you can also configure it on the RADIUS server. Prefer to use the parameters assigned by the authentication server than the parameters configured on the NAS.

Notes

- Configure accurate RADIUS parameters so that the basic RADIUS communication is proper.
- The 802.1X authentication method list and accounting method list must be configured in AAA. Otherwise, errors may occur during authentication and accounting.
- Due to chipset restriction on switches, if 802.1X is enabled on one port, all ports will send 802.1X packets to the CPU.
- If 802.1X is enabled on a port but the number of authenticated users exceeds the maximum number of users configured for port security, port security cannot be enabled.
- If port security and 802.1X are both enabled but the security address has aged, 802.1X users must re-initiate authentication requests to continue the communication.
- Users with IP addresses statically configured or compliant with IP-MAC binding can access the network without authentication.
- 802.1X uses the default method list by default. If the default method list is not configured for AAA, run the **dot1x authentication** and **dot1x accounting** commands to reconfigure it.
- When RG-SAM/SMP is used, accounting must be enabled. Otherwise, the RADIUS server will fail to detect users going offline, causing offline users remaining in the online user table.

Configuration Steps

↳ Enabling AAA

- (Mandatory) 802.1X authentication and accounting take effect only after AAA is enabled.
- Enable AAA on the NAS that needs to control user access by 802.1X.

Command	aaa new-model
Parameter	N/A
Description	
Defaults	AAA is disabled by default.
Command Mode	Global configuration mode
Usage Guide	AAA is disabled by default. This command is mandatory for the deployment of 802.1X authentication.

↳ Enabling an AAA Authentication Method List

- Mandatory.
- The AAA authentication method list must be consistent with the 802.1X authentication method list.
- Enable an AAA authentication method list after 802.1X authentication is enabled on the NAS.

Command	aaa authentication dot1x <i>list-name</i> group radius
Parameter	<i>list-name</i> : Indicates the 802.1X authentication method list of AAA.
Description	

Defaults	No AAA authentication method list is configured by default.
Command Mode	Global configuration mode
Usage Guide	AAA authentication modes are disabled by default. The AAA authentication mode must be consistent with the 802.1X authentication mode.

▾ Configuring the RADIUS Server Parameters

- (Mandatory) The RADIUS server parameters must be configured to ensure proper communication between the NAS and the RADIUS server.
- Configure RADIUS server parameters after 802.1X authentication is enabled on the NAS.

Command	radius-server host <i>ip-address</i> [auth-port <i>port1</i>] [acct-port <i>port2</i>]
Parameter Description	<i>ip-address</i> : Indicates the IP address of the RADIUS server. <i>port1</i> : Indicates the authentication port. <i>port2</i> : Indicates the accounting port.
Defaults	No RADIUS server parameters are configured by default.
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Configuring the Preshared Key for Communication between the NAS and RADIUS Server

- (Mandatory) The preshared key for communication between the NAS and RADIUS server must be configured to ensure proper communication between the NAS and the RADIUS server.
- Configure the preshared key of the RADIUS server after 802.1X authentication is enabled on the NAS.

Command	radius-server key <i>string</i>
Parameter Description	<i>string</i> : Indicates the preshared key.
Defaults	No preshared key is configured for communication between the NAS and RADIUS server by default.
Command Mode	Global configuration mode
Usage Guide	The IP address of the NAS must be the same as that registered on the RADIUS server. The preshared key on the NAS must be the same as that on the RADIUS server. If the default RADIUS communication ports are changed on the RADIUS server, you need to change the communication ports on the NAS correspondingly.

▾ Enabling 802.1X on a Port

- This command is mandatory for a wired network.
- Enable 802.1X on switches.

Command	dot1x port-control auto
Parameter	N/A

Description	
Defaults	802.1X is disabled on a port by default.
Command Mode	Interface configuration mode
Usage Guide	802.1X is disabled on a port by default. This command is mandatory for the deployment of 802.1X authentication. The default method list is used by default. If the 802.1X authentication method list in AAA is not the default one, the configured 802.1X authentication method list should match.

Verification

Start Ruijie Supplicant, enter the correct account information, and initiate authentication. Then check whether the 802.1X and RADIUS configurations are correct.

▾ Checking for 802.1X Authentication Entries

Command	show dot1x summary
Parameter Description	N/A
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	Display entries of authenticated users to check the authentication status of users, for example, authenticating, authenticated, or quiet.
Command Display	N/A

▾ Checking for AAA User Entries

Command	show aaa user all
Parameter Description	N/A
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	Display information of AAA users.
Command Display	<pre>Ruijie#show aaa user all ----- Id ----- Name 2345687901 wwxy -----</pre>

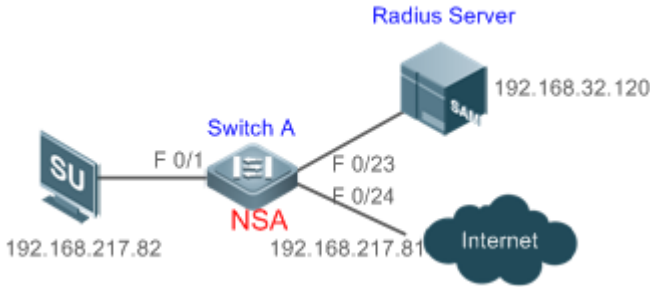

- Check whether the RADIUS server responds to authentication based on the RADIUS packets between the NAS and the RADIUS server. If no, it means that the network is disconnected or parameter configurations are incorrect. If the

RADIUS server directly returns a rejection reply, check the log file on the RADIUS server to identify the cause, e.g., of the authentication mode of the authentication server is incorrectly configured.

Configuration Example

i In this example, RG-SAM acts as the authentication server.

Configuring 802.1X Authentication on a Switch

<p>Scenario Figure 4-5</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Register the IP address of the switch on the RADIUS server and configure the communication key between the switch and the RADIUS server. ● Create an account on the RADIUS server. ● Enable AAA on the switch. ● Configure RADIUS parameters on the switch. ● Enable 802.1X authentication on ports of the switch. <p>Switch configurations are as follows. For detailed configuration on the RADIUS server, see the <i>Configuring RADIUS</i>.</p>
	<pre>ruijie# configure terminal ruijie (config)# aaa new-model ruijie (config)# radius-server host 192.168.32.120 ruijie (config)# radius-server key ruijie ruijie (config)# interface FastEthernet 0/1 ruijie (config-if)# dot1x port-control auto</pre>
<p>Verification</p>	<p>Check whether authentication is proper and network access behaviors change after authentication.</p> <ul style="list-style-type: none"> ● The account is successfully created, such as username:tests-user,password:test. ● The user fails to ping 192.168.32.120 before authentication. ● After the user enters account information and click Authenticate on Ruijie Supplicant, the authentication succeeds and the user can successfully ping 192.168.32.120. ● Information of the authenticated user is displayed. <pre>ruijie# show dot1x summary ID Username MAC Interface VLAN Auth-State Backend-State Port-Status User-Type Time -----</pre>

16778217	ts-user	0023.aaaa.4286	Fa0/1	2	Authenticated	Idle	Authed
static	0days 0h 0m 7s						

Common Errors

- RADIUS parameters are incorrectly configured.
- The RADIUS server has a special access policy, for example, the RADIUS packets must carry certain attributes.
- The AAA authentication mode list is different from the 802.1X authentication mode list, causing authentication failure.

4.4.2 Configuring 802.1X Parameters

Configuration Effect

- Adjust 802.1X parameter configurations based on the actual network situation. For example, if the authentication server has poor performance, you can raise the authentication server timeout.

Notes

- 802.1X and RADIUS have separate server timeouts. By default, the authentication server timeout of 802.1X is 5 seconds while that of RADIUS is 15 seconds. In actual situations, ensure that the former is greater than the latter. You can run the **dot1x timeout server-timeout** command to adjust the authentication server timeout of 802.1X. For detailed configuration about the RADIUS server timeout, see the *Configuring RADIUS*.
- Online client detection applies only to Ruijie Supplicant.

Configuration Steps

↘ Enabling Re-authentication

- (Optional) After re-authentication is enabled, the NAS can periodically re-authenticate online users.
- Enable re-authentication after 802.1X authentication is enabled on the NAS.

Command	dot1x re-authentication
Parameter	N/A
Description	
Defaults	Re-authentication is disabled by default.
Command Mode	Global configuration mode
Usage Guide	You can run this command to periodically re-authenticate users.

↘ Configuring the Re-authentication Interval

- (Optional) You can configure the re-authentication interval for users.
- Configure the re-authentication interval after 802.1X authentication is enabled on the NAS. The re-authentication interval takes effect only after re-authentication is enabled.

Command	dot1x timeout re-authperiod <i>period</i>
----------------	--

Parameter Description	<i>period</i> : Indicates the re-authentication interval in the unit of seconds.
Defaults	The default value is 3,600 seconds.
Command Mode	Global configuration mode
Usage Guide	Adjust the re-authentication interval as required.

▾ Configuring the Interval of EAP-Request/Identity Packet Retransmission

- (Optional) A larger value indicates a longer interval of packet retransmission.
- Configure the interval of EAP-Request/Identity packet retransmission after 802.1X authentication is enabled on the NAS.

Command	dot1x timeout tx-period <i>period</i>
Parameter Description	<i>period</i> : Indicates the interval of EAP-Request/Identity packet retransmission in the unit of seconds.
Defaults	The default value is 3 seconds.
Command Mode	Global configuration mode
Usage Guide	It is recommended to use the default value. Adjust the value based on how long the authentication client responds to the NAS's requests.

▾ Configuring the Maximum Times of EAP-Request/Identity Packet Retransmission

- (Optional) A larger value indicates more frequent retransmissions.
- Configure the maximum times of EAP-Request/Identity packet retransmission after 802.1X authentication is enabled on the NAS.

Command	dot1x reauth-max <i>num</i>
Parameter Description	<i>num</i> : Indicates the maximum times of EAP-Request/Identity packet retransmission.
Defaults	The default value is 3 for switches devices.
Command Mode	Global configuration mode
Usage Guide	It is recommended to use the default value. In the case of high-rate packet loss, increase this value so that the clients can easily receive packets from the NAS.

▾ Configuring the Interval of EAP-Request/Challenge Packet Retransmission

- (Optional) A larger value indicates a longer retransmission interval.
- Configure the interval of EAP-Request/Challenge packet retransmission after 802.1X authentication is enabled on the NAS.

Command	dot1x timeout supp-timeout <i>time</i>
Parameter	<i>time</i> : Indicates the interval of EAP-Request/Challenge packet transmission in the unit of seconds.

Description	
Defaults	The default value is 3 seconds for switches while devices.
Command Mode	Global configuration mode
Usage Guide	It is recommended to use the default value. Increase this value in the case of high-rate packet loss.

▾ Configuring the Maximum Times of EAP-Request/Challenge Packet Retransmission

- (Optional) A larger value indicates more frequent retransmissions.
- Configure the maximum times of EAP-Request/Challenge packet retransmission after 802.1X authentication is enabled on the NAS.

Command	dot1x max-req <i>num</i>
Parameter Description	<i>num</i> : Indicates the maximum times of EAP-Request/Challenge packet retransmission in the unit of seconds.
Defaults	The default value is 3.
Command Mode	Global configuration mode
Usage Guide	Optional. It is recommended to use the default value. Increase this value in the case of high-rate packet loss.

▾ Configuring the Authentication Server Timeout

- (Optional) A larger value indicates a longer authentication server timeout.
- Configure the authentication server timeout after 802.1X authentication is enabled on the NAS.
- The server timeout of RADIUS must be greater than that of 802.1X.

Command	dot1x timeout server-timeout <i>time</i>
Parameter Description	<i>time</i> : Indicates the authentication server timeout in the unit of seconds.
Defaults	The default value is 5 seconds.
Command Mode	Global configuration mode
Usage Guide	It is recommended to use the default value. Increase this value if the communication between the NAS and RADIUS server is unstable.

▾ Configuring the Quiet Period after Authentication Fails

- (Optional) A larger value indicates a longer quiet period.
- Configure the quiet period after 802.1X authentication is enabled on the NAS.

Command	dot1x timeout quiet-period <i>time</i>
Parameter Description	<i>time</i> : Indicates the quiet period after authentication fails. The unit is second.

Defaults	The default value is 10 seconds.
Command Mode	Global configuration mode
Usage Guide	It is recommended to use the default value. Increase this value to prevent users from frequently initiating authentication to the RADIUS server, thereby reducing the load of the authentication server.

↘ Specifying the Authentication Mode

- (Optional) Configure the mode for 802.1X authentication.
- Configure the authentication mode after 802.1X authentication is enabled on the NAS.

Command	dot1x auth-mode {eap chap pap}
Parameter Description	eap: Indicates EAP authentication. chap: Indicates CHAP authentication. pap: Indicates PAP authentication.
Defaults	The default value is eap .
Command Mode	Global configuration mode
Usage Guide	Select the authentication mode supported by Ruijie Supplicant and authentication server.

↘ Enabling Online Ruijie Client Detection

- (Optional) If online Ruijie client detection is enabled, the NAS can find clients going offline in a timely manner to prevent incorrect accounting.
- This function applies only to Ruijie 802.1X authentication clients.
- Enable online Ruijie client detection after 802.1X authentication is enabled on the NAS.

Command	dot1x client-probe enable
Parameter Description	N/A
Defaults	Online Ruijie client detection is disabled by default.
Command Mode	Global configuration mode
Usage Guide	It is recommended to enable this function when Ruijie Supplicant is used.

↘ Configuring the Interval of Online Ruijie Client Detection

- (Optional) A larger value indicates a longer time interval at which Ruijie clients send detection packets.
- Configure the interval of online Ruijie client detection after 802.1X authentication is enabled on the NAS.

Command	dot1x probe-timer interval <i>time</i>
Parameter Description	<i>time</i> : Indicates the time interval at which Ruijie Supplicant sends a heartbeat packet to the NAS. The unit is second.
Defaults	The default value is 20 seconds.

Command Mode	Global configuration mode
Usage Guide	It is recommended to use the default value.

▾ **Configuring the Duration of Online Ruijie Client Detection**

- (Optional) A larger value indicates a longer interval at which the NAS finds clients going offline.
- Configure the duration of online Ruijie client detection after 802.1X authentication is enabled on the NAS.

Command	dot1x probe-timer alive <i>time</i>
Parameter Description	<i>time</i> : Indicates the duration of online Ruijie client detection in the unit of seconds.
Defaults	The default value is 250 seconds.
Command Mode	Global configuration mode
Usage Guide	Optional. If the NAS does not receive any detection packets from an online client within the detection duration, it regards the client offline. It is recommended to use the default value.

Verification

Run the **show dot1x** command to check whether parameter configurations take effect.

Configuration Example

▾ **Specifying the Authentication Mode**

Scenario	The NAS is deployed in standalone mode.
Configuration Steps	Set the authentication mode to chap .
	<pre>Ruijie(config)#dot1x auth-mode chap</pre>
Verification	Display the configurations. <pre>Ruijie(config)#show dot1x 802.1X basic information: 802.1X Status enable Authentication Mode chap Authorization mode disable Total User Number 0 (exclude dynamic user) Authenticated User Number 0 (exclude dynamic user) Dynamic User Number 0 Re-authentication disable Re-authentication Period 3600 seconds</pre>

Re-authentication max 3 times Quiet Period 10 seconds Tx Period 30 seconds Supplicant Timeout 3 seconds Server Timeout 5 seconds Maximum Request 3 times Client Online Probe disable Eapol Tag disable 802.1x redirect disable Private supplicant only disable

▾ **Enabling Online Client Detection**

Scenario Figure 4-6	
Configuration Steps	Enable online client detection.
	Ruijie(config)#dot1x client-probe enable
	<ul style="list-style-type: none"> Users can remain online only when their Ruijie Supplicant sends online detection packets as scheduled.
Verification	<ul style="list-style-type: none"> Display the configurations. <div style="background-color: #f0f0f0; padding: 5px;"> <pre> Ruijie(config)#show dot1x 802.1X basic information: 802.1X Status enable Authentication Mode chap Authorization mode disable Total User Number 0 (exclude dynamic user) Authenticated User Number 0 (exclude dynamic user) Dynamic User Number 0 Re-authentication disable Re-authentication Period 3600 seconds Re-authentication max 3 times Quiet Period 10 seconds Tx Period 30 seconds </pre> </div>

Supplicant Timeout	3 seconds
Server Timeout	5 seconds
Maximum Request	3 times
Client Online Probe	enable
Eapol Tag	disable
802.1x redirect	disable

Common Errors

- The server timeout is shorter than the RADIUS timeout.
- Online client detection is enabled but the authentication program is not Ruijie Supplicant.

4.4.3 Configuring Authorization

Configuration Effect

- In IP authorization, authenticated users have to use the specified IP addresses to access the network, preventing IP address fake. IP authorization can be enabled in global configuration mode or interface configuration mode. IP authorization enabled in interface configuration mode takes priority over that configured in global configuration mode.
- Enable non-Ruijie client filtering. If this function is enabled, users must use Ruijie Supplicant for authentication so that they will enjoy services provided by Ruijie Supplicant, such as anti-proxy or SMS.
- Enable Web redirection to support 2G Ruijie Supplicant deployment. 2G Ruijie Supplicant deployment means that a user needs to download Ruijie Supplicant through the browser and then initiate authentication through Ruijie Supplicant. 2G Ruijie Supplicant deployment facilitates quick deployment of Ruijie Supplicant in the case of massive users.

Notes

- If the real-time kickoff function of RG-SAM/SMP is used, you need to configure correct SNMP parameters. For details, see the *Configuring SNMP*.
- If multiple authentication supplicants are used, disable this function.
- If the IP authorization mode is changed, all authenticated users will go offline and have to get re-authenticated before online again.
- In mixed authorization mode, IP authorization with a higher priority is used during user authentication. For example, if Ruijie Supplicant provides an IP address for this RADIUS-authentication user during its re-authentication, this IP address will be used for authorization.
- For 802.1X authentication, when a user attempts to obtain an IP address through DHCP in gateway authentication mode and IP authorization mode, you can enable IP DHCP snooping and IP source guard to prevent the user from stealing an IP address.
- In gateway authentication mode and DHCP or mixed authorization mode, the NAS automatically grants the latest IP address obtained though DHCP to a user so that the user can properly communicate after being migrated to the same Super VLAN.

- 2G Ruijie Supplicant deployment and Web authentication cannot be used at the same time.
- 2G Ruijie Supplicant deployment requires the setting of the **redirect** parameter. For details, see the *Configuring Web Authentication*.
- The kickoff function of RG-SAM/SMP is implemented through SNMP. Therefore, you need to configure SNMP parameters. For details, see the *Configuring SNMP*.

Configuration Steps

▾ Specifying the Global IP Authorization Mode

- The **supplicant** mode only applies to Ruijie Supplicant.
- In **radius-server** mode, the authentication server needs to assign IP addresses based on the **framed-ip** parameters.
- In **dhcp-server** mode, DHCP snooping must be enabled on the NAS.
- (Optional) Configure an IP-MAC binding.
- Configure the IP authorization mode after 802.1X authentication is enabled on the NAS.

Command	aaa authorization ip-auth-mode { disable supplicant radius-server dhcp-server mixed }
Parameter Description	disable : Disables IP authorization. supplicant : Indicates IP authorization by the supplicant. radius-server : Indicates IP authorization by the RADIUS server. dhcp-server : Indicates IP authorization by the DHCP server. mixed : Indicates IP authorization in a mixed manner.
Defaults	IP authorization is disabled by default.
Command Mode	Global configuration mode
Usage Guide	Select the IP authorization mode based on actual deployment.

▾ Enabling Web Redirection for 2G Ruijie Supplicant Deployment

- (Optional) If the redirection for 2G Ruijie Supplicant deployment is enabled, users not having any 802.1X authentication clients on a controlled port can download and install an 802.1X authentication client through Web pages.
- Enable Web redirection for 2G Ruijie Supplicant deployment after 802.1X authentication is enabled on the NAS.
- The **redirect** parameter must be configured. For details, see the *Configuring Web Authentication*.

Command	dot1x redirect
Parameter Description	N/A
Defaults	The redirection for 2G Ruijie Supplicant deployment is disabled by default.
Command Mode	Global configuration mode
Usage Guide	The redirect parameter must be configured. For details, see the <i>Configuring Web Authentication</i> .

➤ **Enabling Non-Ruijie Client Filtering**

- (Optional) If this function is enabled, non-Ruijie clients cannot perform authentication.
- Enable non-Ruijie client filtering after 802.1X authentication is enabled on the NAS.

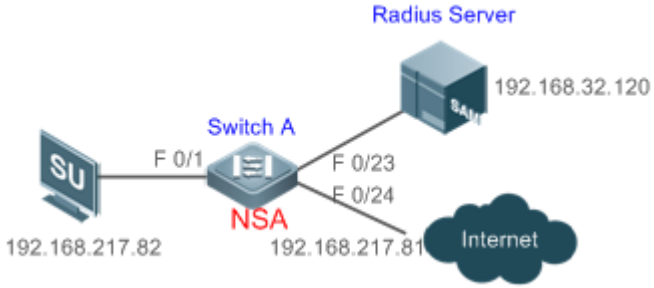

Command	dot1x private-supplicant-only
Parameter Description	N/A
Defaults	Non-Ruijie client filtering is disabled by default.
Command Mode	Global configuration mode
Usage Guide	This function can be enabled only when Ruijie Supplicant is used.

Verification

- After IP authorization is enabled, use the client to initiate authentication and go online, and then change the IP address. As a result, the client cannot access the network.
- Enable Web redirection for 2G Ruijie Supplicant deployment. When you start the browser to visit a website, the system automatically redirects to the download Web page and downloads the authentication client. You can access the network only when authenticated by the client.
- After a user is authenticated and goes online, enable the kickoff function on RG-SAM/SMP. The NAS will force the user offline and the user will fail to access the network.

Configuration Example

➤ **Configuring the IP Authorization Mode**

<p>Scenario Figure 4-7</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable AAA. ● Configure RADIUS. ● Enable 802.1X on a controlled port. ● Globally enable IP authorization in supplicant mode.
	<pre>Ruijie(config)#aaa authorization ip-auth-mode supplicant</pre>
	<ul style="list-style-type: none"> ● Ruijie Supplicant initiates authentication and the authentication succeeds. ● Ruijie Supplicant only uses 192.168.217.82 for communication.

Verification	<ul style="list-style-type: none"> ● Display the configurations. <pre style="background-color: #f0f0f0; padding: 10px;"> Ruijie(config)#show dot1x user name ts-user Supplicant information: MAC address b048.7a7f.f9f3 Username ts-user User ID 16777303 Type static VLAN 1 Online duration 0days 0h 0m21s Up average bandwidth 0 kBps Down average bandwidth 0 kBps Authorized VLAN 1 Authorized session time 20736000 seconds Authorized flux unlimited Accounting No Proxy user Permit Dial user Permit IP privilege 0 Private supplicant no Max user number on this port 0 Authorization ip address 192.168.217.82 </pre>
---------------------	---

Common Errors

- There are multiple authentication clients on the network but non-Ruijie client filtering is enabled, causing some users to fail authentication.
- RG-SAM/SMP is used but SNMP parameters are not configured on the switch, causing kickoff failure.
- The **redirect** parameter is incorrectly configured, causing abnormalities in redirection for 2G Ruijie Supplicant downloading.

4.4.4 Configuring MAB

Configuration Effect

- If the MAC address of an access user is used as the authentication account, the user does not need to install any supplicants. This applies to some dumb users such as networking printers.
- Single-user MAB applies to two scenarios:
 - There is only one dumb user connected to a port.
 - Only one user needs to be authenticated. After this, all other users can access the network
- Multi-user MAB applies to the scenario where multiple dumb users connected to a port. For example, multiple VoIP devices are deployed in the network call center.

- Multi-user MAB can be used with 802.1X authentication. It applies to mixed access scenarios such as the PC-VoIP daisy-chain topology.

Notes

- A MAB-enabled port sends an authentication request packet as scheduled by **tx-period**. If the number of the sent packets exceeds the number specified by **reauth-max** but still no client responds, this port enters the MAB mode. Ports in MAB mode can learn the MAC addresses and use them as the account information for authentication.
- When using the MAC address as the user name and password on the authentication server, delete all delimiters. For example, if the MAC address of a user is 00-d0-f8-00-01-02, the user name and password should be set to 00d0f8000102 on the authentication server.
- 802.1X takes priority over MAB. Therefore, if a user having passed MBA authentication uses a client to initiate 802.1X authentication, MAB entries will be removed.
- MAB supports only PAP authentication. PAP authentication should be enabled also on the authentication server.
- Only when active authentication is enabled, can MAB detect whether the user can perform 802.1X authentication. Therefore, automatic authentication must be enabled for MAB deployment.

Configuration Steps

▾ Enabling Single-User MAB

- Optional.
- Single-user MAB applies when only one user connected to a port needs to be authenticated.
- Enable single-user MAB on the 802.1X controlled port of the NAS.

Command	dot1x mac-auth-bypass
Parameter	N/A
Description	
Defaults	Single-user MAB is disabled by default.
Command Mode	Interface configuration mode
Usage Guide	This command applies only to switches. Single-user MAB applies when only one dumb user connected to a port needs to be authenticated. If you want to restrict the number of users, enable the violation mode.

▾ Configuring the Timeout of MAB Users

- Optional.
- After a MAC address in MAB mode is authenticated and goes online, the NAS regards the MAC address online unless re-authentication fails, the port goes down, or the MAC address goes offline due to management policies such as kickoff. You can configure the timeout of authenticated MAC addresses. The default value is 0, indicating always online.
- Configure the timeout of MAB users on the 802.1X controlled port of the NAS.

Command	dot1x mac-auth-bypass timeout-activity <i>value</i>
Parameter	<i>value</i> : Indicates the maximum online time of MAB users in the unit of seconds.
Description	
Defaults	The default value is 0, indicating no time restriction.
Command Mode	Interface configuration mode
Usage Guide	The MAB timeout applies to both single-user MAB and multi-user MAB.

▾ Enabling the MAB Violation Mode

- Optional.
- Enable MAB violation on the 802.1X controlled port of the NAS.
- By default, after one MAC address passes MAB authentication, data of all switches connected to the port can be forwarded. However, for security purposes, the administrator may request one MAB port to support only one MAC address. In this case, you can enable MAB violation on the port. If more than one MAC address is found connected to a MAB violation-enabled port after the port enters MAB mode, the port will become a violation.

Command	dot1x mac-auth-bypass violation
Parameter	N/A
Description	
Defaults	MAB violation is disabled by default.
Command Mode	Interface configuration mode
Usage Guide	This command applies only to switches. Configure this command only when only one dumb user is connected to the port. MAB violation applies only to single-user MAB.

▾ Enabling Multi-user MAB

- Optional.
- Enable multi-user MAB on the 802.1X controlled port of the NAS.

Command	dot1x mac-auth-bypass multi-user
Parameter	N/A
Description	
Defaults	Multi-user MAB is disabled by default.
Command Mode	Interface configuration mode
Usage Guide	This command applies only to switches. Configure this command when multiple dumb users connected to the port need to be authenticated.

▾ Configuring the Quiet Period after Multi-user MAB Fails

- Optional.

- Configure the quiet period of the multi-user MAB failure after multi-user MAB is enabled on the NAS.
- If multi-user MAB is enabled, you should prohibit unauthorized users from frequently initiating authentication to protect the NAS from attacks of these users and thereby reduce the load of the authentication server. Configure the quiet period of the multi-user MAB failure in global configuration mode. That is, if a MAC address fails authentication, it needs to re-initiate authentication after the quiet period. Configure this quiet period based on the actual situation. The default value is 0, indicating that a user can re-initiate authentication immediately after authentication fails.

Command	dot1x multi-mab quiet-period <i>value</i>
Parameter Description	<i>value</i> : Indicates the quiet period after authentication fails.
Defaults	The default value is 0s.
Command Mode	Global configuration mode
Usage Guide	This command applies only to switches. If too many dumb users connected to a port are authenticated, run this command to limit the authentication rate.

📌 Configuring VLAN-based MAB

- Optional.
- Enable VLAN-based MAB after multi-user MAB is enabled on the NAS.
- If you configure VLANs as MAB VLANs, only users in these VLANs can perform MAB.

Command	dot1x mac-auth-bypass vlan <i>vlan-list</i>
Parameter Description	<i>vlan-list</i> : Indicates the VLANs supporting MAB.
Defaults	VLAN-based MAB is disabled by default.
Command Mode	Interface configuration mode
Usage Guide	This command applies only to switches. Run this command when a port allows only users in specified VLANs to perform MAB.

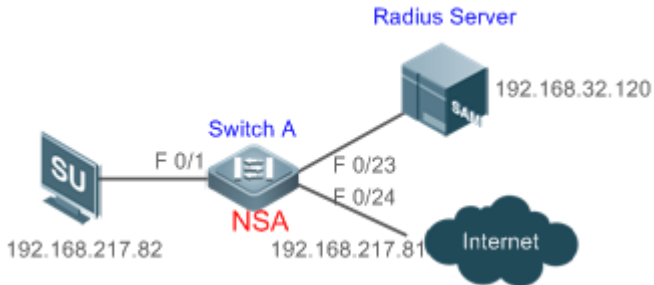

Verification

Check whether the dumb user can access the network. If yes, MAB takes effect. If no, MAB does not take effect.

- Check whether MAB functions are configured on the authentication server and NAS.
- Check whether dumb users with illegitimate MAC addresses cannot access the network.
- Check whether dumb users with illegitimate MAC addresses can access the network.

Configuration Example

📌 Enabling Multi-user MAB on a Switch

<p>Scenario Figure 4-8</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Register the IP address of the Switch A on the RADIUS server and configure the communication key between Switch A and the RADIUS server. ● Create an account on the RADIUS server. ● Enable AAA on Switch A. ● Configure RADIUS parameters on Switch A. ● Enable 802.1X and multi-user MAB on a port of Switch A. <p>Switch configurations are as follows. For detailed configuration on the RADIUS server, see the <i>Configuring RADIUS</i>.</p>
	<pre>ruijie# configure terminal ruijie (config)# aaa new-model ruijie (config)# radius-server host 192.168.32.120 ruijie (config)# radius-server key ruijie ruijie (config)# interface FastEthernet 0/1 ruijie (config-if)# dot1x port-control auto ruijie (config-if)# dot1x mac-auth-bypass multi-user</pre>
<p>Verification</p>	<p>Check whether authentication is proper and network access behaviors change after authentication.</p> <ul style="list-style-type: none"> ● The account is successfully created, such as username: 0023aeaa4286,password: 0023aeaa4286. ● The user fails to ping 192.168.32.120 before authentication. ● The user connects to the switch, the authentication succeeds, and the user can successfully ping 192.168.32.120. ● Information of the authenticated user is displayed. <pre>ruijie# show dot1x summary ID Username MAC Interface VLAN Auth-State Backend-State Port-Status User-Type Time ----- 16778217 0023aea... 0023.aeaa.4286 Fa0/1 2 Authenticated Idle Authed static 0days 0h 5m 8s</pre>

4.4.5 Configuring MAB Auto Authentication

Configuration Effect

- When a STA accesses the network for the first time, Web authentication is performed. When the STA is disconnected from and then reconnects to the network, authentication is not required.

Notes

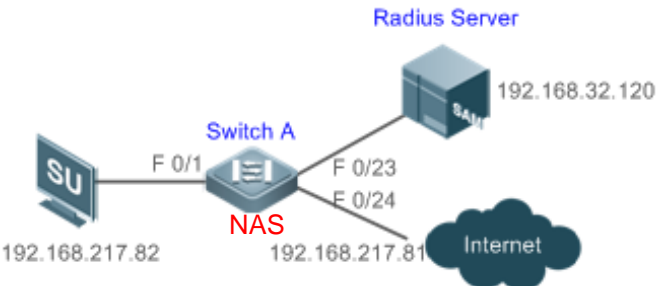

- Wireless MAB authentication is triggered by a STA advertisement. If a STA is already online, MAB authentication will not be triggered again. MAB authentication is triggered only after the STA is disconnected from and then reconnects to the network.
- When a STA accesses the network for the second time, a dialog box may be displayed for MAB authentication. When the STA accesses the network for the third time, the dialog box will not be displayed.
- If MAB authentication fails, a dialog box is displayed for Web authentication when the STA accesses the network next time.

Configuration Steps

For details about Web authentication configuration, see the Web authentication configuration document. For details about MAB authentication configuration, see section “Configuring MAB”.

Configuration Example

Configuring MAB Auto Authentication

<p>Scenario Figure 4-9</p>	 <p>The diagram illustrates a network setup for MAB auto authentication. A central switch, labeled 'Switch A' and 'NAS', is connected to a server 'SU' (IP 192.168.217.82) via interface F 0/1. The switch is also connected to a 'Radius Server' (IP 192.168.32.120) via interfaces F 0/23 and F 0/24. The switch's IP address is 192.168.217.81. The switch is connected to the 'Internet' cloud.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Register the IP address of the NAS on the RADIUS server and configure the communication key between the NAS and the RADIUS server. ● Create an account on the RADIUS server and bind it with a MAC address for imperceptible authentication. ● Enable AAA on the NAS. ● Configure RADIUS parameters on the NAS. ● Enable 802.1X authentication and MAB authentication on an interface of the NAS. ● Enable second-generation (or first-generation/embedded) Web authentication on an interface of the NAS and configure the Web authentication template globally.

	<p>The following describes the NAS configurations. For detailed configuration on the RADIUS server, see the related configuration guide (The following describes configuration on the switch, which is similar to that on the AC/AP, except that the configuration on the switch is performed in interface configuration mode instead of WLAN RSNA configuration mode.)</p>
	<pre>ruijie#configure terminal ruijie (config)#aaa new-model ruijie (config)#aaa authentication web-auth default group radius ruijie (config)#aaa authentication dot1x default group radius ruijie (config)aaa accounting net-work default start-stop group radius ruijie (config)#radius-server host 192.168.32.120 ruijie (config)#radius-server key ruijie ruijie (config)#web-auth template eportalv2 ruijie (config-tmpl-v2)#ip 192.158.32.9 ruijie (config-tmpl-v2)#url http://192.168.32.9:8080/eportal/index.jsp ruijie (config-tmpl-v2)#exit ruijie (config)#interface FastEthernet 0/1 ruijie (config-if)#dot1x port-control auto ruijie (config-if)#dot1x mac-auth-bypass multi-user ruijie (config-if)#web-auth enable eportalv2</pre>
<p>Verification</p>	<p>Check whether authentication is normal and network access behaviors change after authentication.</p> <ul style="list-style-type: none"> ● The account is successfully created, for example, the username is 0023aeaa4286 and the password is 0023aeaa4286. ● The STA fails to ping 192.168.32.120 before authentication. ● The STA connects to the NAS, a page indicating the authentication succeeds is displayed, and the STA can successfully ping 192.168.32.120. ● The STA is disconnected from and then reconnects to the network and can successfully ping 192.168.32.120. <pre>ruijie#show dot1x summary ID Username MAC Interface VLAN Auth-State Backend-State Port-Status User-Type Time ----- ----- 16778217 0023aea... 0023.aeaa.4286 Fa0/1 2 Authenticated Idle Authed static 0days 0h 5m 8s</pre>

Common Errors

- The MAC account format is incorrect on the authentication server.

4.4.6 Configuring IAB

Configuration Effect

- Enable IAB. After IAB is enabled, newly authenticated users can access the network even when all RADIUS servers configured on the NAS are inaccessible.
- Enable IAB recovery. When RADIUS servers recover to their reachable status, re-verify the users authorized during inaccessibility.

Notes

- Configure an account and standards for testing RADIUS server accessibility. For details, see the *Configuring RADIUS*.
- IAB takes effect only when only RADIUS authentication exists in the globally configured 802.1X authentication mode list and all RADIUS servers in the list are inaccessible. If other authentication modes (for example, local and none) exist in the list, IAB does not take effect.
- After multi-domain AAA is enabled, 802.1X authentication does not need the globally configured authentication mode list any more. If IAB detects that all RADIUS servers configured in the globally configured 802.1X authentication mode list are inaccessible, it directly returns an authentication success reply to users, with no need to enter the user name. Therefore, multi-domain AAA does not take effect on this port.
- Users authenticated in IAB mode do not need to initiate accounting requests to the accounting server.
- Authenticated users can properly access the network, not affected by server inaccessibility.
- In access authentication configuration mode, when 802.1X-based IP authentication is enabled globally, users on this port, except those having been authenticated, cannot be authenticated in IAB mode. In gateway authentication mode, users are IP authorized if their IP addresses are obtained.
- Complete 802.1X authentication is required on such 802.1X authentication clients as those of Windows. It is possible that though these clients already pass the IAB authentication, there are prompts on the clients suggesting failed authentication.

Configuration Steps

▾ Enabling IAB

- (Optional) After IAB is enabled, the NAS authorizes newly authenticated users if the authentication server is faulty.
- Enable IAB after 802.1X authentication is enabled on the NAS.

Command	dot1x critical
Parameter	N/A
Description	
Defaults	IAB is disabled by default.
Command Mode	Interface configuration mode
Usage Guide	This command applies to ports on which newly authenticated users need to be authorized when the authentication server is inaccessible.

➤ **Enabling IAB Recovery**

- (Optional) After the authentication server is recovered, the NAS re-authenticates users that are authorized when the authentication server is inaccessible.
- Enable IAB recovery actions after 802.1X authentication is enabled on the NAS.

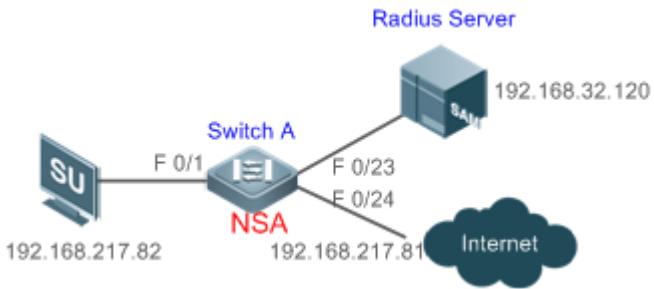

Command	dot1x critical recovery action reinitialize
Parameter	N/A
Description	
Defaults	IAB recovery is disabled by default.
Command Mode	Interface configuration mode
Usage Guide	If IAB recovery is enabled on a port, properly authenticated users on the port can access the network without re-authentication after the authentication server is recovered. After the authentication server is recovered, the NAS initiates authentication only to users authenticated in IAB mode during server inaccessibility.

Verification

- When the authentication server is accessible, check whether users can go online only by using the correct user name and password.
- When the authentication server is inaccessible, check whether new users can be authorized to access the network immediately after connecting to the NAS.

Configuration Example

➤ **Enabling IAB**

<p>Scenario Figure 4-10</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Register the IP address of the NAS on the RADIUS server and configure the communication key between the NAS and the RADIUS server. ● Create an account on the RADIUS server. ● Enable AAA on the NAS. ● Configure RADIUS parameters and enable server accessibility probe on the NAS. ● Enable 802.1X and multi-user MAB on a port of the NAS. <p>NAS configurations are as follows. For detailed configuration on the RADIUS server, see the <i>Configuring RADIUS</i>.</p>

	<pre>ruijie# configure terminal ruijie (config)# aaa new-model ruijie (config)# radius-server host 192.168.32.120 ruijie (config)# radius-server key ruijie ruijie (config)# interface FastEthernet 0/1 ruijie (config-if)# dot1x port-control auto</pre>																												
Verification	<p>Check whether authentication is proper and network access behaviors change after authentication.</p> <ul style="list-style-type: none"> ● The account is successfully created, such as username: test,password: test. ● When the authentication server is accessible, the user fails to ping 192.168.32.120 before authentication. ● When the authentication server becomes inaccessible, the user connects to the NAS, authentication succeeds, and the user can successfully ping 192.168.32.120. ● Information of the authenticated user is displayed. <pre>ruijie# show dot1x summary</pre> <table border="1"> <thead> <tr> <th>ID</th> <th>Username</th> <th>MAC</th> <th>Interface</th> <th>VLAN</th> <th>Auth-State</th> <th>Backend-State</th> </tr> <tr> <th>Port-Status</th> <th>User-Type</th> <th>Time</th> <th></th> <th></th> <th></th> <th></th> </tr> </thead> <tbody> <tr> <td>16778217</td> <td>test</td> <td>0023.aeea.4286</td> <td>Fa0/1</td> <td>2</td> <td>Authenticated</td> <td>Idle</td> </tr> <tr> <td>static</td> <td>0days 0h10m20s</td> <td></td> <td></td> <td></td> <td></td> <td>Authed</td> </tr> </tbody> </table>	ID	Username	MAC	Interface	VLAN	Auth-State	Backend-State	Port-Status	User-Type	Time					16778217	test	0023.aeea.4286	Fa0/1	2	Authenticated	Idle	static	0days 0h10m20s					Authed
ID	Username	MAC	Interface	VLAN	Auth-State	Backend-State

16778217	test	0023.aeea.4286	Fa0/1	2	Authenticated	Idle																							
static	0days 0h10m20s					Authed																							

4.4.7 Configuring Extended Functions

Configuration Effect

- Some users use authentication clients embedded in the operating system. These clients may not initiate authentication immediately after the users access the network, affecting user experience on network access. Enable active authentication to so that such users can initiate authentication immediately after accessing the network.
- Active authentication means that the NAS sends a request/id packet to trigger Ruijie Supplicant to perform 802.1 authentication. Therefore, you can use this function to detect whether Ruijie Supplicant is used. For example, this function is required for MAB deployment.
- Configure the authenticable host list to specify users that can be authenticated on the port, which restricts physical access points of users to enhance network security
- The multi-account function allows a user to switch its account upon re-authentication. In special scenarios such as Windows domain authentication, multiple authentications are required to access the domain and the user account changes during authentication. This function applies to these scenarios.
- By default, the NAS uses its own MAC address as the source MAC address of EAP packets during 802.1X authentication. Some versions of Ruijie supplicants check whether the access switch is a Ruijie switch based on the

MAC address of EAP packets and implement some private features. When performing 802.1X authentication with these supplicants, you can enable the virtual source MAC address to use related private features.

- 802.1X allows users to obtain IP addresses before accounting. In this manner, the IP address is carried during user accounting, meeting service requirements. After a user is authenticated and goes online, the NAS can obtain the IP address of the user from the supplicant or through DHCP snooping, and then 802.1X server initiates an accounting request. To avoid the case in which the NAS does not initiate accounting for a long time due to failure to obtain the IP address of the authentication client, configure the IP detection timeout for this function. If the NAS does not obtain the IP address of the user within the configured time (5 minutes by default), it forces the user offline.
- When 802.1X authentication is performed for an H3C inode client on a Ruijie switch, the user name provided by the client for authentication is an unrecognized format. As a result, the authentication fails. In addition, the H3C authentication server requires the user name to be in xx-xx-xx-xx-xx-xx format for MAB authentication, which is different from the default MAB authentication user name format xxxxxxxxxxxx of Ruijie devices. As a result, the authentication fails. A command needs to be provided to control the 802.1X authentication user name and MAB authentication user name to be compatible with this scenario.

Notes

- The multi-account function must be disabled if accounting is enabled. Otherwise, accounting may be inaccurate.
- MAB requires active authentication. Therefore, active authentication must be enabled if MAB is enabled.
- IP-based accounting is not required in two situations:
 - IPv4 addresses and Ruijie Supplicant are deployed. This function is not required because Ruijie Supplicant can upload the IPv4 addresses of users.
 - Static IP addresses are deployed.

Configuration Steps

▾ Enabling Active Authentication

- (Optional) If active authentication is enabled, the controlled port sends an authentication request actively after configuration. After receiving this request, the authentication client initiates 802.1X authentication.
- Enable active authentication after 802.1X authentication is enabled on the NAS.

Command	dot1x auto-req
Parameter	N/A
Description	
Defaults	Apart from on N1800K switches, active authentication is enabled by default.
Command Mode	Global configuration mode
Usage Guide	The destination addresses of active authentication packets are the multicast address. If the connected clients may not initiate authentication automatically, configure this command to make the NAS actively initiate authentication. When controlled ports are Trunk ports, enable active authentication so that authentication requests can be sent based on each VLAN of trunk ports.

▾ Configuring the Number of Active Authentication Requests

- (Optional) Configure the number of active authentication requests sent by the NAS.
- Configure the number of active authentication requests after 802.1X authentication is enabled on the NAS.

Command	dot1x auto-req packet-num <i>num</i>
Parameter Description	<i>num</i> : Indicates the number of active authentication requests.
Defaults	The number of active authentication request is not configured by default.
Command Mode	Global configuration mode
Usage Guide	If active authentication is enabled, configure this command to restrict the number of active authentication packets sent by a port and thereby avoid sending excessive packets.

▾ Enabling User Detection for Active Authentication

- (Optional) Configure the NAS not to send authentication requests actively if there are authenticated users on a controlled port.
- Enable user detection for active authentication after 802.1X authentication is enabled on the NAS.

Command	dot1x auto-req user-detect
Parameter Description	N/A
Defaults	User detection for active authentication is enabled by default.
Command Mode	Global configuration mode
Usage Guide	After this command is configured, the NAS does not send authentication packets actively if there are authenticated users on controlled Access ports. On Trunk ports, the NAS checks for authenticated users based each VLAN. If there are authenticated users on a VLAN, the NAS does not send authentication packets automatically.

▾ Configuring the Interval of Active Authentication Request

- (Optional) Configure the interval at which the NAS sends an authentication request actively.
- Enable the interval of active authentication request after 802.1X authentication is enabled on the NAS.

Command	dot1x auto-req req-interval <i>time</i>
Parameter Description	<i>Time</i> : Indicates the interval of active authentication request.
Defaults	The default value is 30s.
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Configuring the Authenticatable Client List

- (Optional) Configure the authenticatable client list on a controlled port. Only clients on the list can perform 802.1X authentication.
- Configure the authenticatable client list after 802.1X authentication is enabled on the NAS.

Command	dot1x auth-address-table address <i>mac-addr</i> interface <i>interface</i>
Parameter	<i>mac-addr</i> : Indicates the MAC address of the access user.
Description	<i>interface</i> : Indicates the port of the access user.
Defaults	All users can perform authentication.
Command Mode	Global configuration mode
Usage Guide	Configure this command when specified users should be able to perform authentication on a controlled port.

▾ Enabling 802.1X Packets Sending with the Pseudo Source MAC Address

- (Optional) Configure the **dot1x pseudo source-mac** command when Ruijie Supplicant fails to identify the NAS as a Ruijie device based on the MAC address of the NAS.
- Configure the pseudo MAC address as the source MAC address for 802.1X authentication after 802.1X authentication is enabled on the NAS.

Command	dot1x pseudo source-mac
Parameter	N/A
Description	
Defaults	User detection for active authentication is enabled by default.
Command Mode	Global configuration mode
Usage Guide	Configure this command when Ruijie Supplicants cannot identify the NAS as a Ruijie device based on the source MAC address in the EAPOL packet sent by the NAS or implement private attributes during authentication. If this command is configured, the EAPOL packet sent by the NAS uses 00-1A-A9-17-FF-FF as the source MAC address so that these Ruijie Supplicants can identify the NAS as a Ruijie device.

▾ Enabling Multi-account Authentication with One MAC Address

- (Optional) Run the **dot1x multi-account enable** command to allow the same MAC address to be used by multiple accounts.
- Enable multi-account authentication with one MAC address after 802.1X authentication is enabled on the NAS.

Command	dot1x multi-account enable
Parameter	N/A
Description	
Defaults	Multi-account authentication is disabled by default.
Command Mode	Global configuration mode

Usage Guide	Configure this command when multi-account authentication is required in 802.1X authentication, e.g. in the case of Windows domain authentication. In this case, the authentication client can directly use a new account to initiate authentication while the previous account is still online. Multi-account authentication is disabled by default.
--------------------	--

↘ Configuring the Maximum Number of Authenticated Users on a Port

- (Optional) You can restrict the number of online users on a controlled port, including static users and dynamic users.
- Configure the maximum number of authenticated users on a port after 802.1X authentication is enabled on the NAS.

Command	dot1x default-user-limit <i>num</i>
Parameter Description	<i>num</i> : Indicates the maximum number of online users.
Defaults	There is no restriction on the number of users on a port by default.
Command Mode	Interface configuration mode
Usage Guide	Configure this command when there is a need to restrict the number of authenticated users on a port.

↘ Enabling IP-triggered Accounting

- (Optional) If IP-triggered accounting is enabled, the NAS sends an accounting request to the authentication server after obtaining the IP address of the user.
- Enable IP-triggered accounting after 802.1X authentication is enabled on the NAS.

Command	dot1x valid-ip-acct enable
Parameter Description	N/A
Defaults	IP-triggered accounting is disabled by default.
Command Mode	Global configuration mode
Usage Guide	If both accounting and IP-triggered accounting are enabled, the NAS initiates accounting only after obtaining the IP address of the authentication client, and forces the user offline if it fails to obtain the IP address. If accounting is disabled but IP-triggered accounting is enabled, the NAS does not initiate accounting after obtaining the IP address of the authentication client, and forces the user offline if it fails to obtain the IP address within the timeout.

↘ Configuring the Timeout of Obtaining IP Addresses After Authentication

- (Optional) Configure the timeout of obtaining IP addresses if IP-triggered accounting is enabled.
- Configure the IP address obtaining timeout after 802.1X authentication is enabled on the NAS.

Command	dot1x valid-ip-acct timeout <i>time</i>
Parameter Description	<i>time</i> : Indicates the timeout in the unit of minutes.
Defaults	The default value is 5 minutes.

Command Mode	Global configuration mode
Usage Guide	It is recommended to use the default value. Configure this command when there is a need to change the IP address obtaining timeout after users pass authentication.

➤ **Configuring the Compatibility Function for H3C 802.1X Authentication Clients and Authentication Servers**

- (Optional) This function is effective to 802.1X-authenticated and MAB-authenticated users.

Command	dot1x user-name compatible
Parameter Description	-
Defaults	This function is disabled by default.
Command Mode	Global configuration mode
Usage Guide	Enable this function when the H3C authentication client and authentication server are used for 802.1X authentication or the H3C authentication server is used for MAB authentication.

4.5 Monitoring

Clearing

 Authentication user information can be cleared after 802.1X is disabled.

Description	Command
Clears 802.1X user information.	no do1x port-control auto
Clears 802.1X user information.	clear dot1x user
Restores the default 802.1X configuration.	dot1x default

Notes

- The **dot1x default** command is used to restore global configurations.

Description	Command
Restore the default value of status machine timeout duration.	dot1x timeout quiet-period dot1x timeout server-timeout dot1x timeout supp-timeout dot1x timeout tx-period
Restore default values of configurations related to re-authentication.	dot1x re-authentication dot1x timeout re-authperiod dot1x reauth-max

Restore default values of configurations related to proactive requests.	dot1x auto-req dot1x auto-req user-detect dot1x auto-req req-interval dot1x auto-req packet-num
Restores the default value of the number of retransmission times.	dot1x mac-req
Restores the default value of the authentication mode.	dot1x auth-mode
Restore the default values of configurations related to client probing.	dot1x client-probe enable dot1x probe-timer alive dot1x probe-timer interval
Restores the default value of the function of supporting only the private client.	dot1x private-supPLICANT-only
Restores the default value of the pseudo source MAC address function.	dot1x pseudo source-mac
Restores the default value of the number of VLAN redirection times upon authentication failures.	dot1x auth-fail max-attempt
Restores the default value of the function of one MAC address for multiple accounts.	dot1x multiaccount enable
Restores the default value of the dot1x redirection function.	dot1x redirect
Restores the default value of the silent timeout duration.	dot1x multi-mab quiet-period
Restore the default values of functions related to accounting after obtaining the IP address.	dot1x valid-ip-acct enable dot1x valid-ip-acct timeout

Displaying

Description	Command
Displays the parameters and status of the RADIUS server.	show radius server
Displays 802.1X status and parameters.	show dot1x
Displays the authenticable host list.	show dot1x auth-address-table
Displays the active authentication status.	show dot1x auto-req
Displays the port control status.	show dot1x port-control

Displays the status and parameters of host probe.	show dot1x probe-timer
Displays of the information of authenticated users.	show dot1x summary
Displays the maximum times of EAP-Request/Challenge packet retransmission.	show dot1x max-req
Displays the information of controlled ports.	show dot1x port-control
Displays the non-Ruijie client filtering information.	show dot1x private-suppllicant-only
Displays the re-authentication status.	show dot1x re-authentication
Displays the maximum times of EAP-Request/Identity packet retransmission.	show dot1x reauth-max
Displays the quiet period after authentication fails.	show dot1x timeout quiet-period
Displays the re-authentication interval.	show dot1x timeout re-authperiod
Displays the authentication server timeout.	show dot1x timeout server-timeout
Displays the supplicant timeout.	show dot1x timeout supptimeout
Displays the interval of EAP-Request/Identity packet retransmission.	show dot1x timeout tx-period
Displays user information based on the user ID.	show dot1x user id
Displays user information based on the MAC address.	show dot1x user mac
Displays user information based on the user name.	show dot1x user name

Debugging

 System resources are occupied when debugging information is output. Therefore, disable the debugging switch immediately after use.

Description	Command
Debugs AAA. (For details, see the <i>Configuring AAA</i> .)	debug aaa
Debugs RADIUS. (For details, see the <i>Configuring RADIUS</i> .)	debug radius

Debugs 802.1X events.	debug dot1x event
Debugs 802.1X packets.	debug dot1x packet
Debugs 802.1X state machine (STM).	debug dot1x stm
Debugs 802.1X internal communication.	debug dot1x com
Debugs 802.1X errors.	debug dot1x error

5 Configuring Web Authentication

5.1 Overview

5.1.1 Web Authentication

Web authentication controls user access to networks. It requires no authentication software on clients. Instead, users can perform authentication on common browsers.

When unauthenticated clients attempt to access the Internet using browsers, the network access server (NAS) forcibly redirects the browsers to a specified site pointing to a Web authentication server, also called a portal server. Users can access the services on the portal server before being authenticated, such as downloading security patches and reading notices. If a user wants to access network resources beyond the portal server, the user must get authenticated by the portal server through a browser.

Besides providing convenient authentication, the portal server performs Webpage interaction with browsers, providing personalized services, such as advertisements, notices, and business links on the authentication page.

Ruijie Web Authentication Versions

There are three versions of Ruijie Web authentication, including Ruijie First-Generation Web Authentication, Ruijie Second-Generation Web Authentication, and Ruijie Internal Portal (iPortal) Web Authentication. The Web authentication process varies with authentication versions. For details, see Section 5.3 "Features".

-
-  The three versions of Web authentication are highly divergent in features and configurations. It is recommended to read through the relevant chapters carefully before configuration.
 -  Both Ruijie Second-Generation Web Authentication and Ruijie iPortal Web Authentication support local account authentication on the NAS. Because Remote Authentication Dial In User Service (RADIUS) authentication is more commonly used in reality, it is used as an example in the chapter "Applications".
 -  The concept of "interface" varies with product types. For example, the interfaces on a layer-2 switch are physical ports. This document uses the unified term "interface" to include them. In application, recognize the real meaning based on specific products and functions.
 -  Web authentication supports user online traffic detection. For details, see the Configuring SCC.
 -  Web authentication supports the authentication of domain names. That is, accounts can be authenticated in the format of user name@domain name. This requires enabling the domain-name-based authentication, authorization and accounting (AAA) service. For details, see the Configuring AAA.
-

Protocols and Standards

- HTTP: RFC1945 and RFC2068

- HTTPS: RFC2818
- SNMP: RFC1157 and RFC 2578
- RADIUS: RFC2865, RFC2866, and RFC3576

5.2 Applications

Application	Description
Basic Scenario of Web Authentication	Basic layer-2 authentication scenario, where a NAS, portal server, and RADIUS server constitute an authentication system which connects a client with the NAS through the layer-2 network.

5.2.1 Basic Scenario of Web Authentication

Scenario

See Figure 5-1.

- Deploy a Web authentication scheme on the NAS.
- The client connected to the NAS needs to pass Web authentication before accessing the Internet.

Figure 5-1 Networking Topology of Web Authentication

Remarks	<p>Web authentication is applicable to both layer-2 and layer-3 networks. At layer 3, the source MAC address and VID of a packet are changed after it is routed, but the source IP address remains the same as the only identifier of a client. Therefore, the binding policy of Web authentication on layer-3 devices must adopt the IP-only binding mode. Here, layer-2 NAS is used as an example.</p> <p>RG-SAM program is installed on the RADIUS server. RG-ePortal program is installed on the portal server.</p>
----------------	---

Deployment

- Enable Web authentication on the client-accessed interface or globally on the NAS (globally on EG devices).
- Configure the ePortal server and the communication key on the NAS (for only Ruijie First-Generation and Second-Generation Web Authentication).

- Configure the Simple Network Management Protocol (SNMP) communication parameters of the ePortal server on the NAS (for only Ruijie First-Generation and Second-Generation Web Authentication).
- Configure the consistent communication parameters on the ePortal server and SAM server (for only Ruijie First-Generation Web Authentication).
- Create user accounts on the SAM server.
- Configure AAA and method lists on the NAS (for only Ruijie Second-Generation and iPortal Web Authentication).
- Configure the IP address of the SAM server on the NAS (for only Ruijie Second-Generation and iPortal Web Authentication).
- Configure the names of the Web authentication method lists on the NAS (for only Ruijie Second-Generation and iPortal Web Authentication).

5.3 Features

Basic Concepts

▾ Ruijie First-Generation Web Authentication

Ruijie First-Generation Web Authentication should cooperate with the RG-ePortal software. The server installed with RG-ePortal provides a login page to submit user authentication information, and initiates an authentication request to the RADIUS server directly. After authentication succeeds, the NAS gets user information delivered through the SNMP protocol, and thereby controls user access permissions. Communication during Web authentication of this version depends on private SNMP nodes. Moreover, the ePortal server takes the place of the NAS in authentication and accounting, which relieves the NAS from service burden.

▾ Ruijie Second-Generation Web Authentication

Ruijie Second-Generation Web Authentication complies with the *CMCC WLAN Service Portal Specification*. The portal server is responsible only for Webpage interaction with users. The NAS interacts with the RADIUS server to implement authentication. The interaction between the portal server and the NAS complies with the *CMCC WLAN Service Portal Specification*. The portal server provides a login page for users to submit their information, and informs the NAS of user information through the portal protocols. The NAS completes authentication by interacting with the RADIUS server based on the user information, assigns access permissions to authenticated clients, and returns authentication results to the portal server.

The implementation process of Ruijie Second-Generation Web Authentication is mainly completed on the NAS. This raises a higher demand on the NAS's capability to handle heavy tasks. Meanwhile, the portal server is simplified. The standard *CMCC WLAN Service Portal Specification*, which gains highly industry support, enables various vendors to develop compatible products.

▾ Version Comparison

Authentication roles:

- Client: Its functions are the same among the three types of Web authentication.

- **NAS:** In Ruijie First-Generation Web Authentication, the NAS implements only URL redirection and exchanges user login/logout notifications with the portal server. In Ruijie Second-Generation Web Authentication, the NAS is responsible for redirecting and authenticating users as well as notifying the portal server of authentication results. In Ruijie iPortal Web authentication, the NAS integrates multiple functions including the URL redirection, Webpage interaction, and authentication.
- **Portal server:** In Ruijie First-Generation Web Authentication, the portal server is responsible for interaction with clients through Webpages, authenticating users, and notifying the NAS of authentication results. In Ruijie Second-Generation Web Authentication, the portal server is responsible for interacting with clients through Webpages, notifying the NAS of users' authentication information, and receiving authentication results from the NAS. In Ruijie iPortal Web Authentication, the portal server is built into the NAS and provides simplified functions, mainly responsible for Web page interaction with clients.
- **RADIUS server:** Its functions are the same among the three types of Web authentication.

Authentication process:

- In Ruijie Second-Generation Web Authentication, the authentication and accounting functions are transferred from the portal server to the NAS.
- Because authentication proceeds on the NAS, the second-generation NAS does not need to wait for the authentication results notified by the portal server as the first generation.

Logout process:

- In Ruijie First-Generation Web Authentication, a logout action may be triggered by a notification from the portal server, or traffic detection or port status detection performed by the NAS.
- In Ruijie Second-Generation Web Authentication, a logout action may be triggered by a notification from the portal server, a kickout notification from the RADIUS server, or traffic detection or port status detection performed by the NAS.
- In Ruijie First-Generation Web Authentication, Accounting Stop packets are sent by the portal server.
- In Ruijie Second-Generation Web Authentication, Accounting Stop packets are sent by the NAS.

- i** The selection of the Web authentication versions depends on the type of the portal server in use.
- i** Command parameters in this document may be shared by the three Web authentication versions or not. Read through this document carefully to avoid parameter misconfiguration that will affect Web authentication.

Overview

Feature	Description
Ruijie First-Generation Web Authentication	The portal server is deployed and supports only Ruijie First-Generation Web Authentication.
Ruijie Second-Generation Web Authentication	The portal server is deployed and complies with the <i>CMCC WLAN Service Portal Specification</i> .

5.3.1 Ruijie First-Generation Web Authentication

HTTP Interception

HTTP interception means the NAS intercepts to-be-forwarded HTTP packets. Such HTTP packets are initiated by the browsers of the clients connected to the NAS, but they are not destined for the NAS. For example, when a client attempts to visit the website www.google.com using the Internet Explorer, the NAS is expected to forward the HTTP request packets to the gateway. If HTTP interception is enabled, these packets will not be forwarded.

After HTTP interception is successful, the NAS redirects the HTTP requests from the client to itself to establish a session between them. Then, the NAS pushes a Webpage to the client through HTTP redirection, which can be used for authentication, software downloading or other purposes.

You can specify the clients and destination interfaces to enable or disable HTTP interception for Web authentication. In general, HTTP requests from unauthenticated clients will be intercepted, and those from authenticated clients will not. HTTP interception is the foundation of Web authentication. Web authentication is automatically triggered once HTTP interception succeeds.

HTTP Redirection

According to HTTP protocols, after the NAS receives a HTTP GET or HEAD request packet from a client, a packet with 200 (Ok) status code is replied if it is able to provide the required resources, or a packet with 302 (Moved Temporarily) status code is returned if unable. Another URL is provided in the 302 packet. After receiving the packet, the client may resend a HTTP GET or HEAD request packet to the new URL for requesting resources. This process is called redirection.

HTTP redirection is an important procedure following HTTP interception in Web authentication. It takes the advantage of 302 status code defined in HTTP protocols. HTTP interception creates a session between the NAS and a client. The client sends HTTP GET or HEAD request packets (which should have been sent to another site) to the NAS. The NAS responds with a 302 packet with a specific redirection page. Thereby, the client resends the requests to the redirection page.

Because more and more application programs run HTTP protocols, the use of the 302 redirection packet may divert a large amount of HTTP traffic (not sent by browsers) to the portal server, which will affect network authentication. To address this problem, HTTP redirection technology on the NAS adopts noise reduction to replace the 302 packets with the **js** script.

Working Principle

Figure 5-1 shows the networking topology of Web authentication.

First-generation Webauth roles:

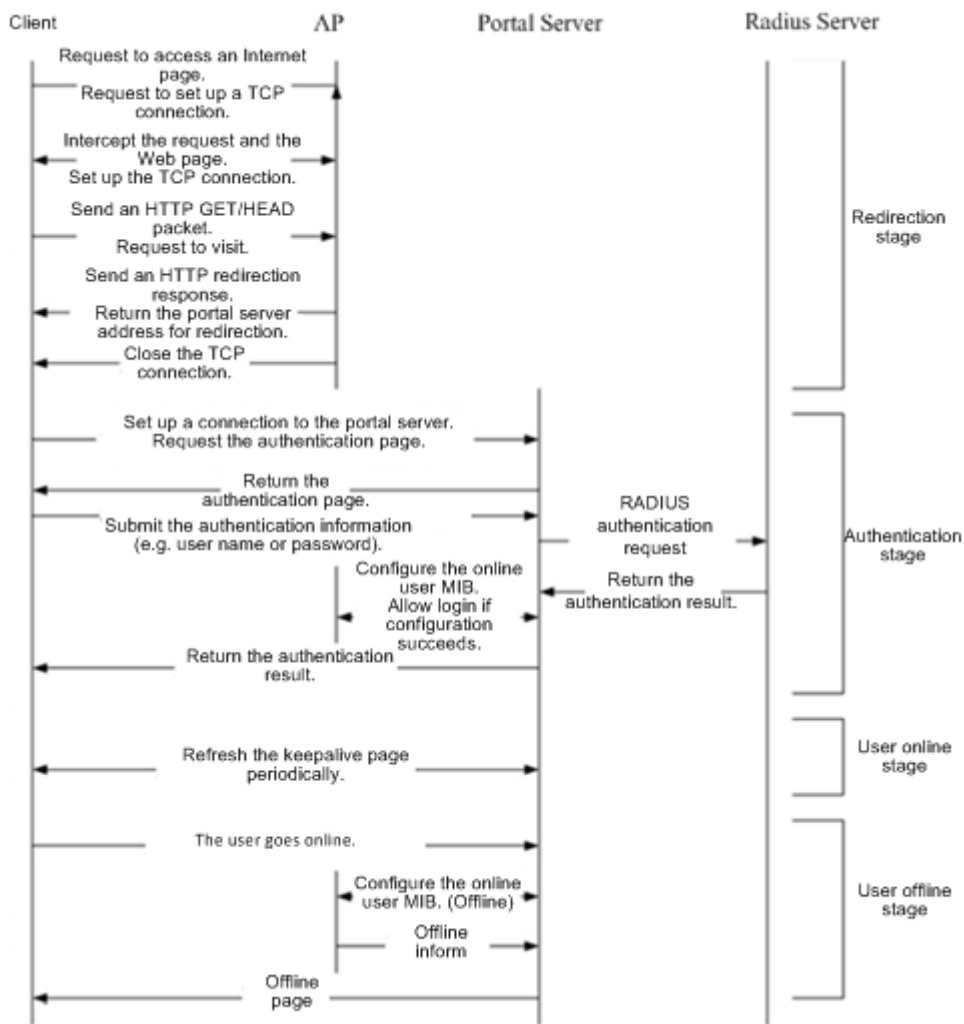

1. Authentication client: Is usually a browser running HTTP protocols. It sends HTTP requests for accessing the Internet.
2. NAS: Is an access-layer device in a network. The NAS is directly connected to clients and must be enabled with Web authentication.
3. Portal server: Provides a Web page for Web authentication and related operations. After receiving an HTTP authentication request from a client, the portal server extracts account information from the request, sends the information to the RADIUS server for authentication, and notifies the client and NAS of the authentication result. Figure 5-1 shows Ruijie ePortal server.
4. RADIUS server: Provides the RADIUS-based authentication service to remote clients. The portal server extracts users' authentication account information from HTTP packets and initiates authentication requests to the RADIUS server through the RADIUS protocol. The RADIUS server returns the authentication result to the portal server through the RADIUS protocol. Figure 5-1 shows the RADIUS server installed with the RG-SAM program.

First-generation Webauth process:

1. Before authentication, the NAS intercepts all HTTP requests from a client and redirects these requests to the iPortal server. Thereafter, an authentication page is displayed on the browser.
2. During authentication, the client enters information, for example, username, password, and verification code, on the Webauth URL to interact with the portal server and complete authentication.
3. After the user is authenticated, the portal server notifies the NAS that the client has passed authentication, and the NAS allows the client to access resources on the Internet.

Figure 5-2 shows the flowchart of Ruijie First-Generation Web Authentication by using an AP as the NAS.

Figure 5-2 Flowchart of Ruijie First-Generation Web Authentication

First-generation client logout process:

There are two scenarios of client logout. One scenario is detected by the NAS that a client gets offline for the maximum online time is out, the upper traffic limit is reached, or the link is disconnected. The other scenario is detected by the portal server that a client logs out by clicking the **Logout** button on the logout page or the keep-alive page is invalid.

1. Scenario 1: The NAS detects a client to logout and informs the portal server. Then the portal server deletes the user information on the NAS through SNMP and displays a logout page to the client.
2. Scenario 2: The portal server detects a client to logout and informs the NAS through SNMP and displays a logout page to the client.
3. In the two scenarios, the portal server sends an Accounting Stop request to the RADIUS server and notifies the RADIUS server that the client has logged out.

Related Configuration

↘ [Configuring the First-Generation Webauth Template](#)

By default, the first-generation Webauth template is not configured.

Run the **web-auth template eportalv1** command in global configuration mode to create the first-generation Webauth template.

The template is used to implement Web authentication.

↘ [Configuring the IP Address of the Portal Server](#)

By default, the IP address of the portal server is not configured.

Run the **ip {ip-address}** command in template configuration mode to configure the IP address of the portal server.

Any request packets to access the portal server will be filtered and rate-limited by the NAS.

↘ [Configuring the Webauth URL of the Portal Server](#)

By default, the Webauth URL of the portal server is not configured.

Run the **url {url-string}** command in template configuration mode to configure the Webauth URL of the portal server.

The URL to which clients are redirected is the address of the Webauth URL provided by the portal server.

↘ [Specifying the Webauth Binding Mode](#)

The default Webauth binding mode is IP-MAC binding mode.

Run the **bindmode** command in template configuration mode to specify the Webauth binding mode.

In Web authentication on layer-3 networks, the source MAC address in a packet is changed after the packet is routed. In such case, configure the IP-only binding mode.

↘ [Configuring the Webauth Communication Key](#)

By default, the Webauth communication key is not configured.

Run the **web-auth portal key {string}** command in global configuration mode to configure the Webauth communication key.

The communication key is used to encrypt URL parameters to avoid information disclosure.

↘ [Enabling Ruijie First-Generation Web Authentication](#)

By default, Ruijie First-Generation Web Authentication is disabled.

Run the **web-auth enable** command in interface configuration mode to enable Ruijie First-Generation Web Authentication on the client-connected ports.

After Web authentication is enabled, the unauthenticated clients connecting to a port will be redirected to the Webauth URL.

▾ **Configuring the SNMP-Server Host**

By default, the SNMP-server host and community string are not configured.

Run the **snmp-server host** *{ip-address}* **version 2c** *{community-string}* **web-auth** command in global configuration mode to configure the SNMP-server host and community string for Web authentication.

The SNMP-server host is configured to receive Inform/Trap packets of user logout.

▾ **Configuring the SNMP-Server Community String**

By default, the SNMP-server community string is not configured.

Run the **snmp-server community** *{community-string}* **rw** command in global configuration mode to configure the SNMP-server community string.

The SNMP-server community string is configured to read/write user information from/to the NAS.

▾ **Enabling the SNMP Trap/Inform Function**

By default, the SNMP Trap/Inform function is disabled.

Run the **snmp-server enable traps web-auth** command in global configuration mode to enable the SNMP Trap/Inform function.

The SNMP Trap/Inform function is configured to enable the NAS to inform the portal server of user logout.

5.3.2 Ruijie Second-Generation Web Authentication

HTTP Interception

Same as the HTTP interception technology of Ruijie First-Generation Web Authentication.

HTTP Redirection

Same as the HTTP redirection technology of Ruijie First-Generation Web Authentication.

Working Principle

Figure 5-3 shows the networking topology of Web authentication.

Second-generation Webauth roles:

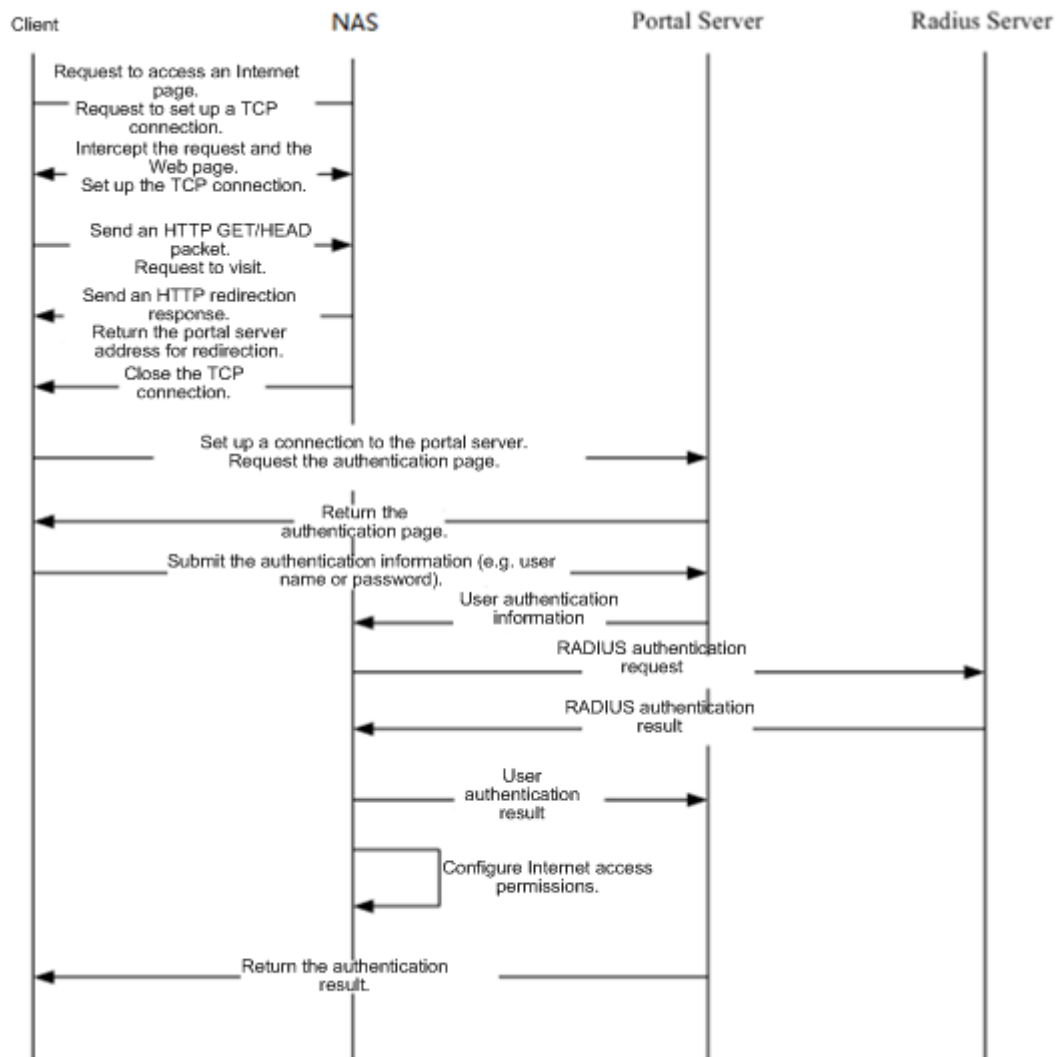

1. Authentication client: Is usually a browser running HTTP protocols. It sends HTTP requests for accessing the Internet.
2. NAS: Is an access-layer device in a network. The NAS is directly connected to clients and must be enabled with Web authentication. The NAS receives user authentication information from the portal server, sends authentication requests to the RADIUS server, determines whether users can access the Internet according to authentication results, and returns the authentication results to the portal server.

3. Portal server: Provides a Web page for Web authentication and related operations. After receiving an HTTP authentication request from a client, the portal server extracts account information from the request, transfers the information to the NAS, and displays the authentication result returned by the NAS to the user on a page. Figure 5-3 shows Ruijie ePortal server.
4. RADIUS server: Provides the RADIUS-based authentication service to remote clients. Figure 5-3 shows the RADIUS server installed with the RG-SAM program.

Second-generation Webauth process:

1. Before authentication, the NAS intercepts all HTTP requests from a client and redirects these requests to the iPortal server. Thereafter, an authentication page is displayed on the browser.
2. During authentication, the client enters information, for example, username, password, and verification code, on the Webauth URL to interact with the portal server.
3. The portal server sends the user authentication information to the NAS.
4. The NAS initiates authentication to the RADIUS server and returns the authentication result to the portal server.
5. The portal server displays the authentication result (success or failure) to the user on a page.

Figure 5-3 Flowchart of Ruijie Second-Generation Web Authentication

Second-generation client logout process:

There are two scenarios of client logout. One scenario is detected by the NAS that a client gets offline for the maximum online time is out, the upper traffic limit is reached, or the link is disconnected. The other scenario is detected by the portal server that a client logs out by clicking the **Logout** button on the logout page or the keep-alive page is invalid.

1. When a user clicks the **Logout** button on the online page, the portal server notifies the NAS to get the user offline.
2. The NAS gets a client offline with traffic lower than the threshold based on the parameters of user online traffic detection.
3. When the RADIUS server plans to force a client offline based on a certain policy, the NAS notifies the portal server to push a logout page to the client.

Related Configuration

➤ [Configuring the Second-Generation Webauth Template](#)

By default, the second-generation Webauth template is not configured.

Run the **web-auth template**{*eportalv2* | *template-name v2*} command in global configuration mode to create a second-generation Webauth template.

The template is used to implement Web authentication.

↘ **Configuring the IP Address of the Portal Server**

By default, the IP address of the portal server is not configured.

Run the **ip** { *ip-address* } command in template configuration mode to configure the IP address of the portal server.

Any request packets to access the portal server will be filtered and rate-limited by the NAS.

↘ **Configuring the Webauth URL of the Portal Server**

By default, the Webauth URL of the portal server is not configured.

Run the **url** {*url-string*} command in template configuration mode to configure the Webauth URL of the portal server.

The URL to which clients are redirected is the address of the Webauth URL provided by the portal server.

↘ **Specifying the Webauth Binding Mode**

The default Webauth binding mode is IP-MAC binding mode.

Run the **bindmode** command in template configuration mode to specify the Webauth binding mode.

In Web authentication on layer-3 networks, the source MAC address in a packet is changed after the packet is routed. In such case, configure the IP-only binding mode.

↘ **Configuring the Webauth Communication Key**

By default, the Webauth communication key is not configured.

Run the **web-auth portal key** { *string* } command in global configuration mode to configure the Webauth communication key.

The communication key is used to encrypt URL parameters to avoid information disclosure.

↘ **Enabling Ruijie Second-Generation Web Authentication**

By default, Ruijie Second-Generation Web Authentication is disabled.

Run the **web-auth enable** command in interface configuration mode to enable Ruijie Second-Generation Web Authentication on the client-connected ports.

After Web authentication is enabled, the unauthenticated clients connecting to a port will be redirected to the Webauth URL.

↘ **Enabling AAA**

By default, AAA is disabled.

Run the **aaa new-model** command in global configuration mode to enable AAA.

Ruijie Second-Generation Web Authentication relies on AAA. Enable AAA before you implement the former.

↘ **Configuring the RADIUS-Server Host and Communication Key**

By default, the RADIUS-server host and communication key are not configured.

Run the **radius-server host** command in global configuration mode to configure the RADIUS-server host and communication key.

The RADIUS-server host is responsible for authenticating users.

▾ [Configuring an AAA Method List for Ruijie Second-Generation Web Authentication](#)

By default, no AAA method list is configured for Ruijie Second-Generation Web Authentication.

Run the **aaa authentication web-auth** command in global configuration mode to configure an AAA method list for Ruijie Second-Generation Web Authentication.

The AAA authentication method list is used for interaction during the Webauth process.

▾ [Configuring an AAA Method List for Ruijie Second-Generation Web Accounting](#)

By default, no AAA method list is configured for Ruijie Second-Generation Web Accounting.

Run the **aaa accounting network** command in global configuration mode to configure an AAA method list for Ruijie Second-Generation Web Accounting.

The AAA method list for Web accounting is used for accounting interaction during the Webauth process.

▾ [Specifying an AAA Method List](#)

The default AAA method list is used if no list is specified.

Run the **authentication** command in template configuration mode to specify an AAA method list.

The AAA method list is specified to send authentication requests to AAA.

▾ [Specifying an AAA Accounting Method List](#)

The default AAA accounting method list is used if no list is specified.

Run the **accounting** command in template configuration mode to specify an AAA accounting method list.

The AAA accounting method list is specified to send accounting requests to AAA.

▾ [Specifying the UDP Port of the Portal Server](#)

By default, UDP Port 50100 is used.

Run the **port** command in template configuration mode to specify the UDP port of the portal server.

The UDP port is specified for the portal server to communicate with the NAS.

5.4 Configuration

Configuration	Description and Command
-------------------------------	-------------------------

Configuration	Description and Command	
Configuring Ruijie First-Generation Web Authentication	 (Mandatory) It is used to set the basic parameters of Ruijie First-Generation Web Authentication.	
	web-auth template eportalv1	Configures the first-generation Webauth template.
	ip { <i>ip-address</i> }	Configures the IP address of the portal server.
	url { <i>url-string</i> }	Configures the Webauth URL of the portal server.
	web-auth portal key { <i>key-string</i> }	Configures the Webauth communication key.
	snmp-server community { <i>community-string</i> } rw	Configures the SNMP-server community string.
	snmp-server host { <i>ip-address</i> } inform version 2c { <i>community-string</i> } web-auth	Configures the SNMP-server host.
	snmp-server enable traps web-auth	Enables the SNMP-server Trap/Inform function.
web-auth enable	Enables Ruijie First-Generation Web Authentication on an interface.	
Configuring Ruijie Second-Generation Web Authentication	 (Mandatory) It is used to set the basic parameters of Ruijie Second-Generation Web Authentication.	
	aaa new-model	Enables AAA.
	radius-server host { <i>ip-address</i> } [auth-port <i>port-number</i>] [acct-port <i>port-number</i>] key { <i>string</i> }	Configures the RADIUS-server host and communication key.
	aaa authentication web-auth { default <i>list-name</i> } <i>method1</i> [<i>method2...</i>]	Configures an AAA method list for Web authentication. (RADIUS authentication is implemented.)
	aaa accounting network { default <i>list-name</i> } start-stop <i>method1</i> [<i>method2...</i>]	Configures an AAA method list for Web Accounting. (RADIUS accounting is implemented.)
	web-auth template { eportalv2 <i>portal-namev2</i> }	Configures a second-generation Webauth template.
	ip { <i>ip-address</i> }	Configures the IP address of the portal server.
	url { <i>url-string</i> }	Configures the Webauth URL of the portal server.
web-auth portal key { <i>key-string</i> }	Configures the Webauth communication key.	

Configuration	Description and Command	
	web-auth enable	Enables Ruijie Second-Generation Web Authentication on an interface.
Specifying an Authentication Method List	 (Optional) It is used to specify an AAA authentication method list in template configuration mode. The name of the method list must be correctly specified.	
	authentication { <i>mlist-name</i> }	Specifies an AAA authentication method list(only for Ruijie Second-Generation Web Authentication and Ruijie iPortal Web Authentication.)
Specifying an Accounting Method List	 (Optional) It is used to specify an AAA accounting method in template configuration mode. The name of the method list must be correctly specified.	
	accounting { <i>mlist-name</i> }	Specifies an AAA accounting method list(only for Ruijie Second-Generation Web Authentication and Ruijie iPortal Web Authentication.)
Configuring the Communication Port of the Portal Server	 (Optional) It is used to specify the UDP port of the portal server in template configuration mode. The configured port number must be consistent with that on the RADIUS server.	
Specifying the Webauth Binding Mode	 (Optional) It is used to specify the entry binding mode in template configuration mode. bindmode { <i>ip-mac-mode</i> <i>ip-only-mode</i> }	Specifies the template binding mode.
Configuring the Redirection HTTP Port	 (Optional) It is used to configure the TCP interception port for redirection, so that the packets on the specified port can be redirected when interception is enabled.	
Configuring Rate Limit Webauth Logging	 (Optional) It is used to configure the syslog function in Web authentication. web-auth logging enable { <i>num</i> }	Configures the rate limit Webauth logging.
Configuring the Maximum Number of HTTP Sessions for Unauthenticated Clients	 (Optional) It is used to adjust the HTTP session limit. The limit value needs to be increased when there are many sessions in the background.	
Configuring the HTTP Redirection Timeout	 (Optional) It is used to modify the timeout period for redirection connections. The timeout needs to be increased to complete redirection when the network condition is bad. http redirect session-limit { <i>session-num</i> } [port { <i>port-session-num</i> }] http redirect timeout { <i>seconds</i> }	Configures the maximum number of HTTP sessions for unauthenticated clients. Configures the HTTP redirection timeout.

Configuration	Description and Command	
Configuring the Straight-Through ARP Resource Range	 (Optional) It is used to permit the ARP of the specified addresses to pass. The gateway ARP must be permitted to pass when ARP check is enabled.	<p>http redirect direct-arp { <i>ip-address</i> [<i>ip-mask</i>] }</p> Configures the straight-through ARP resource.
Configuring an Authentication-Exempted Address Range	 (Optional) It is used to exempt clients from authentication when accessing the Internet.	<p>web-auth direct-host { <i>ip-address</i> [<i>ip-mask</i>] [arp] } [port <i>interface-name</i> <i>mac-address</i>] }</p> Configures the range of the IP or MAC addresses of clients free from authentication.
Configuring the Interval for Updating Online User Information	 (Optional) It is used to configure the interval for updating online user information.	<p>web-auth update-interval { <i>seconds</i> }</p> Configures the interval for updating online user information.
Configuring Portal Detection	 (Optional) It is used to detect the availability of the portal server. If it is not available, the services are switched to the standby portal server. This function must be used together with portal standby function.	<p>web-auth portal-check [interval <i>intsec</i> [timeout <i>tosec</i>] [retransmit <i>retries</i>] }</p> Configures the portal server detection interval, timeout period, and timeout retransmission times.
Configuring Portal Escape	 (Optional) It is used to allow new clients to access the Internet without authentication when the portal server is not available.	<p>web-auth portal-escape</p> Configures portal escape.
Configuring Jitter-off Accounting	 (Optional) It is used to configure whether the jitter-off duration is included into the online duration, in order to improve accounting precision. The jitter-off duration depends on the jitter-off configuration of a specific product.	<p>web-auth accounting jitter-off</p> Configures the jitter-off duration. (Use the no form of this command to disable this function.)
Configuring the Portal Communication Port	 (Optional) It is used to configure the port (source port) used for the communication between the NAS and portal server.	<p>ip portal source-interface <i>interface-type</i> <i>interface-num</i></p> Specifies the port used for the communication between the NAS and portal server.
Configuring VLAN-Based Authentication on a Port	 (Optional) It is used to configure the VLAN in which only the STAs inside the configured VLAN cannot initiate Web authentication.	

Configuration	Description and Command	
	web-auth vlan-control <i>vlan-list</i>	Configures the VLAN-based authentication on a port.
Disabling ARP Detection	 (Optional) It is used to disable ARP detection. After the function is disabled, it is not detected that the IP address or MAC address of a client migrates.	
	no web-auth station-move arp-detect	Disables ARP detection.
Configuring the Accounting Method List of Web Authentication	 (Optional) It is used to configure an accounting method based on the template.	
	web-auth accounting v2 { default <i>name</i> }	Configures an accounting method based on the template.
Configuring a Web Authentication Method List	 (Optional) It is used to configure an authentication method based on the template.	
	web-auth authentication v2 { default <i>name</i> }	Configures an authentication method based on the template.

5.4.1 Configuring Ruijie First-Generation Web Authentication

Configuration Effect

Redirect unauthenticated clients to the Webauth URL to perform authentication.

Notes

N/A

Configuration Steps

📌 **Configuring the Portal Server**

- (Mandatory) To enable Web authentication successfully, you must configure and apply the portal server.
- When the NAS or convergence device finds an unauthenticated client attempting to access network resources through HTTP, it redirects the access request to the specified Webauth URL, where the client can initiate authentication to the portal server. If the IP address of the portal server is configured as a free network resource, unauthenticated clients can directly visit this IP address through HTTP.

📌 **Configuring the Communication Key Between the NAS and Portal Server**

- (Mandatory) To enable Web authentication successfully, you must configure the key used for the communication between the NAS or convergence device and portal server.
- When the NAS finds an unauthenticated client attempting to access network resources, it redirects the client to the specified Webauth URL, where the client can initiate authentication to the portal server. During the authentication process, the communication key is used to encrypt some data exchanged between the NAS and portal server to improve security.

Setting the SNMP Parameters Between the NAS and Portal Server

- (Mandatory) To enable Web authentication successfully, you must set the SNMP network management parameters used for the communication between the NAS and portal server.
- The NAS or convergence device and portal server jointly manage authenticated clients through SNMP/MIB. A table of authenticated clients is managed by MIB on the NAS. The portal server is able to access the MIB to obtain client statistics so as to control client login and logout. When a client logs out, the NAS or convergence device will inform the portal server by Webauth Inform packets.

Enabling Ruijie First-Generation Web Authentication on an Interface

- Mandatory.
- When Ruijie First-Generation Web Authentication is enabled in interface configuration mode, Web authentication is not enabled on any port by default. The users connecting to the port do not need to perform Web authentication.

Verification

- Check whether unauthenticated clients are required to perform authentication.
- Check whether authenticated clients can access the Internet normally.

Related Commands

Configuring the First-Generation Webauth Template

Command	web-auth template eportalv1
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	eportalv1 is the default template of Ruijie First-Generation Web Authentication.

Configuring the IP Address of the Portal Server

Command	ip {ip-address}
Parameter	Indicates the IP address of the portal server.
Description	
Command Mode	Webauth template configuration mode
Usage Guide	N/A

Configuring the Webauth URL of the Portal Server

Command	url {url-string}
Parameter	<i>url-string</i> : Indicates the Webauth URL of the portal server.
Description	
Command	Webauth template configuration mode

Mode	
Usage Guide	The URL starts with http:// or https:// .

↘ Specifying the Webauth Binding Mode

Command	bindmode { ip-mac-mode ip-only-mode }
Parameter Description	Indicates the Webauth binding mode.
Command Mode	Webauth template configuration mode
Usage Guide	N/A

↘ Specifying the Redirection Method

Command	redirect { http js }
Parameter Description	Indicates the encapsulation format of redirected packets.
Command Mode	Webauth template configuration mode
Usage Guide	For JavaScript-incapable Apps, you need to specify the HTTP encapsulation format to trigger redirection.

↘ Configuring the Webauth Communication Key

Command	web-auth portal key {key-string}
Parameter Description	<i>key-string</i> : Indicates the Webauth communication key used for the communication between the NAS and portal server. The key contains up to 255 characters.
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Configuring the SNMP-Server Community String

Command	snmp-server community {community-string}rw
Parameter Description	<i>community-string</i> : Indicates the community string. rw : Must be set to rw to support the read and write operations as the Set operation on MIB is required.
Command Mode	Global configuration mode
Usage Guide	The SNMP-server community string is used by the portal server to manage the online clients on the NAS or convergence device.

↘ Configuring the SNMP-Server Host

Command	snmp-server host {ip-address} inform version 2c {community-string} web-auth
Parameter Description	<i>ip-address</i> : Indicates the IP address of the SNMP-server host, that is, the portal server. <i>community-string</i> : Configures the community string used to send an SNMP Inform message.

Command Mode	Global configuration mode
Usage Guide	<p>Configure the SNMP-server host to receive Webauth messages, including the type, version, community string, and other parameters.</p> <p>inform: Enables the SNMP Inform function. The NAS or convergence device will send a message to the portal server when a client logs out. The message type is set to Inform instead of Trap to avoid message loss.</p> <p>version 2c: Indicates SNMPv2 for SNMP Inform is not supported in all SNMP versions excluding SNMPv1.</p> <p>web-auth: Indicates the preceding parameters to be used for Web authentication.</p> <hr/> <p>For details regarding SNMP configuration and others, see the <i>Configuring SNMP</i>.</p> <p>The SNMP parameter version 2c listed here is aimed at SNMPv2. SNMPv3 is recommended if higher security is required for the SNMP communication between the NAS and portal server. To use SNMPv3, change SNMP Community to SNMP User, version 2c to SNMPv3, and set SNMPv3-related security parameters. For details, see the <i>Configuring SNMP</i>.</p>

↳ Enabling the Webauth Trap/Inform Function

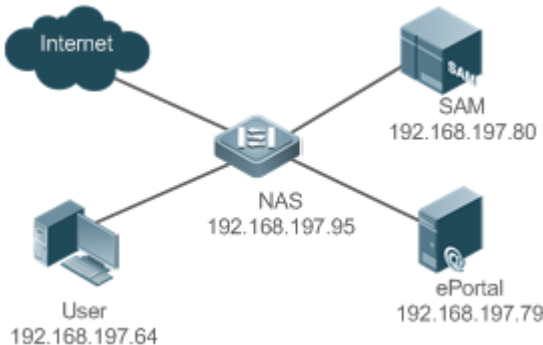

Command	snmp-server enable traps web-auth
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	<p>Configure the NAS or convergence device to send Webauth Trap and Inform messages externally.</p> <p>web-auth: Indicates Web authentication messages.</p>

↳ Enabling Ruijie First-Generation Web Authentication on an Interface

Command	web-auth enable
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

↳ Configuring Ruijie First-Generation Web Authentication

<p>Scenario Figure 5-4</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● On the NAS, configure the IP address of the ePortal server and the key (ruijie) used for communicating with the ePortal server. ● Configure the Webauth URL on the NAS. ● Set the SNMP network management parameters (community string: public) used for the communication between the NAS and ePortal server. ● Enable Web authentication on ports GigabitEthernet 0/2 and GigabitEthernet 0/3 on the NAS.
	<pre>Ruijie# config Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)#web-auth template eportalv1 Ruijie(config.tmpl.eportalv1)#ip 192.168.197.79 Ruijie(config.tmpl.eportalv1)#exit Ruijie(config)# web-auth portal key ruijie</pre>
	<pre>Ruijie(config)# web-auth template eportalv1 Ruijie(config.tmpl.eportalv1)#url http://192.168.197.79:8080/eportal/index.jsp Ruijie(config.tmpl.eportalv1)#exit</pre>
	<pre>Ruijie(config)# snmp-server community public rw Ruijie(config)# snmp-server enable traps web-auth Ruijie(config)# snmp-server host 192.168.197.79 inform version 2c public web-auth Ruijie(config)# exit</pre>
	<pre>Ruijie(config)# interface range GigabitEthernet 0/2-3 Ruijie(config-if-range)# web-auth enable Ruijie(config-if-range)# exit</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● Check whether Web authentication is configured successfully.

	<pre>Ruijie(config)#show running-config ... snmp-server host 192.168.197.79 inform version 2c public web-auth snmp-server enable traps web-auth snmp-server community public rw ... web-auth template eportalv1 ip 192.168.197.79 url http://192.168.197.79:8080/eportal/index.jsp ! web-auth portal key ruijie ... interface GigabitEthernet 0/2 web-auth enable ! interface GigabitEthernet 0/3 web-auth enable</pre>
	<pre>Ruijie#show web-auth control Port Control Server Name Online User Count ----- ... GigabitEthernet 0/20n eportalv1 0 GigabitEthernet 0/30n eportalv1 0 ...</pre>
	<pre>Ruijie#show web-auth template Webauth Template Settings: ----- Name: eportalv1 Url: http://17.17.1.21:8080/eportal/index.jsp Ip: 17.17.1.21 BindMode: ip-mac-mode</pre>

Type:	v1
.....	

Common Errors

- The SNMP parameters used for the communication between the portal server and NAS are configured incorrectly, causing authentication failures.
- Specify the IP-MAC binding mode to deploy Web authentication on layer-3 networks, causing authentication failures.
- When Web authentication is used in conjunction with VRRP, run the `snmp-server trap-source ip` command to specify the VRRP address; otherwise, the portal server cannot process Trap packets correctly.

5.4.2 Configuring Ruijie Second-Generation Web Authentication

Configuration Effect

Redirect unauthenticated clients to the Webauth URL to perform authentication. IPv6 is supported.

Notes

- Ruijie Second-Generation Web Authentication complies with the CMCC WLAN Service Portal Specification. Furthermore, it is extended to support Ruijie portal server. Perform compatible configuration based on the server performance in actual deployment. For details, see the subsequent chapter.
- The `cmcc-normal` and `cmcc-ext1` parameters in the `fmt` command support only IPv4. If IPv6 is used, the configuration of the portal server is invalid.

Configuration Steps

↳ Enabling AAA

- (Mandatory) To enable Ruijie Second-Generation Web Authentication, you must enable AAA.
- The NAS is responsible for initiating authentication to the portal server through AAA in Ruijie Second-Generation Web Authentication.

↳ Configuring the RADIUS-Server Host and Communication Key

- (Mandatory) To enable Ruijie Second-Generation Web Authentication, you must configure the RADIUS server.
- Clients' account information is stored on the RADIUS server. The NAS needs to connect to the RADIUS server to validate a client.

↳ Configuring an AAA Method List for Web Authentication

- (Mandatory) To enable Ruijie Second-Generation Web Authentication, you must configure an AAA authentication method list.
- An AAA authentication method list associates Web authentication requests with the RADIUS server. The NAS selects an authentication method and server based on the method list.

↘ **Configuring an AAA Method List for Web Accounting**

- (Mandatory) To enable Ruijie Second-Generation Web Authentication, you must configure an AAA method list for Web accounting.
- An accounting method list is used to associate an accounting method and server. In Web authentication, accounting is implemented to record client fees.

↘ **Configuring the Portal Server**

- (Mandatory) To enable Ruijie Second-Generation Web Authentication, you must configure and apply the portal server.
- When the NAS or convergence device finds an unauthenticated client attempting to access network resources through HTTP, it redirects the access request to the specified Webauth URL, where the client can initiate authentication to the portal server. If the IP address of the portal server is configured as a free network resource, unauthenticated clients can directly visit this IP address through HTTP.

↘ **Configuring the Communication Key Between the NAS and Portal Server**

- (Mandatory) To enable Ruijie Second-Generation Web Authentication, you must configure the key used for the communication between the NAS or convergence device and portal server.
- When the NAS finds an unauthenticated client attempting to access network resources, it redirects the client to the specified Webauth URL, where the client can initiate authentication to the portal server. During the authentication process, the communication key is used to encrypt some data exchanged between the NAS and portal server to improve security.

↘ **Configuring the Portal Server in Global or Interface Configuration Mode**

- (Mandatory) To enable Ruijie Second-Generation Web Authentication, you must specify the use of the second generation portal server in global or interface configuration mode.
- The NAS first selects the portal server in interface configuration mode. If such a portal server does not exist, the NAS selects the portal server in global configuration mode. If such a portal server does not exist, eportalv1 is used by default. The NAS redirects users to the selected portal server.

↘ **Enabling Ruijie Second-Generation Web Authentication on an Interface**

- Mandatory.
- When Ruijie Second-Generation Web Authentication is enabled in interface configuration mode, Web authentication is not enabled on any port by default. The users connecting to the port do not need to perform Web authentication.

Verification

- Check whether unauthenticated clients are required to perform authentication.
- Check whether authenticated clients can access the Internet normally.

Related Commands

↘ **Enabling AAA**

Command	aaa new-model
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	You can configure the AAA authentication and accounting method lists only after AAA is enabled.

↘ Configuring the RADIUS-Server Host and Communication Key

Command	radius-server host { <i>ip-address</i> } [auth-port <i>port-number1</i>] [acct-port <i>port-number2</i>] key { <i>string</i> }
Parameter	<i>ip-address</i> : Indicates the IP address of the RADIUS server host.
Description	<i>port-number1</i> : Indicates the authentication port. <i>port-number2</i> : Indicates the accounting port. <i>string</i> : Indicates the key string.
Command Mode	Global configuration mode
Usage Guide	By default, the authentication port number is 1812, and the accounting port number is 1813.

↘ Configuring an AAA Method List for Web Authentication

Command	aaa authentication web-auth { default <i>list-name</i> } <i>method1</i> [<i>method2...</i>]
Parameter	<i>list-name</i> : Creates a method list.
Description	<i>method1</i> : Configures method 1. <i>method2</i> : Configures method 2.
Command Mode	Global configuration mode
Usage Guide	Ruijie Second-Generation Web Authentication adopts the RADIUS authentication method.

↘ Configuring an AAA Method List for Web Accounting

Command	aaa accounting network { default <i>list-name</i> } start-stop <i>method1</i> [<i>method2...</i>]
Parameter	<i>list-name</i> : Creates a method list.
Description	<i>method1</i> : Configures method 1. <i>method2</i> : Configures method 2.
Command Mode	Global configuration mode
Usage Guide	Ruijie Second-Generation Web Authentication adopts the RADIUS accounting method.

↘ Configuring the Second-Generation Webauth Template

Command	web-auth template { <i>eportalv2</i> <i>portal-name v2</i> }
Parameter	<i>portal-name</i> : Indicates the customized portal server name.
Description	
Command Mode	Global configuration mode

Mode	
Usage Guide	portalv2 indicates the default template of Ruijie Second-Generation Web Authentication.

▾ Configuring the IP Address of the Portal Server

Command	ip { <i>ip-address</i> }
Parameter Description	Indicates the IP address of the portal server.
Command Mode	Webauth template configuration mode
Usage Guide	N/A

▾ Configuring the Webauth URL of the Portal Server

Command	url { <i>url-string</i> }
Parameter Description	Indicates the Webauth URL of the portal server.
Command Mode	Webauth template configuration mode
Usage Guide	The URL starts with http:// or https:// .

▾ Specifying the Webauth Binding Mode

Command	bindmode { ip-mac-mode ip-only-mode }
Parameter Description	ip-mac-mode : Indicates IP-MAC binding mode. ip-only-mode : Indicates IP-only binding mode.
Command Mode	Webauth template configuration mode
Usage Guide	N/A

▾ Specifying the Encapsulation Format of the Webauth URL

Command	redirect { http js }
Parameter Description	Indicates the encapsulation format of redirected packets.
Command Mode	Webauth template configuration mode
Usage Guide	For JavaScript-incapable Apps, you need to specify the HTTP encapsulation format to trigger redirection.

▾ Configuring the Webauth Communication Key

Command	web-auth portal key { <i>key-string</i> }
Parameter	<i>key-string</i> : Indicates the Webauth communication key used for the communication between the NAS and

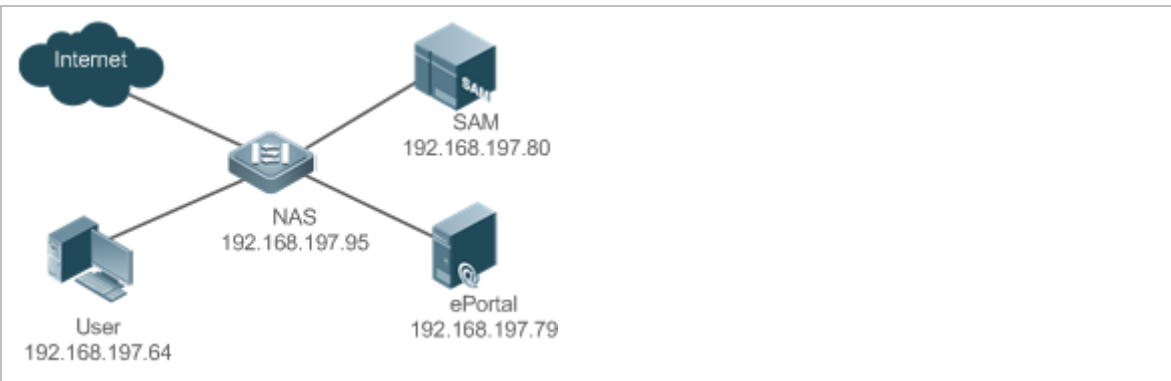

Description	portal server. The key contains up to 255 characters.
Command	Global configuration mode
Mode	
Usage Guide	N/A

➤ **Enabling Ruijie Second-Generation Web Authentication on an Interface**

Command	web-auth enable
Parameter	Indicates a Webauth template.
Description	
Command	Interface configuration mode
Mode	
Usage Guide	N/A

Configuration Example

Common Errors

- The communication key between the portal server and NAS is configured incorrectly or only on the portal server or NAS, causing authentication errors.
- The communication parameters of the RADIUS server and NAS are set incorrectly, causing authentication errors.
- The portal server does not support the *CMCC WLAN Service Portal Specification*, causing compatibility failure.

5.4.3 Specifying an Authentication Method List

Configuration Effect

- The portal server sends an authentication request to the NAS when a user submits authentication information. The NAS resolves the authentication server information and other information based on the configured authentication method list name before initiating authentication.

- The NAS selects the authentication server based on the specified authentication method list.

Notes

- Before you configure an authentication method list name, ensure that the authentication methods in the list have been configured on the AAA module. The command used to configure authentication methods on the AAA module is **aaa authentication web-auth** { *default* | *list-name* }*method1* [*method2...*].

Configuration Steps

- Optional.
- The default authentication method is used if no authentication method list is configured. Run the **authentication** { *mlist-name* } command to configure an authentication method list name when the authentication method list name on the AAA module needs to be modified or multiple method lists exist.

Verification

- Configure two authentication method lists on the AAA module. Apply list 1 to server 1 and list 2 to server 2.
- Create user a and configured a password for the user on server 1. Create user b on server 2.
- Configure the use of list 1.
- Perform authentication as user b and check that authentication fails.
- Perform authentication as user a and check that authentication is successful.

Related Commands

↘ Specifying an Authentication Method List

Command	authentication { <i>mlist-name</i> }
Parameter Description	Indicates a method list name.
Command Mode	Webauth template configuration mode
Usage Guide	Ensure that the configured authentication method list name is consistent with that on the AAA module.

5.4.4 Specifying an Accounting Method List

Configuration Effect

- The NAS sends an accounting request when a user passes authentication. The recipient of the request depends on the configuration of the accounting method list and is usually the portal server.
- Specify an accounting method list for the NAS to perform accounting.

Notes

- Ensure that the accounting method list has been configured on the AAA module. The command used to configure accounting methods on the AAA module is **aaa accounting network {default | list-name }start-stop method1 [method2...]**.

Configuration Steps

- Optional.
- The default accounting method is used if no accounting method list is configured. Run the **accounting {mlist-name }** command to configure an accounting method list name when the accounting method list name on the AAA module needs to be modified or multiple method list names exist.

Verification

- Configure two accounting method lists on the AAA module. Apply list 1 to server 1 and list 2 to server 2.
- Configure the use of list 1.
- Use a valid account to perform authentication to access the Internet.
- View user accounting information on server1 and server2. Check that the user accounting information exists only on server1.

Related Commands

▾ Specifying an Accounting Method List

Command	accounting { <i>mlist-name</i> }
Parameter Description	Indicates a method list name.
Command Mode	Webauth template configuration mode
Usage Guide	Ensure that the configured accounting method list name is consistent with that on the AAA module.

Configuration Example

▾ Specifying an Accounting Method List

Configuration Steps	<ul style="list-style-type: none"> ● Specify the accounting method list mlist1. <pre>Ruijie(config.tmpl.eportalv2)#accounting mlist1</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful. <pre>Ruijie#show web-auth template Webauth Template Settings: -----</pre>

Configuration Steps	<ul style="list-style-type: none"> Specify the accounting method list mlist1.
	<pre>Ruijie(config.tmlt.eportalv2)#accounting mlist1</pre>
Verification	<ul style="list-style-type: none"> Check whether the configuration is successful.
	<pre>Name: eportalv2 Url: http://17.17.1.21:8080/eportal/index.jsp Ip: 17.17.1.21 BindMode: ip-mac-mode Type: v2 Port: 50100 State: Active Acctmlist: mlist1 Authmlist: mlist1</pre>

5.4.5 Configuring the Communication Port of the Portal Server

Configuration Effect

- When the NAS detects that a user logs out, it notifies the portal server. The NAS interacts with the portal server through the portal specification, which specifies the port number used to listen to and send/receive packets.
- When the listening port of the portal server is changed, the communication port of the portal server must be modified on the NAS to enable the NAS to interact with the portal server.
- In Ruijie iPortal Web Authentication, this function is used to configure the HTTP listening port of the NAS. The default port number is 8081.

Notes

- The configured port number must be consistent with the port actually used by the portal server.
- This function is applicable to Ruijie Second-Generation Web Authentication and iPortal Web Authentication. The two authentication schemes use different default port numbers. In Ruijie Second-Generation Web Authentication, the configured port number is used for the interaction between the NAS and portal server through the portal specification. In Ruijie iPortal Web Authentication, the configured port number is used for packet listening on the NAS.

Configuration Steps

- Optional.
- Run the **port port-num** command to maintain port configuration consistency when the portal server does not use the default port number or the listening port of the NAS conflicts with other port and needs to be adjusted.

Verification

- Configure Ruijie Second-Generation Web Authentication.
- Change the listening port of the server to 10000.
- Run the **port** *port-num* command to configure the port number 10000.
- Simulate the scenario where a user performs authentication to access the Internet.
- Force the user offline on the NAS, refresh the online page, and check that a user logout notification is displayed.

Related Commands

↘ Configuring the Communication Port of the Portal Server

Command	port <i>port-num</i>
Parameter Description	<i>port-num</i> : Indicates the port number.
Command Mode	Webauth template configuration mode
Usage Guide	N/A

Configuration Example

↘ Configuring the Communication Port of the Portal Server

Configuration Steps	<ul style="list-style-type: none"> ● Configure the communication port of the portal server as port 10000.
	<pre>Ruijie(config.tmlt.eportalv2)#port 10000</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful.
	<pre>Ruijie#show web-auth template Webauth Template Settings: ----- Name: eportalv2 Url: http://17.17.1.21:8080/eportal/index.jsp Ip: 17.17.1.21 BindMode: ip-only-mode Type: v2 Port: 10000 Acctmlist: Authmlist:</pre>

5.4.6 Specifying the Webauth Binding Mode

Configuration Effect

- When a user goes online, the user's entry needs to be written to a forwarding rule. The forwarding rule mapping method can be modified by specifying different binding modes, which further affects the Internet access rules applied to users. In IP-only mode, all the packets carrying the specified IP address are permitted to pass, and the STAs who send the packets can access the Internet. In IP+MAC mode, only the packets carrying both the specified IP address and MAC address are permitted to pass, and the STAs who send the packets can access the Internet.

Notes

- In Layer-3 authentication, the MAC addresses visible to the NAS are the gateway addresses of STAs. Because these MAC addresses are not accurate, the IP-only mode should be used.

Configuration Steps

- (Optional) The default Webauth binding mode is IP+MAC.
- Determine a binding mode based on the accuracy of user information obtained by the NAS. When the IP and MAC addresses of STAs are accurate (in L2 authentication, for example), IP+MAC is recommended. When the IP and MAC addresses are not accurate, select IP-only.

Verification

- Change the binding mode to IP-only.
- Simulate the scenario where a user performs authentication to access the Internet.
- Modify the MAC address of the user, or use a client with the same IP address but a different MAC address to access the Internet.
- Check that the user accesses the Internet normally.

Related Commands

▾ Specifying the Webauth Binding Mode

Command	bindmode {ip-mac-mode ip-only-mode}
Parameter	ip-mac-mode: Indicates IP-MAC binding mode.
Description	ip-only-mode: Indicates IP-only binding mode.
Command Mode	Webauth template configuration mode
Usage Guide	N/A

Configuration Example

▾ Specifying the Webauth Binding Mode

Configuration Steps	<ul style="list-style-type: none"> Set the binding mode to IP-only.
	<pre>Ruijie(config.tmlt.eportalv2)#bindmode ip-only-mode</pre>
Verification	<ul style="list-style-type: none"> Check whether the configuration is successful.
	<pre>Ruijie#show web-auth template Webauth Template Settings: ----- Name: eportalv2 Url: http://17.17.1.21:8080/eportal/index.jsp Ip: 17.17.1.21 BindMode: ip-only-mode Type: v2 Port: 10000 Acctmlist: Authmlist:</pre>

5.4.7 Configuring the Redirection HTTP Port

Configuration Effect

- When an STA accesses network resources (for example, the user accesses the Internet using a browser), the STA sends HTTP packets. The NAS or convergence device intercepts these HTTP packets to determine whether the STA is accessing network resources. If the NAS or convergence device detects that the STA is not authenticated, it prevents the STA from accessing network resources and displays an authentication page to the STA. By default, the NAS intercepts the HTTP packets that STAs send to port 80 to determine whether STAs are accessing network resources.
- After a redirection HTTP port is configured, the HTTP requests that STAs send to the specified destination port can be redirected.

Notes

- The commonly used management ports on the NAS or convergence device, such as ports 22, 23 and 53, and ports reserved by the system are not allowed to be configured as the redirection port. All ports except port 80 with numbers smaller than 1000 are seldom used by the HTTP protocol. To avoid a conflict with the well-known TCP port, do not configure a port with a small number as the redirection port unless necessary.

Configuration Steps

- Optional.

- When you configure automatic client acquisition, if you need to enable the NAS to intercept the HTTP packets that STAs send to the specified destination port, configure a redirection HTTP port.

Verification

- Configure an interception port.
- Open the browser of a PC and access the Internet through the port without performing authentication.
- Check whether the access requests are redirected to an authentication page.

Related Commands

⌵ Configuring the Redirection HTTP Port

Command	http redirect port <i>port-num</i>
Parameter Description	<i>port-num</i> : Indicates the port number.
Command Mode	Global configuration mode
Usage Guide	A maximum of 10 different destination port numbers can be configured, not including default ports 80 and 443.

Configuration Example

⌵ Configuring the Redirection HTTP Port

Configuration Steps	<ul style="list-style-type: none"> ● Configure port 8080 as the redirection HTTP port. <pre>Ruijie(config)#http redirect port 8080</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful. <pre>Ruijie(config)#show web-auth rdport Rd-Port: 80 443 8080</pre>

5.4.8 Configuring Rate Limit Webauth Logging

Configuration Effect

- The Web authentication module sends syslog messages to the administrator to display the information and relevant events of users who perform login/logout. By default, syslog messages are shielded.
- After syslog output rate limiting is configured, syslog messages are sent at a certain rate.

Notes

- When the login/logout rate is high, syslog messages are output frequently, which affects device performance and results in spamming.

Configuration Steps

- Optional.
- Configure syslog output rate limiting when you need to view the syslog messages about user login/logout.

Verification

- Configure logging rate limiting.
- Check whether users log in and out at a certain rate.
- Check that syslog messages are printed out at the limit rate.

Related Commands

▾ Configuring Rate Limit Webauth Logging

Command	web-auth logging enable <i>num</i>
Parameter Description	<i>num</i> : Indicates the syslog output rate (entry/second).
Command Mode	Global configuration mode
Usage Guide	When the syslog output rate is set to 0 , syslog messages are output without limit. The output of syslog messages of the critical level and syslog messages indicating errors is not limited.

Configuration Example

▾ Configuring Rate Limit Webauth Logging

Configuration Steps	<ul style="list-style-type: none"> ● Disable rate limit Webauth Logging. <pre>Ruijie(config)#web-auth logging enable 0</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful. <pre>Ruijie(config)#show running-config ... web-auth logging enable 0 ...</pre>

5.4.9 Configuring the Maximum Number of HTTP Sessions for Unauthenticated Clients

Configuration Effect

- When an unauthenticated user accesses network resources, the user's PC sends requests for HTTP session connection. The NAS or convergence device intercepts the HTTP packets and redirects the user to a Web authentication page. To prevent an unauthenticated user from initiating too many HTTP connection requests and save resources on the NAS, it is necessary to limit the maximum number of HTTP sessions that the unauthenticated user can initiate on the NAS.
- A user occupies an HTTP session when performing authentication, and the other application programs of the user may also occupy HTTP sessions. For this reason, it is recommended that the maximum number of HTTP sessions for an unauthenticated user be not set to 1. By default, each unauthenticated user can initiate 255 HTTP sessions globally, and each port supports up to 300 HTTP sessions initiated by unauthenticated clients.

Notes

- If the authentication page fails to be displayed during Web authentication, the maximum number of HTTP sessions may be reached. When this happens, the user can close the application programs that may occupy HTTP sessions and then perform Web authentication again.

Configuration Steps

- Optional.
- Perform this configuration when you need to change the maximum number of HTTP sessions that each unauthenticated user can initiate and the maximum number of HTTP sessions that unauthenticated clients can initiate on each port.
- Perform this configuration when you configure automatic SU client acquisition.

Verification

- Modify the maximum number of HTTP sessions that an unauthenticated user can initiate.
- Simulate the scenario where an unauthenticated user constructs identical sessions to connect to the NAS continuously.
- Simulate the scenario where the unauthenticated user accesses the Internet using a browser. Check whether the access requests are redirected and the NAS notifies the user that the maximum number of sessions is reached.

Related Commands

▾ Configuring the Maximum Number of HTTP Sessions for Unauthenticated Clients

Command	http redirect session-limit { <i>session-num</i> } [port { <i>port-session-num</i> }]
Parameter Description	<p><i>session-num</i>: Indicates the maximum number of HTTP sessions for unauthenticated clients. The value range is 1 to 255. The default value is 255.</p> <p><i>port-session-num</i>: Indicates the maximum number of HTTP sessions on each port for authenticated clients. The value range is 1 to 65,535. The default value is 300.</p>

Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring the Maximum Number of HTTP Sessions for Unauthenticated Clients

Configuration Steps	<ul style="list-style-type: none"> Set the maximum number of HTTP sessions for unauthenticated clients to 3.
	<pre>Ruijie(config)#http redirect session-limit 3</pre>
Verification	<ul style="list-style-type: none"> Check whether the configuration is successful.
	<pre>Ruijie(config)#show web-auth parameter HTTP redirection setting: session-limit: 3 timeout: 3 Ruijie(config)#</pre>

5.4.10 Configuring the HTTP Redirection Timeout

Configuration Effect

- Configure the HTTP redirection timeout to maintain redirection connections. When an unauthenticated user tries to access network resources through HTTP, the TCP connection requests sent by the user will be intercepted and re-established with the NAS or convergence device. Then, the NAS or convergence device waits for the HTTP GET/HEAD packets from the user and responds with HTTP redirection packets to close the connection. The redirection timeout is intended to prevent the user from occupying the TCP connection for a long time without sending GET/HEAD packets. By default, the timeout for maintaining a redirection connection is 3s.

Notes

N/A

Configuration Steps

- Optional.
- Perform this configuration to change the timeout for maintaining redirection connections.

Verification

- Change the timeout period.
- Use a network packet delivery tool to set up a TCP connection.

- View the status of the TCP connection on the NAS. Check whether the TCP connection is closed when the timeout is reached.

Related Commands

↘ Configuring the HTTP Redirection Timeout

Command	<code>http redirect timeout { seconds }</code>
Parameter Description	<i>Seconds</i> : Indicates the timeout for maintaining redirection connections, in the unit of seconds. The value ranges from 1 to 10. The default value is 3s.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

↘ Configuring the HTTP Redirection Timeout

Configuration Steps	<ul style="list-style-type: none"> ● Set the HTTP redirection timeout to 5s. <pre>Ruijie(config)#http redirect timeout 5</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful. <pre>Ruijie(config)#show web-auth parameter HTTP redirection setting: session-limit: 255 timeout: 5</pre>

5.4.11 Configuring the Straight-Through Network Resources

Configuration Effect

- After Web authentication or 802.1X authentication is enabled on a port, the users connecting to the port need to pass Web authentication or 802.1X authentication before accessing network resources.
- Perform this configuration to exempt users from authentication when accessing some network resources.
- If a website is configured as a network resource of authentication exemption, all users, including unauthenticated clients, can access the website. By default, authentication exemption is not configured, and unauthenticated clients are not allowed to access network resources.

Notes

- The maximum number of free resources and the maximum number of unauthenticated clients cannot exceed 1000 respectively. The actual number of available resources may be reduced because of other security modules. Therefore, it is recommended that network segments be configured if many addresses need to be set.
- **http redirect direct-site** is used to configure the straight-through URL address for users, and **http redirect** is used to configure the straight-through IP address of the Web authentication server. The addresses configured using the two commands can be accessed without authentication, but they have different usages. It is recommended not to configure the IP address of the Web authentication server by using **http redirect direct-site**.

Configuration Steps

- Optional.
- Run the **http redirect direct-site** command to enable unauthenticated clients to access network resources.

Verification

- Configure the straight-through network resources.
- Check whether unauthenticated clients can access the configured network resources using PCs.

Related Commands

⌵ Configuring the Straight-Through Network Resources

Command	http redirect direct-site { <i>ipv4-address</i> [<i>ip-mask</i>] [arp] <i>mac-address</i> range <i>startip-address</i> <i>endip-address</i> } [description <i>description-str</i>] [group <i>group-name</i>]
Parameter Description	<p><i>ipv4-address</i>: Indicates the IPv4 address of the network exempt from authentication.</p> <p><i>ip-mask</i>: Indicates the mask of the IPv4 address of the network exempt from authentication.</p> <p><i>mac-address</i>: Indicates the destination MAC address of the network exempt from authentication.</p> <p><i>startip-address</i>: Indicates the start IP address of consecutive networks exempt from authentication.</p> <p><i>endip-address</i>: Indicates the end IP address of consecutive networks exempt from authentication.</p> <p><i>group-name</i>: Indicates the group to which the network exempt from authentication belongs.</p> <p><i>description-str</i>: Indicates the description of the network exempt from authentication.</p>
Command Mode	Global configuration mode
Usage Guide	To set authentication-exempted ARP resource, use the http redirect direct-arp command preferentially.

Configuration Example

⌵ Configuring the Straight-Through Network Resources

Configuration Steps	<ul style="list-style-type: none"> ● Configure the straight-through network resources as 192.168.0.0/16.
	<pre>Ruijie(config)#http redirect direct-site 192.168.0.0 255.255.0.0</pre>

	<ul style="list-style-type: none"> Set the range of consecutive networks exempt from authentication to 10.0.0.1-12.0.0.1. <pre>Ruijie(config)# http redirect direct-site range 10.0.0.1 12.0.0.1</pre> 																		
Verification	<ul style="list-style-type: none"> Check whether the configuration is successful. 																		
	<pre>Ruijie(config)#show web-auth direct-site</pre> <p>Direct sites:</p> <table border="1"> <thead> <tr> <th>Address</th> <th>Mask</th> <th>ARP Binding</th> <th>Group</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>192.168.0.0</td> <td>255.255.0.0</td> <td>Off</td> <td>N/A</td> <td>N/A</td> </tr> </tbody> </table> <pre>Ruijie(config)#</pre> <pre>Ruijie(config)#show web-auth direct-site range</pre> <p>Direct site Ranges: 1</p> <table border="1"> <thead> <tr> <th>Start Address</th> <th>End Address</th> <th>Group</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>10.0.0.1</td> <td>12.0.0.1</td> <td>N/A</td> <td>N/A</td> </tr> </tbody> </table> <pre>Ruijie(config)#</pre>	Address	Mask	ARP Binding	Group	Description	192.168.0.0	255.255.0.0	Off	N/A	N/A	Start Address	End Address	Group	Description	10.0.0.1	12.0.0.1	N/A	N/A

Start Address	End Address	Group	Description																
10.0.0.1	12.0.0.1	N/A	N/A																

5.4.12 Configuring the Straight-Through ARP Resource Range

Configuration Effect

When ARP check or similar functions are enabled, the ARP learning performed by clients is controlled. As a result, clients cannot learn the ARPs of the gateway and other devices, which affects user experience. You can configure the straight-through ARP resource range to permit the ARP learning packets destined for the specified address to pass.

Notes

- When ARP check is enabled, you need to configure the gateway of the PCs connecting to the Layer-2 access device as a straight-through ARP resource. Note the following point when you perform the configuration:
- When you configure straight-through websites and ARP resources in the same address or network segment, the **http redirect direct-arp** command automatically combines the websites and ARP resources. If no ARP option is specified for the configured websites, an ARP option will be automatically added after the combination.
- When ARP check is enabled, if the outbound addresses of the PCs connecting to the Layer-2 access device are not the gateway address, configure the outbound addresses as straight-through ARP resources. If multiple outbound addresses exist, configure these addresses as straight-through ARP resources.

Configuration Steps

- Optional.

- If ARP check is enabled on the NAS, you must configure the free resources and gateway address as straight-through ARP resources.

Verification

- Configure straight-through ARP resources.
- Clear the ARP cache of the PC of an unauthenticated user. (Run the **arp -d** command in the Windows operating system.)
- Run the **ping** command on the PC to access the straight-through ARP resources.
- View the ARP cache on the PC (run the **arp -a** command in the Windows operating system) and check whether the PC learns the ARP address of the straight-through ARP resources.

Related Commands

↘ Configuring the Straight-Through ARP Resource Range

Command	http redirect direct-arp { <i>ip-address</i> [<i>ip-mask</i>] }
Parameter	<i>ip-address</i> : Indicates the IP address of free resources.
Description	<i>ip-mask</i> : Indicates the mask of free resources.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

↘ Configuring the Straight-Through ARP Resource

Configuration Steps	<ul style="list-style-type: none"> ● Configure the straight-through ARP resource as 192.168.0.0/16.
	<pre>Ruijie(config)#http redirect direct-arp 192.168.0.0 255.255.0.0</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful.
	<pre>Ruijie(config)#show web-auth direct-arp Direct arps: Address Mask ----- 192.168.0.0 255.255.0.0 Ruijie(config)#</pre>

5.4.13 Configuring an Authentication-Exempted Address Range

Configuration Effect

- Exempt users from Web authentication when accessing reachable network resources. By default, no authentication-exempted address range is configured. All users must pass Web authentication before accessing network resources.
- The authentication-exempted address range can be configured as an IP address range or MAC address range.

Notes

N/A

Configuration Steps

- Optional.
- Perform this configuration to allow unauthenticated clients to access network resources.

Verification

- Configure an authentication-exempted user.
- Check whether the user can access the Internet without authentication.

Related Commands

↳ Configuring an Authentication-Exempted Address Range

Command	web-auth direct-host { <i>ipv4-address</i> [<i>ipv4-mask</i>] [arp] [port <i>interface-name</i>] <i>mac-address</i> range <i>startip-address</i> <i>endip-address</i> } [description <i>description-str</i>] [group <i>group-name</i>]
Parameter Description	<p><i>ipv4-address</i>: Indicates the IPv4 address of the user exempt from authentication.</p> <p><i>ip-mask</i>: Indicates the mask of the IPv4 address of the user exempt from authentication.</p> <p><i>interface-name</i>: Indicates the name of the interface on which authentication exemption is enabled.</p> <p><i>mac-address</i>: Indicates the MAC address of the user exempt from authentication.</p> <p><i>startip-address</i>: Indicates the start IP address of consecutive users exempt from authentication.</p> <p><i>endip-address</i>: Indicates the end IP address of consecutive users exempt from authentication.</p> <p><i>group-name</i>: Indicates the group to which the user exempt from authentication belongs.</p> <p><i>description-str</i>: Indicates the description of the user exempt from authentication.</p>
Command Mode	Global configuration mode
Usage Guide	<p>The arp field is used to assign pass permissions to ARP packets. This field must be set when ARP check is enabled.</p> <p>After the port field is set, authentication exemption takes effect only on the configured interface.</p>

Configuration Example

▾ Configuring an Authentication-Exempted Address Range

Configuration Steps	<ul style="list-style-type: none"> Configure an authentication-exempted address range. 																						
	<pre>Ruijie (config)# web-auth direct-host 192.168.197.64</pre>																						
	<ul style="list-style-type: none"> Set the range of consecutive users exempt from authentication to 10.0.0.1-12.0.0.1. <pre>Ruijie(config)# web-auth direct-host range 10.0.0.1 12.0.0.1</pre>																						
Verification	<ul style="list-style-type: none"> Check whether the configuration is successful.

10.0.0.1	12.0.0.1	Gi0/2	N/A	N/A																			

5.4.14 Configuring the Interval for Updating Online User Information

Configuration Effect

- The NAS or convergence device maintains and periodically updates the information of online users, including users' online duration, to monitor the usage of network resources. When the online duration threshold is reached, users will be prevented from using network resources.

Notes

- The user information updating interval must be configured as 60 or multiple of 60; otherwise, the system will select the minimum multiple of 60 above and closest to the actual configuration as the interval.

Configuration Steps

- Optional.
- Perform this configuration to allow unauthenticated clients to access network resources.

Verification

- Configure the interval for updating online user information.

- View the information of online users after the update interval has elapsed.

Related Commands

↘ Configuring the Interval for Updating Online User Information

Command	web-auth update-interval { <i>seconds</i> }
Parameter Description	<i>seconds</i> : Indicates the interval for updating online user information, in the unit of seconds. The value ranges from 30 to 3,600. The default value is 180s.
Command Mode	Global configuration mode
Usage Guide	To restore the default updating interval, run the no web-auth update-interval command in global configuration mode.

Configuration Example

↘ Configuring the Interval for Updating Online User Information

Configuration Steps	<ul style="list-style-type: none"> ● Set the interval for updating online user information to 60s. <pre>Ruijie (config)# web-auth update-interval 60</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful. <pre>Ruijie(config)#show run include web-auth update-interval web-auth update-interval 60</pre>

5.4.15 Configuring Portal Detection

Configuration Effect

- Detect the availability of the active portal server periodically. When the active portal server is unavailable, the standby portal server takes over the services.
- Ruijie Second-Generation Web Authentication provides two detection methods. One is that the NAS constructs and sends portal packets to the portal server. If the portal server returns response packets, the NAS determines that the portal server is available. Another is the NAS sends ping packets to the portal server. If the portal server returns response packets, the NAS determines that the portal server is available. Because some servers or intermediate network segments filter ping packets, the first method is commonly used. The ping detection method is only used based on special requirements. In Ruijie First-Generation Web Authentication, the NAS connects to a port of the portal server and checks whether the port is reachable. If the portal is reachable, the NAS determines that the portal server is available.
- For the first method in the second-generation authentication, the interval of server availability detection is specified by the **interval** parameter, and the maximum number of packets that can be sent during each time of detection is specified by the **retransmit** parameter. If the portal server does not respond, the NAS determines that the portal server is

unavailable. The timeout period for each packet is specified by the **timeout** parameter. The parameter settings are also supported by Ruijie First-Generation Web Authentication.

- Portal server detection takes effect for Ruijie First- and Second-Generation Web Authentication.
- If multiple portal servers are configured, these servers are working in active/standby mode.

Notes

- Multiple portal servers must be configured to realize failover when an error is detected on one server.
- Only one of the two detection methods can be used at a time in case of collision. If both detection methods are configured, a detection algorithm conflict will occur or the detection results will be inaccurate.
- The system will automatically select a detection method based on whether Ruijie First- or Second-Generation Web Authentication is used.

Configuration Steps

- Optional.
- Configure multiple portal server templates applicable to Ruijie First- or Second-Generation Web Authentication.

Verification

- Configure two portal server templates for Ruijie First- or Second-Generation Web Authentication. Make the first template point to an unavailable server and the second template point to an available server.
- When the Console displays a log indicating that the portal server is not available, simulate the scenario where a user opens a browser to perform login authentication. Check whether the user is redirected to the second portal server.

Related Commands

📄 Configuring Portal Detection

Command	web-auth portal-check [interval <i>intsec</i> [timeout <i>tosec</i>] [retransmit <i>retries</i>]
Parameter	<i>intsec</i> : Indicates the detection interval. The default value is 10s.
Description	<i>tosec</i> : Indicates the packet timeout period. The default value is 5s. <i>intsec</i> : Indicates the timeout retransmission times. The default value is 3 (times).
Command Mode	Global configuration mode
Usage Guide	In many network environments, only one portal server is deployed, and portal server detection does not need to be configured. If multiple portal servers exist, it is recommended that the parameters of portal server detection be not set to small values; otherwise, the NAS will send many packets within a short time, affecting performance.

Configuration Example

📄 Configuring Portal Detection

Configuration Steps	<ul style="list-style-type: none"> Configure portal detection.
	<pre>Ruijie(config)#web-auth portal-check interval 20 timeout 2 retransmit 2</pre>
Verification	<ul style="list-style-type: none"> Check whether the configuration is successful.
	<pre>Ruijie(config)#show running-config ... web-auth portal-check interval 20 timeout 2 retransmit 2 ...</pre>

5.4.16 Configuring Portal Escape

Configuration Effect

- Allow new users to access the Internet without authentication when the portal server is not available.

Notes

- To use the portal escape function, you must configure portal detection.
- If multiple portal servers are configured, the escape function takes effect only when all the portal servers are not available.
- The escape function is intended only for the portal server, instead of the RADIUS server.

Configuration Steps

- Optional.
- Configure portal detection.
- Configure portal escape.
- (Optional) Configure the nokick attribute.

Verification

- Configure a portal server and disable the server.
- Configure the portal detection and escape functions.
- When the NAS detects that the portal server is not available, check whether a client accesses the Internet without authentication.

Related Commands

↘ [Configuring Portal Escape](#)

Command	web-auth portal-escape [nokick]
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Configure portal escape if the continuity of some critical services on the network needs to be maintained when the portal server is faulty. You must configure portal detection when you use this function. If the nokick attribute is configured, the system does not force users offline when the escape function takes effect. If the nokick attribute is deleted, the system forces users offline.

Configuration Example

Configuring Portal Escape

Configuration Steps	<ul style="list-style-type: none"> Configure portal escape.
	<pre>Ruijie(config)#web-auth portal-escape</pre>
Verification	<ul style="list-style-type: none"> Check whether the configuration is successful.
	<pre>Ruijie(config)#show running-config ... web-auth portal-escape ...</pre>

5.4.17 Configuring Jitter-off Accounting

Configuration Effect

- If jitter-off or low traffic detection is configured on the NAS, the time of jitter-off or low traffic detection will be accounted into the online duration. Jitter-off accounting is used to reduce the accounting error. Configure this function if the accounting policy does not allow the deduction of the anti-jitter time or low traffic detection time from the online duration.

Notes

- The NAS needs to support anti-jitter or low traffic detection.
- A client logs out for the link is disconnected for a long time or the NAS detects its low traffic.
- When the jitter-off and low traffic detection functions are enabled, the first logout is accounted with jitter-off time only. For example, the jitter-off duration is set to 5 minutes and the low traffic detection duration is set to 10 minutes; if the client is disconnected from the network, the jitter-off function first triggers Web authentication to log the client out. In this case, only the 5-minute duration is deducted from the online duration in the accounting packet.

Configuration Steps

- Optional.
- Configure the accounting function.
- Configure jitter-off or low traffic detection.
- Configure jitter-off accounting.

Verification

- Simulate the scenario where a client goes online after authentication and then offline because the low traffic threshold is reached.
- Capture the stop-accounting packet sent by the NAS and check whether the time of low traffic detection is deducted from the online duration.

Related Commands

▾ Configuring Jitter-off Accounting

Command	web-auth accounting jitter-off
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	Run this command to include the jitter-off duration or low traffic detection time into the online duration in the stop-accounting packet based on the server accounting policy. By default, they are not included.

Configuration Example

▾ Configuring Jitter-off Accounting

Configuration Steps	<ul style="list-style-type: none"> ● Configure jitter-off accounting. <pre>Ruijie(config)#web-auth accounting jitter-off</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful. <pre>Ruijie(config)#show running-config ... web-auth accounting jitter-off ...</pre>

5.4.18 Configuring the Portal Communication Port

Configuration Effect

- Configure the port (source port) used for the communication between the NAS and portal server.

Notes

- Only one port can be configured for the communication between the NAS and portal server.

Configuration Steps

- Configure a port as the portal communication port.

Verification

- After Web authentication is enabled, capture a packet on the portal server during the authentication process and check whether the source IP address of the packet is the IP address of the specified port.

Related Commands

▾ Configuring the Portal Communication Port

Command	ip portal source-interface <i>interface-type interface-num</i>
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

▾ Configuring the Portal Communication Port

Configuration Steps	<ul style="list-style-type: none"> ● Configure an aggregate port as the portal communication port.
	<pre>Ruijie(config)#ip portal source-interface Aggregateport 1</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful.
	<pre>Ruijie(config)#show running-config ip portal source-interface Aggregateport 1</pre>

5.4.19 Configuring VLAN-Based Authentication on a Port

Configuration Effect

- With this function enabled, clients in a VLAN configured on a port of the NAS can initiate authentication. Otherwise, the authentication will not start.

Notes

- This function supports configuration of multiple VLANs. If no VLAN is specified, Web authentication is implemented based on ports.

Configuration Steps

- Configure port-based Web authentication.
- Configure the VLAN for Web authentication.

Verification

- After Web authentication is enabled, specify the VLAN in which clients can initiate authentication. The HTTP packets sent outside the specified VLAN cannot be redirected.

Related Commands

Configuring VLAN-Based Authentication on a Port

Command	<code>web-auth vlan-control <i>vlan-list</i></code>
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

Configuring VLAN-Based Authentication on a Port

Configuration Steps	<ul style="list-style-type: none"> ● Specify VLAN1 as the VLAN in which users can initiate authentication.
	<pre>Ruijie(config-if-GigabitEthernet 0/14)#web-auth vlan-control 1</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful.
	<pre>Ruijie(config)#show running-config ... web-auth vlan-control 1</pre>

5.4.20 Disabling ARP Detection

Configuration Effect

- Disable the detection of user migration after its IP address or MAC address migrates.

Notes

- Address migration attacks may occur after ARP detection is disabled. ARP detection can be disabled in global configuration mode or in interface configuration mode. The interface configuration has a higher priority than the global configuration, and ARP detection is enabled by default in both global configuration mode and interface configuration mode. When the **no web-auth station-move arp-detect** command is executed on an interface, ARP detection is not performed when users of the interface are migrated to other interfaces.

Configuration Steps

Disabling ARP Detection

- Disable ARP detection.

Command	no web-auth station-move arp-detect
Parameter Description	N/A
Command Mode	Global configuration mode and interface configuration mode
Usage Guide	ARP detection is enabled by default. The interface configuration has a higher priority than the global configuration. Disable ARP detection on an interface that does not need ARP detection to prevent transmission of ARP detection packets during migration.

Verification

- After ARP detection is disabled, configure MAC address migration notices on different authentication ports, and check whether the users that perform Web authentication can migrate.

Configuration Example

Disabling ARP Detection

Configuration Steps	<ul style="list-style-type: none"> ● Disable ARP detection. <pre>Ruijie(config)#no web-auth station-move arp-detect Ruijie(config-if-GigabitEthernet 2/1)# no web-auth station-move arp-detect</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful. <pre>Ruijie(config)#show running-config ... no web-auth station-move arp-detect</pre>

Configuration Steps	<ul style="list-style-type: none"> ● Disable ARP detection.
	<pre>Ruijie(config)#no web-auth station-move arp-detect Ruijie(config-if-GigabitEthernet 2/1)# no web-auth station-move arp-detect</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful.
	<pre>interface GigabitEthernet 2/1 no web-auth station-move arp-detect</pre>

5.4.21 Configuring the Accounting Method List of Web Authentication

Configuration Effect

- Configure Web authentication accounting methods based on different templates.

Notes

- If no accounting method is configured for Web authentication, the default method is used.

Configuration Steps

▾ Configuring an Accounting Method

- Configure an accounting method in global or template configuration mode.

Command	web-auth accounting v2 { default name }
Parameter Description	<i>name</i> : Indicates the name of the accounting method list to be used.
Command Mode	Global or template configuration mode
Usage Guide	N/A

Verification

- View the destination IP address of accounting packets.

Configuration Example

▾ Configuring an Accounting Method

Configuration Steps	<ul style="list-style-type: none"> ● Configure an accounting method.
----------------------------	---

	<pre>Ruijie(config.tmpl.eportalv2)#web-auth accounting v2 default</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful.
	<pre>Ruijie(config)#show running-config ... web-auth accounting v2 default</pre>

5.4.22 Configuring a Web Authentication Method List

Configuration Effect

- Configure Web authentication methods based on different templates.

Notes

- If no Web authentication method is configured, the default method is used.

Configuration Steps

▾ Configuring a Web Authentication Method List

- Configure a Web authentication method in global or template configuration mode.

Command	web-auth authentication v2 { default name }
Parameter	<i>name</i> : Indicates the name of the Web authentication method list to be used.
Description	
Command Mode	Global or template configuration mode
Usage Guide	N/A

Verification

- View the destination IP address of authentication packets.

Configuration Example

▾ Configuring a Web Authentication Method

Configuration Steps	<ul style="list-style-type: none"> ● Configure a Web authentication method.
	<pre>Ruijie(config.tmpl.eportalv2)#web-auth authentication v2 default</pre>

Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful.
	<pre>Ruijie(config)#show running-config ... web-auth authentication v2 default</pre>

5.4.23 Upgrade Compatibility

Configuration Effect

- Some configuration commands are optimized in the 11.X series software and the command formats are changed. For details, see the subsequent description.
- The 10.X series software supports smooth upgrade without function loss. However, some commands are displayed in new formats after upgrade.
- When you run the commands in earlier formats in the **no** form in the 11.X series software, a message is displayed, indicating the **no** form is not supported. You need to perform the **no** operation in new command formats.

Configuration Steps

- It is recommended that you run commands in new formats.

Verification

- Check that function loss does not occur when the 10.X series software is upgraded to the 11.X series software, and commands are displayed and stored in new formats.
- The commands in new formats have the same functions as the commands in earlier formats.

Related Commands

↘ [Configuring the Address of the Portal Server in Ruijie First-Generation Web Authentication](#)

Command	http redirect <i>ip-address</i>
Parameter Description	<i>url</i> : Indicates the ip address of the ePortal server in Ruijie First-Generation Web Authentication.
Command Mode	Global configuration mode
Usage Guide	In the 11.X version, the command is converted into an eportalv1 template, and the ip command in template configuration mode is executed to configure and display the IP address of the portal server. For details, see section 5.4.1"Configuring Ruijie First-Generation Web Authentication."

↘ [Configuring the Portal Server](#)

Command	portal-server [eportal1 eportalv2]
Parameter	eportav1 : Indicates the information of the portal server used in Ruijie First-Generation Web Authentication.

Description	eportav2 : Indicates the information of the portal server used in Ruijie Second-Generation Web Authentication.
Command Mode	Global configuration mode
Usage Guide	In the 11.X version, the command is converted into an eportalv1 or eportalv2 template, and relevant information is filled in. The main parameters of the portal server include the IP address and URL of the server. The original command will be replaced by the ip command and url command in the template.

↘ Configuring Web Authentication Control on a Port

Command	web-auth port-control
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	In the 11.X version, the command is converted into web-auth enable <type> , in which type specifies the type (first or second generation) of Web authentication. The default type is Ruijie First-Generation Web Authentication.

↘ Configuring the IP-Only Binding Mode

Command	web-auth port-control ip-only-mode
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	In the 11.X version, the command is converted into an eportalv1 or eportalv2 template, depending on the actual configuration. The server binding mode is configured and displayed by using the bindmode command in template configuration mode. For details, see section 5.4.1 "Configuring Ruijie First-Generation Web Authentication" and section 5.4.2 "Configuring Ruijie Second-Generation Web Authentication."

↘ Configuring VLAN-Based Web Authentication

Command	web-auth allow-vlan list
Parameter Description	<i>list</i> : Indicates the list of VLANs for which Web authentication is enabled.
Command Mode	Global configuration mode
Usage Guide	In the 11.X version, the command is converted into a command used to configure VLAN-based SCC authentication exemption.

↘ Displaying the Configuration Information of Ruijie First-Generation Web Authentication

Command	show http redirect
----------------	---------------------------

Parameter Description	N/A
Command Mode	Privileged mode
Usage Guide	In the 11.X version, the command is unavailable and changed to show web-auth template .

▾ Displaying the Port Control Information

Command	show web-auth port-control
Parameter Description	N/A
Command Mode	Privileged mode
Usage Guide	In the 11.X version, the command is unavailable and changed to show web-auth control .

Configuration Example

▾ Configuring Ruijie First-Generation Web Authentication

Configuration Steps	<ul style="list-style-type: none"> Check that the NAS runs on the 10.X version and is configured with the IP address of the portal server used by Ruijie First-Generation Web Authentication.
	<pre>Ruijie(config)# http redirect 192.168.197.64</pre>
	<ul style="list-style-type: none"> Upgrade the NAS to 11.X.
Verification	<ul style="list-style-type: none"> Run the show running-config command after the upgrade and check whether the new command formats are used.
	<pre>Ruijie#sh running-config web-auth template eportalv1 Ip 192.168.197.64 !</pre>

5.4.24 Enabling the Perception-Free Feature

Configuration Effect

- Enable the perception-free feature to maintain the online state of users after port migration.

Configuration Steps

▾ Enabling the Perception-Free Feature in Global Configuration Mode

Command	web-auth station-move auto
Parameter	N/A

Description	
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Check that users do not go offline after migration.

Configuration Example

Configuring the Authenticated User Logout Delay on a Port

Configuration Steps	<ul style="list-style-type: none"> ● Enable the perception-free feature. <pre>Ruijie(config)# web-auth station-move auto</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful. <pre>Ruijie(config)#show running-config</pre>

5.5 Monitoring

Clearing

Description	Command
Forces users offline.	clear web-auth user { all ip <i>ip-address</i> mac <i>mac-address</i> name <i>name-string</i> }
Clears all the straight-through network resources.	clear web-auth direct-site
Clears all the authentication-exempted users.	clear web-auth direct-host

Displaying

Description	Command
Displays the basic parameters of Web authentication.	show web-auth parameter
Displays the Webauth template configuration.	show web-auth template
Displays the authentication-exempted host range.	show web-auth direct-host [range]

Description	Command
Displays the straight-through address range.	show web-auth direct-site [range]
Displays the straight-through ARP range.	show web-auth direct-arp
Displays the TCP interception port.	show web-auth rdport
Displays the online information of all users or specified users.	show web-auth user{ all ip <i>ip-address</i> mac <i>mac-address</i> name <i>name-string</i> }
Displays the basic global Webauth information.	show web-auth global
Displays the global Webauth template.	show web-auth global authentication
Displays the customized Webauth page suite.	show web-auth global customized-pages
Displays the iPortal server information.	show web-auth global local-portal
Displays the global Webauth template.	show web-auth global template
Displays the global Webauth type.	show web-auth global webauth-type
Displays the Webauth configuration.	show web-auth info
Displays the iPortal Webauth information.	show web-auth local-portal
Displays the Webauth portal check information.	show web-auth portal-check
Displays online and offline records about users.	show web-auth syslog ip <i>ip-address</i>

Debugging

 System resources are occupied when debugging information is output. Disable the debugging switch immediately after use.

Description	Command
Debugs Web authentication.	debug web-auth all

6 Configuring SCC

6.1 Overview

The Security Control Center (SCC) provides common configuration methods and policy integration for various access control and network security services, so that these access control and network security services can coexist on one device to meet diversified access and security control requirements in various scenarios.

Typical access control services are dot1x, Web authentication, Address Resolution Protocol (ARP) check, and IP Source Guard. The network security services include Access Control List (ACL), Network Foundation Protection Policy (NFPP), and anti-ARP gateway spoofing. When two or more access control or network security services are simultaneously enabled on the device, or when both access control and network security services are simultaneously enabled on the device, the SCC coordinates the coexistence of these services according to relevant policies.

 For details about the access control and network security services, see the related configuration guide. This document describes the SCC only.

Protocol and Standards

N/A

6.2 Application

Typical Application	Scenario
Access Control of Extended Layer 2 Campus Networks	Students on a campus network can access the Internet based on dot1x client authentication or Web authentication. ARP spoofing between the students should be prevented. In addition, terminal devices in some departments (such as the headmaster's office) can access the Internet without authentication.

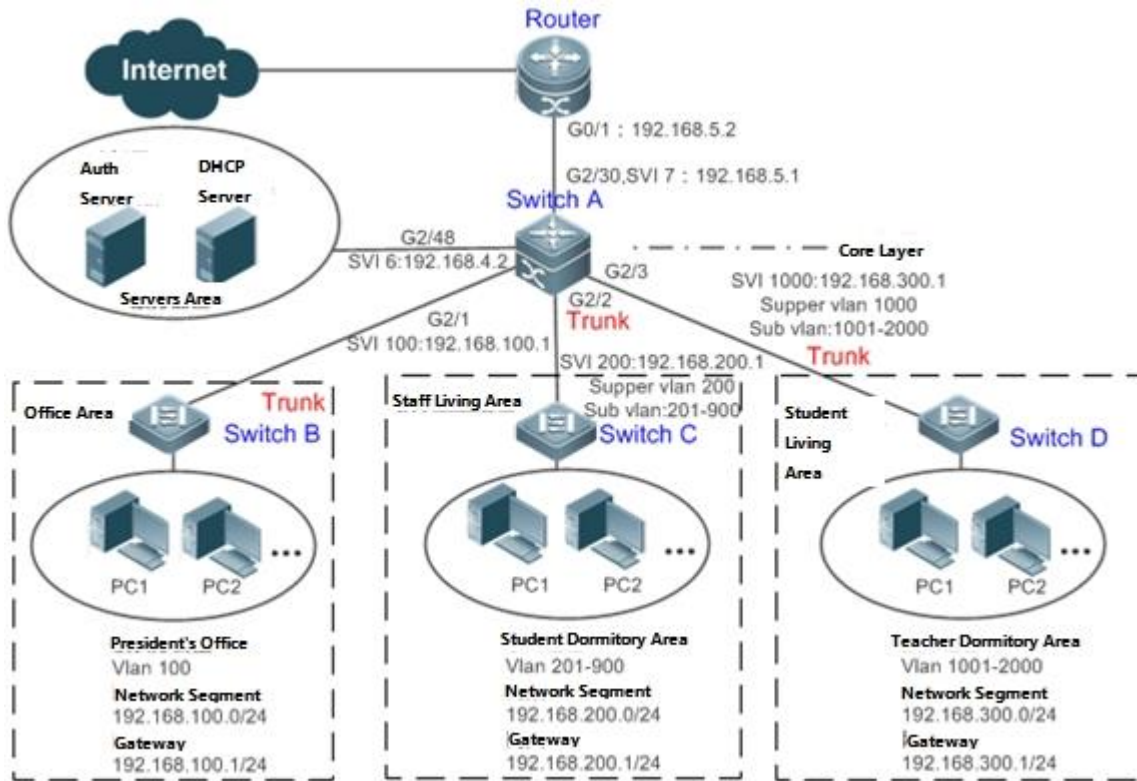

6.2.1 Access Control of Extended Layer 2 Campus Networks

Scenario

Students on a campus network of a university usually need to be authenticated through the dot1x client or Web before accessing the Internet, so as to facilitate accounting and guarantee the benefits of the university.

- The students can access the Internet through dot1x client authentication or Web authentication.
- ARP spoofing between the students is prevented, so as to guarantee the stability of the network.
- Terminal devices in some departments (such as the headmaster's office) can access the Internet without authentication.

Figure 6-1

<p>Remarks</p>	<p>A traditional campus network is hierarchically designed, which consists of an access layer, a convergence layer and a core layer, where the access layer performs user access control. On an extended Layer 2 campus network, however, user access control is performed by a core switch, below which access switches exist without involving any convergence device in between. The ports between the core switch and the access switches (such as switches B, C, and D in Figure 1-1) are all trunk ports.</p> <p>The user access switches B, C, and D connect to PCs in various departments via access ports, and VLANs correspond to sub VLANs configured on the downlink ports of the downlink ports of the core switch, so that access users are in different VLANs to prevent ARP spoofing.</p> <p>The core switch A connects to various servers, such as the authentication server and the DHCP server. Super VLANs and sub VLANs are configured on the downlink ports. One super VLAN correspond to multiple sub VLANs, and each sub VLAN represents an access user.</p>
-----------------------	--

Deployment

- On the core switch, different access users are identified by VLAN and port numbers. Each access user (or a group of access users) corresponds to one VLAN. The ports on each access switch that connect to downstream users are configured as access ports, and one user VLAN is assigned to each access user according to VLAN planning. The core switch does not forward ARP requests. The core switch replies to the ARP requests from authenticated users only, so as to prevent ARP spoofing. On the core switch A, user VLANs are regarded as sub VLANs, super VLANs are configured, and SVIs corresponding to the super VLANs are configured as user gateways.

- On the downlink ports of the core switch (switch A in this example) that connect to the teachers' living area and the students' living area, both dot1x authentication and Web authentication are enabled, so that users can freely select either authentication mode for Internet access.
- Any special department (such as the headmaster's office in this example) can be allocated to a particular VLAN, and this VLAN can be configured as an authentication-exemption VLAN so that users in this department can access the Internet without authentication.

6.3 Basic Concepts

Authentication Mode

There are two authentication modes: access authentication and gateway authentication. On a traditional hierarchical network, access authentication is usually performed by access switches. On an extended Layer 2 network, the access function moves forward to a core switch while the access devices need only to support basic VLAN and Layer 2 forwarding functions. As the access authentication is performed by access switches on a traditional hierarchical network while performed by a core switch on a de-layered extended Layer 2 network, some extrinsic functions and behaviors will differ accordingly with the two different authentication modes. Therefore, the authentication mode falls into gateway authentication and access authentication. If the access authentication moves to the core switch, the core switch needs to be enabled with the gateway authentication mode to support a large number of user entries, typically including a large-capacity MAC address table, ARP table and routing table. Otherwise, the supported user capacity is subject to hardware ACL entry restrictions. In general, the capacity of hardware ACL entries is limited and cannot support a large user capacity. The access authentication mode is generally applicable only in scenarios where the access authentication is deployed on access switches.

Authentication-Exemption VLAN

Some special departments may be allocated to authentication-exemption VLANs to simplify network management, so that users in these departments can access network resources without authentication. For example, the headmaster's office can be divided into the authentication-exemption VLANs on the campus network, so that users in the headmaster's office can access the Internet without authentication.

IPv4 User Capacity

The number of IPv4 access users can be restricted to protect the access stability of online users on the Internet and improve the operational stability of the device.

 The number of IPv4 access users is not restricted by default; that is, a large number of users can get online after being authenticated, till reaching the maximum hardware capacity of the device.

 IPv4 access users include IP users (such as IP authenticated users) based on dot1x authentication, users based on Web authentication, and IP users manually bound (using IP source guard, ARP check, or other means).

Authenticated-User Migration

Online-user migration means that an online user can get authenticated again from different physical locations to access the network. On the campus network, however, for ease of management, students are usually requested to get authenticated from a specified location before accessing the Internet, but cannot get authenticated on other access ports. This means that the users cannot migrate. In another case, some users have the mobile office requirement and can get authenticated from different access locations. Then the users can migrate.

User Online-Status Detection

For a chargeable user, accounting starts immediately after the user passes the authentication and gets online. The accounting process does not end until the user actively gets offline. Some users, however, forget to get offline when leaving their PCs, or cannot get offline because of terminal problems. Then the users suffer certain economical losses as the accounting process continues. To more precisely determine whether a user is really online, we can preset a traffic value, so that the user is considered as not accessing the Internet and therefore directly brought offline when the user's traffic is lower than the preset value in a period of time or there is not traffic of the user at all in a period of time.

Features

Feature	Function
Authentication Mode	This feature determines whether access control is deployed on access switches or core switches depending on network deployment needs.
Authentication-Exemption VLAN	Users in a specified VLAN can be configured as authentication-exemption users.
IPv4 User Capacity	The IPv4 user capacity of a specified interface can be restricted to guarantee the access stability of users on the Internet.
Authenticated-User Migration	You can specify whether the authenticated can migrate.
User Online-Status Detection	You can specify whether to detect the traffic of online users, so that a user is forced offline when the traffic of the user is lower than a preset value in a period of time.

6.3.1 Authentication Mode

There are two authentication modes: access authentication and gateway authentication. In access authentication mode, access control such as dot1x or Web authentication is enabled on access switches. In gateway authentication mode, access control is enabled on core switches. On a large-scale network such as a campus network, there are hundreds of access switches. Compared with the access authentication mode, the gateway authentication mode simplifies the routine maintenance and management on the access switches, because the access switches need only to support basic VLAN and Layer 2 forwarding functions. Therefore, the gateway authentication mode is recommended.

Working Principle

The authentication mode on a device depends on the network layer where the access control device works. If access control is deployed on core switches (for example, on an extended Layer 2 network), gateway authentication mode on core switches

is required. If access control is deployed on access switches, the authentication mode should be set to access authentication on the access switches.

-  The access authentication mode applies by default. In addition, only the N18000 switches support authentication mode switching.
-  Restart the device after the authentication mode is changed, so that the new authentication mode takes effect. Save the current configuration before restarting the device.

6.3.2 Authentication-Exemption VLAN

Authentication-exemption VLANs are used to accommodate departments with special access requirements, so that users in these departments can access the Internet without authentication such as dot1x or Web authentication.

Working Principle

Suppose the authentication-exemption VLAN feature is enabled on a device. When the device detects that a packet comes from an authentication-exemption VLAN, access control is not performed. In this way, users in the authentication-exemption VLAN can access the Internet without authentication. The authentication-exemption VLAN feature can be regarded as a kind of applications of secure channels.

-  A maximum of 100 authentication-exemption VLANs can be configured.
-  The authentication-exemption VLANs occupy hardware entries. When access control such as authentication is disabled, configuring authentication-exemption VLANs has the same effect as the case where no authentication-exemption VLANs are configured. Therefore, it is recommended that authentication-exemption VLANs be configured for users who need to access the Internet without authentication, only when the access control function has been enabled.
-  Although packets from authentication-exemption VLANs are exempt from access control, they still need to be checked by a security ACL. If the packets of the users in an authentication-exemption VLAN are denied according to the security ACL, the users still cannot access the Internet.
-  In gateway authentication mode, the device does not initiate any ARP request to a user in an authentication-exemption VLAN, and the ARP proxy will not work. Therefore, in gateway authentication mode, users in different authentication-exemption VLANs cannot access each other unless the users have been authenticated.

6.3.3 IPv4 User Capacity

To improve the operational stability of the device and guard against brutal force impacts from unauthorized users, you can restrict the total number of IPv4 access users on a certain port of the device.

Working Principle

If the total number of IPv4 access users is restricted, new users going beyond the total number cannot access the Internet.

-  Only the switches support the restriction on the number of IPv4 access users.
-  The number of IPv4 access users is not restricted on the device by default, but depends on the hardware capacity of the device.

 The number of IPv4 access users includes the IPv4 authenticated users based on dot1x authentication, IPv4 users based on Web authentication, and IPv4 users based on various binding functions. Because the number of IPv4 access users is configured in interface configuration mode, the restriction includes both the number of IPv4 users generated on the port and IPv4 users globally generated. For example, you can set the maximum number of IPv4 access users on the Gi 0/1 port to 2, run commands to bind an IPv4 user to the port, and then run commands to bind a global IPv4 user to the port. Actually there are already two access users on the port. If you attempt to bind another IPv4 user or another global IPv4 user to the port, the binding operation fails.

6.3.4 Authenticated-User Migration

On an actual network, users do not necessarily access the Internet from a fixed place. Instead, users may be transferred to another department or office after getting authenticated at one place. They do not actively get offline but remove network cables and carry their mobile terminals to the new office to access the network. Then this brings about an issue about authenticated-user migration. If authenticated-user migration is not configured, a user who gets online at one place cannot get online at another place without getting offline first.

Working Principle

When authenticated-user migration is enabled, the dot1x or Web authentication module of the device detects that the port number or VLAN corresponding to a user's MAC address has changed. Then the user is forced offline and needs to be authenticated again before getting online.

-  Only the switches devices support authenticated-user migration. In addition, cross-switch migration is not supported. For example, authentication and migration are enabled on two N18000, and a user gets online after being authenticated on one of the two N18000. If the user attempts to migrate to the other N18000, the migration fails.
-  The authenticated-user migration function requires a check of users' MAC addresses, and is invalid for users who have IP addresses only.
-  The authenticated-user migration function enables a user who gets online at one place to get online at another place without getting offline first. If the user gets online at one place and then gets offline at that place, or if the user does not get online before moving to another place, the situation is beyond the control range of authenticated-user migration.
-  During migration, the system checks whether the VLAN ID or port number that corresponds to a user's MAC address has changed, so as to determine whether the user has migrated. If the VLAN ID or port number is the same, it indicates that the user does not migrate; otherwise, it indicates that the user has migrated. According to the preceding principle, if another user on the network uses the MAC address of an online user, the system will wrongly disconnect the online user unless extra judgment is made. To prevent such a problem, the dot1x or Web authentication will check whether a user has actually migrated. For a user who gets online through Web authentication or dot1x authentication with IP authorization, the dot1x or Web authentication sends an ARP request to the original place of the user if detecting that the same MAC address is online in another VLAN or on another port. If no response is received within the specified time, it indicates that the user's location has indeed changed and then the migration is allowed. If a response is received within the specified time, it indicates that the user actually does not migrate and a fraudulent user may exist on the network. In the latter case, the migration is not performed. The ARP request is sent once every second by default, and sent for a total of five times. This means that the migration cannot be confirmed until five seconds later. Timeout-related

parameters, including the probe interval and probe times, can be changed using the **arp retry times** *times* and **arp retry interval** *interval* commands. For details about the specific configuration, see *ARP-SCG.doc*. It should be noted that the migration check requires the configuration of IP authorization for users based on dot1x authentication. In addition, the ARP probe is triggered only for user migration in gateway authentication mode but not triggered for user migration in access authentication mode.

6.3.5 User Online-Status Detection

After a user accesses the Internet, the user may forget to get offline or cannot actively get offline due to terminal faults. In this case, the user will keep being charged and therefore will suffer a certain economical loss. To protect the benefits of users on the Internet, the device provides a function to detect whether the users are really online. If the device considers that a user is not online, the device actively disconnects the user.

Working Principle

A specific detection interval is preset on the device. If a user's traffic is lower than a certain value in this interval, the device considers that the user is not using the network and therefore directly disconnects the user.

-  Only the switches devices support the user online-status detection function.
 -  The user online-status detection function applies to only users who get online through dot1x or Web authentication.
 -  Currently, the N18000 supports zero-traffic detection only.
 -  Currently, due to hardware chip restrictions of the N18000, the time to disconnect a user without any traffic relates to the configured MAC address aging time. If the traffic detection interval is set to *m* minutes and the MAC address aging time is set to *n* minutes, the interval from the moment when an authenticated user leaves the network without actively getting offline to the moment when the user is disconnected upon detection of zero traffic is about [*m*, *m+n*] minutes. In other words, if an online user does not incur any Internet access traffic, the user is disconnected about [*m*, *m+n*] minutes later.
-

6.4 Configuration

Configuration Item	Suggestions and Related Commands	
Configuring the Authentication Mode	 Optional configuration, which is used to configure the authentication mode for the device.	
	[no] auth-mode gateway	Configures the authentication mode.
Configuring Authentication-Exemption VLANs	 Optional configuration, which is used to specify the users of which VLANs can access the Internet without authentication.	
	[no] direct-vlan	Configures authentication-exemption VLANs.
Configuring the IPv4 User Capacity	 Optional configuration, which is used to specify the maximum number of users who are allowed to access a certain interface.	
	[no] nac-author-user maximum	Configures the number of IPv4 users who are allowed to access a certain interface.
Configuring Authenticated-User Migration	 Optional configuration, which is used to specify whether online users with static MAC addresses can migrate.	
	[no] station-move permit	Configures whether authenticated users can migrate.
Configuring User Online-Status Detection	 Optional configuration, which is used to specify whether to enable the user online-status detection function.	
	offline-detect interval threshold	Configures the parameters of the user online-status detection function.
	no offline-detect	Disables the user online-status detection function.
	default offline-detect	Restores the default user online-status detection mode.

6.4.1 Configuring the Authentication Mode

Configuration Effect

Perform this configuration or not perform this configuration, which shall depend on actual network deployment. On a hierarchical network, access switches perform access control and you do not need to specify the authentication mode but can simply keep the default configuration. On a de-layered extended Layer 2 network, the gateway device performs access control and then you need to set the authentication mode to gateway authentication, so that users can be authenticated and get online after the access control service such as dot1x or Web authentication is enabled on the gateway device.

Precautions

- If access control is deployed on the core switch, you need to change the authentication mode on the core switch to gateway authentication. If access control is not deployed on the core switch, you do not need to configure the authentication mode.
- You need to restart the device after the authentication mode is changed, so that the new authentication mode takes effect. Save the current configuration before restarting the device.

Configuration Method

▾ Configuring the Authentication Mode

- Optional configuration. It determines the access position of the device on the actual network.
- Perform the configuration according to actual network deployment. If the core switch performs access control, set the authentication mode to gateway authentication on the core switch; otherwise, simply keep the default configuration.

Command	[no] auth-mode gateway
Parameter Description	no: If the command carries this parameter, it indicates that the authentication mode is restored to access authentication; that is, the local device is only an access device and not a gateway device any longer. auth-mode gateway: If the command carries this parameter, it indicates that the authentication mode is set to gateway authentication; that is, the local device is both a gateway device and an access device.
Defaults	Access authentication mode
Command Mode	Global configuration mode
Usage Guide	Use this command to determine the access position of the device on the network. Perform this configuration or not perform this configuration, which depends on whether the access control function is deployed on access switches on the network or deployed on the gateway device. Use this command to change the authentication mode configured on the device from access authentication to gateway authentication. Use the no auth-mode gateway command to change the authentication mode configured on the device from gateway authentication back to access authentication.

Verification

Check the configuration using the following method:

- Enable dot1x or Web authentication on one port of the device, and perform corresponding authentication on the client. After getting online, check whether you can access network resources. Then get offline, and check whether you cannot access specified network resources.

Configuration Examples

 The following configuration example describes SCC-related configuration only.

▾ Setting the Authentication Mode to Gateway Authentication so that the Access Control Function Moves Up to the Core Gateway Device on a De-layered extended Layer 2 Network

<p>Scenario Figure 6-2</p>	<p>The diagram illustrates a network topology. At the top, a Router is connected to the Internet. The Router's G0/1 interface has IP 192.168.5.2, and its G2/20, SVI 7 interface has IP 192.168.5.1. Below the Router is Switch A. Switch A is connected to the Router via G2/20. Switch A has a Core Layer with SVI 1000:192.168.300.1, Supper vlan 1000, and Sub vlan:1001-2000. Switch A is connected to three other switches: Switch B (Office Area), Switch C (Staff Living Area), and Switch D (Student Living Area). All connections are Trunk links. Switch A's G2/1 interface is connected to Switch B (SVI 100:192.168.100.1), G2/2 to Switch C (SVI 200:192.168.200.1), and G2/3 to Switch D. Each switch is connected to a group of PCs. The Office Area (VLAN 100) has a Network Segment of 192.168.100.0/24 and a Gateway of 192.168.100.1/24. The Staff Living Area (VLAN 201-900) has a Network Segment of 192.168.200.0/24 and a Gateway of 192.168.200.1/24. The Student Living Area (VLAN 1001-2000) has a Network Segment of 192.168.300.0/24 and a Gateway of 192.168.300.1/24.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> On switch A (which is a core gateway device), set the authentication mode to gateway authentication.
<p>Switch A</p>	<pre>SwitchA(config)#auth-mode gateway Please save config and reload system. SwitchA(config)#exit *Nov 7 10:13:27: %SYS-5-CONFIG_I: Configured from console by console SwitchA#reload Reload system?(Y/N)y SwitchA#</pre>
<p>Verification</p>	<ul style="list-style-type: none"> Use the show running command to check whether the configuration has taken effect.
<p>Switch A</p>	<pre>SwitchA(config)#show running-config include auth-mode auth-mode gateway SwitchA(config)#</pre>

6.4.2 Configuring Authentication-Exemption VLANs

Configuration Effect

Configure authentication-exemption VLANs, so that users in these VLANs can access the Internet without experiencing dot1x or Web authentication.

Configure authentication-exemption VLANs on a port, so that only users in specified VLANs on the port can access the Internet without experiencing authentication.

Precautions

Authentication-exemption VLANs only mean that users in these VLANs do not need to experience a check related to access authentication, but still need to experience a check based on a security ACL. If specified users or VLANs are denied according to the security ACL, corresponding users still cannot access the Internet. Therefore, during ACL configuration, you need to ensure that specified VLANs or specified users in the authentication-exemption VLANs are not blocked if you hope that users in the authentication-exemption VLANs can access the Internet without being authenticated.

Configuration Method

Configuring Authentication-Exemption VLANs

- Optional configuration. To spare all users in certain VLANs from dot1x or Web authentication, configure these VLANs as authentication-exemption VLANs.
- Perform this configuration on access, convergence, or core switches depending on user distribution.
- Authentication-exemption VLANs can be configured in interface configuration mode.

Command	[no] direct-vlan <i>vlanlist</i>
Parameter Description	no: If the command carries this parameter, it indicates that the authentication-exemption VLAN configuration will be deleted. <i>vlanlist:</i> This parameter indicates the list of authentication-exemption VLANs to be configured or deleted.
Defaults	No authentication-exemption VLAN has been configured.
Command Mode	Global configuration mode, or interface configuration mode
Usage Guide	Use this command to configure or delete authentication-exemption VLANs.

Verification

Check the authentication-exemption VLAN configuration using the following method:

- Enable dot1x authentication on downlink ports that connect to user terminals, add the downlink ports that connect to the user terminals to a specific VLAN, and configure the VLAN as an authentication-exemption VLAN. Then open the Internet Explorer, and enter a valid extranet address (such as www.google.com). If the users can open the corresponding webpage on the Internet, it indicates that the authentication-exemption VLAN is valid; otherwise, the authentication-exemption VLAN does not take effect.
- Use the **show direct-vlan** command to check the authentication-exemption VLAN configuration on the device.

Command	show direct-vlan
Parameter Description	-

Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	Global configuration mode
Usage Example	<pre> Ruijie#show direct-vlan direct-vlan 100 Ruijie#show direct-vlan interface gi 0/1 Port direct-vlan ----- - Gi0/1 5, 7, 100 </pre>

Configuration Examples

i The following configuration example describes SCC-related configuration only.

Configuring Authentication-exemption VLANs so that Specific Users Can Access the Internet Without Being Authenticated

<p>Scenario Figure 6-3</p>	<p>The diagram illustrates a network architecture with a central Core Layer (Switch A) connected to three edge switches (Switch B, Switch C, and Switch D) via Trunk links. The Core Layer is connected to a Router, which is in turn connected to the Internet. The Core Layer includes a Supper vlan 1000 and Sub vlan:1001-2000. The edge switches are connected to three network segments: Headmaster's Office (Vlan 100), Staff Living Area (Vlan 201-900), and Student Living Area (Vlan 1001-2000). Each segment has its own gateway and network segment details.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> On switch A (which is the core gateway device), set the GI 2/1 port as a trunk port, and enable dot1x authentication on this port. On switch A (which is the core gateway device), configure VLAN 100 to which the headmaster's office belongs as an authentication-exemption VLAN.

Switch A	<pre>SwitchA(config)#vlan 100 SwitchA(config-vlan)#exit SwitchA(config)#direct-vlan 100 SwitchA(config)#int GigabitEthernet 0/1 SwitchA(config-if-GigabitEthernet 0/1)#switchport mode trunk SwitchA(config-if-GigabitEthernet 0/1)#dot1x port-control auto *Oct 17 16:06:45: %DOT1X-6-ENABLE_DOT1X: Able to receive EAPOL packet and DOT1X authentication enabled.</pre>
Verification	<ul style="list-style-type: none"> ● Open the Internet Explorer from any PC in the headmaster's office, enter a valid extranet address, and confirm that the corresponding webpage can be opened. ● Use the show direct-vlan command to check whether the authentication-exemption VLAN is valid.
Switch A	<pre>SwitchA(config)#show direct-vlan direct-vlan 100</pre>

6.4.3 Configuring the IPv4 User Capacity

Configuration Effect

Configure the IPv4 user capacity, so as to restrict the number of users who are allowed to access an access port.

Precautions

N/A

Configuration Method

▾ Configuring the IPv4 User Capacity

- Optional configuration. To limit the maximum of users who are allowed to access an access port, configure the IPv4 user capacity. The access user capacity is not limited on an access port by default. Suppose the user capacity limit is configured on a specific interface. When the number of authenticated users on the interface reaches the maximum, new users cannot be authenticated on this interface and cannot get online, until existing authenticated users get offline on the interface.
- Perform this configuration on access switches, which may be access switches on the network edge or core gateway devices.

Command	<p>nac-author-user maximum <i>max-user-num</i></p> <p>no nac-author-user maximum</p>
Parameter Description	<p>no: If the command carries this parameter, it indicates that the limit on the IPv4 access user capacity will be removed from the port.</p>

	<i>max-user-num</i> : This parameter indicates the maximum number of IPv4 users who allowed to access the port. The value range is from 1 to 1024.
Defaults	The number of IPv4 access users is not limited.
Command Mode	Interface configuration mode
Usage Guide	Use this command to limit the number of IPv4 access users on a specific access port.

Verification

Check the IPv4 user capacity configuration on a port using the following method:

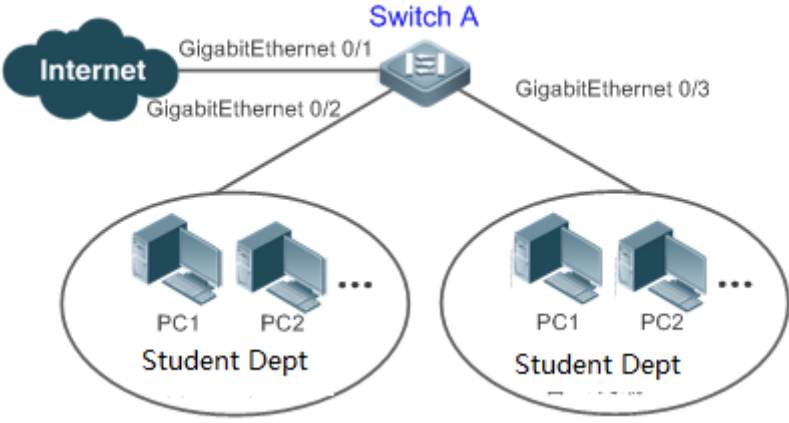

- dot1x authentication: When the number of users who get online based on 1x client authentication on the port reaches the specified user capacity, no any new user can get online from this port.
- Web authentication: When the number of users who get online based on Web authentication on the port reaches the specified user capacity, no any new user can get online from this port.
- Use the **show nac-author-user [interface interface-name]** command to check the IPv4 user capacity configured on the device.

Command	show nac-author-user [interface interface-name]
Parameter Description	interface-name : This parameter indicates the interface name.
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	Global configuration mode
Usage Example	<pre>Ruijie#show nac-author-user interface GigabitEthernet 0/1 Port Cur_num Max_num ----- - Gi0/1 0 4</pre>

Configuration Examples

 The following configuration example describes SCC-related configuration only.

- [Restricting the Number of IP4 Users on a Port to Prevent Excessive Access Terminals from Impacting the Network](#)

<p>Scenario Figure 6-4</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> Assume that the dot1x authentication environment has been well configured on the access switch A, and dot1x authentication is enabled on the Gi 0/2 port. Set the maximum number of IPv4 access users on the Gi 0/2 port to 4.
<p>Switch A</p>	<pre>SwitchA(config)#int GigabitEthernet 0/2 SwitchA(config-if-GigabitEthernet 0/2)#nac-author-user maximum 4</pre>
<p>Verification</p>	<ul style="list-style-type: none"> Perform dot1x authentication for all the four PCs in the dormitory, so that the PCs get online. Then take an additional terminal to access the network, and attempt to perform dot1x authentication for this terminal. Verify that the terminal cannot be successfully authenticated to get online. Use the show nac-author-user command to check whether the configuration has taken effect.
<p>Switch A</p>	<pre>SwitchA(config)#show nac-author-user Port Cur_num Max_num ----- Gi0/1 0 4</pre>

6.4.4 Configuring Authenticated-User Migration

Configuration Effect

By default, when a user gets online after passing dot1x or Web authentication at a physical location (which is represented by a specific access port plus the VLAN number) and quickly moves to another physical location without getting offline, the user cannot get online through dot1x or Web authentication from the new physical location, unless the authenticated-user migration feature has been configured in advance.

Precautions

- If the authenticated-user migration feature is not yet configured, an online user cannot get online from the new physical location after quickly moving from one physical location to another physical location without getting offline first. However,

if the user gets offline before changing the physical location or gets offline during the location change (for example, the user online-status detection function disconnects the user), the user can still normally get online after being authenticated at the new physical location, even if the authenticated-user migration feature is not configured.

- After moving to the new physical location, the online user needs to perform dot1x or Web authentication so as to get online.

Configuration Method

▾ Configuring Authenticated-User Migration

- Optional configuration. To allow users to be authenticated and get online from different physical locations, enable the authenticated-user migration function.
- Perform this configuration on access, convergence, or core switches depending on user distribution.

Command	[no] station-move permit
Parameter Description	no station-move permit: Indicates that authenticated-user migration is not permitted. station-move permit: Indicates that authenticated-user migration is permitted.
Defaults	Authenticated-user migration is not permitted; that is, when a user getting online from one physical location on the network moves to another physical location and attempts to get online from the new physical location without getting offline first, the authentication fails and the user cannot get online from the new physical location.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure authenticated-user migration.

Verification

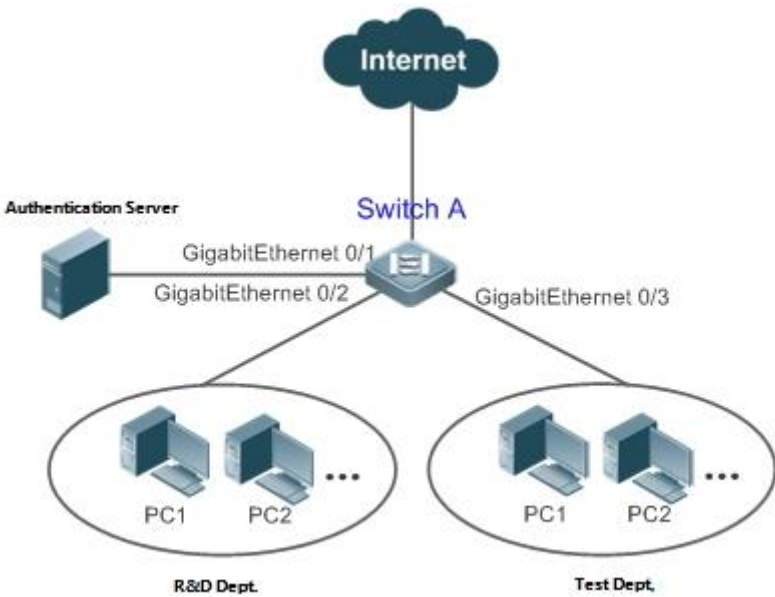

Check the authenticated-user migration configuration using the following method:

- A PC is authenticated and gets online from a dot1x-based port of the device using dot1x SU client, and does not actively get offline. Move the PC to another port of the device on which dot1x authentication is enabled, and perform dot1x authentication again. Check whether the PC can successfully get online.

Configuration Examples

 The following configuration example describes SCC-related configuration only.

▾ Configuring Online-User Migration so that an Online User Can Perform Authentication and Get Online from Different Ports Without Getting Offline First

<p>Scenario Figure 6-5</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable dot1x authentication on access ports Gi 0/2 and Gi 0/3, and configure authentication parameters. The authentication is MAC-based. ● Configure online-user migration.
<p>Switch A</p>	<pre>swl(config)#station-move permit</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● A lap-top PC in the R&D department performs authentication using dot1x SU client, and gets online. Remove the network cable from the PC, connect the PC to the LAN where the test department resides, and perform dot1x authentication for the PC again using dot1x SU client. Confirm that the PC can successfully get online.
<p>Switch A</p>	<pre>swl(config)#show running-config include station station-move permit</pre>

6.4.5 Configuring User Online-Status Detection

Configuration Effect

After the user online-status detection function is enabled, if a user's traffic is lower than a certain threshold within the specified period of time, the device automatically disconnects the user, so as to avoid the economical loss incurred by constant charging to the user.

Precautions

It should be noted that if disconnecting zero-traffic users is configured, generally software such as 360 Security Guard will run on a user terminal by default. Then such software will send packets time and again, and the device will disconnect the user only when the user's terminal is powered off.

Configuration Method

▾ Configuring User Online-Status Detection

- Optional configuration. A user is disconnected if the user does not involve any traffic within eight hours by default.
- Perform this configuration on access, convergence, or core switches depending on user distribution. The configuration acts on only the configured device instead of other devices on the network.
- If the traffic threshold parameter `threshold` is set to 0, it indicates that zero-traffic detection will be performed.

Command	offline-detect interval <i>interval</i> threshold <i>threshold</i> no offline-detect default offline-detect
Parameter Description	<i>interval</i> : This parameter indicates the offline-detection interval. The value range is from 6 to 65,535 in minutes on a switch <i>threshold</i> : This parameter indicates the traffic threshold. The value range is from 0 to 4294967294 in bytes. The default value is 0, indicating that the user is disconnected when no traffic of the user is detected. no offline-detect : Disables the user online-status detection function. default offline-detect : Restores the default value. In other words, an online user will be disconnected when the device detects that the user does not have any traffic within eight hours.
Defaults	8 hours
Command Mode	Global configuration mode
Usage Guide	Use this command to configure user online-status detection, so that a user is disconnected when its traffic is lower than a specific threshold within a specific period of time. Use the no offline-detect command to disable the user online-status detection function, or use the default offline-detect command to restore the default detection mode.

Verification

Check the user online-status detection configuration using the following method:

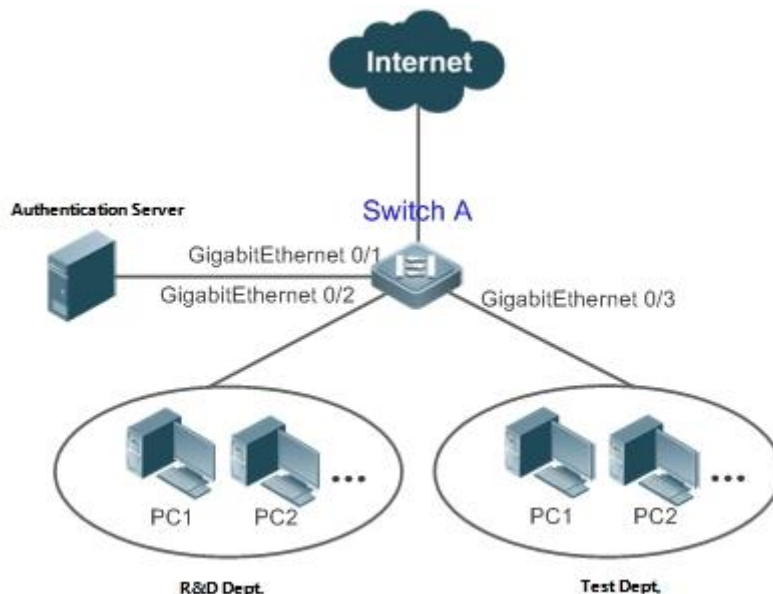

- After the user online-status detection function is enabled, power off the specified authenticated terminal after the corresponding user gets online. Then wait for the specified period of time, and run the online user query command associated with dot1x or Web authentication on the device to confirm that the user is already offline.

Configuration Examples

 The following configuration example describes SCC-related configuration only.

▾ Configuring User Online-Status Detection so that a User Is Disconnected if the User Does Not Have Traffic Within Five Minutes

Scenario
Figure 6-6

Configuration Steps

- Enable dot1x authentication on the access port Gi 0/2, and configure authentication parameters. The authentication is MAC-based.
- Configure user online-status detection so that a user is disconnected if the user does not have traffic within five minutes.

Switch A

```
sw1(config)# offline-detect interval 5 threshold 0
```

Verification

- Perform dot1x authentication using dot1x SU client for a PC in the R&D department, so that the PC gets online. Then power off the PC, wait for 6 minutes, and run the online user query command available with dot1x authentication on switch 1 to confirm that the user of the PC is already offline.

Switch A

```
sw1(config)#show running-config | include offline-detect
offline-detect interval 5
```

6.5 Monitoring

Displaying

Command	Function
<code>show direct-vlan</code>	Displays the authentication-exemption VLAN configuration.
<code>show nac-author-user [interface interface-name]</code>	Displays information about IPv4 user entries on a specific interface.

Debugging

 System resources are occupied when debugging information is output. Therefore, close the debugging switch immediately after use.

Command	Function
debug scc event	Debugs the SCC running process.
debug scc user [mac author mac]	Debugs SCC user entries.
debug scc acl-show summary	Debugs ACLs stored in the current SCC and delivered by various services.
debug scc acl-show all	Debugs all ALCs stored in the current SCC.

7 Configuring Global IP-MAC Binding

7.1 Overview

Enable the global IP-MAC binding function manually to verify the input packets. If a specified IP address is bound with a MAC address, the device receives only the IP packets containing matched IP address and MAC address. The other packets are discarded.

The address bounding feature is used to verify the input packets. Note that the address binding feature takes precedence over the 802.1X authentication, port security, and access control list (ACL).

7.2 Applications

Application	Description
Global IP-MAC Binding	Only hosts with the specified IP addresses can access the network, and the hosts connected to a device can move freely.

7.2.1 Global IP-MAC Binding

Scenario

The administrator assigns a fixed IP address for each host to facilitate management.

- Only hosts with the specified IP addresses can access the external network, which prevents IP address embezzlement by unauthorized hosts.
- Hosts can move freely under the same device.

Figure 7-1

Remarks	A is an access device. A user is a host configured with a static IP address.
----------------	---

IP Network is an external IP network.

Deployment

- Manually configure the global IP-MAC binding. (Take three users as an example.)

User	MAC Address	IP Address
User 1	00d0.3232.0001	192.168.1.10
User 2	00d0.3232.0002	192.168.1.20
User 3	00d0.3232.0003	192.168.1.30

- Enable the IP-MAC binding function globally.
- Configure the uplink port (Gi0/5 port in this example) of the device as the exclude port.

7.3 Features

Basic Concepts

IPv6 Address Binding Mode

IPv6 address binding modes include Compatible, Loose, and Strict. The default mode is Strict. If IPv4-MAC binding is not configured, the IPv6 address binding mode does not take effect, and all IPv4 and IPv6 packets are allowed to pass through. If IPv4-MAC binding is configured, the IPv6 address binding mode takes effect, and the device forwards IPv4 and IPv6 packets based on the forwarding rules described in the following table:

Mode	IPv4 Packet Forwarding Rule	IPv6 Packet Forwarding Rule
Strict	Packets matching the global IPv4-MAC binding are forwarded.	Packets matching the global IPv6-MAC binding are forwarded. (The binding is generated by other access security functions, such as port security and IPv6 Source Guard.)
Loose	Packets matching the global IPv4-MAC binding are forwarded.	If IPv6+MAC address binding is configured, packets matching the IPv6-MAC binding are forwarded. (The binding is generated by other access security functions, such as port security and IPv6 Source Guard.) If IPv6-MAC binding does not exist, all IPv6 packets are forwarded.
Compatible	Packets matching the global IPv4-MAC binding are forwarded.	If the IPv6 packets contain a MAC address matching the MAC address in the IPv4-MAC binding, the IPv6 packets are forwarded. Packets matching the global IPv6-MAC binding conditions are forwarded. (The binding is generated by other access security functions, such as port security and IPv6 Source Guard.)

Exclude Port

By default, the IP-MAC binding function takes effect on all ports of the device. You can configure exclude ports so that the address binding function does not take effect on these ports. In practice, the IP-MAC bindings of the input packets on the uplink port are not fixed. Generally, the uplink port of the device is configured as the exclude port so that the packets on the uplink port are not checked for IP-MAC binding.

Overview

Feature	Description
Configuring Global IP-MAC Binding	Control forwarding of IPv4 or IPv6 packets.
Configuring the IPv6 Address Binding Mode	Change the IPv6 packet forwarding rules.
Configuring the Exclude Port	Disable the global address binding function on the specified port.

7.3.1 Configuring Global IP-MAC Binding

Working Principle

Enable the global IP-MAC binding function manually to verify the input packets. If a specified IP address is bound with a MAC address, the device receives only the IP packets containing matched IP address and MAC address. The other packets are discarded.

Related Configuration

▾ [Configuring IP-MAC Binding](#)

Run the **address-bind** command in global configuration mode to add or delete an IPv4-MAC binding.

▾ [Enabling the IP-MAC Binding Function](#)

Run the **address-bind install** command in global configuration mode to enable the IP-MAC binding function. By default, this function is disabled.

7.3.2 Configuring the IPv6 Address Binding Mode

Working Principle

After the global IPv4-MAC binding is configured and enabled, IPv6 packets are forwarded based on the IPv6 address binding mode. IPv6 binding modes include Compatible, Loose, and Strict.

Related Configuration

▾ [Configuring the IPv6 Address Binding Mode](#)

By default, the IPv6 address binding mode is Strict.

Run the **address-bind ipv6-mode** command to specify an IPv6 address binding mode.

7.3.3 Configuring the Exclude Port

Working Principle

Configure an exclude port so that the address binding function does not take effect on this port.

Related Configuration

↘ [Configuring the Exclude Port](#)

Run the **address-bind uplink** command to configure an exclude port. By default, no port is the exclude port.

7.4 Configuration

Configuration	Description and Command	
Configuring Global IP-MAC Binding	⚠ (Mandatory) It is used to configure and enable address binding.	
	address-bind	Configures a global IPv4-MAC binding.
	address-bind install	Enables the address binding function.
Configuring the IPv6 Address Binding Mode	⚠ (Optional) It is used to configure the IPv6 address binding mode.	
	address-bind ipv6-mode	Configures the IPv6 address binding mode.
Configuring the Exclude Port	⚠ (Optional) It is used to disable the address binding function on a specified port.	
	address-bind uplink	Configures an exclude port.

7.4.1 Configuring Global IP-MAC Binding

Configuration Effect

- Configure a global IPv4-MAC binding.
- Enable the address binding function to control forwarding of the IPv4 or IPv6 packets.

Notes

- If you run the **address-bind install** command without IP-MAC binding configured, IP-MAC binding does not take effect and all packets are allowed to pass through.

Configuration Steps

↘ [Configuring Global IP-MAC Binding](#)

- (Mandatory) Perform this configuration in global configuration mode.

↘ [Enabling the Address Binding Function](#)

- (Mandatory) Perform this configuration in global configuration mode.

Verification

Run the **show run** or **show address-bind** command to check whether the configuration takes effect.

Related Commands

↘ Configuring Global IP-MAC Binding

Command	address-bind { <i>ip-address</i> <i>ipv6-address</i> } <i>mac-address</i>
Parameter	<i>ip-address</i> : Indicates the bound IPv4 address.
Description	<i>ipv6-address</i> : Indicates the bound IPv6 address. <i>mac-address</i> : Indicates the bound MAC address.
Command Mode	Global configuration mode
Configuration Usage	Run this command to configure the binding relationship between an IPv4/IPv6 address and a MAC address.

↘ Enabling the Address Binding Function

Command	address-bind install
Parameter	N/A
Description	
Command Mode	Global configuration mode
Configuration Usage	Run this command to enable the global IP-MAC binding function. This function is used to control forwarding of IPv4 or IPv6 packets.

Configuration Example

↘ Configuring Global IP-MAC Binding and Enabling Address Binding

Configuration Steps	<ul style="list-style-type: none"> ● Configure a global IPv4-MAC binding. ● Enable the address binding function.
	<pre>Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# address-bind 192.168.5.1 00d0.f800.0001 Ruijie(config)# address-bind install</pre>
Verification	Display the global IP-MAC binding on the device.
	<pre>Ruijie#show address-bind Total Bind Addresses in System : 1</pre>

IP Address	Binding MAC Addr
-----	-----
192.168.5.1	00d0.f800.0001

7.4.2 Configuring the IPv6 Address Binding Mode

Configuration Effect

- Change the IPv6 address binding mode so as to change the forwarding rules for IPv6 packets.

Configuration Steps

↳ Configuring the IPv6 Address Binding Mode

- (Optional) Perform this configuration when you want to change the forwarding rules for IPv6 packets.

Verification

- Run the **show run** command to check whether the configuration takes effect.

Related Commands

↳ Configuring the IPv6 Address Binding Mode

Command	address-bind ipv6-mode { compatible loose strict }
Parameter Description	compatible: Indicates the Compatible mode. loose: Indicates the Loose mode. strict: Indicates the strict mode.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuration Example

↳ Configuring the IPv6 Address Binding Mode

Configuration Steps	<ul style="list-style-type: none"> ● Configure a global IP-MAC binding. ● Enable the address binding function. ● Set the IPv6 address binding mode to Compatible.
	<pre>Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# address-bind 192.168.5.1 00d0.f800.0001 Ruijie(config)# address-bind install</pre>

	Ruijie(config)# address-bind ipv6-mode compatible
Verification	Run the show run command to display the configuration on the device.

7.4.3 Configuring the Exclude Port

Configuration Effect

- The address binding function is disabled on the exclude port, and all IP packets can be forwarded.

Notes

- The configuration can be performed only on a switching port or an L2 aggregate port.

Configuration Steps

▾ Configuring the Exclude Port

- (Optional) Perform this configuration in global configuration mode when you want to disable the address binding function on a specified port.

Verification

Run the **show run** or **show address-bind uplink** command to check whether the configuration takes effect.

Related Commands

▾ Configuring the Exclude Port

8 Configuring Password Policy

8.1 Overview

The Password Policy is a password security function provided for local authentication of the device. It is configured to control users' login passwords and login states.

 The following sections introduce password policy only.

Protocols and Standards

N/A

8.2 Features

Basic Concepts

Minimum Password Length

Administrators can set a minimum length for user passwords according to system security requirements. If the password input by a user is shorter than the minimum password length, the system does not allow the user to set this password but displays a prompt, asking the user to specify another password of an appropriate length.

Strong Password Detection

The less complex a password is, the more likely it is to crack the password. For example, a password that is the same as the corresponding account or a simple password that contains only characters or digits may be easily cracked. For the sake of security, administrators can enable the strong password detection function to ensure that the passwords set by users are highly complex. After the strong password detection function is enabled, a prompt will be displayed for the following types of passwords:

1. Passwords that are the same as corresponding accounts;
2. Simple passwords that contain characters or digits only.

Password Dictionary Detection

The so-called password dictionary is used in combination with password cracking software. It contains many conventional passwords, and therefore improves the cracking rate and shortens the time taken to crack a password.

The password dictionary detects the input password and prevents the user from configuring any password contained in itself, thereby improving the security of the password configured by the user and helping to guard against password cracking.

The password dictionary detection function detects a user-input password based on the following aspects:

- Detects a system-defaulted password dictionary: If the user-input password exists in the system-defaulted password dictionary, the user-configured password fails to pass the detection and the system displays a prompt indicating that the user cannot use this password.
- Detects a date dictionary, which is a birthday dictionary in most cases: The system detects a combination of four to eight digits for the user-input password, because the birthday password format is 4-digit **mmdd**, 5-digit **yymmdd** or **yymdd**, 6-digit **yymmdd** or **yyyymdd**, 7-digit **yyyymdd** or **yyyymdd**, or 8-digit **yyyymdd**, where the year **yy** ranges from 00 to 99, the year **yyyy** ranges from 1900 to 2100, the month **mm** ranges from 1 to 12, and the day **dd** ranges from 1 to 31.
- Detects a surname spelling dictionary: The system checks the user-input password against the spellings of the latest 100 common surnames.
- Detects a combination of the date dictionary and the name spelling dictionary: The system checks the user-input password against a combination of the date dictionary and the name spelling dictionary, which can be the combination of a birthday and a surname, the combination of a surname and a birthday, or a birthday or surname only.

📄 Password Life Cycle

The password life cycle defines the validity time of a user password. When the service time of a password exceeds the life cycle, the user needs to change the password.

If the user inputs a password that has already expired during login, the system will give a prompt, indicating that the password has expired and the user needs to reset the password. If the new password input during password resetting does not meet system requirements or the new passwords consecutively input twice are not the same, the system will ask the user to input the new password once again.

📄 Guard Against Repeated Use of Passwords

When changing the password, the user will set a new password while the old password will be recorded as the user's history records. If the new password input by the user has been used previously, the system gives an error prompt and asks the user to specify another password.

The maximum number of password history records per user can be configured. When the number of password history records of a user is greater than the maximum number configured for this user, the new password history record will overwrite the user's oldest password history record.

📄 Storage of Encrypted Passwords

Administrators can enable the storage of encrypted passwords for security consideration. When administrators run the **show running-config** command to display configuration or run the **write** command to save configuration files, various user-set passwords are displayed in the cipher text format. If administrators disable the storage of encrypted passwords next time, the passwords already in cipher text format will not be restored to plaintext passwords.

8.3 Configuration

Configuration	Description and Command
---------------	-------------------------

Configuring the Password Security Policy	 Optional configuration, which is used to configure a combination of parameters related to the password security policy.	
	password policy life-cycle	Configures the password life cycle.
	password policy min-size	Configures the minimum length of user passwords.
	password policy no-repeat-times	Sets the no-repeat times of latest password configuration, so that the passwords specified in these times of latest password configuration can no longer be used in future password configuration.
	password policy strong	Enables the strong password detection function.
	service password-encryption	Sets the storage of encrypted passwords.

Networking Requirements

- Provide a password security policy for local authentication of the device. Users can configure different password security policies to implement password security management.

Notes

- The configured password security policy is valid for global passwords (configured using the commands **enable password** and **enable secret**) and local user passwords (configured using the **username name password password** command). It is invalid for passwords in Line mode.

Configuration Steps

▾ Configuring the Password Life Cycle

- Optional
- Perform this configuration on each device that requires the configuration of a password life cycle unless otherwise stated.

▾ Configuring the Minimum Length of User Passwords

- Optional
- Perform this configuration on each device that requires a limit on the minimum length of user passwords unless otherwise stated.

▾ Setting the No-Repeat Times of Latest Password Configuration

- Optional
- Perform this configuration on each device that requires a limit on the no-repeat times of latest password configuration unless otherwise stated.

↘ Setting the Storage of Encrypted Passwords

- Optional
- Perform this configuration on each device that requires the storage of passwords in encrypted format unless otherwise stated.

Verification

Configure a local user on the device, and configure a valid password and an invalid password for the user.

- When you configure the valid password, the device correctly adds the password.
- When you configure the invalid password, the device displays a corresponding error log.

Related Commands

↘ Configuring the Password Life Cycle

Command Syntax	password policy life-cycle <i>days</i>
Parameter Description	life-cycle <i>days</i> : Indicates the password life cycle in the unit of days. The value range is from 1 to 65535.
Command Mode	Global configuration mode
Usage Guide	The password life cycle is used to define the validity period of user passwords. If the user logs in with a password whose service time already exceeds the life cycle, a prompt is given, asking the user to change the password.

↘ Configuring the Minimum Length of User Passwords

Command Syntax	password policy min-size <i>length</i>
Parameter Description	min-size <i>length</i> : Indicates the minimum length of passwords. The value range is from 1 to 31.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the minimum length of passwords. If the minimum length of passwords is not configured, users can input a password of any length.

↘ Setting the No-Repeat Times of Latest Password Configuration

Command Syntax	password policy no-repeat-times <i>times</i>
Parameter Description	no-repeat-times <i>times</i> : Indicates the no-repeat times of latest password configuration. The value range is from 1 to 31.
Command Mode	Global configuration mode

Usage Guide	<p>After this function is enabled, all old passwords used in the several times of latest password configuration will be recorded as the user's password history records. If the new password input by the user has been used previously, the system gives an error prompt and the password modification fails.</p> <p>You can configure the maximum number of password history records per user. When the number of password history records of a user is greater than the maximum number configured for the user, the new password history record will overwrite the user's oldest password history record.</p>
--------------------	--

▾ Enabling the Strong Password Detection Function

Command Syntax	password policy strong
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	<p>After the strong password detection function is enabled, a prompt is displayed for the following types of passwords:</p> <ol style="list-style-type: none"> 1. Passwords that are the same as corresponding accounts; 2. Simple passwords that contain characters or digits only.

▾ Setting the Storage of Encrypted Passwords

Command Syntax	service password-encryption
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	<p>Before the storage of encrypted passwords is set, all passwords used in the configuration process will be displayed and stored in plaintext format, unless the passwords are configured in cipher text format. You can enable the storage of encrypted passwords for security consideration. When you run the show running-config command to display configuration or run the write command to save configuration files, various user-set passwords are displayed in the cipher text format. If you disable the storage of encrypted passwords next time, the passwords already in cipher text format will not be restored to plaintext passwords.</p>

▾ Checking User-Configured Password Security Policy Information

Command Syntax	show password policy
Parameter Description	-
Command	Privileged EXEC mode/ Global configuration mode/ Interface configuration mode

Mode	
Usage Guide	Use this command to display the password security policy configured on the device.

8.4 Monitoring

Displaying

Command	Function
show password policy	Displays user-configured password security policy information.

9 Configuring Port Security

9.1 Overview

Port security is used to restrict access to a port. Source MAC addresses of packets can be used to restrict the packets that enter the ports of a switch. You can set the number of static MAC addresses or the number of MAC addresses that are dynamically learned to restrict the packets that can enter the port. Ports enabled with port security are called secure ports.

9.2 Applications

Application	Description
Allowing Only Specified Hosts to Use Ports	For network security, certain ports of a device can be used only by specified hosts.

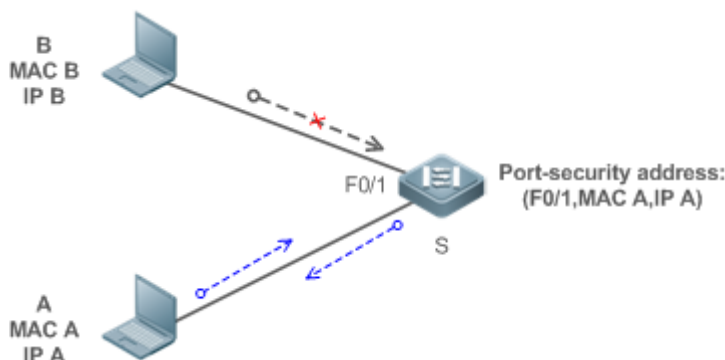

9.2.1 Allowing Only Specified Hosts to Use Ports

Scenario

In a scenario that has requirements for the network security, devices cannot be completely isolated physically. In this case, the devices need to be configured to restrict the PCs that connected to the ports of the devices.

- Only specified PCs can connect to the ports and normally use the network.
- Other PCs cannot use the network even if connected to the ports.
- After the configuration is complete, the administrator does not need to perform regular maintenance.

Figure 9-1

Remarks	S is the access device. A is a PC that can use the port F0/1. B is an unknown PC.
----------------	---

Deployment

- Enable ARP Check for port F0/1 (omitted).
- Enable port security on access device S and set the violation handling mode to protect.
- Set the maximum number of secure addresses allowed by port F0/1 to 1.
- Configure a static port security address on the port F0/1.

9.3 Features

Basic Concepts

Secure Port

Ports configured with port security are called secure ports. At present, Ruijie devices require that secure ports cannot be destination ports of mirroring.

Secure Addresses

Addresses bound to secure ports are called secure addresses. Secure addresses can be layer-2 addresses, namely MAC addresses, and can also be layer-3 addresses, namely, IP or IP+MAC addresses. When a secure address is bound to IP+MAC and a static secure MAC address is configured, the static secure MAC address must be the same as the MAC address bound to IP+MAC; otherwise, communication may fail due to inconsistency with the binding. Similarly, if only IP binding is set, only packets whose secure MAC addresses are statically configured or learned and whose source IP addresses are the bound IP address can enter the device.

Dynamic Binding

A method for a device to automatically learn addresses and convert learned addresses into secure addresses.

Static Binding

A command for manually binding secure addresses.

Aging of Secure Addresses

Regularly delete secure address records. Secure addresses for port security support aging configuration. You can specify only dynamically learned addresses for aging or specify both statically configured and dynamically learned secure addresses for aging.

Sticky MAC Address

Convert dynamically learned secure addresses into statically configured addresses. Addresses will not age. After the configurations are saved, dynamic secure addresses will not be learned again upon restart. If this function is not enabled, the secure MAC addresses dynamically learned must be learned again after device restart.

Security Violation Events

When the number of learned MAC addresses learned by a port exceeds the maximum number of secure addresses, security violation events will be triggered. You can configure the following modes for handing security violation events:

- protect: When security violation occurs, a corresponding secure port will stop learning MAC addresses and discard all packets of newly accessed users. This is the default mode for handling violation.
- restrict: When violation occurs, a port violation trap notification will be sent in addition to the behavior in the protect mode.
- shutdown: When violation occurs, the port will be disabled in addition to the behaviors in the preceding two modes.

↘ Maximum Number of Secure Addresses

The maximum number of secure addresses indicates the total number of secure addresses statically configured and dynamically learned. When the number of secure addresses under a secure port does not reach the maximum number of secure addresses, the secure port can dynamically learn new dynamic secure addresses. When the number of secure addresses reaches the maximum number, the secure port will not learn dynamic secure addresses any longer. If new users access the secure port in this case, security violation events will occur.

Overview

Feature	Description
Enabling Port Security	Creates a secure address list for a port.
Filtering Layer-2 Users	Processes the packets received by a port from non-secure addresses.
Filtering Layer-3 Users	Checks the layer-2 and layer-3 addresses of packets passing a port.
Aging of Secure Addresses	Regularly deletes secure addresses.

9.3.1 Enabling Port Security

Enable port security for a port to restrict packets that access the network through the port.

Working Principle

When port security is enabled, the device security module will check the sources of received packets. Only packets from addresses in the secure address list can be normally forwarded; otherwise, the packets will be discarded or the port performs other violation handling behaviors.

When the port security and 802.1x are configured at the same time, packets can enter a switch only when the MAC addresses of the packets meet the static MAC address configurations of 802.1x or port security. If a port is configured with a secure channel or is bound to global IP+MAC, packets in compliance with the secure channel or bound to global IP+MAC can avoid checking of port security.

Related Configuration

↘ Enabling Port Security for a Port

By default, port security is disabled.

You can run the **switchport port-security** command to enable or disable the port security function for a port.

You cannot enable this function for a destination port of SPAN.

▾ Setting the Maximum Number of Secure Addresses for a Port

By default, the maximum number of secure addresses for a port is 128.

You can run the **switchport port-security maximum** command to adjust the maximum number of secure addresses for the port.

A smaller number of secure addresses mean fewer users that access the network through this port.

▾ Setting the Mode for Handling Violation

By default, when the number of secure addresses reaches the maximum number, the secure port will discard packets from unknown addresses (none of the secure addresses of the port).

You can run the **switchport port-security violation** command to modify the violation handling mode.

▾ Setting Secure Addresses That Can Be Dynamically Saved

By default, no secure address dynamically learned will be saved.

You can run the **switchport port-security mac-address sticky** command to save dynamically learned addresses to the configuration file. As long as the configuration file is saved, the device does not need to re-learn the secure addresses after the device is restarted.

9.3.2 Filtering Layer-2 Users

Set the secure addresses on a port to ensure that only devices whose MAC addresses are the same as the secure addresses can access the network through this port.

Working Principle

Add secure addresses for a secure port. When the number of secure addresses for a secure port does not reach the maximum number, the secure port can dynamically learn new dynamic secure addresses. When the number of secure addresses for the secure port reaches the maximum number, the secure port will not learn dynamic secure addresses any longer. The MAC addresses of users connecting to this port must be in the secure address list; otherwise, violation events will be triggered.

Related Configuration

▾ Adding Secure Addresses for a Secure port

By default, a port dynamically learns secure addresses. If an administrator has special requirements, the administrator can manually configure secure addresses.

You can run the **switch portport-security interface** command to add or delete secure addresses for a device.

9.3.3 Filtering Layer-3 Users

Add binding of secure addresses and check layer-2 and layer-3 addresses of packets passing a port.

Working Principle

Layer-3 secure addresses support only IP binding and IP+MAC binding, and supports only static binding (not dynamic binding).

When a layer-3 secure port receives packets, layer-2 and layer-3 addresses need to be parsed. Only packets whose addresses are bound are valid packets. Other packets are considered as invalid packets and will be discarded, but no violation event will be triggered.

Related Configuration

📌 [Configuring Binding of Secure Addresses on Secure Ports](#)

Binding of layer-3 secure addresses must be added manually.

You can run the **switchport port-security binding** command to add binding of secure addresses.

If only IP addresses are input, only IP addresses are bound. If IP addresses and MAC addresses are input, IP+MAC will be bound.

9.3.4 Aging of Secure Addresses

Regularly delete secure addresses. When this function is enabled, you need to set the maximum number of secure addresses. In this way, the device can automatically add and delete secure addresses on this port.

Working Principle

Enable the aging timer to regularly query and delete secure addresses whose aging time expires.

Related Configuration

📌 [Configuring Aging Time of Secure Addresses](#)

By default, no secure address of a port will be aged.

You can run the **switchport port-security aging** command to enable aging time.

The **static** parameter can be used to age static addresses.

9.4 Configuration

Configuration	Description and Command	
Configuring Secure ports and Violation Handling Modes	 (Mandatory) It is used to enable the port security service.	
	switchport port-security	Enables port security.

	switchport port-security maximum	Sets the maximum number of secure addresses for a port.
	switchport port-security violation	Configures the violation handling mode for port security.
	switchport port-security mac-address sticky	Configures automatic saving of dynamic addresses.
Configuring Secure Addresses on Secure Ports	 (Optional) It is used to configure security filtering items.	
	switchport port-security mac-address	Configures the static secure addresses in the interface configuration mode.
	switchport port-security interface mac-address	Configures the static secure addresses in the global configuration mode.
	switchport port-security binding	Configures binding of secure addresses in the interface configuration mode.
	switchport port-security interface binding	Configures binding of secure addresses in the global configuration mode.
	switchport port-security aging	Configures aging time for all secure addresses on a port.

9.4.1 Configuring Secure ports and Violation Handling Modes

Configuration Effect

- Restrict the number of MAC addresses that can be learned from a port.
- Filter invalid packets based on MAC addresses, IP addresses or IP+MAC.

Notes

- A secure port cannot be the destination port of SPAN.
- The port security function cannot be configured for a DHCP Snooping trusted port.
- The port security function cannot be configured for excluded ports of global IP+MAC.
- The security function can be enabled only for wired switching ports and layer-2 AP ports in the interface configuration mode.
- The port security can work with other access control functions such as the 802.1x, global IP+MAC binding, and IP source guard. When these functions are used together, packets can enter a switch only when passing all security checks. If a security channel is configured for a port, packets in compliance with the security channel will avoid checking of the port security.

Configuration Steps

▾ Enabling the Port Security Service

- Mandatory.

- If there is no special requirement, enable the port security service for a port on the access device.

↘ **Configuring the Maximum Number of Secure Addresses for a Port**

- Optional. To adjust the maximum number of secure addresses running on a secure port, you can configure this item.
- Configure this item on a port enabled with port security.

↘ **Configuring Violation Handling Modes**

- Optional. If you hope that other handling modes except discarding packets are implemented in case of violation, you can configure other handling modes.
- Configure this item on a port enabled with port security.

↘ **Saving Dynamically Learned Addresses**

- Optional. If you hope that secure addresses are not re-learned after the device is restarted, you can configure this item.
- Configure this item on a port enabled with port security.

Verification

Run the command of the device for displaying the port security configurations to check whether the configurations take effect.

Related Commands

↘ **Setting Port Security**

Command	switchport port-security
Parameter Description	-
Command Mode	Interface configuration mode
Usage Guide	By using the port security feature, you can strictly control the input of a port of a device by restricting the MAC addresses and IP addresses (optional) that access the port.

↘ **Setting the Maximum Number of Secure Addresses for a Port**

Command	switchport port-security maximum <i>value</i>
Parameter Description	<i>value</i> : Indicates the number of secure addresses, ranging from 1 to 128.
Command Mode	Interface configuration mode
Usage Guide	If you set the maximum number to 1 and configure a secure address for this port, the workstation (whose address is the configured secure address) connected to this port will exclusively use all bandwidth of the port.

↘ **Configuring the Violation Handling Mode for Port Security**

Command	switchport port-security violation { protect restrict shutdown }
Parameter	protect: Discards violated packets.
Description	restrict: Discards violated packets and send trap notifications. shutdown: Discards packets and disables the port.
Command Mode	Interface configuration mode
Usage Guide	-

▾ Saving Dynamic Secure Addresses to a Configuration File

Command	switchport port-security mac-address sticky mac-address [vlan vlan-id]
Parameter	<i>mac-address</i> : Indicates a static secure address.
Description	<i>vlan-id</i> : Indicates the VID of a MAC address.
Command Mode	Interface configuration mode
Usage Guide	-

Configuration Example

▾ Enabling Port Security for the Port gigabitethernet 0/3, Setting the Maximum Number of Addresses to 8, and Setting the Violation Handling Mode to protect

Configuration Steps	<ul style="list-style-type: none"> ● Enable port security. ● Set the maximum number of secure addresses. ● Modify the violation handling mode.
	<pre>Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# interface gigabitethernet 0/3 Ruijie(config-if-GigabitEthernet 0/3)# switchport mode access Ruijie(config-if-GigabitEthernet 0/3)# switchport port-security Ruijie(config-if-GigabitEthernet 0/3)# switchport port-security maximum 8 Ruijie(config-if-GigabitEthernet 0/3)# switchport port-security violation protect Ruijie(config-if-GigabitEthernet 0/3)# switchport port-security mac-address sticky Ruijie(config-if-GigabitEthernet 0/3)# end</pre>
Verification	Check the port security configuration on the device.
	<pre>Ruijie# show port-security interface gigabitethernet 0/3 Interface : Gi0/3 Port Security: Enabled</pre>

```
Port status : down
Violation mode: Protect
Maximum MAC Addresses:8
Total MAC Addresses:0
Configured MAC Addresses:0
Aging time : 0 mins
SecureStatic address aging : Disabled
```

Common Errors

- Port security is enabled on a SPAN port.
- Port security is enabled on a DHCP trusted port.
- The configured maximum number of secure addresses is smaller than the number of existing secure addresses.

9.4.2 Configuring Secure Addresses on Secure Ports

Configuration Effect

- Allow specified users to use ports.
- Regularly update secure addresses of users.

Notes

- Sticky MAC addresses are special MAC addresses not affected by the aging mechanism. No matter dynamic or static aging is configured, sticky MAC addresses will not be aged.

Configuration Steps

↘ Configuring Secure Addresses

- Optional. You need to manually add secure addresses for configuration.
- Configure this item on a port enabled with port security.

↘ Configuring Binding of Secure Addresses

- Optional. You need to add layer-3 secure addresses for configuration.
- Configure this item on a port enabled with port security.

↘ Configuring Aging Time

- Optional.
- Configure this item on a port enabled with port security.

Verification

- Run the command of the device for displaying the port security configurations to check whether the configurations take effect.

10 Configuring Storm Control

10.1 Overview

When a local area network (LAN) has excess broadcast data flows, multicast data flows, or unknown unicast data flows, the network speed will slow down and packet transmission will have an increased timeout probability. This situation is called a LAN storm. A storm may occur when topology protocol execution or network configuration is incorrect.

Storm control can be implemented to limit broadcast data flows, multicast data flows, or unknown unicast data flows. If the rate of data flows received by a device port is within the configured bandwidth threshold, packets-per-second threshold, or kilobits-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the thresholds, excess data flows are discarded until the rate falls within the thresholds. This prevents flood data from entering the LAN causing a storm.

10.2 Applications

Application	Description
Network Attack Prevention	Enable storm control to prevent flooding.

10.2.1 Network Attack Prevention

Scenario

The application requirements of network attack prevention are described as follows:

- Protect devices from flooding of broadcast packets, multicast packets, or unknown unicast packets.

Figure 10-1

Remarks	Switch A and Switch B are access devices. PC 1, PC 2, PC 3, and PC 4 are desktop computers.
----------------	--

Deployment

- Enable storm control on the ports of all access devices (Switch A and Switch B).

10.3 Features

Basic Concepts

▾ Storm Control

If the rate of data flows (broadcast packets, multicast packets, or unknown unicast packets) received by a device port is within the configured bandwidth threshold, packets-per-second threshold, or kilobits-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the thresholds, excess data flows are discarded until the rate falls within the thresholds.

▾ Storm Control Based on the Bandwidth Threshold

If the rate of data flows received by a device port is within the configured bandwidth threshold, the data flows are permitted to pass through. If the rate exceeds the threshold, excess data flows are discarded until the rate falls within the threshold.

▾ Storm Control Based on the Packets-per-Second Threshold

If the rate of data flows received by a device port is within the configured packets-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the threshold, excess data flows are discarded until the rate falls within the threshold.

▾ Storm Control Based on the Kilobits-per-Second Threshold

If the rate of data flows received by a device port is within the configured kilobits-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the threshold, excess data flows are discarded until the rate falls within the threshold.

Overview

Feature	Description
Unicast Packet Storm Control	Limits unknown unicast packets to prevent flooding.
Multicast Packet Storm Control	Limits multicast packets to prevent flooding.
Broadcast Packet Storm Control	Limits broadcast packets to prevent flooding.

10.3.1 Unicast Packet Storm Control

The unicast packet storm control feature monitors the rate of unknown unicast data flows received by a device port to limit LAN traffic and prevent flooding caused by excess data flows.

Working Principle

If the rate of unknown unicast data flows received by a device port is within the configured bandwidth threshold, packets-per-second threshold, or kilobits-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the thresholds, excess data flows are discarded until the rate falls within the thresholds.

Related Configuration

↳ **Enabling Unicast Packet Storm Control on Ports**

By default, unicast packet storm control is disabled on ports.

Run the **storm-control unicast** [{ **level percent** | **pps packets** | *rate-bps* }] command to enable unicast packet storm control on ports.

Run the **no storm-control unicast** or **default storm-control unicast** command to disable unicast packet storm control on ports.

The default command parameters are determined by related products.

10.3.2 Multicast Packet Storm Control

The multicast packet storm control feature monitors the rate of multicast data flows received by a device port to limit LAN traffic and prevent flooding caused by excess data flows.

Working Principle

If the rate of multicast data flows received by a device port is within the configured bandwidth threshold, packets-per-second threshold, or kilobits-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the thresholds, excess data flows are discarded until the rate falls within the thresholds.

Related Configuration

↳ **Enabling Multicast Packet Storm Control on Ports**

By default, multicast packet storm control is disabled on ports.

Run the **storm-control multicast** [{ **level percent** | **pps packets** | *rate-bps* }] command to enable multicast packet storm control on ports.

Run the **no storm-control multicast** or **default storm-control multicast** command to disable multicast packet storm control on ports.

The default command parameters are determined by related products.

10.3.3 Broadcast Packet Storm Control

The broadcast packet storm control feature monitors the rate of broadcast data flows received by a device port to limit LAN traffic and prevent flooding caused by excess data flows.

Working Principle

If the rate of broadcast data flows received by a device port is within the configured bandwidth threshold, packets-per-second threshold, or kilobits-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the thresholds, excess data flows are discarded until the rate falls within the thresholds.

Related Configuration

↳ Enabling Broadcast Packet Storm Control on Ports

By default, broadcast packet storm control is disabled on ports.

Run the **storm-control broadcast** [{ *level percent* | **pps packets** | *rate-bps* }] command to enable broadcast packet storm control on ports.

Run the **no storm-control broadcast** or **default storm-control broadcast** command to disable broadcast packet storm control on ports.

10.4 Configuration

Configuration	Description and Command
Configuring Basic Functions of Storm Control	 (Mandatory) It is used to enable storm control.
	storm-control { broadcast multicast unicast } [{ <i>level percent</i> pps packets <i>rate-bps</i> }] Enables storm control.

10.4.1 Configuring Basic Functions of Storm Control

Configuration Effect

- Prevent flooding caused by excess broadcast packets, multicast packets, and unknown unicast packets.

Notes

- When you run a command (for example, **storm-control unicast**) to enable storm control, if you do not set the parameters, the default values are used.

Configuration Steps

↳ Enabling Unicast Packet Storm Control

- Mandatory.
- Enable unicast packet storm control on every device unless otherwise specified.

↳ Enabling Multicast Packet Storm Control

- Mandatory.
- Enable multicast packet storm control on every device unless otherwise specified.

▾ Enabling Broadcast Packet Storm Control

- Mandatory.
- Enable broadcast packet storm control on every device unless otherwise specified.

Verification

- Run the **show storm-control** command to check whether the configuration is successful.

Related Commands

▾ Enabling Unicast Packet Storm Control

Command	storm-control unicast [{ level percent pps packets <i>rate-bps</i> }]
Parameter	level percent : Indicates the bandwidth percentage.
Description	pps packets : Indicates the number of packets per second. <i>rate-bps</i> : Indicates the packet rate.
Command Mode	Interface configuration mode
Usage Guide	Storm control can be enabled only on switch ports.

▾ Enabling Multicast Packet Storm Control

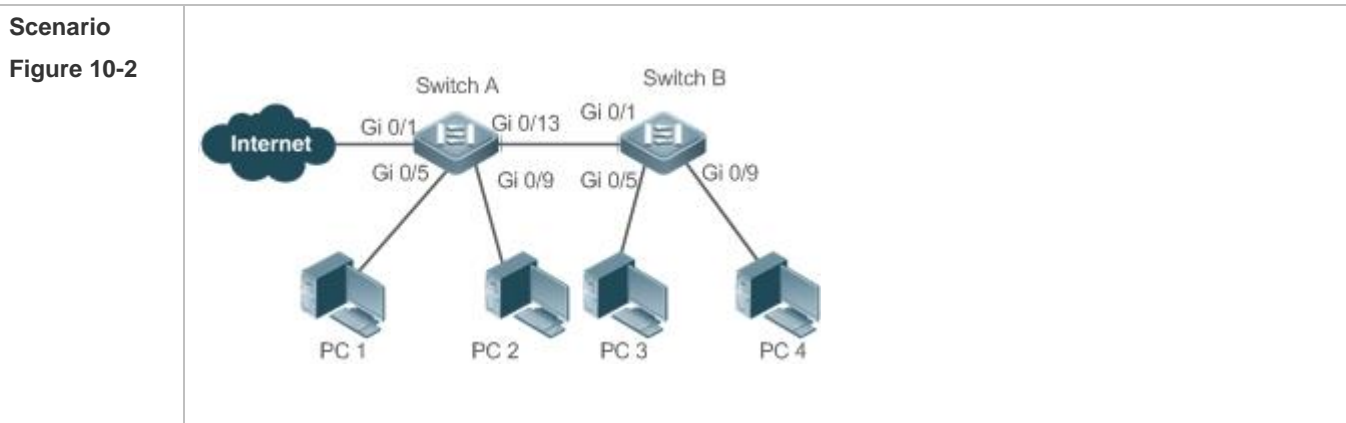

Command	storm-control multicast [{ level percent pps packets <i>rate-bps</i> }]
Parameter	level percent : Indicates the bandwidth percentage.
Description	pps packets : Indicates the number of packets per second. <i>rate-bps</i> : Indicates the packet rate.
Command Mode	Interface configuration mode
Usage Guide	Storm control can be enabled only on switch ports.

▾ Enabling Broadcast Packet Storm Control

Command	storm-control broadcast [{ level percent pps packets <i>rate-bps</i> }]
Parameter	level percent : Indicates the bandwidth percentage.
Description	pps packets : Indicates the number of packets per second. <i>rate-bps</i> : Indicates the packet rate.
Command Mode	Interface configuration mode
Usage Guide	Storm control can be enabled only on switch ports.

Configuration Example

▾ Enabling Storm Control on Devices

Configuration Step

- Enable storm control on Switch A and Switch B.

Switch A

```
Ruijie(config)#interface range gigabitEthernet 0/5,0/9,0/13
Ruijie(config-if-range)#storm-control broadcast
Ruijie(config-if-range)#storm-control multicast
Ruijie(config-if-range)#storm-control unicast
```

Switch B

```
Ruijie(config)#interface range gigabitEthernet 0/1,0/5,0/9
Ruijie(config-if-range)#storm-control broadcast
Ruijie(config-if-range)#storm-control multicast
Ruijie(config-if-range)#storm-control unicast
```

Verification Check whether storm control is enabled on Switch A and Switch B.

Switch A

```
Ruijie# sho storm-control
Interface                Broadcast Control Multicast Control Unicast Control Action
-----
GigabitEthernet 0/1      Disabled          Disabled          Disabled  none
GigabitEthernet 0/5      default          default          default   none
GigabitEthernet 0/9      default          default          default   none
GigabitEthernet 0/13     default          default          default   none
```

Switch B

```
Ruijie#sho storm-control
Interface                Broadcast Control Multicast Control Unicast Control Action
-----
GigabitEthernet 0/1      default          default          default   none
```

	GigabitEthernet 0/5	default	default	default	none
	GigabitEthernet 0/9	default	default	default	none

10.5 Monitoring

Displaying

Displays storm control information.	show storm-control [<i>interface-type interface-number</i>]

11 Configuring SSH

11.1 Overview

Secure Shell (SSH) connection is similar to a Telnet connection except that all data transmitted over SSH is encrypted. When a user in an insecure network environment logs into a device remotely, SSH helps ensure information security and powerful authentication, protecting the device against attacks such as IP address spoofing and plain-text password interception.

An SSH-capable device can be connected to multiple SSH clients. In addition, the device can also function as an SSH client, and allows users to set up an SSH connection with a SSH-server device. In this way, the local device can safely log in to a remote device through SSH to implement management.

-  Currently, a device can work as either the SSH server or an SSH client, supporting SSHv1 and SSHv2 versions. Ruijie SSH service supports both IPv4 and IPv6.
-  Unless otherwise specified, SSH in this document refers to SSHv2.

Protocols and Standards

- RFC 4251: The Secure Shell (SSH) Protocol Architecture
- RFC 4252: The Secure Shell (SSH) Authentication Protocol
- RFC 4253: The Secure Shell (SSH) Transport Layer Protocol
- RFC 4254: The Secure Shell (SSH) Connection Protocol
- RFC 4419: Diffie-Hellman Group Exchange for the Secure Shell (SSH) Transport Layer Protocol
- RFC 4716: The Secure Shell (SSH) Public Key File Format
- RFC 4819: Secure Shell Public Key Subsystem
- RFC 3526: More Modular Exponential (MODP) Diffie-Hellman groups for Internet Key Exchange (IKE)
- RFC 2409: The Internet Key Exchange (IKE)
- RFC 1950: ZLIB Compressed Data Format Specification version 3.3
- draft-ietf-secsh-filexfer-05: SSH File Transfer Protocol
- draft-ylonen-ssh-protocol-00: The version of the SSH Remote Login Protocol is 1.5. Comware implements the SSH server functions, but not the SSH client functions.

11.2 Applications

Application	Description
SSH Device Management	Use SSH to manage devices.
SSH Local Line Authentication	Use the local line password authentication for SSH user authentication.

Application	Description
SSH AAA Authentication	Use the authentication, authorization and accounting (AAA) mode for SSH user authentication.
SSH Public Key Authentication	Use the public key authentication for SSH user authentication.
SSH File Transfer	Use the Secure Copy (SCP) commands on the client to exchange data with the SSH server.
SSH Client Application	Use the SSH client to safely log in to a remote device for management.

11.2.1 SSH Device Management

Scenario

You can use SSH to manage devices on the precondition that the SSH server function is enabled. By default, this function is disabled. The Telnet component that comes with the Windows system does not support SSH. Therefore, a third-party client software must be used. Currently, well-compatible software includes PuTTY, Linux, and SecureCRT. The following takes the PuTTY as an example to introduce the configurations of the SSH client. Figure 11-1 shows the network topology.

Figure 11-1 Networking Topology of SSH Device Management

Deployment

Configure the SSH client as follows:

- Start the PuTTY software.
- On the **Session** option tab of PuTTY, type in the host IP address of the SSH server and SSH port number **22**, and select the connection type **SSH**.
- On the **SSH** option tab of PuTTY, select the preferred SSH protocol version **2**.
- On the **SSH authentication** option tab of PuTTY, select the authentication method **Attempt "keyboard-interactive" auth**.
- Click **Open** to connect to the SSH server.
- Type in the correct user name and password to enter the terminal login interface.

11.2.2 SSH Local Line Authentication

Scenario

SSH clients can use the local line password authentication mode, as shown in Figure 11-2. To ensure security of data exchange, PC 1 and PC 2 function as the SSH clients, and use the SSH protocol to log in to the network device where the SSH server function is enabled. The requirements are as follows:

- SSH users use the local line password authentication mode.
- Five lines, including Line 0 to Line 4, are activated concurrently. The login password is "passzero" for Line 0 and "pass" for the remaining lines. Any user name can be used.

Figure 11-2 Networking Topology of SSH Local Line Password Authentication

Deployment

- Configure the SSH server as follows:
 1. Enable the SSH server function globally. By default, the SSH server supports two SSH versions: SSHv1 and SSHv2.
 2. Configure the key. With this key, the SSH server decrypts the encrypted password received from the SSH clients, compares the decrypted plain text with the password stored on the server, and returns a message indicating the successful or unsuccessful authentication. SSHv1 uses an RSA key, whereas SSHv2 adopts an RSA or DSA key.
 3. Configure the IP address of the FastEthernet 0/1 interface on the SSH server. The SSH client is connected to the SSH server using this IP address. The routes from the SSH clients to the SSH server are reachable.

- Configure the SSH client as follows:

Diversified SSH client software is available, including PuTTY, Linux, and OpenSSH. This document takes PuTTY as an example to explain the method for configuring the SSH clients.

1. Open the PuTTY connection tab, and select SSHv1 for authenticated login. (The method is similar if SSHv2 is selected.)
2. Set the IP address and connected port ID of the SSH server. As shown in the network topology, the IP address of the server is 192.168.23.122, and the port ID is 22. Click Open to start the connection. As the current authentication mode does not require a user name, you can type in any user name, but cannot be null. (In this example, the user name is "anyname".)

11.2.3 SSH AAA Authentication

Scenario

SSH users can use the AAA authentication mode for user authentication, as shown in Figure 11-3. To ensure security of data exchange, the PCs function as the SSH clients, and uses the SSH protocol to log in to the network device where the SSH

server is enabled. To better perform security management, the AAA authentication mode is used for user login on the SSH clients. Two authentication methods, including Radius server authentication and local authentication, are provided in the AAA authentication method list to ensure reliability. The Radius server authentication method is preferred. If the Radius server does not respond, it turns to the local authentication.

Figure 11-3 Networking Topology of SSH AAA Authentication

Deployment

- The routes from the SSH clients to the SSH server are reachable, and the route from the SSH server to the Radius server is also reachable.
- Configure the SSH server on the network device that functions as an SSH client.
- Configure the AAA parameters on the network device. When the AAA authentication mode is used, method lists are created to define the identity authentication and types, and applied to a specified service or interface.

11.2.4 SSH Public Key Authentication

Scenario

SSH clients can use the public keys for authentication, and the public key algorithm can be RSA or DSA, as shown in Figure 11-4. SSH is configured on the client so that a secure connection is set up between the SSH client and the SSH server.

Figure 11-4 Network Topology for Public Key Authentication of SSH Users

Deployment

- To implement public key authentication for the client, generate a key pair (RSA or DSA) on the client, configure the public key on the SSH server, and select the public key authentication mode.

- After the key is generated on the client, the SSH server will copy the file of the public key from the client to the flash and associates the file with the SSH user name. Each user can be associated with one RSA public key and one DSA public key.

11.2.5 SSH File Transfer

Scenario

The SCP service is enabled on the server, and SCP commands are used on the client to transfer data to the server, as shown in Figure 11-5.

Figure 11-5 Networking Topology of SSH File Transfer

Deployment

- Enable the SCP service on the server.
- On the client, use SCP commands to upload files to the server, or download files from the server.

11.2.6 SSH Client Application

Scenario

The SSH service is enabled on a remote SSH server, and the **ssh** command is used on the local client to set up an SSH connection with the server for secure data transmission, as shown in Figure 11-6.

Figure 11-6 Networking Topology of SSH Client Application

Deployment

- Enable the SSH service on the server.
- On the client, run the **ssh** command to set up an SSH connection with the server for secure data transmission.

11.3 Features

Basic Concepts

↘ User Authentication Mechanism

- Password authentication

During the password authentication, a client sends a user authentication request and encrypted user name and password to the server. The server decrypts the received information, compares the decrypted information with those stored on the server, and then returns a message indicating the successful or unsuccessful authentication.

- Public key authentication

During the public key authentication, digital signature algorithms, such as RSA and DSA, are used to authenticate a client. The client sends a public key authentication request to the server. This request contains information including the user name, public key, and public key algorithm. On receiving the request, the server checks whether the public key is correct. If wrong, the server directly sends an authentication failure message. If right, the server performs digital signature authentication on the client, and returns a message indicating the successful or unsuccessful authentication.

 Public key authentication is applicable only to the SSHv2 clients.

SSH Communication

To ensure secure communication, interaction between an SSH server and an SSH client undergoes the following seven stages:

- Connection setup

The server listens on Port 22 to the connection request from the client. After originating a socket initial connection request, the client sets up a TCP socket connection with the server.

- Version negotiation

If the connection is set up successfully, the server sends a version negotiation packet to the client. On receiving the packet, the client analyzes the packet and returns a selected protocol version to the server. The server analyzes the received information to determine whether version negotiation is successful.

- Key exchange and algorithm negotiation

If version negotiation is successful, key exchange and the algorithm negotiation are performed. The server and the client exchange the algorithm negotiation packet with each other, and determine the final algorithm based on their capacity. In addition, the server and the client work together to generate a session key and a session ID according to the key exchange algorithm and host key, which will be applied to subsequent user authentication, data encryption, and data decryption.

- User authentication

After the encrypted channel is set up, the client sends an authentication request to the server. The server repeatedly conducts authentication for the client until the authentication succeeds or the server shuts down the connection because the maximum number of authentication attempts is reached.

- Session request

After the successful authentication, the client sends a session request to the server. The server waits and processes the client request. After the session request is successfully processed, SSH enters the session interaction stage.

- Session interaction

After the session request is successfully processed, SSH enters the session interaction stage. Encrypted data can be transmitted and processed in both directions. The client sends a command to be executed to the client. The server decrypts, analyzes, and processes the received command, and then sends the encrypted execution result to the client. The client decrypts the execution result.

- Session ending

When the interaction between the server and the client is terminated, the socket connection disconnects, and the session ends.

Overview

Feature	Description
SSH Server	Enable the SSH server function on a network device, and you can set up a secure connection with the network device through the SSH client.
SCP Service	After the SCP service is enabled, you can directly download files from the network device and upload local files to the network device. In addition, all interactive data is encrypted, featuring authentication and security.
SSH Client	You can use the SSH client on the device to set up a secure connection with the SSH server on a network device.

11.3.1 SSH Server

Enable the SSH server function on a network device, and you can set up a secure connection with the network device through the SSH client. You can also shut down the SSH server function to disconnect from all SSH clients.

Working Principle

For details about the working principle of the SSH server, see the "SSH Communication" in "Basic Concepts." In practice, after enabling the SSH server function, you can configure the following parameters according to the application requirements:

- Version: Configure the SSH version as SSHv1 or SSHv2 to connect SSH clients.
- Authentication timeout: The SSH server starts the timer after receiving a user connection request. The SSH server is disconnected from the client either when the authentication succeeds or when the authentication timeout is reached.
- Maximum number of authentication retries: The SSH server starts authenticating the client after receiving its connection request. If authentication does not succeed when the maximum number of user authentication retries is reached, a message is sent, indicating the authentication failure.
- Public key authentication: The public key algorithm can be RSA or DSA. It provides a secure connection between the client and the server. The public key file on the client is associated with the user name. In addition, the public key authentication mode is configured on the client, and the corresponding private key file is specified. In this way, when the client attempts to log in to the server, public key authentication can be implemented to set up a secure connection.

Related Configuration

▾ [Enabling the SSH Server](#)

By default, the SSH server is disabled.

In global configuration mode, run the **[no] enable service ssh-server** command to enable or disable the SSH server.

To generate the SSH key, you also need to enable the SSH server.

▾ Specifying the SSH Version

By default, the SSH server supports both SSHv1 and SSHv2, connecting either SSHv1 clients or SSHv2 clients.

Run the **ip ssh version** command to configure the SSH version supported by the SSH server.

If only SSHv1 or SSHv2 is configured, only the SSH client of the configured version can be connected to the SSH server.

▾ Configuring the SSH Authentication Timeout

By default, the user authentication timeout is 120s.

Run the **ip ssh time-out** command to configure the user authentication timeout of the SSH server. Use the **no** form of the command to restore the default timeout. The SSH server starts the timer after receiving a user connection request. If authentication does not succeed before the timeout is reached, authentication times out and fails.

▾ Configuring the Maximum Number of SSH Authentication Retries

By default, the maximum number of user authentication retries is 3.

Run the **ip ssh authentication-retries** command to configure the maximum number of user authentication retries on the SSH server. Use the **no** form of the command to restore the default number of user authentication retries. If authentication still does not succeed when the maximum number of user authentication retries is reached, user authentication fails.

▾ Specifying the SSH Encryption Mode

By default, the encryption mode supported by the SSH server is Compatible, that is, supporting cipher block chaining (CBC), counter (CTR) and other encryption modes.

Run the **ip ssh cipher-mode** command to configure the encryption mode supported by the SSH server. Use the **no** form of the command to restore the default encryption mode supported by the SSH server.

▾ Specifying the SSH Message Authentication Algorithm

By default, the message authentication algorithms supported by the SSH server are as follows: (1) For the SSHv1, no algorithm is supported; (2) For the SSHv2, four algorithms, including MD5,SHA1,SHA1-96, and MD5-96, are supported.

Run the **ip ssh hmac-algorithm** command to configure the message authentication algorithm supported by the SSH server. Use the **no** form of the command to restore the default message authentication algorithm supported by the SSH server.

▾ Enabling the Public Key Authentication on the SSH Server

Run the **ip ssh peer** command to associate the public key file on the client with the user name. When the client is authenticated upon login, a public key file is specified based on the user name.

11.3.2 SCP Service

The SSH server provides the SCP service to implement secure file transfer between the server and the client.

Working Principle

- SCP is a protocol that supports online file transfer. It runs on Port 22 based on the BSC RCP protocol, whereas RCP provides the encryption and authentication functions based on the SSH protocol. RCP implements file transfer, and SSH implements authentication and encryption.
- Assume that the SCP service is enabled on the server. When you use an SCP client to upload or download files, the SCP client first analyzes the command parameters, sets up a connection with a remote server, and starts another SCP process based on this connection. This process may run in source or sink mode. (The process running in source mode is the data provider. The process running in sink mode is the destination of data.) The process running in source mode reads and sends files to the peer end through the SSH connection. The process running in sink mode receives files through the SSH connection.

Related Configuration

↘ [Enabling the SCP Server](#)

By default, the SCP server function is disabled.

Run the **ip scp server enable** command to enable SCP server function on a network device.

11.3.3 SSH Client

The SSH client is used to set up a secure connection with a remote network device on which the SSH server runs.

Working Principle

For details about the working principle of the SSH client, see the "SSH Communication" in "Basic Concepts."

Related Configuration

↘ [Specifying the Source Interface of the SSH Client](#)

By default, the source address of SSH packets is searched based on the destination address.

Run the **ip ssh source-interface** *interface-name* command to specify the source interface of the SSH client.

↘ [Establishing a Session with the SSH Server](#)

Run the **ssh** command to log in to a remote device that supports the SSH Server

↘ [Recovering an Established SSH Session](#)

- Run the **ssh-session** *session-id* command to recover an established SSH session.

↘ [Disconnecting a Suspended SSH Session](#)

- Run the **disconnect ssh-session** *session-id* command to disconnect a specified SSH session.

11.4 Configuration

Configuration	Description and Command
Configuring the SSH Server	 It is mandatory to enable the SSH server.
	enable service ssh-server Enables the SSH server.
	disconnect ssh [vty] <i>session-id</i> Disconnects an established SSH session.
	crypto key generate {rsa dsa} Generates an SSH key.
	ip ssh version {1 2} Specifies the SSH version.
	ip ssh time-out <i>time</i> Configures the SSH authentication timeout.
	ip ssh authentication-retries <i>retry times</i> Configures the maximum number of SSH authentication retries.
	ip ssh cipher-mode {cbc ctr others } Specifies the SSH encryption mode.
	ip ssh hmac-algorithm {md5 md5-96 sha1 sha1-96} Specifies the SSH message authentication algorithm.
	ip ssh peer test public-key rsa flash : <i>rsa.pub</i> Associates an RSA public key file with a user.
ip ssh peer test public-key dsa flash : <i>dsa.pub</i> Associates a DSA public key file with a user.	
Configuring the SCP Service	 Mandatory.
	ip scp server enable Enables the SCP server.
Configuring the SSH Client	 (Optional)It is used to set up a secure connection with a remote network device that supports the SSH server.
	ip ssh source-interface <i>interface-name</i> Specifies the source interface of the SSH client.
	ssh [oob] [-v { 1 2 }] [-c { 3des aes128-cbc aes192-cbc aes256-cbc }] [-l <i>username</i>] [-m { hmac-md5-96 hmac-md5-128 hmac-sha1-96 hmac-sha1-160 }] [-p <i>port-num</i>] { <i>ip-addr</i> <i>hostname</i> } [via <i>mgmt-name</i>] [/source { ip <i>A.B.C.D</i> ipv6 <i>X:X:X:X::X</i> interface <i>interface-name</i> }] [/vrf <i>vrf-name</i>] Establishes an encrypted session with a remote network device.

11.4.1 Configuring the SSH Server

[Configuration Effect](#)

- Enable the SSH server function on a network device so that you can set up a secure connection with a remote network device through the SSH client. All interactive data is encrypted before transmitted, featuring authentication and security.
- You can use diversified SSH user authentications modes, including local line password authentication, AAA authentication, and public key authentication.
- You can generate or delete an SSH key.
- You can specify the SSH version.
- You can configure the SSH authentication timeout.
- You can configure the maximum number of SSH authentication retries.
- You can specify the SSH encryption mode.
- You can specify the SSH message authentication algorithm.
- You can specify ACL filtering of the SSH server.

Notes

- The precondition of configuring a device as the SSH server is that communication is smooth on the network that the device resides, and the administrator can access the device management interface to configure related parameters.
- The **no crypto key generate** command does not exist. You need to run the **crypto key zeroize** command to delete a key.
- The SSH module does not support hot standby. Therefore, for products that supports hot standby on the supervisor modules, if no SSH key file exist on the new active module after failover, you must run the **crypto key generate** command to re-generate a key before using SSH.

Configuration Steps

▾ Enabling the SSH Server

- Mandatory.
- By default, the SSH server is disabled. In global configuration mode, enable the SSH server and generate an SSH key so that the SSH server state changes to ENABLE.

▾ Specifying the SSH Version

- Optional.
- By default, the SSH server supports SSHv1 and SSHv2, connecting either SSHv1 or SSHv2clients. If only SSHv1 or SSHv2 is configured, only the SSH client of the configured version can be connected to the SSH server.

▾ Configuring the SSH Authentication Timeout

- Optional.
- By default, the SSH authentication timeout is 120s. You can configure the user authentication timeout as required. The value ranges from 1 to 120. The unit is second.

↘ **Configuring the Maximum Number of SSH Authentication Retries**

- Optional.
- Configure the maximum number of SSH authentication retries to prevent illegal behaviors such as malicious guessing. By default, the maximum number of SSH authentication retries is 3, that is, a user is allowed to enter the user name and password three times for authentication. You can configure the maximum number of retries as required. The value ranges from 0 to 5.

↘ **Specifying the SSH Encryption Mode**

- Optional.
- Specify the encryption mode supported by the SSH server. By default, the encryption mode supported by the SSH server is Compatible, that is, supporting CBC, CTR and other encryption modes.

↘ **Specifying the SSH Message Authentication Algorithm**

- Optional.
- Specify the message authentication algorithm supported by the SSH server. By default, the message authentication algorithms supported by the SSH server are as follows: (1) For the SSHv1, no algorithm is supported; (2) For the SSHv2, four algorithms, including MD5, SHA1, SHA1-96, and MD5-96, are supported.

↘ **Setting ACL Filtering of the SSH Server**

- Optional.
- Set ACL filtering of the SSH server. By default, ACL filtering is not performed for all connections to the SSH server. According to needs, set ACL filtering to perform for all connections to the SSH server.

↘ **Enabling the Public Key Authentication for SSH Users**

- Optional.
- Only SSHv2 supports authentication based on the public key. This configuration associates a public key file on the client with a user name. When a client is authenticated upon login, a public key file is specified based on the user name.

Verification

- Run the **show ip ssh** command to display the current SSH version, authentication timeout, and maximum number of authentication retries of the SSH server.
- Run the **show crypto key mypubkey** command to display the public information of the public key to verify whether the key has been generated.
- Configure the public key authentication login mode on the SSH client and specify the private key file. Check whether you can successfully log in to the SSH server from the SSH client. If yes, the public key file on the client is successfully associated with the user name, and public key authentication succeeds.

Related Commands

↘ **Enabling the SSH Server**

Command	enable service ssh-server
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	To disable the SSH server, run the no enable service ssh-server command in global configuration mode. After this command is executed, the SSH server state changes to DISABLE.

↘ Disconnecting an Established SSH Session

Command	disconnect ssh[<i>vty</i>] <i>session-id</i>
Parameter	vty: Indicates an established virtual teletype terminal (VTY) session.
Description	<i>session-id</i> : Indicates the ID of the established SSH session. The value ranges from 0 to 35.
Command Mode	Privileged EXEC mode
Usage Guide	Specify an SSH session ID to disconnect the established SSH session. Alternatively, specify a VTY session ID to disconnect a specified SSH session. Only an SSH session can be disconnected.

↘ Generating an SSH Key

Command	crypto key generate {rsa dsa}
Parameter	rsa: Generates an RSA key.
Description	dsa: Generates a DSA key.
Command Mode	Global configuration mode
Usage Guide	The no crypto key generate command does not exist. You need to run the crypto key zeroize command to delete a key. SSHv1 uses an RSA key, whereas SSHv2 uses an RSA or DSA key. If an RSA key is generated, both SSHv1 and SSHv2 are supported. If only a DSA key is generated, only SSHv2 can use the key.

↘ Specifying the SSH Version

Command	ip ssh version {1 2}
Parameter	1: Indicates that the SSH server only receives the connection requests sent by SSHv1 clients.
Description	2: Indicates that the SSH server only receives the connection requests sent by SSHv2 clients.
Command Mode	Global configuration mode
Usage Guide	Run the no ip ssh version command to restore the default settings. By default, the SSH server supports both SSHv1 and SSHv2.

↘ Configuring the SSH Authentication Timeout

Command	ip ssh time-out <i>time</i>
----------------	------------------------------------

Parameter Description	<i>time</i> : Indicates the SSH authentication timeout. The value ranges from 1 to 120. The unit is second.
Command Mode	Global configuration mode
Usage Guide	Run the no ip ssh time-out command to restore the default SSH authentication timeout, which is 120s.

↘ Configuring the Maximum Number of SSH Authentication Retries

Command	ip ssh authentication-retries <i>retry times</i>
Parameter Description	<i>retry times</i> : Indicates the maximum number of user authentication retries. The value ranges from 0 to 5.
Command Mode	Global configuration mode
Usage Guide	Run the no ip ssh authentication-retries command to restore the default number of user authentication retries, which is 3.

↘ Specifying the SSH Encryption Mode

Command	ip ssh cipher-mode {cbc ctr others }
Parameter Description	<p>cbc: Sets the encryption mode supported by the SSH server to the CBC mode. Corresponding algorithms include DES-CBC,3DES-CBC,AES-128-CBC,AES-192-CBC,AES-256-CBC, and Blowfish-CBC.</p> <p>ctr: Sets the encryption mode supported by the SSH server to the CTR mode. Corresponding algorithms include AES128-CTR, AES192-CTR, and AES256-CTR.</p> <p>others: Sets the encryption mode supported by the SSH server to others. The corresponding algorithm is RC4.</p>
Command Mode	Global configuration mode
Usage Guide	<p>This command is used to configure the encryption mode supported by the SSH server.</p> <p>On Ruijie devices, the SSHv1 server supports the DES-CBC, 3DES-CBC, and Blowfish-CBC encryption algorithms; the SSHv2 server supports the AES128-CTR, AES192-CTR, AES256-CTR, DES-CBC, 3DES-CBC, AES-128-CBC, AES-192-CBC, AES-256-CBC, Blowfish-CBC, and RC4 encryption algorithms. These algorithms can be grouped into three encryption modes: CBC, CTR, and others.</p> <p>As the cryptography continuously develops, it is approved that encryption algorithms in the CBC and others modes can be decrypted in a limited period of time. Therefore, organizations or companies that have high security requirements can set the encryption mode supported by the SSH server to CTR to increase the security level of the SSH server.</p>

↘ Specifying the SSH Message Authentication Algorithm

Command	ip ssh hmac-algorithm {md5 md5-96 sha1 sha1-96}
Parameter Description	<p>md5: Indicates that the message authentication algorithm supported by the SSH server is MD5.</p> <p>md5-96: Indicates that the message authentication algorithm supported by the SSH server is MD5-96.</p> <p>sha1: Indicates that the message authentication algorithm supported by the SSH server is SHA1.</p> <p>sha1-96: Indicates that the message authentication algorithm supported by the SSH server is SHA1-96.</p>

Command Mode	Global configuration mode
Usage Guide	This command is used to configure the message authentication algorithm supported by the SSH server. On Ruijie devices, the SSHv1 server does support any message authentication algorithm; the SSHv2 server supports the MD5, SHA1, SHA1-96, and MD5-96 message authentication algorithms. You can select message authentication algorithms supported by the SSH server as required.

▾ Configuring RSA Public Key Authentication

Command	ip ssh peer test public-key rsaflash:rsa.pub
Parameter Description	<i>test</i> : Indicates the user name. rsa : Indicates that the public key type is RSA. <i>rsa.pub</i> : Indicates the name of a public key file.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the RSA public key file associated with user <i>test</i> . Only SSHv2 supports authentication based on the public key. This command associates the public key file on the client with the user name. When the client is authenticated upon login, a public key file is specified based on the user name.

▾ Configuring DSA Public Key Authentication

Command	ip ssh peer test public-key dsaflash:dsa.pub
Parameter Description	<i>test</i> : Indicates the user name. dsa : Indicates that the public key type is DSA. <i>dsa.pub</i> : Indicates the name of a public key file.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the DSA key file associated with user test . Only SSHv2 supports authentication based on the public key. This command associates the public key file on the client with the user name. When the client is authenticated upon login, a public key file is specified based on the user name.

Configuration Example

 The following configuration examples describe only configurations related to SSH.

▾ Generating a Public Key on the SSH Server

Configuration Steps	<ul style="list-style-type: none"> Run the crypto key generate { rsa dsa } command to generate a RSA public key for the server.
----------------------------	---

<p>SSH Server</p>	<pre>Ruijie#configure terminal Ruijie(config)# crypto key generate rsa Choose the size of the rsa key modulus in the range of 512 to 2048 and the size of the dsa key modulus in the range of 360 to 2048 for your Signature Keys. Choosing a key modulus greater than 512 may take a few minutes. How many bits in the modulus [512]:</pre> <ul style="list-style-type: none"> ● If the generation of the RSA key is successful, the following information is displayed: <pre>% Generating 512 bit RSA1 keys ... [ok] % Generating 512 bit RSA keys ... [ok]</pre> ● If the generation of the RSA key fails, the following information is displayed: <pre>% Generating 512 bit RSA1 keys ... [fail] % Generating 512 bit RSA keys ... [fail]</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● Run the show crypto key mypubkey rsa command to display the public information about the RSA key. If the public information about the RSA key exists, the RSA key has been generated.
<p>SSH Server</p>	<pre>Ruijie(config)#show crypto key mypubkey rsa % Key pair was generated at: 1:49:47 UTC Jan 4 2013 Key name: RSA1 private Usage: SSH Purpose Key Key is not exportable. Key Data: AAAAAwEA AQAAAHJM 6izXt1pp rUSOEGZ/ UhFpRRrW nngP4BU7 mG836apf jajSYwcu 803LojHL ayJ8G4pG 7j4T4ZSf FKg09kfr 92JpRNHQ gbwaPc5/ 9UnTtX9t qFIKDJ1j 0dKBcCfN tr0r/CT+ cs5t1GKV S0ICGifz oB+pYaE= % Key pair was generated at: 1:49:47 UTC Jan 4 2013 Key name: RSA private Usage: SSH Purpose Key Key is not exportable. ➤ **Specifying the SSH Version**

<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Run the ip ssh version { 1 2 } command to set the version supported by the SSH server to SSHv2.
<p>SSH Server</p>	<pre>Ruijie#configure terminal Ruijie(config)#ip ssh version 2</pre>

Verification	<ul style="list-style-type: none"> Run the show ip ssh command to display the SSH version currently supported by the SSH server.
SSH Server	<pre>Ruijie(config)#show ip ssh SSH Enable - version 2.0 Authentication timeout: 120 secs Authentication retries: 3 SSH SCP Server: disabled</pre>

▾ Configuring the SSH Authentication Timeout

Configuration Steps	<ul style="list-style-type: none"> Run the ip ssh time-out <i>time</i> command to set the SSH authentication timeout to 100s.
SSH Server	<pre>Ruijie#configure terminal Ruijie(config)#ip ssh time-out 100</pre>
Verification	<ul style="list-style-type: none"> Run the show ip ssh command to display the configured SSH authentication timeout.
SSH Server	<pre>Ruijie(config)#show ip ssh SSH Enable - version 2.0 Authentication timeout: 100 secs Authentication retries: 3 SSH SCP Server: disabled</pre>

▾ Configuring the Maximum Number of SSH Authentication Retries

Configuration Steps	<ul style="list-style-type: none"> Run the ip ssh authentication-retries <i>retry times</i> command to set the maximum number of user authentication retries on the SSH server to 2.
SSH Server	<pre>Ruijie#configure terminal Ruijie(config)#ip ssh authentication-retries 2</pre>
Verification	<ul style="list-style-type: none"> Run the show ip ssh command to display the configured maximum number of authentication retries.
SSH Server	<pre>Ruijie(config)#show ip ssh SSH Enable - version 2.0 Authentication timeout: 100 secs Authentication retries: 3 SSH SCP Server: disabled</pre>

▾ Specifying the SSH Encryption Mode

Configuration Steps	<ul style="list-style-type: none"> Run the ip ssh cipher-mode {cbc ctr others } command to set the encryption mode supported by the SSH server to CTR.
SSH Server	<pre>Ruijie#configure terminal Ruijie(config)# ip ssh cipher-mode ctr</pre>
Verification	<ul style="list-style-type: none"> Select the CTR encryption mode on the SSH client, and verify whether you can successfully log in to

the SSH server from the SSH client.

➤ **Specifying the SSH Message Authentication Algorithm**

Configuration Steps	<ul style="list-style-type: none"> Run the <code>ip ssh hmac-algorithm {md5 md5-96 sha1 sha1-96 }</code> command to set the message authentication algorithm supported by the SSH server to SHA1.
SSH Server	<pre>Ruijie#configure terminal Ruijie(config)# ip ssh hmac-algorithmsha1</pre>
Verification	<ul style="list-style-type: none"> Select the SHA1 message authentication algorithm on the SSH client, and verify whether you can successfully log in to the SSH server from the SSH client.

➤ **Configuring the Public Key Authentication**

Configuration Steps	<ul style="list-style-type: none"> Run the <code>ip ssh peer username public-key { rsa dsa}filename</code> command to associate a public key file of the client with a user name. When the client is authenticated upon login, a public key file (for example, RSA) is specified based on the user name.
SSH Server	<pre>Ruijie#configure terminal Ruijie(config)# ip ssh peer test public-key rsaflash:rsa.pub</pre>
Verification	<ul style="list-style-type: none"> Configure the public key authentication login mode on the SSH client and specify the private key file. Check whether you can successfully log in to the SSH server from the SSH client. If yes, the public key file on the client is successfully associated with the user name, and public key authentication succeeds.

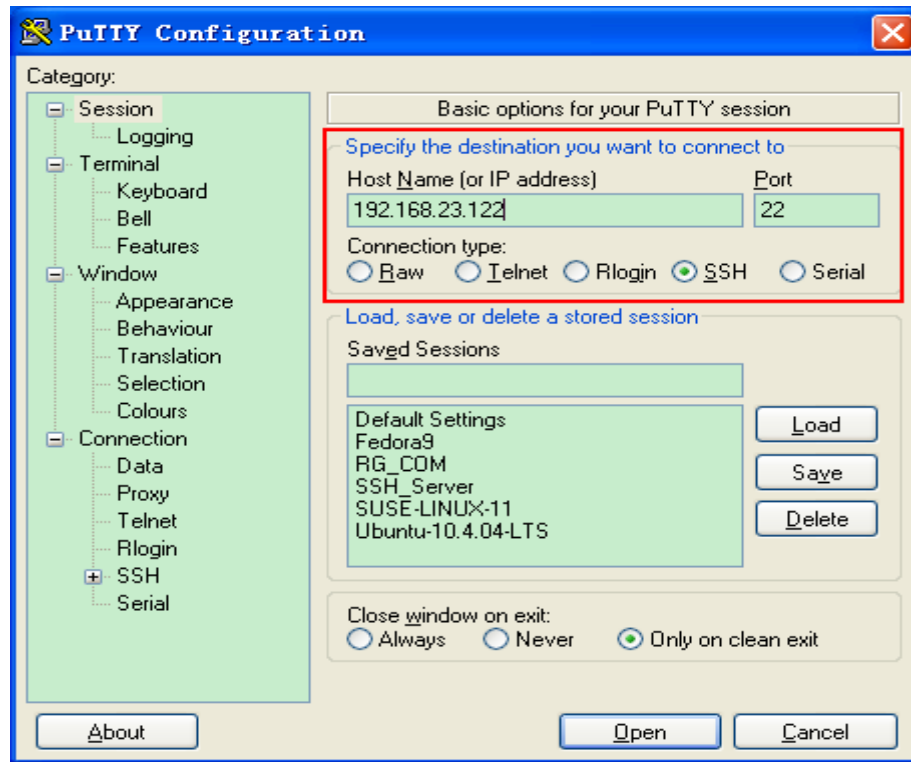

➤ **Configuring SSH Device Management**

<p>Scenario Figure 11-7</p>  <p>The diagram illustrates the SSH device management scenario. On the left, an icon of a laptop represents the 'SSH Client' with IP address '192.168.23.83'. A line connects it to a central cloud icon representing the 'IP Network'. Another line connects the cloud to a server rack icon representing the 'SSH Server' with IP address '192.168.23.122'.</p> <p>You can use SSH to manage devices on the precondition that the SSH server function is enabled. By default, this function is disabled. The Telnet component that comes with the Windows does not support SSH. Therefore, a third-party client software must be used. Currently, well-compatible client software includes PuTTY, Linux, and SecureCRT. The following takes the PuTTY as an example to introduce the configurations of the SSH client.</p>	
Configuration Steps	<ul style="list-style-type: none"> Start the PuTTY software. On the Session option tab of PuTTY, type in the host IP address 192.168.23.122 and SSH port number 22, and select the connection type SSH. On the SSH option tab of PuTTY, select the preferred SSH protocol version 2. On the SSH authentication option tab of PuTTY, select the authentication method Attempt "keyboard-interactive" auth. Click Open to connect to the SSH server.

- Type in the correct user name and password to enter the terminal login interface.

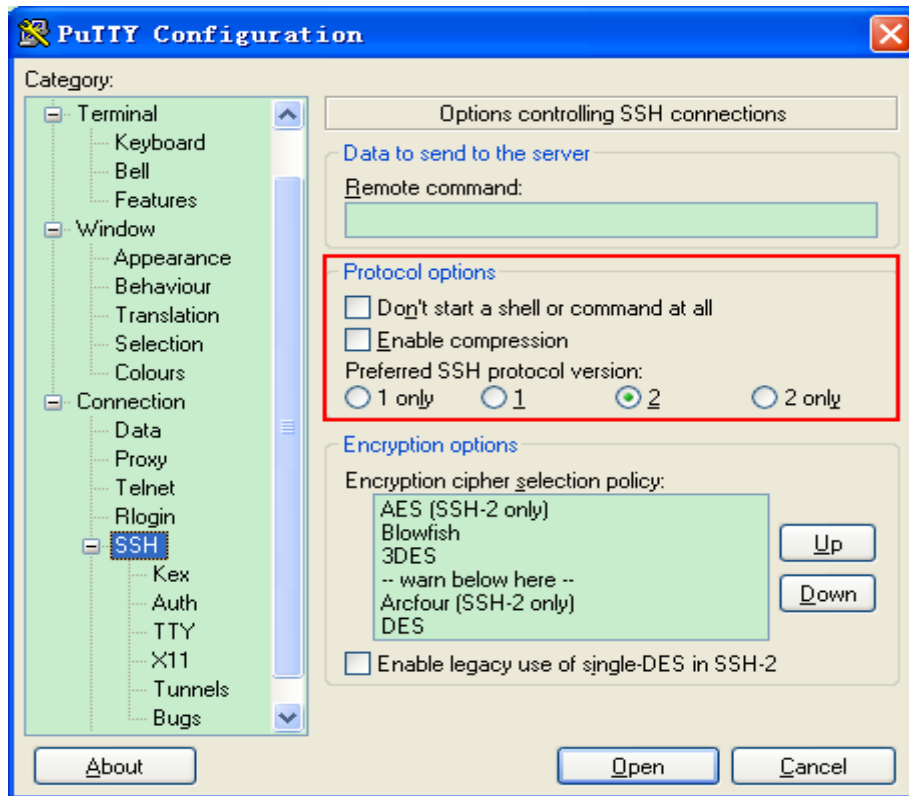

SSH Client

Figure 11-8

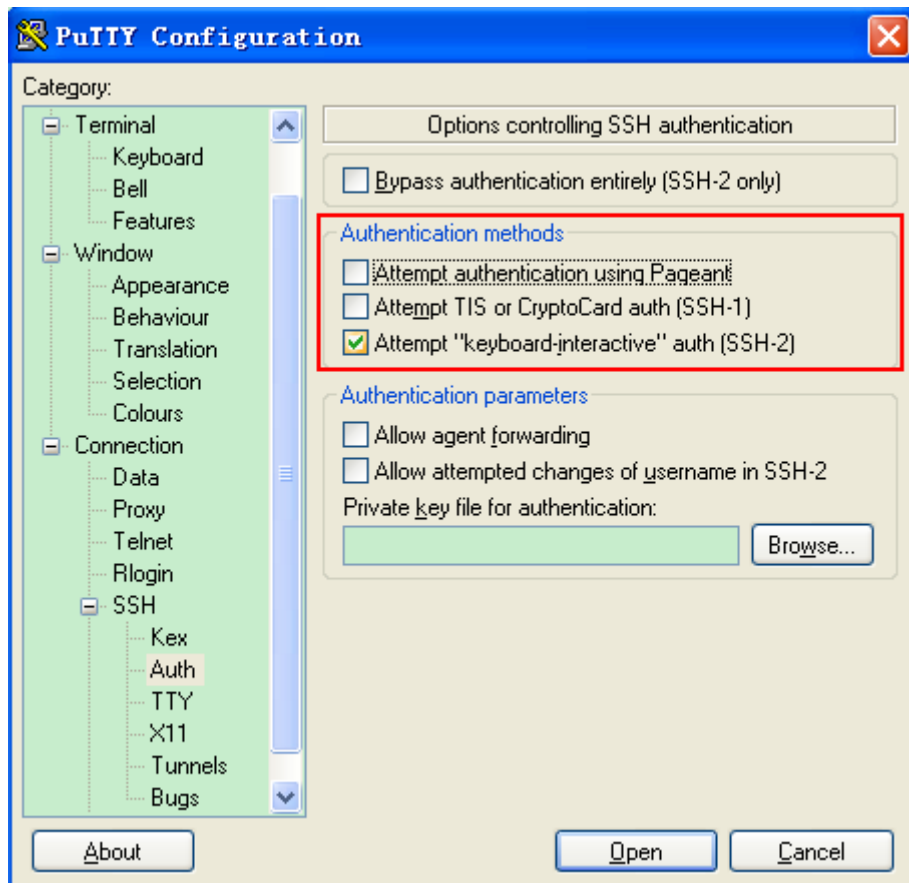

Host Name (or IP address) indicates the IP address of the host to be logged in. In this example, the IP address is 192.168.23.122. **Port** indicates the port ID 22, that is, the default ID of the port listened by SSH. **Connection type** is SSH.

Figure 11-9

As shown in Figure 11-9, select **2** as the preferred SSH protocol version in the **Protocol options** pane because SSHv2 is used for login.

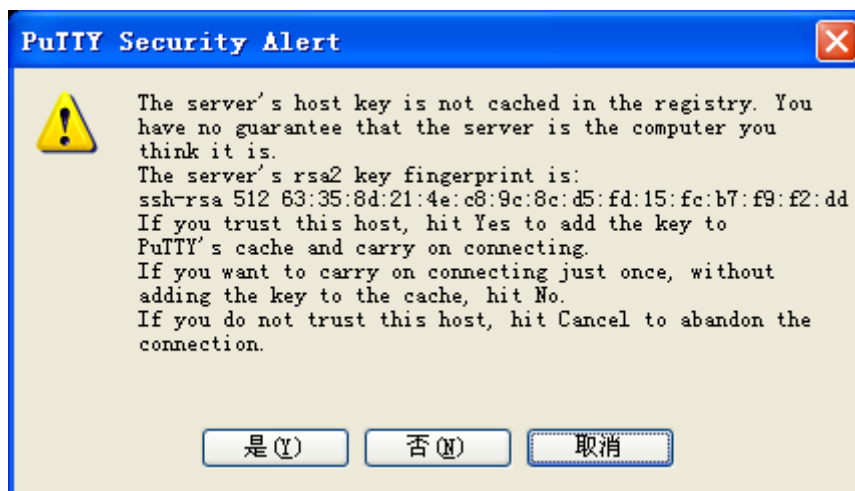

Figure 11-10

As shown in Figure 11-10, select **Attempt "keyboard-interactive" auth** as the authentication method to support authentication based on the user name and password.

Then, click **Open** to connect to the configured server host, as shown in Figure 11-10.

Figure 11-11

The **PuTTY Security Alert** box indicates that you are logging in to the client of the server 192.168.23.122, and asks you whether to receive the key sent from the server.

If you select **Yes**, a login dialog box is displayed, as shown in Figure 11-11.

Figure 11-12

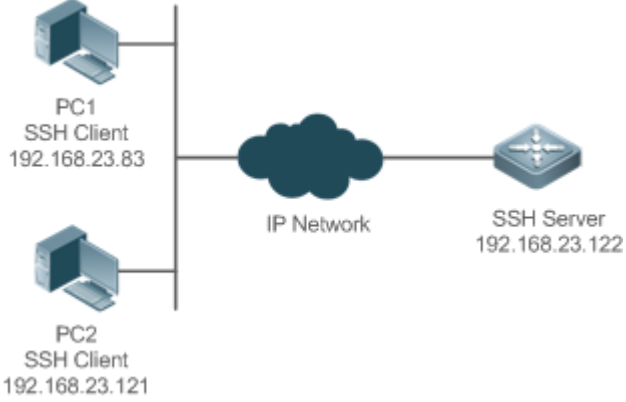

Type in the correct user name and password, and you can log in to the SSH terminal interface, as shown in Figure 11-12

Figure 11-13

<p>Verification</p>	<ul style="list-style-type: none"> ● Run the show ip ssh command to display the configurations that are currently effective on the SSH server. ● Run the show ssh command to display information about every SSH connection that has been established.
	<pre>Ruijie#show ip ssh SSH Enable - version 1.99 Authentication timeout: 120 secs Authentication retries: 3 Ruijie#show ssh Connection Version Encryption Hmac State Username 0 2.0 aes256-cbc hmac-sha1 Session started test</pre>

↘ **Configuring SSH Local Line Authentication**

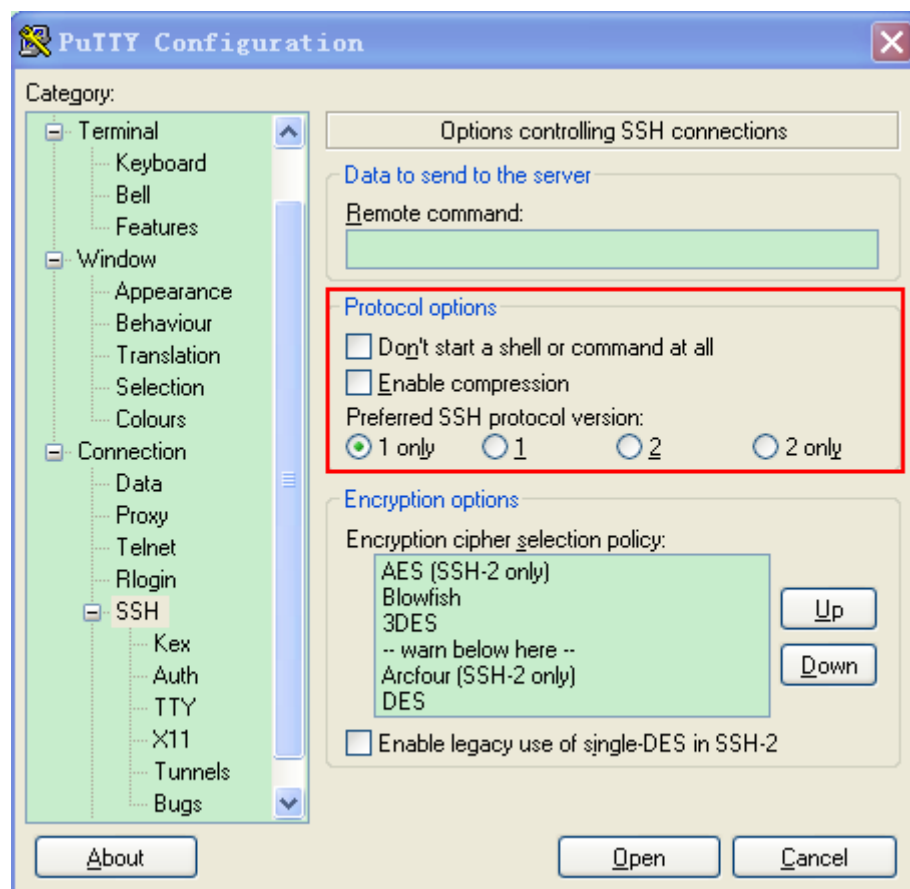

<p>Scenario Figure 11-14</p>	 <p>SSH users can use the local line password for user authentication, as shown in Figure 11-14. To ensure security of data exchange, PC 1 and PC 2 function as the SSH clients, and use the SSH protocol to log in to the network device where the SSH server is enabled. The requirements are as follows:</p> <ul style="list-style-type: none"> ● SSH users use the local line password authentication mode. ● Five lines, including Line 0 to Line 4, are activated concurrently. The login password is "passzero" for Line 0 and "pass" for the remaining lines. Any user name can be used.
<p>Configuration Steps</p>	<p>Configure the SSH server as follows:</p> <ul style="list-style-type: none"> ● Enable the SSH server function globally. By default, the SSH server supports two SSH versions: SSHv1 and SSHv2. ● Configure the key. With this key, the SSH server decrypts the encrypted password received from the SSH client, compares the decrypted plain text with the password stored on the server, and returns a message indicating the successful or unsuccessful authentication. SSHv1 uses the RSA key, whereas SSHv2 uses the RSA or DSA key. ● Configure the IP address of the FastEthernet 0/1 interface on the SSH server. The SSH client is connected to the SSH server based on this IP address. The route from the SSH client to the SSH server is reachable. <p>Configure the SSH client as follows:</p> <ul style="list-style-type: none"> ● Diversified SSH client software is available, including PuTTY, Linux, and SecureCRT. This document takes PuTTY as an example to explain the method for configuring the SSH client. For details about the configuration method, see "Configuration Steps."
<p>SSH Server</p>	<p>Before configuring SSH-related function, ensure that the route from the SSH user to the network segment of the SSH server is reachable. The interface IP address configurations are shown in Figure 11-15. The detailed procedures for configuring IP addresses and routes are omitted.</p> <pre>Ruijie(config)# enable service ssh-server Ruijie(config)#crypto key generate rsa % You already have RSA keys. % Do you really want to replace them? [yes/no]: Choose the size of the key modulus in the range of 360 to 2048 for your Signature Keys. Choosing a key modulus greater than 512 may take a few minutes.</pre>

```

How many bits in the modulus [512]:
% Generating 512 bit RSA1 keys ... [ok]
% Generating 512 bit RSA keys ... [ok]
Ruijie(config)#interface fastEthernet0/1
Ruijie(config-if-fastEthernet0/1)#ip address 192.168.23.122 255.255.255.0
Ruijie(config-if-fastEthernet0/1)#exit
Ruijie(config)#line vty 0
Ruijie(config-line)#password passzero
Ruijie(config-line)#privilege level 15
Ruijie(config-line)#login
Ruijie(config-line)#exit
Ruijie(config)#line vty 4
Ruijie(config-line)#password pass
Ruijie(config-line)#privilege level 15
Ruijie(config-line)#login
Ruijie(config-line)#exit
    
```

SSH Client (PC1/ PC2)

Figure 11-15

Set the IP address and port ID of the SSH server. As shown in the network topology, the IP address of the

	<p>server is 192.168.23.122, and the port ID is 22 (For details about the configuration method, see "Configuring SSH Device Management."). Click Open to start the SSH server. As the current authentication mode does not require a user name, you can type in any user name, but cannot leave the user name unspecified. (In this example, the user name is "anyname".)</p>
Verification	<ul style="list-style-type: none"> ● Run the show running-config command to display the current configurations. ● Verify that the SSH client configurations are correct.
SSH Server	<pre>Ruijie#show running-config Building configuration... ! enable secret 5 \$1\$eyy2\$xs28FDw4s2q0tx97 enable service ssh-server ! interface fastEthernet0/1 ip address 192.168.23.122 255.255.255.0 ! line vty 0 privilege level 15 login password passzero line vty 1 4 privilege level 15 login password pass ! end</pre>
SSH Client	<p>Set up a connection, and enter the correct password. The login password is "passzero" for Line 0 and "pass" for the remaining lines. Then, the SSH server operation interface is displayed, as shown in Figure 11-16.</p> <p>Figure 11-16</p>

Ruijie#show users

Line	User	Host(s)	Idle	Location
* 0 con 0	---	idle	00:00:00	---
1 vty 0	---	idle	00:08:02	192.168.23.83
2 vty 1	---	idle	00:00:58	192.168.23.121

Configuring AAA Authentication of SSH Users

Scenario
Figure 11-17

SSH users can use the AAA authentication mode for user authentication, as shown in Figure 11-17. To ensure security of data exchange, the PC functions as the SSH client, and uses the SSH protocol to log in to the network device where the SSH server is enabled. To better perform security management, the AAA authentication mode is used on the user login interface of the SSH client. Two authentication methods,

	<p>including Radius server authentication and local authentication, are provided in the AAA authentication method list to ensure reliability. The Radius server authentication method is preferred. If the Radius server does not respond, select the local authentication method.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● The route from the SSH client to the SSH server is reachable, and the route from the SSH server to the Radius server is also reachable. ● Configure the SSH server on the network device. The configuration method is already described in the previous example, and therefore omitted here. ● Configure the AAA parameters on the network device. When the AAA authentication mode is used, method lists are created to define the identity authentication and types, and applied to a specified service or interface.
<p>SSH Server</p>	<pre>Ruijie(config)# enable service ssh-server Ruijie(config)#crypto key generate rsa % You already have RSA keys. % Do you really want to replace them? [yes/no]: Choose the size of the key modulus in the range of 360 to 2048 for your Signature Keys. Choosing a key modulus greater than 512 may take a few minutes. How many bits in the modulus [512]: % Generating 512 bit RSA1 keys ... [ok] % Generating 512 bit RSA keys ... [ok] Ruijie(config)#crypto key generate dsa Choose the size of the key modulus in the range of 360 to 2048 for your Signature Keys. Choosing a key modulus greater than 512 may take a few minutes. How many bits in the modulus [512]: % Generating 512 bit DSA keys ... [ok] Ruijie(config)#interface gigabitEthernet1/1 Ruijie(config-if-gigabitEthernet1/1)#ip address 192.168.217.81 255.255.255.0 Ruijie(config-if-gigabitEthernet1/1)#exit Ruijie#configure terminal Ruijie(config)#aaa new-model Ruijie(config)#radius-server host 192.168.32.120 Ruijie(config)#radius-server key aaradius Ruijie(config)#aaa authentication login methodgroup radius local Ruijie(config)#line vty 0 4 Ruijie(config-line)#login authentication method Ruijie(config-line)#exit Ruijie(config)#username user1 privilege 1 password 111 Ruijie(config)#username user2 privilege 10 password 222</pre>

📌 **Configuring Public Key Authentication of SSH Users**

<p>Scenario Figure 11-18</p>	 <p>SSH Client 192.168.23.83</p> <p>IP Network</p> <p>SSH Server 192.168.23.122</p> <p>SSH users can use the public key for user authentication, and the public key algorithm is RSA or DSA, as shown in Figure 11-18. SSH is configured on the client so that a secure connection is set up between the SSH client and the SSH server.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● To implement public key authentication on the client, generate a key pair (for example, RSA key) on the client, place the public key on the SSH server, and select the public key authentication mode. <p>i After the key pair is generated on the client, you must save and upload the public key file to the server and complete the server-related settings before you can continue to configure the client and connect the client with the server.</p> <ul style="list-style-type: none"> ● After the key is generated on the client, copy the public key file from the client to the flash of the SSH server, and associate the file with an SSH user name. A user can be associated with one RSA public key and one DSA public key.
<p>SSH Client</p>	<p>Run the puttygen.exe software on the client. Select SSH-2 RSA in the Parameters pane, and click Generate to generate a key, as shown in Figure 11-19.</p> <p>Figure 11-19</p>

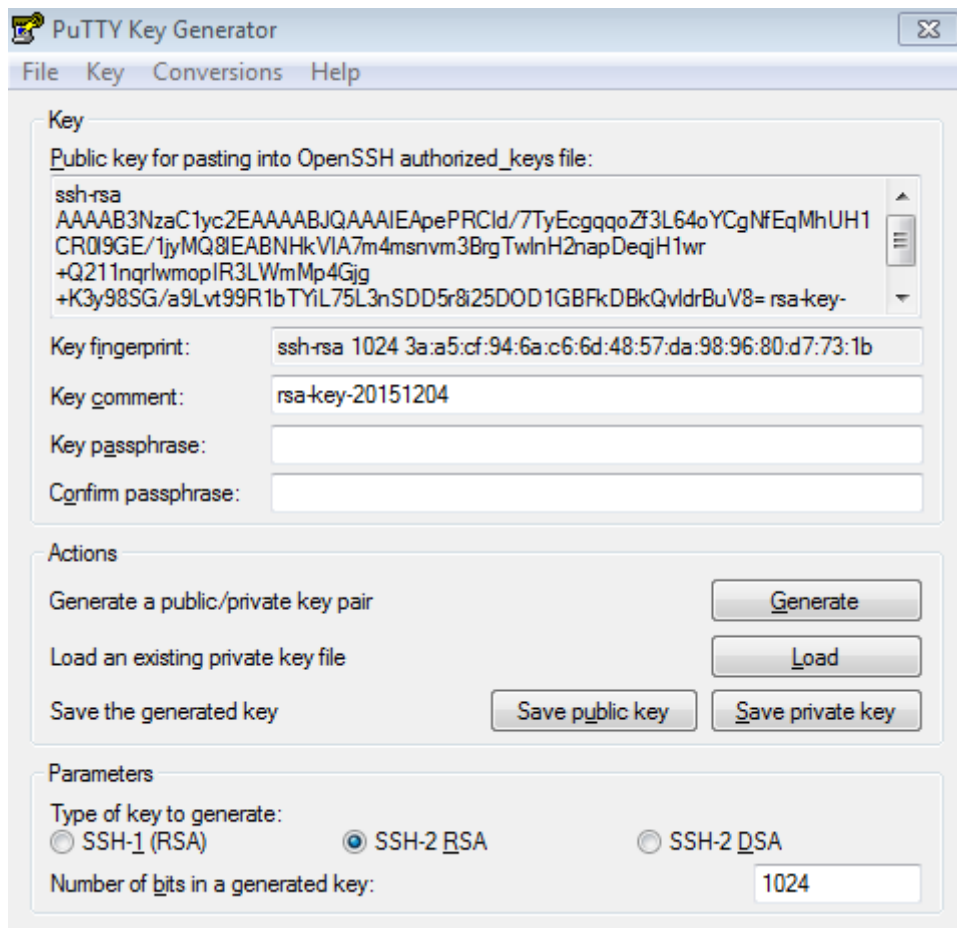

When a key is being generated, you need to constantly move the mouse over a blank area outside the green progress bar; otherwise, the progress bar does not move and key generation stops, as shown in Figure 11-20.

Figure 11-20

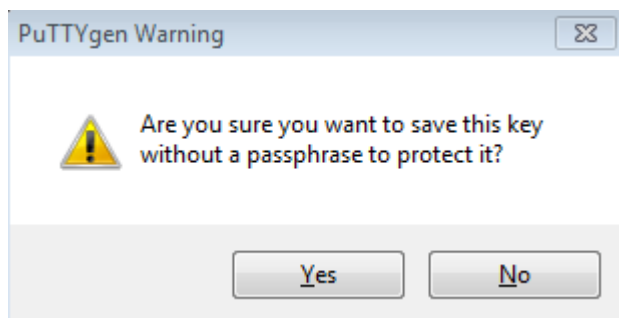

To ensure security of the RSA public key authentication, the length of the generated RSA key pair must be equal to or larger than 768 bits. In this example, the length is set to 1024 bits.

Figure 11-21

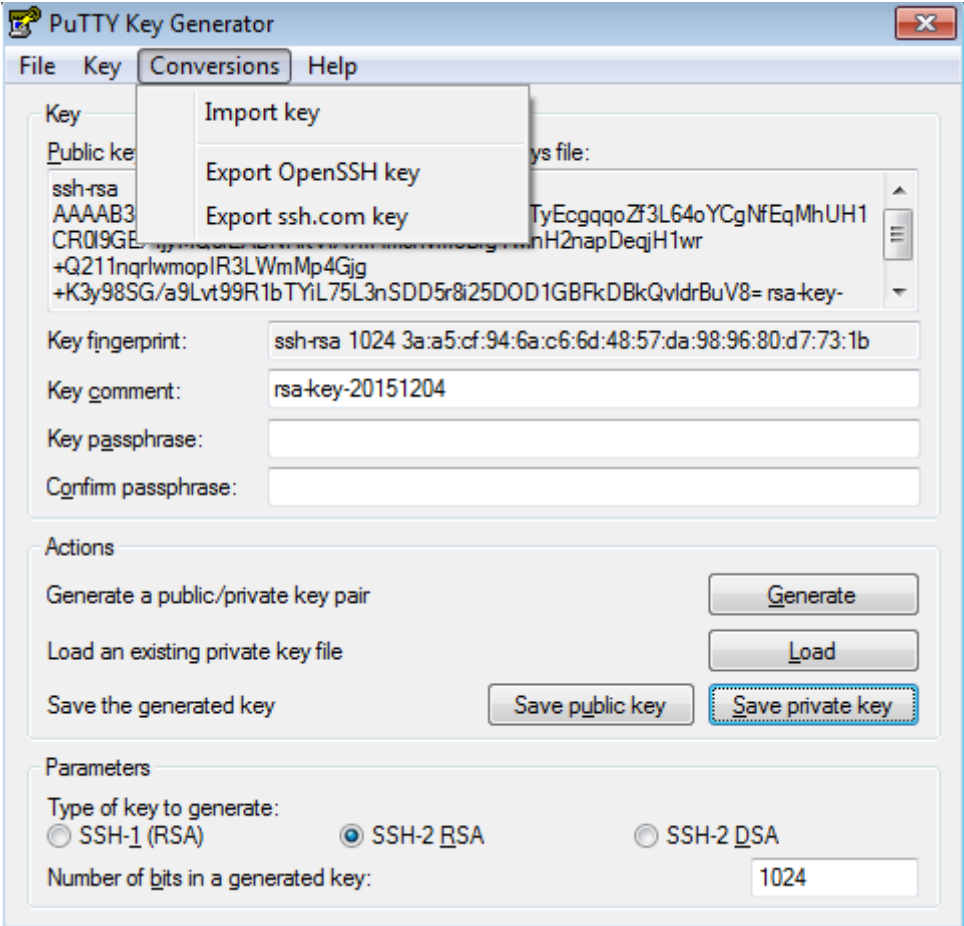

After the key pair is generated, click **Save public key**, type in the public key name **test_key.pub**, select the storage path, and click **Save**. Then click **Save private key**. The following prompt box is displayed. Select **Yes**, type in the public key name **test_private**, and click **Save**.

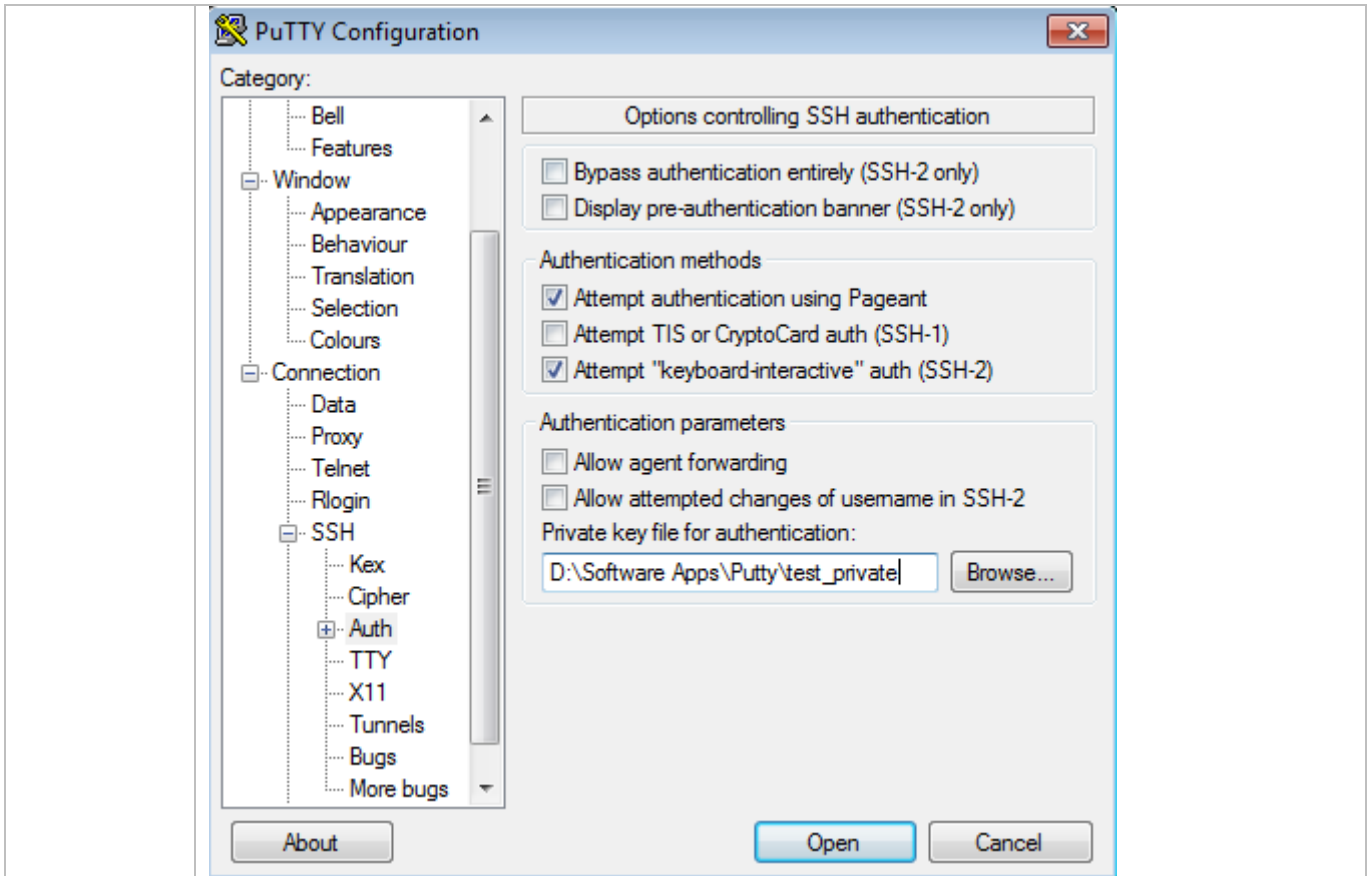

Figure 11-22

You must select the OpenSSH key file; otherwise, the key file cannot be used. The **puttygen.exe** software can be used to generate a key file in OpenSSH format, but this file cannot be directly used by the PuTTY client. You must use **puttygen.exe** to convert the private key to the PuTTY format. Format conversion is not required for the public key file stored on the server, and the format of this file is still OpenSSH, as shown in Figure 11-23.

Figure 11-23

	 <p>The screenshot shows the PuTTY Key Generator application window. The 'Conversions' menu is open, displaying options: 'Import key', 'Export OpenSSH key', and 'Export ssh.com key'. The 'Save private key' button in the 'Actions' section is highlighted with a blue dashed border. The 'Parameters' section shows 'SSH-2 RSA' selected as the key type and '1024' bits for the key length.</p>
<p>SSH Server</p>	<pre>Ruijie#configure terminal Ruijie(config)# ip ssh peer test public-key rsaflash:test_key.pub</pre>
<p>Verification</p>	<ul style="list-style-type: none"> After completing the basic configurations of the client and the server, specify the private key file test_private on the PuTTY client, and set the host IP address to 192.168.23.122 and port ID to 22 to set up a connection between the client and the server. In this way, the client can use the public key authentication mode to log in to the network device.
	<p>Figure 11-24</p>

Common Errors

- The `no crypto key generate` command is used to delete a key.

11.4.2 Configuring the SCP Service

Configuration Effect

After the SCP function is enabled on a network device, you can directly download files from the network device and upload local files to the network device. In addition, all interactive data is encrypted, featuring authentication and security.

Notes

- The SSH server must be enabled in advance.

Configuration Steps

▾ Enabling the SCP Server

- Mandatory.
- By default, the SCP server function is disabled. Run the `ip scp server enable` command to enable the SCP server function in global configuration mode.

Verification

Run the **show ip ssh** command to check whether the SCP server function is enabled.

Related Commands

▾ Enabling the SCP Server

Command	ip scp server enable
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	This command is used to enable the SCP server. Run the no ip scp server enable command to disable the SCP server.

Configuration Example

▾ Enabling the SCP Server

Configuration Steps	<ul style="list-style-type: none"> Run the ip scp server enable command to enable the SCP server. <pre>Ruijie#configure terminal Ruijie(config)#ip scp server enable</pre>
Verification	<ul style="list-style-type: none"> Run the show ip ssh command to check whether the SCP server function is enabled. <pre>Ruijie(config)#show ipssh SSH Enable - version 1.99 Authentication timeout: 120 secs Authentication retries: 3 SSH SCP Server: enabled</pre>

▾ Configuring SSH File Transfer

Scenario Figure 11-25	<p>SSH Client 192.168.23.83</p> <p>IP Network</p> <p>SSH Server 192.168.23.122</p> <p>The SCP service is enabled on the server, and SCP commands are used on the client to transfer data to the server.</p>
Configuration Steps	<ul style="list-style-type: none"> Enable the SCP service on the server. <p>i The SCP server uses SSH threading. When connecting to a network device for SCP transmission, the client occupies a VTY session (You can find out that the user type is SSH by running the show user</p>

	<p>command).</p> <ul style="list-style-type: none"> On the client, use SCP commands to upload files to the server, or download files from the server. <p>Syntax of the SCP command:</p> <pre>scp [-1246BCpqr] [-c cipher] [-F ssh_config] [-i identity_file] [-l limit] [-o ssh_option] [-P port] [-S program] [[user@]host1:]file1 [...] [[user@]host2:]file2</pre> <p>Descriptions of some options:</p> <ul style="list-style-type: none"> -1: Uses SSHv1 (If not specified, SSHv2 is used by default); -2: Uses SSHv2 (by default); -C: Uses compressed transmission. -c: Specifies the encryption algorithm to be used. -r: Transmits the whole directory; -i: Specifies the key file to be used. -l: Limits the transmission speed (unit: Kbit/s). <p>For other parameters, see the filescp.0.</p> <p>Most options are related to terminals. Few options are supported on both terminals and servers. Ruijie's SCP servers do not support d-p-q-r options. When these options are applied, there are prompts.</p>
SSH Server	<pre>Ruijie#configure terminal Ruijie(config)# ip scp server enable</pre>
Verification	<ul style="list-style-type: none"> File transmission example on the Ubuntu 7.10 system: <p>Set the username of a client to test and copy the config.text file from the network device with the IP address of 192.168.195.188 to the /root directory on the local device.</p> <pre>root@dhcpd:~#scp test@192.168.23.122:/config.text /root/config.text test@192.168.195.188's password: config.text 100% 1506 1.5KB/s 00:00 Read from remote host 192.168.195.188: Connection reset by peer</pre>

11.4.3 Configuring the SSH Client

Configuration Effect

On the network device that supports the SSH server, enable the SSH server function, and specify the user authentication method and supported SSH versions. Then, you can use the built-in SSH client function of the device to set up a secure connection with the SSH server, implementing remote device management.

Notes

- The SSH server function must be configured in advance on the device that needs to remotely support the SSH server.
- The SSH client must communicate with the SSH server properly.

Configuration Steps

↘ Specifying the Source Interface of the SSH Client

- (Optional) This configuration must be performed on the SSH-client device.

↘ Establishing a Session with the SSH Server

- (Optional) Use the **ssh** command on the client to set up a connection with a remote server.
- Before using this command, enable the SSH server function and configure the SSH key and authentication mode on the server.

↘ Recovering an Established SSH Session

- (Optional) Run the related command to recover a session after temporary stop if necessary.

↘ Disconnecting a Suspended SSH Session

- (Optional) This configuration must be performed on the SSH client if you need to disconnect a specified SSH session.

Verification

Run the **show ssh-session** command to display information about every established SSH client session.

Related Commands

↘ Specifying the Source Interface of the SSH Client

Command	ip ssh source-interface <i>interface-name</i>
Parameter Description	<i>interface-name</i> : Specifies an interface, the IP address of which will be used as the source address of an SSH client session.
Command Mode	Global configuration mode
Usage Guide	This command is used to specify an interface, the IP address of which will be used as the global source address of an SSH client session. When the ssh command is used to connect to an SSH server, this global configuration will be used if a source interface or a source address is not specified for this connection. Run the no ip ssh source-interface command to restore the default setting.

↘ Establishing a Session with the SSH Server

Command	ssh [oob] [-v {1 2}][-c {3des aes128-cbc aes192-cbc aes256-cbc}] [-l <i>username</i>] [-m { hmac-md5-96 hmac-md5-128 hmac-sha1-96 hmac-sha1-160 }] [-p <i>port-num</i>] [<i>ip-addr</i> <i>hostname</i>][via <i>mgmt-name</i>] [/source { ip <i>A.B.C.D</i> ipv6 <i>X:X:X:X</i> interface <i>interface-name</i> }] [/vrf <i>vrf-name</i>]
Parameter Description	N/A
Command Mode	User EXEC mode
Usage Guide	The ssh command is used to set up a secure and encrypted connection from the local device (an SSH client) to another device (an SSH server) or any other server that supports SSHv1 or SSHv2. This

	<p>connection provides a mechanism similar to the Telnet connection except that all data transmitted over this connection is encrypted. Based on authentication and encryption, the SSH client can set up a secure connection on an insecure network.</p> <p> SSHv1 supports only the DES (56-bit key) and 3DES (168-bit key) encryption algorithms.</p> <p> SSHv2 supports the following Advanced Encryption Standards (AES): ASE128-CBC, AES192-CBC, and AES256-CBC.</p> <p> SSHv1 does not support the Hashed Message Authentication Code (HMAC).</p> <p> If you specify an unmatched encryption or authentication algorithm when selecting an SSH version, the unmatched algorithm will be ignored when a connection is set up.</p>
--	---

↘ Recovering an Established SSH Client Session

Command	ssh-session <i>session-id</i>
Parameter Description	<i>session-id</i> : Indicates the ID of an established SSH client session.
Command Mode	User EXEC mode
Usage Guide	This command is used to restore the use of an established SSH client session. When the ssh command is used to initiate an SSH client session, you can press Ctrl+Shift+6+X to temporarily exit the session. To recover this session, run the ssh-session command. In addition, if the session is already established, you can run the show ssh-session command to display information about the established session.

↘ Disconnecting a Suspended SSH Session

Command	disconnect ssh-session <i>session-id</i>
Parameter Description	<i>session-id</i> : Indicates the ID of a suspended SSH client session.
Command Mode	User EXEC mode
Usage Guide	You can specify an SSH client session ID to disconnect the specified SSH client session.

Configuration Example

↘ Specifying the Source Interface of the SSH Client

Configuration Steps	<ul style="list-style-type: none"> Run the ip ssh source-interface <i>interface-name</i> command to specify an interface, the IP address of which will be used as the global source address of an SSH client session.
	<pre>Ruijie#configure terminal Ruijie(config)#ipsshsource-interface gigabitEthernet 0/1</pre>
Verification	N/A

➤ Establishing a Session with the SSH Server

<p>Scenario Figure 11-26</p>	 <p>The SSH server function is enabled on the server. The ssh command is used on the client to set up a secure connection with the server.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable the SSH server function on the server. ● Configure the SSH key on the server. ● Configure the authentication mode of the SSH server, and use the local line authentication mode for Line 0 to Line 4. ● Configure the IP address of the Gi 0/1 interface of the SSH server. The client will use this address as the source address to connect to the SSH server. ● Configure the SSH client, and specify the source address of the SSH client. <hr/> <p>i By default, the SSH server supports two SSH versions: SSHv1 and SSHv2.</p> <p>i With this key, the SSH server decrypts the encrypted password received from the SSH client, compares the decrypted plain text with the password stored on the server, and returns a message indicating the successful or unsuccessful authentication. 11.5 Monitoring

Displaying

Description	Command
Displays the effective SSH server configurations.	show ipssh
Displays the established SSH connection.	show ssh
Displays the public information of the SSH public key.	show crypto key mypubkey
Displays the established SSH client session.	show ssh-session

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs SSH sessions.	debug ssh
Debugs SSH client sessions.	debug ssh client

12 Configuring URPF

12.1 Overview

Unicast Reverse Path Forwarding (URPF) is a function that protects the network against source address spoofing.

URPF obtains the source address and inbound interface of a received packet, and searches a forwarding entry in the forwarding table based on the source address. If the entry does not exist, the packet is dropped. If the outbound interface of the forwarding entry does not match the inbound interface of the packet, the packet is also dropped. Otherwise, the packet is forwarded.

URPF is implemented in two modes:

- **Strict mode:** It is often deployed on a point-to-point (P2P) interface, and inbound and outbound data streams must go through the network of the P2P interface.
- **Loose mode:** It is applicable to the asymmetric routes or multihomed network that have the problem of asymmetric traffic.

Protocols and Standards

- RFC 2827: Network Ingress Filtering: DDOS Attacks which employ IP Source Address Spoofing
- RFC 3704: Ingress Filtering for Multi-homed Networks

12.2 Applications

Application	Description
Strict Mode	Block the packets with spoofed sourced addresses at the access layer or aggregation layer to prevent sending these packets from PCs to the core network.
Loose Mode	On a multihomed network, the user network is connected to multiple Internet service providers (ISPs), and the inbound and outbound traffic is not symmetric. Deploy the URPF loose mode on the outbound interface connected to ISPs to prevent invalid packets from attacking the user network.

12.2.1 Strict Mode

Scenario

An attacker initiates an attack by sending packets with the spoofed source address 11.0.0.1. As a result, the server sends a lot of SYN or ACK packets to the hosts that do not initiate the attack, and the host with the real source address 11.0.0.1 is also affected. Even worse, if the network administrator determines that this address initiates an attack to the network, and therefore blocks all data streams coming from this source address, the denial of service (DoS) of this source address occurs.

Figure 12-1

Remarks The attacker sends spoofing packets using a spoofed address of the casualty.

Deployment

- Deploy the URPF strict mode on device A to protect the device against source address spoofing.

12.2.2 Loose Mode

Scenario

The asymmetric route is a common network application used to control the network traffic or to meet the routing policy requirements.

As shown in Figure 12-2, if the URPF strict mode is enabled on the G1/1 interface of R 1, R1 receives a packet from the network segment 192.168.20.0/24 on the G1/1 interface, but the interface obtained through the URPF check is G1/2. Therefore, this packet fails in the URPF check and is dropped.

Figure 12-2

Deployment

- Reversely search a route based on the source IP address of a received packet. The purpose is to find a route, and it is not required that the outbound interface of the next hop on the route must be the inbound interface of the received packet.
- The URPF loose mode can resolve the asymmetric traffic problem of the asymmetric route and prevents access of invalid data streams.

12.3 Features

Basic Concepts

↳ URPF Strict Mode

Obtain the source address and inbound interface of a received packet, and search a forwarding entry in the forwarding table based on the source address. If the entry does not exist, the packet is dropped. If the outbound interface of the forwarding entry does not match the inbound interface of the packet, the packet is also dropped. The strict mode requires that the inbound interface of a received packet must be the outbound interface of the route entry to the source address of the packet.

↳ URPF Loose Mode

Reversely search a route based on the source IP address of a received packet. The purpose is to find a route, and it is not required that the outbound interface of the next hop on the route must be the inbound interface of the received packet. However, the route cannot be a route of a host on the local network.

↳ URPF Packet Loss Rate

The URPF packet loss rate is equal to the number of packets dropped due to the URPF check per second. The unit is packets/second, that is, pps.

↳ Calculation Interval of the URPF Packet Loss Rate

It is the interval from the previous time the packet loss rate is calculated to the current time the packet loss rate is calculated.

↳ Sampling Interval of the URPF Packet Loss Rate

It is the interval at which the number of lost packets is collected for calculating the packet loss rate. This interval must be equal to or longer than the calculation interval of the packet loss rate.

↳ Threshold of the URPF Packet Loss Rate

It refers to the maximum packet loss rate that is acceptable. When the packet loss rate exceeds the threshold, alarms can be sent to users through syslogs or trap messages. You can adjust the threshold of the packet loss rate based on the actual conditions of the network.

↳ Alarm Interval of the URPF Packet Loss Rate

It is the interval at which alarms are sent to users. You can adjust the alarm based on the actual conditions of the network to prevent frequently output of logs or trap messages.

↘ Calculation of the URPS Packet Loss Rate

Between the period of time from enabling of URPF to the time that the sampling interval arrives, the packet loss rate is equal to the number of lost packets measured within the sampling interval divided by the URPF enabling duration. After that, the packet loss rate is calculated as follows: Current packet loss rate = (Current number of lost packets measured at the calculation interval – Number of lost packets measured before the sampling interval)/Sampling interval

Overview

Feature	Description
Enabling URPF	Enable URPF to perform a URPF check, thus protecting the device against source address spoofing.
Notifying the URPF Packet Loss Rate	To facilitate monitoring of information about lost packets after URPF is enabled, Ruijie devices support the use of syslogs and trap messages to proactively notify users of the packet loss information detected in the URPF check.

12.3.1 Enabling URPF

Enable URPF to perform a URPF check on IPv4 or IPv6 packets, thus protecting the device against source address spoofing.

Working Principle

URPF can be applied to IP packets based on configurations, but the following packets are not checked by URPF:

1. After URPF is enabled, the source address of a packet is checked only if the destination address of the packet is a unicast address, and is not checked if the packet is a multicast packet or an IPv4 broadcast packet.
2. If the source IP address of a DHCP/BOOTP packet is 0.0.0.0 and the destination IP address is 255.255.255.255, the packet is not checked by URPF.
3. A loopback packet sent by the local device to itself is not checked by URPF.

↘ URPF Configured in Interface Configuration Mode

URPF, including IPv4 URPF and IPv6 URPF, is performed on packets received on the configured interface. URPF configured in global configuration mode is mutually exclusive with URPF configured in interface configuration mode.

- By default, the default route is not used for the URPF check. You can configure data to use the default route for the URPF check if necessary.
 - By default, packets that fail in the URPF check will be dropped. If the ACL (*acl-name*) is configured, the packet is matched against the ACL after it fails in the URPF check. If no ACL exists, or a packet matches a deny ACE, the packet will be dropped. If the packet matches a permit ACE, the packet will be forwarded.
-
- ✔ A switch supports configuration of URPF on a routed port or L3 aggregate port (AP). Some switches also support configuration of URPF on a switch virtual interface (SVI). (For details about the switch products, contact Ruijie technical support engineers.) The following constraints exist:

- URPF does not support association with the ACL option.
- After URPF is enabled on interfaces, a URPF check is performed on all packets received on physical ports corresponding to these interfaces, which increase the scope of packets checked by URPF. If a packet received on a tunnel port is also received on the preceding physical ports, the packet is also checked by URPF. In such a scenario, be cautious in enabling URPF.
- After URPF is enabled, the route forwarding capacity of the device will be reduced by half.
- After the URPF strict mode is enabled, if a packet received on an interface matches an equal-cost route during the URPF check, the packet will be processed according to the URPF loose mode.

Related Configuration

↳ Enabling URPF for a Specified Interface

By default, URPF is disabled for a specified interface.

Run the **ip verify unicast source reachable-via {rx | any} [allow-default] [acl-name]** command to enable or disable the IPv4 or IPv6 URPF function for a specified interface.

By default, the default route is not used for the URPF check. You can use the **allow-default** keyword to use the default route for the URPF check if necessary.

By default, packets that fail in the URPF check will be dropped. If the ACL (*acl-name*) is configured, the packet is matched against the ACL after it fails in the URPF check. If no ACL exists, or a packet matches a deny ACE, the packet will be dropped. If the packet matches a permit ACE, the packet will be forwarded.

12.3.2 Notifying the URPF Packet Loss Rate

To facilitate monitoring of information about lost packets after URPF is enabled, Ruijie devices support the use of syslogs and trap messages to proactively notify users of the packet loss information detected in the URPF check.

Working Principle

Between the period of time from enabling of URPF to the time that the sampling interval arrives, the packet loss rate is equal to the number of lost packets measured within the sampling interval divided by the URPF enabling duration. After that, the packet loss rate is calculated as follows: Current packet loss rate = (Current number of lost packets measured at the calculation interval – Number of lost packets measured before the sampling interval)/Sampling interval

After the function of monitoring the URPF packet loss information is enabled, the device can proactively send syslogs or trap messages to notify users of the packet loss information detected in the URPF check so that users can monitor the network status conveniently.

Related Configuration

↳ Configuring the Calculation Interval of the URPF Packet Loss Rate

By default, the calculation interval of the URPF packet loss rate is 30s. If the calculation interval is found too short, run the **ip verify urpf drop-rate compute interval seconds** command to modify the calculation interval.

The calculation interval of the URPF packet loss rate ranges from 30 to 300.

↘ [Configuring the Alarm Interval of the URPF Packet Loss Rate](#)

By default, the alarm interval of the URPF packet loss rate is 300s. If the alarm interval is found inappropriate, run the **ip verify urpf drop-rate notify hold-down *seconds*** command to modify the alarm interval of the URPF packet loss rate.

The unit of the alarm interval is second. The value ranges from 30 to 300.

↘ [Configuring the Function of Monitoring the URPF Packet Loss Information](#)

By default, the function of monitoring the URPF packet loss information is disabled.

Run the **ip verify urpf drop-rate notify** command to enable or disable the function of monitoring the URPF packet loss information.

↘ [Configuring the Threshold of the URPF Packet Loss Rate](#)

By default, the threshold of the URPF packet loss rate is 1,000 pps. If the threshold is found inappropriate, run the **ip verify urpf notification threshold *rate-value*** command to modify the threshold of the URPF packet loss rate.

The unit of the threshold is pps. The value ranges from 0 to 4,294,967,295.

12.4 Configuration

Configuration Item	Description and Command	
Enabling URPF	 (Mandatory) It is used to enable URPF.	
	ip verify unicast source reachable-via <i>rx</i> <i>(Global configuration mode)</i>	Enables URPF Globally.
	ip verify unicast source reachable-via { <i>rx</i> any } [allow-default] [<i>acl_name</i>] <i>(Interface configuration mode)</i>	Enables URPF for a specified interface.
Configuring the Function of Monitoring the URPF Packet Loss Information	 (Optional) It is used to enable the function of monitoring the URPF packet loss information.	
	ip verify urpf drop-rate compute interval <i>seconds</i>	Configures the calculation interval of the URPF packet loss rate.
	ip verify urpf drop-rate notify	Configures the function of monitoring URPF packet loss information.
	ip verify urpf drop-rate notify hold-down <i>seconds</i>	Configures the alarm interval of the URPF packet loss rate.
	ip erify urpf notification threshold <i>rate-value</i>	Configures the threshold of the URPF packet loss rate.

12.4.1 Enabling URPF

Configuration Effect

- Enable URPF to perform a URPF check on IP packets, thus protecting the device against source address spoofing.
- URPF can be enabled in interface configuration mode or global configuration mode.

Notes

- URPF is implemented with the help of the existing unicast routes on the network. Therefore, unicast routes must be configured on the network.

Configuration Steps

↳ Enabling IPv4 URPF for a Specified Interface

- Mandatory.
- IPv4 URPF configured in interface configuration mode is mutually exclusive with IPv4 URPF configured in global configuration mode.
- Switches supports configuration of IPv4 URPF on a routed port or L3 AP port, other products supports configuration of IPv4 URPF on a routed port.

Verification

Enable URPF and check the source address as follows:

- If the strict mode is used, check whether a packet is forwarded only when the forwarding table contains the source address of the received IPv4 or IPv6 packet and the outbound interface of the searched forwarding entry matches the inbound interface of the packet; otherwise, the packet is dropped.
- If the loose mode is used, check whether a packet is forwarded when a forwarding entry can be found in the forwarding table for the source address of the received IPv4 or IPv6 packet; otherwise, the packet is dropped.

Related Commands

↳ Enabling IPv4 URPF for a Specified Interface

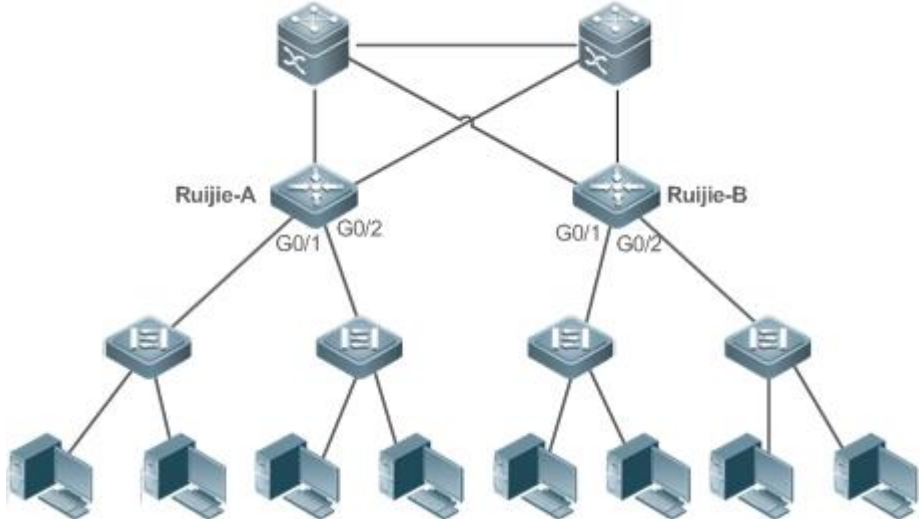

Command	ip verify unicast source reachable-via { rx any } [allow-default] [acl-id]
Parameter Description	<p>rx: Indicates that the URPF check is implemented in strict mode. The strict mode requires that the outbound interface of the forwarding entry found in the forwarding table based on the source address of a received IP packet must match the inbound interface of the packet.</p> <p>any: Indicates that the URPF check is implemented in loose mode. The loose mode only requires that a forwarding entry can be found in the forwarding table based on the source address of a received IP packet.</p> <p>allow-default: (Optional) Indicates that the default route can be used for the URPF check.</p> <p>acl-id: (Optional) Indicates the ID of the ACL. Values include 1 to 99 (IP standard access list), 100 to 199 (IP extended access list), 1300 to 1999 (IP standard access list, expanded range), and 2000 to 2699 (IP extended access list, expanded range).</p>

Command Mode	Interface configuration mode
Usage Guide	<p>Based on the source address of a received IP packet, URPF checks whether any route to the source address exists in the forwarding table and accordingly determines whether the packet is valid. If no forwarding entry is matched, the packet is determined as invalid.</p> <p>You can enable URPF in interface configuration mode to perform a URPF check on packets received on the interface.</p> <p>By default, the default route is not used for the URPF check. You can use the allow-default keyword to use the default route for the URPF check if necessary.</p> <p>By default, packets that fail in the URPF check will be dropped. If the ACL (<i>acl-name</i>) is configured, the packet is matched against the ACL after it fails in the URPF check. If no ACL exists, or a packet matches a deny ACE, the packet will be dropped. If the packet matches a permit ACE, the packet will be forwarded.</p> <hr/> <p>i A switch supports configuration of URPF on a routed port or L3 AP port. In addition, the following constraints exists:</p> <ol style="list-style-type: none"> 1. URPF does not support association with the ACL option. 2. After URPF is enabled on interfaces, a URPF check is performed on all packets received on physical ports corresponding to these interfaces, which increase the scope of packets checked by URPF. If a packet received on a tunnel port is also received on the preceding physical ports, the packet is also checked by URPF. In such as scenario, be cautious in enabling URPF. 3. After URPF is enabled, the route forwarding capacity of the device will be reduced by half. 4. After the URPF strict mode is enabled, if a packet received on an interface matches an equal-cost route during the URPF check, the packet will be processed according to the URPF loose mode. 5. If URPF is configured in global configuration mode, the default route cannot be used for the URPF check. <hr/> <p>i URPF configured in global configuration mode is mutually exclusive with URPF configured in interface configuration mode.</p>

Configuration Example

▾ Configuring the Strict Mode

	<p>Block the packets with spoofed sourced addresses at the access layer or aggregation layer to prevent sending these packets from PCs to the core network.</p> <p>To meet the preceding requirement, enable URPF in strict mode on the interface between the aggregation device and the access device.</p>
--	---

<p>Scenario Figure 12-3</p>	
<p>Verification</p>	<p>As shown in Figure 12-3, enable URPF in strict mode on the aggregation devices, including Ruijie A and Ruijie B. The configurations are as follows:</p>
<p>Ruijie-A</p>	<pre>Ruijie-A# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie-A (config)# interface gigabitEthernet0/1 Ruijie-A (config-if-GigabitEthernet 0/1)# ip address 195.52.1.1 255.255.255.0 Ruijie-A (config-if-GigabitEthernet 0/1)# ip verify unicast source reachable-via rx Ruijie-A (config-if-GigabitEthernet 0/1)# ip verify urpf drop-rate notify Ruijie-A (config-if-GigabitEthernet 0/1)# exit Ruijie-A (config)# interface gigabitEthernet0/2 Ruijie-A (config-if-GigabitEthernet 0/2)# ip address 195.52.2.1 255.255.255.0 Ruijie-A (config-if-GigabitEthernet 0/2)# ip verify unicast source reachable-via rx Ruijie-A (config-if-GigabitEthernet 0/2)# ip verify urpf drop-rate notify Ruijie-A (config-if-GigabitEthernet 0/2)# exit</pre>
<p>Ruijie-B</p>	<pre>Ruijie-B# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie-B (config)# interface gigabitEthernet0/1 Ruijie-B (config-if-GigabitEthernet 0/1)# ip address 195.52.3.1 255.255.255.0 Ruijie-B (config-if-GigabitEthernet 0/1)# ip verify unicast source reachable-via rx Ruijie-B (config-if-GigabitEthernet 0/1)# ip verify urpf drop-rate notify Ruijie-B (config-if-GigabitEthernet 0/1)# exit</pre>

	<pre>Ruijie-B (config)# interface gigabitEthernet0/2 Ruijie-B (config-if-GigabitEthernet 0/2)#ip address 195.52.4.1 255.255.255.0 Ruijie-B (config-if-GigabitEthernet 0/2)#ip verify unicast source reachable-via rx Ruijie-B (config-if-GigabitEthernet 0/2)# ip verify urpf drop-rate notify Ruijie-B (config-if-GigabitEthernet 0/2)#exit</pre>
Verification	<p>If source address spoofing exists on the network, run the show ip urpf command to display the number of spoofing packets dropped by URPF.</p>
A	<pre>Ruijie-A#show ip urpf interface gigabitEthernet 0/1 IP verify source reachable-via RX IP verify URPF drop-rate notify enabled IP verify URPF notification threshold is 1000pps Number of drop packets in this interface is 124 Number of drop-rate notification counts in this interface is 0 Ruijie-A#show ip urpf interface gigabitEthernet 0/2 IP verify source reachable-via RX IP verify URPF drop-rate notify enabled IP verify URPF notification threshold is 1000pps Number of drop packets in this interface is 133 Number of drop-rate notification counts in this interface is 0</pre>
B	<pre>Ruijie-B#show ip urpf interface gigabitEthernet 0/1 IP verify source reachable-via RX IP verify URPF drop-rate notify enabled IP verify URPF notification threshold is 1000pps Number of drop packets in this interface is 124 Number of drop-rate notification counts in this interface is 0 Ruijie-B#show ip urpf interface gigabitEthernet 0/2 IP verify source reachable-via RX IP verify URPF drop-rate notify enabled</pre>

<pre>IP verify URPF notification threshold is 1000pps Number of drop packets in this interface is 250 Number of drop-rate notification counts in this interface is 0</pre>
--

📌 **Configuring the Loose Mode**

	<p>On the egress device Ruijie A of user network A, to prevent invalid packets from attacking the user network, enable URPF in loose mode on the outbound interfaces G3/1 and G3/2 that connect to two ISPs.</p>
<p>Scenario Figure 12-4</p>	<p>The diagram illustrates a network topology. On the left, 'User Network B' is connected to the 'Internet'. The 'Internet' is represented by a cloud and is connected to two 'ISP' nodes. On the right, 'User Network A' is connected to a device labeled 'Ruijie-A'. Ruijie-A has two interfaces, G3/1 and G3/2, which are connected to the two ISPs respectively. Red arrows indicate connections from the ISPs to Ruijie-A, and blue arrows indicate connections from the Internet to the ISPs.</p>
<p>Ruijie-A</p>	<pre>Ruijie-A# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie-A (config)# interface gigabitEthernet3/1 Ruijie-A (config-if-GigabitEthernet 3/1)# ip address 195.52.1.2 255.255.255.252 Ruijie-A (config-if-GigabitEthernet 3/1)# ip verify unicast source reachable-via any Ruijie-A (config-if-GigabitEthernet 3/1)# ip verify urpf drop-rate notify Ruijie-A (config-if-GigabitEthernet 3/1)# exit Ruijie-A (config)# interface gigabitEthernet3/2 Ruijie-A (config-if-GigabitEthernet 3/2)# ip address 152.95.1.2 255.255.255.252 Ruijie-A (config-if-GigabitEthernet 3/2)# ip verify unicast source reachable-via any Ruijie-A (config-if-GigabitEthernet 3/2)# ip verify urpf drop-rate notify Ruijie-A (config-if-GigabitEthernet 3/2)# end</pre>
<p>Verification</p>	<p>If source address spoofing exists on the network, run the show ip urpf command to display the number of spoofing packets dropped by URPF.</p>
<p>A</p>	<pre>Ruijie #show ip urpf IP verify URPF drop-rate compute interval is 300s IP verify URPF drop-rate notify hold-down is 300s Interface gigabitEthernet3/1</pre>

```
IP verify source reachable-via ANY
IP verify URPF drop-rate notify enabled
IP verify URPF notification threshold is 1000pps
Number of drop packets in this interface is 4121
Number of drop-rate notification counts in this interface is 2
Interface gigabitEthernet3/2
IP verify source reachable-via ANY
IP verify URPF drop-rate notify enabled
IP verify URPF notification threshold is 1000pps
Number of drop packets in this interface is 352
Number of drop-rate notification counts in this interface is 0
```

12.4.2 Configuring the Function of Monitoring the URPF Packet Loss Information

Configuration Effect

- After the function of monitoring the URPF packet loss information is enabled, the device can proactively send syslogs or trap messages to notify users of the packet loss information detected in the URPF check so that users can monitor the network status conveniently.

Notes

- URPF must be enabled.

Configuration Steps

▾ Configuring the Calculation Interval of the URPF Packet Loss Rate

- Optional.
- Global configuration mode

▾ Configuring the Alarm Interval of the URPF Packet Loss Rate

- Optional.
- Global configuration mode

▾ Configuring the Function of Monitoring the URPF Packet Loss Information

- Optional.
- Interface configuration mode

▾ Configuring the Threshold of the URPF Packet Loss Rate

- Optional.
- Interface configuration mode

Verification

Simulate a source address spoofing attack, enable URPF, and check as follows:

- Enable the alarm function. After the packet loss rate exceeds the threshold, check whether an alarm can be generated normally.

Related Commands

Configuring the Calculation Interval of the URPF Packet Loss Rate

Command	ip verify urpf drop-rate compute interval <i>seconds</i>
Parameter Description	interval seconds : Indicates the calculation interval of the URPF packet loss rate. The unit is second. The value ranges from 30 to 300. The default value is 30s.
Command Mode	Global configuration mode
Usage Guide	The calculation interval of the URPF packet loss rate is configured in global configuration mode. The configuration is applied to the global and interface-based calculation of the URPF packet loss rate.

Configuring the Alarm Interval of the URPF Packet Loss Rate

Command	ip verify urpf drop-rate notify hold-down <i>seconds</i>
Parameter Description	hold-down seconds : Indicates the alarm interval of the URPF packet loss rate. The unit is second. The value ranges from 30 to 300. The default value is 30s.
Command Mode	Global configuration mode
Usage Guide	The alarm interval of the URPF packet loss rate is configured in global configuration mode. The configuration is applied to the global and interface-based alarms of the URPF packet loss rate

Configuring the Function of Monitoring the IPv4 URPF Packet Loss Information

Command	ip verify urpf drop-rate notify
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	After the function of monitoring the URPF packet loss information is enabled, the device can proactively send syslogs or trap messages to notify users of the packet loss information detected in the URPF check so that users can monitor the network status conveniently.

Configuring the Threshold of the IPv4 URPF Packet Loss Rate

Command	ip verify urpf notification threshold <i>rate-value</i>
----------------	--

Parameter Description	threshold <i>rate-value</i> : Indicates the threshold of the URPF packet loss rate. The unit is pps. The value ranges from 0 to 4,294,967,295. The default value is 1,000 pps.
Command Mode	Interface configuration mode
Usage Guide	If the threshold is 0, a notification is sent for every packet that is dropped because it fails in the URPF check. You can adjust the threshold based on the actual situation of the network.

Configuration Example

Setting the Calculation Interval of the URPF Packet Loss Rate to 120s

Configuration Steps	Set the calculation interval of the URPF packet loss rate to 120s in global configuration mode. The
	<pre>Ruijie#configure terminal Ruijie(config)# ip verify urpf drop-rate compute interval 120 Ruijie(config)# end</pre>
Verification	Run the show ip urpf command to check whether the configuration takes effect.
	<pre>Ruijie# show ip urpf IP verify URPF drop-rate compute interval is 120s</pre>

Setting the Alarm Interval of the URPF Packet Loss Rate to 120s

Configuration Steps	Set the alarm interval of the URPF packet loss rate to 120s in global configuration mode.
	<pre>Ruijie#configure terminal Ruijie(config)# ip verify urpf drop-rate notify hold-down 120 Ruijie(config)# end</pre>
Verification	Run the show ip urpf command to check whether the configuration takes effect.
	<pre>Ruijie# show ip urpf IP verify URPF drop-rate notify hold-down is 120s</pre>

Enabling the Function of Monitoring the IPv4 URPF Packet Loss Information on the Interface GigabitEthernet 0/1

Configuration	Enable the function of monitoring the IPv4 URPF packet loss information on the interface GigabitEthernet 0/1.
	<pre>Ruijie#configure terminal Ruijie(config)# interface gigabitEthernet0/1</pre>

	<pre>Ruijie(config-if-GigabitEthernet 0/1)# ip verify unicast source reachable-via rx Ruijie(config-if-GigabitEthernet 0/1)# ip verify urpf drop-rate notify</pre>
Verification	Run the show ip urpf commands to check whether the function of monitoring the IPv4 URPF packet loss information is enabled on the interface GigabitEthernet 0/1.
	<pre>Ruijie# show ip urpf interface gigabitEthernet 0/1 IP verify source reachable-via RX IP verify URPF drop-rate notify is enabled IP verify URPF notification threshold is 1000pps Number of drop packets in this interface is 0 Number of drop-rate notification counts in this interface is 0</pre>

📌 Setting the Threshold of the IPv4 URPF Packet Loss Rate to 2000 pps on the Interface GigabitEthernet 0/1

Configuration	Set the threshold of the IPv4 URPF packet loss rate to 2000 pps on the interface GigabitEthernet 0/1.
	<pre>Ruijie#configure terminal Ruijie(config)# interface gigabitEthernet0/1 Ruijie(config-if-GigabitEthernet 0/1)# ip verify unicast source reachable-via rx Ruijie(config-if-GigabitEthernet 0/1)#ip verify urpf notification threshold 2000</pre>
Verification	Run the show ip urpf commands to check the threshold of the IPv4 URPF packet loss rate
	<pre>Ruijie# show ip urpf interface gigabitEthernet 0/1 IP verify source reachable-via RX IP verify URPF drop-rate notify is enabled IP verify URPF notification threshold is 2000pps Number of drop packets in this interface is 0 Number of drop-rate notification counts in this interface is 0</pre>

12.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
-------------	---------

Clears statistics of the number of packets dropped during the IPv4 URPF check.	clear ip urpf [interface <i>interface-name</i>]
--	--

Displaying

Description	Command
Displays the IPv4 URPF configuration and statistics.	show ip urpf [interface <i>interface-name</i>]

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the URPF events.	debug urpf event

13 Configuring CPP

13.1 Overview

The CPU Protect Policy (CPP) provides policies for protecting the CPU of a switch.

In network environments, various attack packets spread, which may cause high CPU usages of the switches, affect protocol running and even difficulty in switch management. To this end, switch CPUs must be protected, that is, traffic control and priority-based processing must be performed for various incoming packets to ensure the processing capabilities of the switch CPUs.

CPP can effectively prevent malicious attacks in the network and provide a clean environment for legitimate protocol packets.

CPP is enabled by default. It provides protection during the entire operation of switches.

13.2 Applications

Application	Description
Preventing Malicious Attacks	When various malicious attacks such as ARP attacks intrude in a network, CPP divides attack packets into queues of different priorities so that the attack packets will not affect other packets.
Preventing CPU Processing Bottlenecks	Even when no attacks exist, it would become a bottleneck for CPU to handle excessive normal traffic. CPP can limit the rate of packets being sent to the CPU to ensure normal operation of switches.

13.2.1 Preventing Malicious Attacks

Scenario

Network switches at all levels may be attacked by malicious packets, typically ARP attacks.

As shown in Figure 13-1, switch CPUs process three types of packets: forwarding-plane, control-plane and protocol-plane. Forwarding-plane packets are used for routing, including ARP packets and IP route disconnection packets. Control-plane packets are used to manage services on switches, including Telnet packets and HTTP packets. Protocol-plane packets serve for running protocols, including BPDU packets and OSPF packets.

When an attacker initiates attacks by using ARP packets, the ARP packets will be sent to the CPU for processing. Since the CPU has limited processing capabilities, the ARP packets may force out other packets (which may be discarded) and consume many CPU resources (for processing ARP attack packets). Consequently, the CPU fails to work normally. In the scenario as shown in Figure 13-1, possible consequences include: common users fail to access the network; administrators fail to manage switches; the OSPF link between switch A and the neighbor B is disconnected and route learning fails.

Figure 13-1 Networking Topology of Switch Services and Attacks

Deployment

- By default, CPP classifies ARP packets, Telnet packets, IP route disconnection packets, and OSPF packets into queues of different priorities. In this way, ARP packets will not affect other packets.
- By default, CPP limits the rates of ARP packets and the rates of the priority queue where the ARP packets reside to ensure that the attack packets do not occupy too many CPU resources.
- Packets in the same priority queue with ARP packets may be affected by ARP attack packets. You can divide the packets and the ARP packets into different priority queues by means of configuration.
- When ARP attack packets exist, CPP cannot prevent normal ARP packets from being affected. CPP can only differentiate the packet type but cannot distinguish attack packets from normal packets of the same type. In this case, the Network Foundation Protection Policy (NFPP) function can be used to provide higher-granularity attack prevention.

i For description of NFPP configurations, see the *Configuring NFPP*.

13.2.2 Preventing CPU Processing Bottlenecks

Scenario

Even though no attacks exist, many packets may need to be sent to the CPU for processing at an instant.

For example, the accesses to the core device of a campus network are counted in ten thousands. The traffic of normal ARP packets may reach dozens of thousands packets per second (PPS). If all packets are sent to the CPU for processing, the CPU resources cannot support the processing, which may cause protocol flapping and abnormal CPU running.

Deployment

- By default, the CPP function limits the rates of ARP packets and the rates of the priority queue where the APR packets reside to control the rate of ARP packets sent to the CPU and ensure that the CPU resource consumption is within a specified range and that the CPU can normally process other protocols.
- By default, the CPP function also limits the rates of other packets at the user level, such as Web authentication and 802.1X authentication packets.

13.3 Features

Basic Concepts

↘ QoS, DiffServ

Quality of Service (QoS) is a network security mechanism, a technology used to solve the problems of network delay and congestion.

DiffServ refers to the differentiated service model, which is a typical model implemented by QoS for classifying service streams to provide differentiated services.

↘ Bandwidth, Rate

Bandwidth refers to the maximum allowable data rate, which refers to the rate threshold in this document. Packets whose rates exceed the threshold will be discarded.

The rate indicates an actual data rate. When the rate of packets exceeds the bandwidth, packets out of the limit will be discarded. The rate must be equal to or smaller than the bandwidth.

The bandwidth and rate units in this document are packets per second (pps).

↘ L2, L3, L4

The structure of packets is hierarchical based on the TCP/IP model.

L2 refers to layer-2 headers, namely, the Ethernet encapsulation part; L3 refers to layer-3 headers, namely, the IP encapsulation part; L4 refers to layer-4 headers, usually, the TCP/UDP encapsulation part.

↘ Priority Queue, SP

Packets are cached inside a switch and packets in the output direction are cached in queues. Priority queues are mapped to Strict Priorities (SPs). Queues are not equal but have different priorities.

The SP is a kind of QoS scheduling algorithm. When a higher priority queue has packets, the packets in this queue are scheduled first. Scheduling refers to selecting packets from queues for output and refers to selecting and sending the packets to the CPU in this document.

↘ CPU interface

Before sending packets to the CPU, a switch will cache the packets. The process of sending packets to the CPU is similar to the process of packet output. The CPU interface is a virtual interface. When packets are sent to the CPU, the packets will be output from this virtual interface. The priority queue and SP mentioned above are based on the CPU interface.

Overview

CPP protects the CPU by using the standard QoS DiffServ model.

Figure 13-2 CPP Implementation Model

Feature	Description
Classifier	Classifies packet types and provides assurance for the subsequent implementation of QoS policies.
Meter	Limits rates based on packet types and controls the bandwidth for a specific packet type.
Queue	Queue packets to be sent to the CPU and select different queues based on packet types.
Scheduler	Selects and schedules queues to be sent to the CPU.
Shaper	Performs rate limit and bandwidth control on priority queues and the CPU interface.

13.3.1 Classifier

[Working Principle](#)

The Classifier classifies all packets to be sent to the CPU based on the L2, L3 and L4 information of the packets. Classifying packets is the basis for implementing QoS policies. In subsequent actions, different policies are implemented based on the classification to provide differentiated services. A switch provides fixed classification. The management function classifies packet types based on the protocols supported by the switch, for example, STP BPDU packets and ICMP packets. Packet types cannot be customized.

13.3.2 Meter

[Working Principle](#)

The Meter limits the rates of different packets based on the preset rate thresholds. You can set different rate thresholds for different packet types. When the rate of a packet type exceeds the corresponding threshold, the packets out of the limit will be discarded.

By using the Meter, you can control the rate of a packet type sent to the CPU within a threshold to prevent specific attack packets from exerting large impacts on the CPU resources. This is the level-1 protection of the CPP.

[Related Configuration](#)

- By default, each packet type corresponds to a rate threshold (bandwidth) and Meter policies are implemented based on the rate threshold.
- In application, you can run the `cpu-protect type packet-type bandwidth bandwidth-value` command to set Meter policies for specified packet types.

13.3.3 Queue

[Working Principle](#)

Queues are used to classify packets at level 2. You can select the same queue for different packet types; meanwhile, queues cache packets inside switches and provide services for the Scheduler and Shaper.

CPP queues are SP queues. The SPs of the packets are determined based on the time when they are added to a queue. Packets with a larger queue number have a higher priority.

Related Configuration

- By default, each packet type is mapped to an SP queue.
- In application, you can run the **cpu-protect type** *packet-type* **traffic-class** *traffic-class-num* command to select SP queues for specific packet types.

13.3.4 Scheduler

Working Principle

The Scheduler schedules packets based on SPs of queues. That is, packets in a queue with a higher priority are scheduled first.

Before being scheduled, packets to be sent to the CPU are cached in queues. When being scheduled, the packets are sent to the CPU for processing.

 Only the SP scheduling policy is supported and cannot be modified.

13.3.5 Shaper

Working Principle

The Shaper is used to shape packets to be sent to the CPU, that is, when the actual rate of packets is greater than the shaping threshold, the packets must stay in the queue and cannot be scheduled. When packet rates fluctuate, the Shaper ensures that the rates of packets sent to the CPU are smooth (no more than the shaping threshold).

When the Shaper is available, packets in a queue with a lower priority may be scheduled before all packets in a queue with a higher priority are scheduled. If the rate of packets in a queue with certain priority exceeds the shaping threshold, scheduling of the packets in this queue may be stopped temporarily. Therefore, the Shaper can prevent packets in queues with lower priorities from starvation (which means that only packets in queues with higher priorities are scheduled and packets in queues with higher priorities are not scheduled).

Since the Shaper limits the scheduling rates of packets, it actually plays the rate limit function. The Shaper provides level-2 rate limit for priority queues and all packets sent to the CPU (CPU interface). The Shaper and Meter functions provide 3-level rate limit together and provide level-3 protection for the CPU.

Figure 13-3 3-Level Rate Limit of the CPP

Related Configuration

Configuring the Shaper for priority queues

- By default, each priority queue determines a shaping threshold (bandwidth).
- In application, you can run the **cpu-protect traffic-class traffic-class-num bandwidth bandwidth_value** command to perform Shaper configuration for a specific priority queue.

Configuring the Shaper for the CPU Interface

- By default, the CPU interface determines a shaping threshold (bandwidth).
- Run the **cpu-protect cpu bandwidth bandwidth_value** command to perform Shaper configuration for the CPU interface.

13.4 Configuration

Configuration	Description and Command	
Configuring CPP	 (Optional and configured by default) It is used to adjust the configuration parameters of CPP.	
	cpu-protect type packet-type bandwidth	Configures the Meter for a packet type.
	cpu-protect type packet-type traffic-class	Configures the priority queue for a packet type.
	cpu-protect traffic-class traffic-class-num bandwidth	Configures the Shaper for a priority queue.
	cpu-protect cpu bandwidth	Configures the Shaper for the CPU interface.

13.4.1 Configuring CPP

Configuration Effect

- By configuring the Meter function, you can set the bandwidth and rate limit for a packet type. Packets out of the limit will be directly discarded.
- By configuring the Queue function, you can select a priority queue for a packet type. Packets in a queue with a higher priority will be scheduled first.
- By configuring the Shaper function, you can set the bandwidth and rate limit for a CPU interface and a priority queue. Packets out of the limit will be directly discarded.

Notes

- Pay special attention when the bandwidth of a packet type is set to a smaller value, which may affect the normal traffic of the same type. To provide per-user CPP, combine the NFPP function.
- When the Meter and Shaper functions are combined, 3-level protection will be provided. Any level protection fights alone may bring negative effects. For example, if you want to increase the Meter of a packet type, you also need to adjust the Shaper of the corresponding priority queue. Otherwise, the packets of this type may affect other types of packets in the same priority queue.

Configuration Steps

▾ Configuring the Meter for a packet type

- You can use or modify the default value but cannot disable it.
- You need to modify the configuration in the following cases: when packets of a type are not attackers but are discarded, you need to increase the Meter of this packet type. If attacks of a packet type cause abnormal CPU running, you need to decrease the Meter of this packet type.
- This configuration is available on all switches in a network environment.

▾ Configuring the priority queue for a packet type

- You can use or modify the default value but cannot disable it.
- You need to modify the configuration in the following cases: When attacks of a packet type cause abnormality of other packets in the same queue, you can put the packet type in an unused queue. If a packet type cannot be discarded but the packet type is in the same queue with other packet types in use, you can put this packet type in a queue with a higher priority.
- This configuration is available on all switches in a network environment.

▾ Configuring the Shaper for a priority queue

- You can use or modify the default value and cannot disable it.
- You need to modify the configuration in the following cases: If the Meter value of a packet type is greater which causes that other packets in the corresponding priority queue do not have sufficient bandwidth, you need to increase the

Shaper for this priority queue. If attack packets are put in a priority queue and no other packets are in use, you need to increase the Shaper of this priority queue.

- This configuration is available on all switches in a network environment.

↘ **Configuring the Shaper for the CPU interface**

- You can use or modify the default value and cannot disable it.
- You are not advised to change the Shaper of the CPU interface.
- This configuration is available on all switches in a network environment.

Verification

- Modify the configurations when the system runs abnormally, and view the system running after the modification to check whether the configurations take effect.
- Check whether the configurations take effect by viewing corresponding configurations and statistic values. For details, see the following commands.

Clears the CPP statistics on the master device.	clear cpu-protect counters mboard

Displaying

Description	Command
Displays the configuration and statistics of a packet type.	show cpu-protect type <i>packet-type</i> [device <i>device_num</i>] [slot <i>slot_num</i>]
Displays the configuration and statistics of a priority queue.	show cpu-protect traffic-class <i>traffic-class-num</i> [device <i>device_num</i>] [slot <i>slot_num</i>]
Displays the configuration on a CPU interface.	show cpu-protect cpu
Displays all configurations and statistics on the master device.	show cpu-protect { mboard summary }
Displays all configurations and statistics of CPP.	show cpu-protect [device <i>device_num</i>] [slot <i>slot_num</i>]

Debugging

N/A

-  The preceding monitoring commands are available on both chassis and cassette devices in either the standalone mode or the VSU mode.
-  If the **device** and **slot** values are not specified, the **clear** command is used to clear the statistics of all nodes in the system and the **show** command is used to display the configurations on the master device.
-  In the standalone mode, the parameter **device** is unavailable. For chassis devices, the parameter **slot** is used to specify a line card; for cassette devices, **slot** is unavailable.
-  In the VSU mode, the parameter **device** indicates a chassis or cassette device. If the **device** value is not specified, it indicates the master chassis or the master device. For chassis devices, if the **device** value is specified the **slot** value must also be specified to identify a line card in a chassis; for cassette devices, **slot** is unavailable.

14 Configuring DHCP Snooping

14.1 Overview

DHCP Snooping: DHCP Snooping snoops DHCP interactive packets between clients and servers to record and monitor users' IP addresses and filter out illegal DHCP packets, including client request packets and server response packets. The legal user database generated from DHCP Snooping records may serve security applications like IP Source Guard.

Protocols and Standards

- RFC 2131: Dynamic Host Configuration Protocol
- RFC 2132: DHCP Options and BOOTP Vendor Extensions

14.2 Applications

Application	Description
Guarding against DHCP service spoofing	In a network with multiple DHCP servers, DHCP clients are allowed to obtain network configurations only from legal DHCP servers.
Guarding against DHCP packet flooding	Malicious network users may frequently send DHCP request packets.
Guarding against forged DHCP packets	Malicious network users may send forged DHCP request packets, for example, DHCP-RELEASE packets.
Guarding against IP/MAC spoofing	Malicious network users may send forged IP packets, for example, tampered source address fields of packets.
Preventing Lease of IP Addresses	Network users may lease IP addresses rather than obtaining them from a DHCP server.
Detecting ARP attack	Malicious users forge ARP response packets to intercept packets during normal users' communication.

14.2.1 Guarding Against DHCP Service Spoofing

Scenario

Multiple DHCP servers may exist in a network. It is essential to ensure that user PCs obtain network configurations only from the DHCP servers within a controlled area.

Take the following figure as an example. The DHCP client can only communicate with trusted DHCP servers.

- Request packets from the DHCP client can be transmitted only to trusted DHCP servers.
- Only the response packets from trusted DHCP servers can be transmitted to the client.

Figure 14-1

Remarks:	<p>S is an access device.</p> <p>A is a user PC.</p> <p>B is a DHCP server within the controlled area.</p> <p>C is a DHCP server out of the controlled area.</p>
-----------------	--

Deployment

- Enable DHCP Snooping on S to realize DHCP packet monitoring.
- Set the port on S connecting to B as trusted to transfer response packets.
- Set the rest of ports on S as untrusted to filter response packets.

14.2.2 Guarding Against DHCP Packet Flooding

Scenario

Potential malicious DHCP clients in a network may send high-rate DHCP packets. As a result, legitimate users cannot obtain IP addresses, and access devices are highly loaded or even break down. It is necessary to take actions to ensure network stability.

With the DHCP Snooping rate limit function for DHCP packets, a DHCP client can only send DHCP request packets at a rate below the limit.

- The request packets from a DHCP client are sent at a rate below the limit.
- Packets sent at rates beyond the limit will be discarded.
- Enable DHCP Snooping correlation with ARP, and delete the non-existing entries.

Deployment

- Enable DHCP Snooping on S to realize DHCP monitoring.
- Limit the rates of DHCP packets from the untrusted ports.

- Enable DHCP Snooping correlation with ARP, and detect whether the user is online.

14.2.3 Guarding Against Forged DHCP Packets

Scenario

Potential malicious clients in a network may forge DHCP request packets, consuming applicable IP addresses from the servers and probably preempting legal users' IP addresses. Therefore, it is necessary to filter out illegal DHCP packets.

For example, as shown in the figure below, the DHCP request packets sent from DHCP clients will be checked.

- The source MAC address fields of the request packets from DHCP clients must match the **chaddr** fields of DHCP packets.
- The Release packets and Decline packets from clients must match the entries in the DHCP Snooping binding database.

Figure 14-2

Remarks:	<p>S is an access device.</p> <p>A and C are user PCs.</p> <p>B is a DHCP server within the controlled area.</p>
-----------------	--

Deployment

- Enable DHCP Snooping on S to realize DHCP monitoring.
- Set the port on S connecting to B as trusted to transfer response packets.
- Set the rest of ports on S as untrusted to filter response packets.
- Enable DHCP Snooping Source MAC Verification on untrusted ports of S to filter out illegal packets.

14.2.4 Guarding Against IP/MAC Spoofing

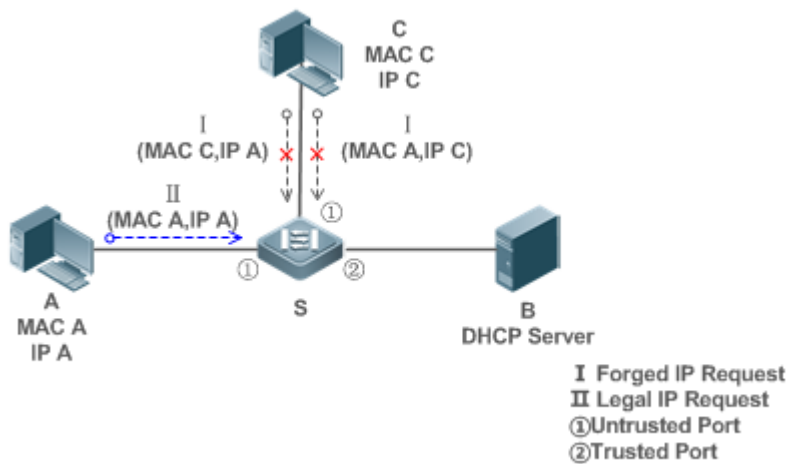

Scenario

Check IP packets from untrusted ports to filter out forged IP packets based on IP or IP-MAC fields.

For example, in the following figure, the IP packets sent by DHCP clients are validated.

- The source IP address fields of IP packets must match the IP addresses assigned by DHCP.
- The source MAC address fields of layer-2 packets must match the **chaddr** fields in DHCP request packets from clients.

Figure 14-3

Remarks:	<p>S is an access device.</p> <p>A and C are user PCs.</p> <p>B is a DHCP server within the controlled area.</p>
-----------------	--

Deployment

- Enable DHCP Snooping on S to realize DHCP monitoring.
- Set all downlink ports on the S as DHCP Snooping untrusted.
- Enable IP Source Guard on S to filter IP packets.
- Enable IP Source Guard in IP-MAC based mode to check the source MAC and IP address fields of IP packets.

14.2.5 Preventing Lease of IP Addresses

Scenario

Validate the source addresses of IP packets from untrusted ports compared with DHCP-assigned addresses.

If the source addresses, connected ports, and layer-2 source MAC addresses of ports in IP packets do not match the assignments of the DHCP server, such packets will be discarded.

The networking topology scenario is the same as that shown in the previous figure.

Deployment

- The same as that in the section "Guarding Against IP/MAC Spoofing".

14.2.6 Detecting ARP Attacks

Scenario

Check the ARP packets from untrusted ports and filter out the ARP packets unmatched with the assignments of the DHCP server.

For example, in the following figure, the ARP packets sent from DHCP clients will be checked.

- The ports receiving ARP packets, the layer-2 MAC addresses, and the source MAC addresses of ARP packets senders shall be consistent with the DHCP Snooping histories.

Figure 14-4

Remarks:	S is an access device. A and C are user PCs. B is a DHCP server within the controlled area.
-----------------	---

Deployment

- Enable DHCP Snooping on S to realize DHCP monitoring.
- Set all downlink ports on the S as untrusted.
- Enable IP Source Guard and ARP Check on all the untrusted ports on S to realize ARP packet filtering.

! All the above security control functions are only effective to DHCP Snooping untrusted ports.

14.3 Features

Basic Concepts

↳ DHCP Request Packets

Request packets are sent from a DHCP client to a DHCP server, including DHCP-DISCOVER packets, DHCP-REQUEST packets, DHCP-DECLINE packets, DHCP-RELEASE packets and DHCP-INFORM packets.

↳ DHCP Response Packets

Response packets are sent from a DHCP server to a DHCP client, including DHCP-OFFER packets, DHCP-ACK packets and DHCP-NAK packets.

↳ DHCP Snooping Trusted Ports

IP address request interaction is complete via broadcast. Therefore, illegal DHCP services will influence normal clients' acquisition of IP addresses and lead to service spoofing and stealing. To prevent illegal DHCP services, DHCP Snooping ports are divided into two types: trusted ports and untrusted ports. The access devices only transmit DHCP response packets received on trusted ports, while such packets from untrusted ports are discarded. In this way, we may configure the ports connected to a legal DHCP Server as trusted and the other ports as untrusted to shield illegal DHCP Servers.

On switches, all switching ports or layer-2 aggregate ports are defaulted as untrusted, while trusted ports can be specified. In fat AP configuration mode, all the layer-2 switching ports and layer-2 encapsulation sub-interfaces are untrusted by default, and can be specified as trusted. In fit AP configuration mode, all the layer-2 switching ports are untrusted by default and can be specified as trusted, and all the layer-2 encapsulation sub-interfaces are trusted and cannot be specified as untrusted. and all the switching ports and layer-2 aggregate ports are untrusted ports by default and can be specified as trusted.

↳ DHCP Snooping Packet Suppression

To shield all the DHCP packets on a specific client, we can enable DHCP Snooping packet suppression on its untrusted ports.

↳ VLAN-based DHCP Snooping

DHCP Snooping can work on a VLAN basis. By default, when DHCP Snooping is enabled, it is effective to all the VLANs of the current client. Specify VLANs help control the effective range of DHCP Snooping flexibly.

↳ DHCP Snooping Binding Database

In a DHCP network, clients may set static IP addresses randomly. This increases not only the difficulty of network maintenance but also the possibility that legal clients with IP addresses assigned by the DHCP server may fail to use the network normally due to address conflict. Through snooping packets between clients and servers, DHCP Snooping summarizes the user entries including IP addresses, MAC address, VLAN ID (VID), ports and lease time to build the DHCP Snooping binding database. Combined with ARP detection and ARP check, DHCP Snooping controls the reliable assignment of IP addresses for legal clients.

↳ DHCP Snooping Rate Limit

DHCP Snooping rate limit function can be configured through the rate limit command of Network Foundation Protection Policy (NFPP). For NFPP configuration, see the *Configuring NFPP*.

↘ DHCP Option82

DHCP Option82, an option for DHCP packets, is also called DHCP Relay Agent Information Option. As the option number is 82, it is known as Option82. Option82 is developed to enhance the security of DHCP servers and improve the strategies of IP address assignment. The option is often configured for the DHCP relay services of a network access device like DHCP Relay and DHCP Snooping. This option is transparent to DHCP clients, and DHCP relay components realize the addition and deduction of the option.

↘ Illegal DHCP Packets

Through DHCP Snooping, validation is performed on the DHCP packets passing through a client. Illegal DHCP packets are discarded, user information is recorded into the DHCP Snooping binding database for further applications (for example, ARP detection). The following types of packets are considered illegal DHCP packets.

- The DHCP response packets received on untrusted ports, including DHCP-ACK, DHCP-NACK and DHCP-OFFER packets
- The DHCP request packets carrying gateway information **giaddr**, which are received on untrusted ports
- When MAC verification is enabled, packets with source MAC addresses different with the value of the **chaddr** field in DHCP packets
- DHCP-RELEASE packets with the entry in the DHCP Snooping binding database Snooping while with untrusted ports inconsistent with settings in this binding database
- DHCP packets in wrong formats, or incomplete

Overview

Feature	Description
Filtering DHCP packets	Perform legality check on DHCP packets and discard illegal packets (see the previous section for the introduction of illegal packets). Transfer requests packets received on trusted ports only.
Building the DHCP Snooping binding database	Snoop the interaction between DHCP clients and the server, and generate the DHCP Snooping binding database to provide basis for other filtering modules.

14.3.1 Filtering DHCP Packets

Perform validation on DHCP packets from untrusted ports. Filter out the illegal packets as introduced in the previous section "Basic Concepts".

Working Principle

During snooping, check the receiving ports and the packet fields of packets to realize packet filtering, and modify the destination ports of packets to realize control of transmit range of the packets.

↘ Checking Ports

In receipt of DHCP packets, a client first judges whether the packet receiving ports are DHCP Snooping trusted ports. If yes, legality check and binding entry addition are skipped, and packets are transferred directly. For not, both the check and addition are needed.

↘ Checking Packet Encapsulation and Length

A client checks whether packets are UDP packets and whether the destination port is 67 or 68. Check whether the packet length match the length field defined in protocols.

↘ Checking Packet Fields and Types

According to the types of illegal packet introduced in the section "Basic Concepts", check the fields **giaddr** and **chaddr** in packets and then check whether the restrictive conditions for the type of the packet are met.

Related Configuration

↘ Enabling Global DHCP Snooping

By default, DHCP Snooping is disabled.

It can be enabled on a device using the **ip dhcp snooping** command.

Global DHCP Snooping must be enabled before VLAN-based DHCP Snooping is applied.

↘ Configuring VLAN-based DHCP Snooping

By default, when global DHCP Snooping is effective, DHCP Snooping is effective to all VLANs.

Use the [**no**] **ip dhcp snooping vlan** command to enable DHCP Snooping on specified VLANs or delete VLANs from the specified VLANs. The value range of the command parameter is the actual range of VLAN numbers.

↘ Configuring DHCP Snooping Source MAC Verification

By default, the layer-2 MAC addresses of packets and the **chaddr** fields of DHCP packets are not verified.

When the **ip dhcp snooping verify mac-address** command is used, the source MAC addresses and the **chaddr** fields of the DHCP request packets sent from untrusted ports are verified. The DHCP request packets with different MAC addresses will be discarded.

14.3.2 Building the Binding Database

DHCP Snooping detects the interactive packets between DHCP clients and the DHCP server, and generate entries of the DHCP Snooping binding database according to the information of legal DHCP packets. All these legal entries are provided to other security modules of a client as the basis of filtering packets from network.

Working Principle

During snooping, the binding database is updated timely based on the types of DHCP packets.

↘ Generating Binding Entries

When a DHCP-ACK packet on a trusted port is snooped, the client's IP address, MAC address, and lease time field are extracted together with the port ID (a wired interface index) and VLAN ID. Then, a binding entry of it is generated.

Deleting Binding Entries

When the recorded lease time of a binding entry is due, it will be deleted if a legal DHCP-RELEASE/DHCP-DECLINE packet sent by the client or a DHCP-NCK packet received on a trusted port is snooped, or the **clear** command is used.

Related Configuration

No configuration is needed except enabling DHCP Snooping.

14.4 Configuration

Configuration	Description and Command	
Configuring basic functions of DHCP Snooping	 (Mandatory) It is used to enable DHCP Snooping.	
	ip dhcp snooping	Enables DHCP Snooping.
	ip dhcp snooping suppression	Enables DHCP Snooping packet suppression.
	ip dhcp snooping vlan	Enables VLAN-based DHCP Snooping.
	ip dhcp snooping verify mac-address	Configures DHCP Snooping source MAC verification.
	ip dhcp snooping database write-delay	Writes the DHCP Snooping binding database to Flash periodically.
	ip dhcp snooping database write-to-flash	Writes the DHCP Snooping binding database to Flash manually.
	renew ip dhcp snooping database	Imports Flash storage to the DHCP Snooping Binding database.
	ip dhcp snooping bootp	Enables BOOTP support.
	ip dhcp snooping check-giaddr	Enables DHCP Snooping to support the function of processing Relay requests.
Configuring Option82	 (Optional) It is used to optimize the address assignment by DHCP servers.	
	ip dhcp snooping information option	Adds Option82 functions to DHCP request packets.
	ip dhcp snooping information option format remote-id	Configures the sub-option remote-id of Option82 as a user-defined character string.
	ip dhcp snooping vlan information option format-type circuit-id string	Configures the sub-option circuit-id of Option82 as a user-defined character string.

14.4.1 Configuring Basic Features

Configuration Effect

- Enable DHCP Snooping.
- Generate the DHCP Snooping binding database.
- Control the transmit range of DHCP packets.
- Filter out illegal DHCP packets.

Notes

- The ports on clients connecting a trusted DHCP server must be configured as trusted.
- DHCP Snooping is effective on the wired switching ports, layer-2 aggregate ports, and layer-2 encapsulation sub-interfaces. The configuration can be implemented in interface configuration mode
- DHCP Snooping and DHCP Relay are mutually exclusive in VRF scenarios.

Configuration Steps

↳ Enabling Global DHCP Snooping

- Mandatory.
- Unless otherwise noted, the feature should be configured on access devices.

↳ Enabling or Disabling VLAN-based DHCP Snooping

- DHCP Snooping can be disabled if not necessary for some VLANs.
- Unless otherwise noted, the feature should be configured on access devices.

↳ Enabling DHCP Snooping Source MAC Validation

- This configuration is required if the **chaddr** fields of DHCP request packets match the layer-2 source MAC addresses of data packets.
- Unless otherwise noted, the feature should be enabled on all the untrusted ports of access devices.

↳ Writing the DHCP Snooping Binding Database to Flash Periodically

- Enable this feature to timely save the DHCP Snooping binding database information in case that client reboot.
- Unless otherwise noted, the feature should be configured on access devices.

↳ Enabling BOOTP Support

- Optional
- Unless otherwise noted, the feature should be configured on access devices.

↳ Enabling DHCP Snooping to Process Relay Requests

- Optional.

- Unless otherwise noted, the feature should be enabled on access devices.

Verification

Configure a client to obtain network configurations through the DHCP protocol.

- Check whether the DHCP Snooping Binding database is generated with entries on the client.

Related Commands

▾ Enabling or Disabling DHCP Snooping

Command	[no] ip dhcp snooping
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After global DHCP Snooping is enabled, you can check DHCP Snooping using the show ip dhcp snooping command.

▾ Configuring VLAN-based DHCP Snooping

Command	[no] ip dhcp snooping vlan { <i>vlan-rng</i> { <i>vlan-min</i> [<i>vlan-max</i>] } }
Parameter Description	<i>vlan-rng</i> : Indicates the range of VLANs <i>vlan-min</i> : The minimum VLAN ID <i>vlan-max</i> : The maximum VLAN ID
Command Mode	Global configuration mode
Usage Guide	Use this command to enable or disable DHCP Snooping on specified VLANs. This feature is available only after global DHCP Snooping is enabled.

▾ Configuring DHCP Snooping Packet Suppression

Command	[no] ip dhcp snooping suppression
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Use this command to reject all DHCP request packets at the port, that is, to forbid all users under the port to apply for addresses via DHCP.

▾ Configuring DHCP Snooping Source MAC Verification

Command	[no] ip dhcp snooping verify mac-address
Parameter Description	N/A
Command	Global configuration mode

Mode	
Usage Guide	Through the source MAC address verification, the MAC addresses in link headers and the CLIENT MAC fields in the request packets sent by a DHCP CLIENT are checked for consistence. When the source MAC address verification fails, packets will be discarded.

✚ Writing DHCP Snooping Database to Flash Periodically

Command	<code>[no] ip dhcp snooping database write-delay [time]</code>
Parameter Description	<i>time</i> : Indicates the interval between two times of writing the DHCP Snooping database to the Flash.
Command Mode	Global configuration mode
Usage Guide	Use this command to write the DHCP Snooping database to FLASH document. This can avoid binding information loss which requires re-obtaining IP addresses to resume communication after the device restarts.

✚ Writing the DHCP Snooping Database to Flash Manually

Command	<code>ip dhcp snooping database write-to-flash</code>
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Use this command to write the dynamic user information in the DHCP Snooping database in FLASH documents in real time. If a device is upgraded from a non-QinQ version to a QinQ version (or vice versa), binding entries cannot be restored from FLASH documents because of version differences between FLASH documents.

✚ Importing the Flash File to the DHCP Snooping Binding Database

Command	<code>renew ip dhcp snooping database</code>
Parameter Description	N/A
Command Mode	Privileged configuration mode
Usage Guide	Use this command to import the information of the flash file to the DHCP Snooping binding database.

✚ Enabling or Disabling BOOTP Support

Command	<code>[no] ip dhcp snooping bootp</code>
Parameter Description	N/A
Command Mode	Global configuration mode

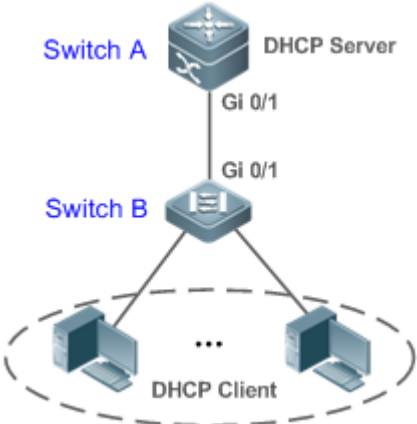

Usage Guide	Use this command to support the BOOTP protocol.
--------------------	---

▾ **Enabling DHCP Snooping to Process Relay Requests**

Command	[no] ip dhcp snooping check-giaddr
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	<p>After the feature is enabled, services using DHCP Snooping binding entries generated based on Relay requests, such as IP Source Guard/802.1x authentication, cannot be deployed. Otherwise, users fail to access the Internet.</p> <p>After the feature is enabled, the ip dhcp snooping verify mac-address command cannot be used. Otherwise, DHCP Relay requests will be discarded and as a result, users fail to obtain addresses.</p>

Configuration Example

▾ **DHCP Client Obtaining IP addresses Dynamically from a Legal DHCP Server**

<p>Scenario Figure 14-5</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable DHCP Snooping on an access device (Switch B in this case). ● Configure the uplink port (port Gi 0/1 in this case) as a trusted port.
<p>B</p>	<pre> B#configure terminal Enter configuration commands, one per line. End with CNTL/Z. B(config)#ip dhcp snooping B(config)#interface gigabitEthernet 0/1 B(config-if-GigabitEthernet 0/1)#ip dhcp snooping trust B(config-if-GigabitEthernet 0/1)#end </pre>
<p>Verification</p>	<p>Check the configuration on Switch B.</p> <ul style="list-style-type: none"> ● Check whether DHCP Snooping is enabled, and whether the configured DHCP Snooping trusted port

	<p>is uplink.</p> <ul style="list-style-type: none"> ● Check the DHCP Snooping configuration on Switch B, and especially whether the trusted port is correct.
B	<pre> B#show running-config ! ip dhcp snooping ! interface GigabitEthernet 0/1 B#show ip dhcp snooping Switch DHCP Snooping status : ENABLE DHCP Snooping Verification of hwaddr status : DISABLE DHCP Snooping database write-delay time : 0 seconds DHCP Snooping option 82 status : DISABLE DHCP Snooping Support BOOTP bind status : DISABLE Interface Trusted Rate limit (pps) ----- GigabitEthernet 0/1 YES unlimited B#show ip dhcp snooping binding Total number of bindings: 1 MacAddress IPAddress Lease(sec) Type VLAN Interface ----- 0013.2049.9014 172.16.1.2 86207 DHCP-Snooping 1 GigabitEthernet 0/11 </pre>

Common Errors

- The uplink port is not configured as a DHCP trusted port.
- Another access security option is already configured for the uplink port, so that a DHCP trusted port cannot be configured.

14.4.2 Configuring Option82

Configuration Effect

- Enable a DHCP server to obtain more information and assign addresses better.
- The Option82 function is client-oblivious.

Notes

- The Option82 functions for DHCP Snooping and DHCP Relay are mutually exclusive.

Configuration Steps

- To realize optimization of address allocation, implement the configuration.
- Unless otherwise noted, enable this function on access devices with DHCP Snooping enabled.

Verification

Check whether the DHCP Snooping configuration options are configured successfully.

Related Commands

Adding Option82 to DHCP Request Packets

Command	[no] ip dhcp snooping information option [standard-format dot1x-format]
Parameter	standard-format : Indicates a standard format of the Option82 options
Description	dot1x-format : Indicates a dot1x format of the Option82 options
Command Mode	Global configuration mode
Usage Guide	Use this command to add Option82 to DHCP request packets so that a DHCP server assigns addresses according to such information. When dot1x-format is used, if DHCP Relay is configured on the local device and the uplink port connected to the DHCP Server is an SVI port, DHCP Snooping needs to be disabled in the VLAN to which the SVI port belongs.

Configuring Sub-option remote-id of Option82 as User-defined Character String

Command	[no] ip dhcp snooping information option format remote-id { string ASCII-string hostname }
Parameter	string ASCII-string : Indicates the content of the extensible format, the Option82 option remote-id , is a user-defined character string
Description	hostname : Indicates the content of the extensible format, the Option82 option remote-id , is a host name.
Configuration mode	Global configuration mode
Usage Guide	Use this command to configure the sub-option remote-id of the Option82 as user-defined content, which is added to DHCP request packets. A DHCP server assigns addresses according to Option82 information.

Configuring Sub-Option circuit -id of Option82 as User-defined Character String

Command	[no] ip dhcp snooping vlan <i>vlan-id</i> information option format-type circuit-id string <i>ascii-string</i>
Parameter	<i>vlan-id</i> : Indicates the VLAN where a DHCP request packet is
Description	<i>ascii-string</i> : Indicates the user-defined string
Configuration mode	Interface configuration mode
Usage Guide	Use this command to configure the sub-option circuit-id of the Option82 as user-defined content, which is added to DHCP request packets. A DHCP server assigns addresses according to Option82 information.

Configuration Example

Configuring Option82 to DHCP Request Packets

Configuration Steps	<ul style="list-style-type: none"> Configuring basic functions of DHCP Snooping. Configuring Option82.
----------------------------	--

B	<pre>Ruijie# configure terminal Ruijie(config)# ip dhcp snooping information option Ruijie(config)# end</pre>
Verification	Check the DHCP Snooping configuration.
B	<pre>B#show ip dhcp snooping Switch DHCP Snooping status : ENABLE DHCP Snooping Verification of hwaddr status : DISABLE DHCP Snooping database write-delay time : 0 seconds DHCP Snooping option 82 status : ENABLE DHCP Snooping Support bootp bind status : DISABLE Interface Trusted Rate limit (pps) ----- - GigabitEthernet 0/1 YES unlimited</pre>

Common Errors

- N/A

14.5 Monitoring

Clearing

 Running the clear commands may lose vital information and thus interrupt services.

Description	Command
Clears the DHCP Snooping binding database.	clear ip dhcp snooping binding [ip] [mac] [vlan vlan-id] [interface interface-id]

Displaying

Description	Command
Displays DHCP Snooping configuration.	show ip dhcp snooping
Displays the DHCP Snooping binding database.	show ip dhcp snooping binding

Debugging

 System resources are occupied when debugging information is output. Disable the debugging switch immediately after use.

Description	Command
Debugs DHCP Snooping events.	debug snooping ipv4 event

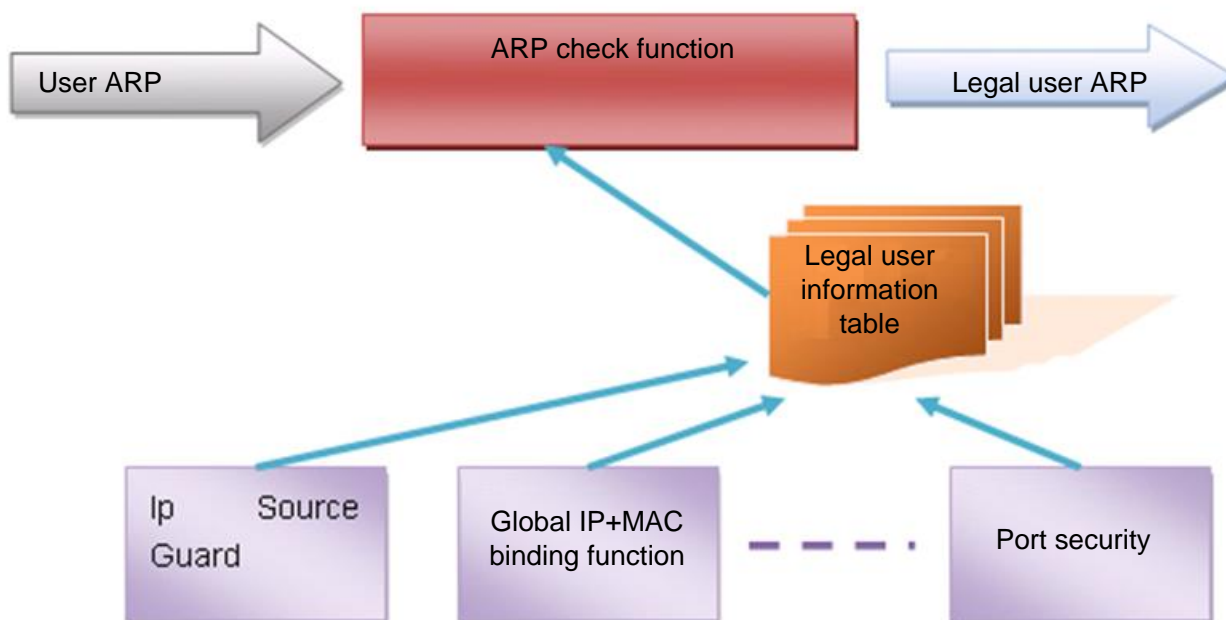

Disables debugging DHCP Snooping events.	no debug snooping ipv4 event
Debugs DHCP Snooping packets.	debug snooping ipv4 packet
Disables debugging DHCP Snooping packets.	no debug snooping ipv4 packet
Enables debugging MAC-based DHCP Snooping.	debug snooping ipv4 mac-address <i>H.H.H</i>
Disables debugging MAC-based DHCP Snooping.	no debug snooping ipv4 mac-address <i>H.H.H</i>
Enables debugging all DHCP Snooping	debug snooping ipv4 all
Disables debugging all DHCP Snooping	no debug snooping ipv4 all

15 Configuring ARP Check

15.1 Overview

The Address Resolution Protocol (ARP) packet check filters all ARP packets under ports (including wired layer-2 switching ports, layer-2 aggregate ports (APs), and layer-2 encapsulation sub-interfaces) and discards illegal ARP packets, so as to effectively prevent ARP deception via networks and to promote network stability. On devices supporting ARP check, illegal ARP packets in networks will be ignored according to the legal user information (IP-based or IP-MAC based) generated by security application modules such as IP Source Guard, global IP+MAC binding, 802.1X authentication, GSN binding, Web authentication and port security.

Figure 15-1

The above figure shows that security modules generate legal user information (IP-based or IP-MAC based). ARP Check uses the information to detect whether the Sender IP fields or the <Sender IP, Sender MAC>fields in all ARP packets at ports matches those in the list of legal user information. If not, all unlisted ARP packets will be discarded.

Protocols and Standards

- RFC826: An Ethernet Address Resolution Protocol or Converting Network Protocol Addresses

15.2 Applications

Application	Description
Filtering ARP packets in Networks	Illegal users in networks launch attacks using forged ARP packets.

15.2.1 Filtering ARP Packets in Networks

Scenario

Check ARP packets from distrusted ports and filter out ARP packets with addresses not matching the results assigned by the DHCP server.

For example, in the following figure, the ARP packets sent by DHCP clients are checked.

- The ports receiving ARP packets, the source MAC addresses of ARP packets, and the source IP addresses of ARP packets shall be consistent with the snooped DHCP-assigned records.

Figure 15-2

Remarks:	S is an access device. A and C are user PCs.
-----------------	---

Deployment

- Enable DHCP Snooping on S to realize DHCP monitoring.
- Set all the downlink ports on S as DHCP distrusted ports.
- Enable IP Source Guard and ARP Check on all distrusted ports on S to realize ARP packet filtration.

15.3 Features

Basic Concepts

Compatible Security Modules

Presently, the ARP Check supports the following security modules.

- IP-based: IP-based mode: port security, and static configuration of IP Source Guard.
- IP-MAC based: IP-MAC based mode: port security, global IP+MAC binding, 802.1X authorization, IP Source Guard, and Web authentication.

Two Modes of APR Check

The ARP Check has two modes: Enabled and Disabled. The default is Enabled.

1. Enabled Mode

Through ARP Check, ARP packets are detected based on the IP/IP-MAC based binding information provided by the following modules.

- Global IP-MAC binding
- 802.1X authorization
- IP Source Guard
- Port security
- Web authentication
- Port security IP+MAC binding or IP binding

 When only ARP Check is enabled on a port but the above-mentioned modules are not enabled, legal user information cannot be generated, and thereby all ARP packets from this port will be discarded.

 When the ARP Check and VRRP functions are enabled on an interface, if the physical IP address and virtual IP address of the interface can be used as the gateway address, the physical IP address and VRRP IP address need to be permitted to pass. Otherwise, ARP packets sent to the gateway will be filtered out.

2. Disabled Mode

ARP packets on a port are not checked.

Overview

Feature	Description
Filtering ARP Packets	Check the source IP and source MAC addresses of ARP packets to filter out illegal ARP packets.

15.3.1 Filtering ARP Packets

Enable ARP Check on specified ports to realize filtration of illegal ARP packets.

Working Principle

A device matches the source IP and source MAC addresses of the ARP packets received at its ports with the legal user information of the device. With successful matching, packets will be transferred, or otherwise they will be discarded.

Related Configuration

↘ Enabling ARP Check on Ports

By default, the ARP Check is disabled on ports.

Use the **arp-check** command to enable ARP Check.

Unless otherwise noted, this function is usually configured on the ports of access devices.

15.4 Configuration

Configuration	Description and Command
Configuring ARP Check	 (Mandatory) It is used to enable APR Check.
	arp-check Enables ARP Check.

15.4.1 Configuring ARP Check

Configuration Effect

- Illegal ARP packets are filtered out.

Notes

- When ARP Check is enabled, the number of policies or users of related security applications may decrease.
- ARP Check cannot be configured on mirrored destination ports.
- ARP Check cannot be configured on the trusted ports of DHCP Snooping.
- ARP Check cannot be configured on global IP+MAC exclude ports.
- ARP Check can be enabled only on wired switching ports, layer-2 APs, layer-2 encapsulation sub-interfaces. Enable ARP check for the wired in interface configuration mode.
- For fit APs in wired access mode, ARP Check needs to be enabled in ap-config all mode.

Configuration Steps

↘ Enabling ARP Check

- (Mandatory) The function is disabled by default. To use the ARP Check function, an administrator needs to run a command to enable it.

Verification

- Use the **show run** command to display the system configuration.
- Use the **show interface { interface-type interface-number } arp-check list** command to display filtering entries.

Related Commands

↘ Enabling ARP Check

Command	arp-check
Parameter	N/A
Description	
Command	Interface configuration mode
Usage Guide	Generate ARP filtration information according to the legal user information of security application modules to filter out illegal ARP packets in networks.

Configuration Example

 The following configuration example introduces only ARP Check related configurations.

↳ Enabling ARP Check on ports

Configuration Steps	<ul style="list-style-type: none"> Enable ARP Check. Restricted ARP packets must conform to entries of IP Source Guard, port security, or global IP+MAC binding.
	<pre> Ruijie# configure terminal Ruijie(config)#address-bind 192.168.1.3 00D0.F800.0003 Ruijie(config)#address-bind install Ruijie(config)#ip source binding 00D0.F800.0002 vlan 1 192.168.1.4 interface gigabitEthernet 0/1 Ruijie(config)# interface GigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)#arp-check Ruijie(config-if-GigabitEthernet 0/1)#ip verify source port-security Ruijie(config-if-GigabitEthernet 0/1)#switchport port-security Ruijie(config-if-GigabitEthernet 0/1)#switchport port-security binding 00D0.F800.0001 vlan 1 192.168.1.1 Ruijie(config-if-GigabitEthernet 0/1)#exit Ruijie(config)#interface gigabitEthernet 0/4 Ruijie(config-if-GigabitEthernet 0/4)#switchport port-security Ruijie(config-if-GigabitEthernet 0/4)#switchport port-security binding 192.168.1.5 Ruijie(config-if-GigabitEthernet 0/4)#arp-check Ruijie(config-if-GigabitEthernet 0/4)#exit Ruijie(config)#interface gigabitEthernet 0/5 Ruijie(config-if-GigabitEthernet 0/5)#arp-check Ruijie(config-if-GigabitEthernet 0/5)#end </pre>
Verification	Use the show interface arp-check list command to display the effective ARP Check list for interfaces.

<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable ARP Check. Restricted ARP packets must conform to entries of IP Source Guard, port security, or global IP+MAC binding.
	<pre> Ruijie# configure terminal Ruijie(config)#address-bind 192.168.1.3 00D0.F800.0003 Ruijie(config)#address-bind install Ruijie(config)#ip source binding 00D0.F800.0002 vlan 1 192.168.1.4 interface gigabitEthernet 0/1 Ruijie(config)# interface GigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)#arp-check Ruijie(config-if-GigabitEthernet 0/1)#ip verify source port-security Ruijie(config-if-GigabitEthernet 0/1)#switchport port-security Ruijie(config-if-GigabitEthernet 0/1)#switchport port-security binding 00D0.F800.0001 vlan 1 192.168.1.1 Ruijie(config-if-GigabitEthernet 0/1)#exit Ruijie(config)#interface gigabitEthernet 0/4 Ruijie(config-if-GigabitEthernet 0/4)#switchport port-security Ruijie(config-if-GigabitEthernet 0/4)#switchport port-security binding 192.168.1.5 Ruijie(config-if-GigabitEthernet 0/4)#arp-check Ruijie(config-if-GigabitEthernet 0/4)#exit Ruijie(config)#interface gigabitEthernet 0/5 Ruijie(config-if-GigabitEthernet 0/5)#arp-check Ruijie(config-if-GigabitEthernet 0/5)#end </pre>

Verification	Use the show interface arp-check list command to display the effective ARP Check list for interfaces.				
	<table border="1"> <tr> <td>GigabitEthernet 0/5</td> <td>00d0.f800.0003</td> <td>192.168.1.3</td> <td>address-bind</td> </tr> </table>	GigabitEthernet 0/5	00d0.f800.0003	192.168.1.3	address-bind
GigabitEthernet 0/5	00d0.f800.0003	192.168.1.3	address-bind		

Common Errors

- If ARP packets at a port need to be checked but APR-Check is disabled, then APR-Check will not be effective.

15.5 Monitoring

Displaying

Description	Command
Displays the effective ARP Check list based on ports.	show interface [interface-type interface-number] arp-checklist

16 Configuring Dynamic ARP Inspection

16.1 Overview

Dynamic Address Resolution Protocol (ARP) inspection (DAI) checks the validity of received ARP packets. Invalid ARP packets will be discarded.

DAI ensures that only valid ARP packets can be forwarded by devices. DAI mainly performs the following steps:

- Intercepts all ARP request packets and ARP reply packets on untrusted ports in the virtual local area networks (VLANs) where the DAI function is enabled.
- Checks the validity of intercepted ARP packets according to user records stored in a security database.
- Discards the ARP packets that do not pass the validity check.
- Sends the ARP packets that pass the validity check to the destination.
- The DAI validity criteria are the same as those of ARP Check. For details, see the *Configuring ARP Check*.

DAI and ARP Check have same functions. The only difference is that DAI takes effect by VLAN whereas ARP Check takes effect by port.

Protocols and Standards

- RFC826: An Ethernet Address Resolution Protocol or Converting Network Protocol Addresses

16.2 Applications

Application	Description
ARP Spoofing Prevention	Prevent ARP spoofing that is mounted by taking advantage of ARP defects.

16.2.1 ARP Spoofing Prevention

Scenario

Due to inherent defects, ARP does not check the validity of received ARP packets. Attackers can take advantage of the defects to mount ARP spoofing. A typical example is man-in-the-middle (MITM) attack. See Figure 16-1.

Figure 16-1

Remarks	<p>Device S is a Ruijie access switch enabled with DAI.</p> <p>User A and User B are connected to Device S, and they are in the same subnet.</p> <p>User C is a malicious user connected to Device S.</p> <p>IP A and MAC A are the IP address and MAC address of User A.</p> <p>IP B and MAC B are the IP address and MAC address of User B.</p> <p>IP C and MAC C are the IP address and MAC address of User C.</p>
----------------	---

When User A needs to initiate network layer communication with User B, User A broadcasts an ARP request in the subnet to query the MAC address of User B. Upon receiving the ARP request packet, User B updates its ARP cache with IP A and MAC A, and sends an ARP reply. Upon receiving the ARP reply packet, User A updates its ARP cache with IP B and MAC B.

In this model, User C can make the ARP entry mapping between User A and User B incorrect by continuously broadcasting ARP reply packets to the network. The reply packets contain IP A, IP B, and MAC C. After receiving these reply packets, User A stores the ARP entry (IP B, MAC C), and User B stores the ARP entry (IP A, MAC C). As a result, the communication between User A and User B is directed to User C, without the knowledge of User A and User B. Here User C acts as the man in the middle by modifying received packets and forwarding them to User A or User B.

If Device S is enabled with DAI, it will filter out forged ARP packets to prevent ARP spoofing as long as the IP addresses of User A and User B meet the validity criteria described in section 16.1 Overview. Figure 16-2 shows the working process of DAI.

Figure 16-2

Remarks	<p>Device S is a Ruijie access switch enabled with DAI.</p> <p>User A and User B are connected to Device S, and they are in the same subnet.</p> <p>User C is a malicious user connected to Device S.</p> <p>IP A and MAC A are the IP address and MAC address of User A.</p> <p>IP B and MAC B are the IP address and MAC address of User B.</p> <p>IP C and MAC C are the IP address and MAC address of User C.</p>
----------------	---

The ARP packets of User A and User B are forwarded normally by Device S. The forged ARP packets of User C are discarded because the packets do not match the records in the security database of Device S.

Deployment

- Enable DHCP Snooping on Device S.
- Enable DAI and IP Source Guard on Device S.

16.3 Features

Basic Concepts

Trust Status of Ports and Network Security

ARP packet check is performed according to the trust status of ports. DAI considers packets received from trusted ports as valid without checking their validity, but it checks the validity of packets received from untrusted ports.

For a typical network configuration, you should configure Layer-2 ports connected to network devices as trusted ports, and configure Layer-2 ports connected to hosts as untrusted ports.

 Network communication may be affected if a Layer-2 port connected to a network device is configured as an untrusted port.

Overview

Feature	Description
Invalid ARP Packet Filter	Checks the source IP addresses and MAC addresses of ARP packets to filter out invalid packets.
DAI Trusted Port	Permits the ARP packets received from specific ports to pass through without checking their validity.

16.3.1 Invalid ARP Packet Filter

Enable DAI in a specific VLAN to filter out invalid ARP packets. The DAI validity criteria are the same as those of ARP Check.

Working Principle

Upon receiving an ARP packet, the device matches the IP address and MAC address of the packet with the valid user records in its security database. If the packet matches a record, it will be forwarded normally. If it does not match any record, it will be discarded.

DAI and ARP Check use the same set of valid user records. For details, see the packet validity check description in the *Configuring ARP Check*.

Related Configuration

↳ Enabling DAI in a VLAN

By default, DAI is disabled in VLANs.

Run the **ip arp inspection vlan** *vlan-id* command to enable DAI in a specific VLAN.

 After DAI is enabled in a VLAN, DAI may not take effect on all ports in the VLAN. A DHCP Snooping trusted port does not perform DAI check.

↳ Disabling DAI in a VLAN

By default, DAI is disabled in VLANs.

After DAI is enabled in a VLAN, you can run the **no ip arp inspection vlan** *vlan-id* command to disable DAI.

 Disabling DAI in a VLAN does not mean disabling packet validity check on all ports in the VLAN. The ports with ARP Check effective still check the validity of received ARP packets.

16.3.2 DAI Trusted Port

Configure specific device ports as DAI trusted ports.

Working Principle

The validity of ARP packets received from trusted ports is not checked. The ARP packets received from untrusted ports are checked against the user records in a security database.

Related Configuration

↳ Configuring DAI Trusted Ports

By default, all ports are untrusted ports.

Run the **ip arp inspection trust** command to set ports to trusted state.

 A port already enabled with access security control cannot be set to DAI trusted state. To set the port to DAI trusted state, first disable access security control.

 In normal cases, uplink ports (ports connected to network devices) can be configured as DAI trusted ports.

16.4 Configuration

Configuration	Description and Command	
Configuring DAI	 (Optional) It is used to enable ARP packet validity check.	
	<code>ip arp inspection vlan</code>	Enables DAI.
	<code>ip arp inspection trust</code>	Configures DAI trusted ports.

16.4.1 Configuring DAI

Configuration Effect

- Check the validity of incoming ARP packets in a specific VLAN.

Notes

- DAI cannot be enabled on DHCP Snooping trusted ports.

Configuration Steps

▾ Enabling ARP Packet Validity Check in a Specific VLAN

- Optional.
- Perform this configuration when you need to enable ARP packet validity check on all ports in a VLAN.
- Perform this configuration on Ruijie access devices unless otherwise specified.

▾ Configuring DAI Trusted Ports

- Optional.
- It is recommended to configure uplink ports as DAI trusted ports after DAI is enabled. Otherwise, the uplink ports enabled with other security features and set to trusted state accordingly may filter out valid ARP packets due to the absence of DAI user entries.
- Perform this configuration on Ruijie access devices unless otherwise specified.

▾ Configuring the ARP Packet Reception Rate

- For details, see the rate limit command description in the *Configuring the NFPP*.

Verification

- Construct invalid ARP packets by using a packet transfer tool and check whether the packets are filtered out on DAI-enabled devices.
- Run the **show** command to check the device configuration.

Related Commands

➤ Enabling DAI

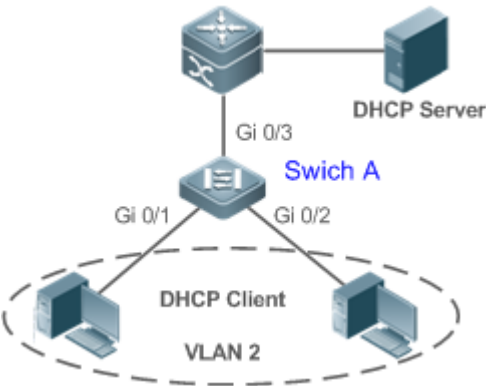

Command	ip arp inspection vlan { <i>vlan-id</i> <i>word</i> }
Parameter	<i>vlan-id</i> : Indicates a VLAN ID.
Description	<i>word</i> : Indicates the VLAN range string, such as 1, 3–5, 7, and 9–11.
Command Mode	Global configuration mode
Usage Guide	N/A

➤ Configuring DAI Trusted Ports

Command	ip arp inspection trust
Parameter	N/A
Description	
Command Mode	Interface configuration mode
Usage Guide	Use this command to configure a DAI trusted port so that the ARP packets received by the port can pass through without validity check.

Configuration Example

➤ Allowing Users' PCs to Use only Addresses Allocated by a DHCP Server to Prevent ARP Spoofing

<p>Scenario Figure 16-3</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ⚠ Enable DHCP Snooping on the access switch (Switch A) and configure its uplink port (GigabitEthernet 0/3) connected to the valid DHCP server as a trusted port. ⚠ Enable IP Source Guard on Switch A. ⚠ Enable DAI.
<p>Switch A</p>	<pre>A#configure terminal Enter configuration commands, one per line. End with CNTL/Z. A(config)#vlan 2</pre>

	<pre>A(config-vlan)#exit A(config)#interface range gigabitEthernet 0/1-2 A(config-if-range)#switchport access vlan 2 A(config-if-range)#ip verify source A(config-if-range)#exit A(config)#ip dhcp snooping A(config)#ip arp inspection vlan 2 A(config)#interface gigabitEthernet 0/3 A(config-if-GigabitEthernet 0/3)#switchport access vlan 2 A(config-if-GigabitEthernet 0/3)#ip dhcp snooping trust A(config-if-GigabitEthernet 0/3)#ip arp inspection trust</pre>
Verification	<ul style="list-style-type: none"> ● Check whether DHCP Snooping, IP Source Guard, and DAI are enabled and whether trusted ports are configured correctly. ● Check whether the uplink port on Switch A is a DHCP Snooping trusted port. ● Check whether DAI is enabled successfully in the VLAN and the uplink ports are DAI trusted ports.
Switch A	<pre>A#show running-config A#show ip dhcp snooping A#show ip arp inspection vlan</pre>

Common Errors

- A port with security control enabled is configured as a DAI trusted port.

16.5 Monitoring

Displaying

Description	Command
Displays the DAI state of a specific VLAN.	show ip arp inspection vlan [<i>vlan-id</i> <i>word</i>]
Displays the DAI configuration state of each Layer-2 port.	show ip arp inspection interface

17 Configuring IP Source Guard

17.1 Overview

i The IP Source Guard function realizes hardware-based IP packet filtering to ensure that only the users having their information in the binding database can access networks normally, preventing users from forging IP packets.

17.2 Applications

Application	Description
Guarding Against IP/MAC Spoofing Attack	In network environments, users set illegal IP addresses and malicious users launch attacks through forging IP packets.

17.2.1 Guarding Against IP/MAC Spoofing Attack

Scenario

Check the IP packets from DHCP untrusted ports. Forged IP packets will be filtered out based on the IP or IP-MAC field.

For example, in the following figure, the IP packets sent by DHCP clients are checked.

- The Source IP Address fields of IP packets should match DHCP-assigned IP addresses.
- The Source MAC Address fields of layer-2 packets should match the MAC addresses in DHCP request packets from clients.

Figure 17-1

Remarks:	S is a network access server (NAS). A and C are user PCs. B is a DHCP server within the control area.
-----------------	---

Deployment

- Enable DHCP Snooping on S to realize DHCP monitoring.
- Set all downlink ports on S as DHCP untrusted ports.
- Enable IP Source Guard on S to realize IP packet filtering.
- Enable IP-MAC match mode for IP Source Guard on S, filtering IP packets based on IP and MAC addresses.

17.3 Features

Basic Concepts

↘ Source IP Address

Indicate the source IP address field of an IP packet.

↘ Source MAC Address

Indicate the source MAC address field of an IP packet.

↘ IP-based Filtering

Indicate a policy of IP packet filtering, where only the source IP addresses of all IP packets (except DHCP packets) passing through a port are checked. It is the default filtering policy of IP Source Guard.

↘ IP-MAC based Filtering

A policy of IP packet filtering, where both the source IP addresses and source MAC addresses of all IP packets are checked, and only those user packets with these IP addresses and MAC addresses existing in the binding database are permitted.

↘ Address Binding Database

As the basis of security control of the IP Source Guard function, the data in the address binding database comes from two ways: the DHCP Snooping binding database and static configuration. When IP Source Guard is enabled, the data of the DHCP Snooping binding database is synchronized to the address binding database of IP Source Guard, so that IP packets can be filtered strictly through IP Source Guard on a device with DHCP Snooping enabled.

↘ Excluded VLAN

By default, when IP Source Guard is enabled on a port, it is effective to all the VLANs under the port. Users may specify excluded VLANs, within which IP packets are not checked and filtered, which means that such IP packets are not controlled by IP Source Guard. At most 32 excluded VLANs can be specified for a port.

Overview

Feature	Description
Checking Source Address Fields of Packets	Filter the IP packets passing through ports by IP-based or IP-MAC based filtering.

17.3.1 Checking Source Address Fields of Packets

Filter the IP packets passing through ports based on source IP addresses or on both source IP addresses and source MAC addresses to prevent malicious attack by forging packets. When there is no need to check and filter IP packets within a VLAN, an excluded VLAN can be specified to release such packets.

Working Principle

When IP Source Guard is enabled, the source addresses of packets passing through a port will be checked. The port can be a wired switching port, a layer-2 aggregate port (AP), or a layer-2 encapsulation sub-interface. Such packets will pass the port only when the source address fields of the packets match the set of the address binding records generated by DHCP Snooping, or the static configuration set by the administrator. There are two matching modes as below.

↘ IP-based Filtering

Packets are allowed to pass a port only if the source IP address fields of them belong to the address binding database.

↘ IP-MAC Based Filtering

Packets are allowed to pass a port only when both the layer-2 source MAC addresses and layer-3 source IP addresses of them match an entry in the address binding database.

↘ Specifying Excluded VLAN

Packets within such a VLAN are allowed to pass a port without check or filtering.

Related Configuration

↘ Enabling IP Source Guard on a Port

By default, the IP Source Guard is disabled on ports.

It can be enabled using the **ip verify source** command.

-
- i** Usually IP Source Guard needs to work with DHCP Snooping. Therefore, DHCP Snooping should also be enabled. DHCP Snooping can be enabled at any time on Ruijie devices, either before or after IP Source Guard is enabled.
-

↘ Configuring a Static Binding

By default, legal users passing IP Source Guard check are all from the binding database of DHCP Snooping.

Bound users can be added using the **ip source binding** command.

↘ Specifying an Excluded VLAN

By default, IP Source Guard is effective to all the VLANs under a port.

Excluded VLANs may be specified which are exempted from IP Source Guard using the **ip verify source exclude-vlan** command.

-
- i** Excluded VLANs can be specified only after IP Source Guard is enabled on a port. Specified excluded VLANs will be deleted automatically when IP Source Guard is disabled on a port.
-

 The above-mentioned port can be a wired switching port, a layer-2 AP port or a layer-2 encapsulation sub-interface

17.4 Configuration

Configuration	Description and Command	
Configuring IP Source Guard	 (Mandatory) It is used to enable IP Source Guard.	
	ip verify source	Enables IP Source Guard on a port.
	ip source binding	Configures a static binding.
	ip verify source exclude-vlan	Specifies an excluded VLAN for IP Source Guard.

17.4.1 Configuring IP Source Guard

Configuration Effect

- Check the source IP addresses of input IP packets.

Notes

- When IP Source Guard is enabled, IP packets forwarding may be affected. In general case, IP Source Guard is enabled together with DHCP Snooping.
- IP Source Guard cannot be configured on the trusted ports controlled by DHCP Snooping.
- IP Source Guard cannot be configured on the global IP+MAC exclusive ports.
- IP Source Guard can be configured and enabled only on wired switch ports, Layer-2 AP ports, Layer-2 encapsulation sub-ports. In a wired access scenario, it is supposed to be configured in the interface configuration mode.
- For a Fit AP in a wired access scenario, IP Source Guard is configured and enabled in WLAN ap-config all configuration mode.

Configuration Steps

- Enable DHCP Snooping.
- Enable IP Source Guard.

Verification

Use the monitoring commands to display the address binding database of IP Source Guard.

Related Commands

↳ Enabling IP Source Guard on a Port

Command	ip verify source [port-security]
Parameter	port-security: Enable IP-MAC based filtering.

Description	
Command	Interface configuration mode
Usage Guide	Detection of users based on IP address or both IP and MAC addresses can be realized by enabling IP Source Guard for a port.

↘ Configuring a Static Binding

Command	ip source binding <i>mac-address</i> { vlan <i>vlan-id</i> } <i>ip-address</i> { interface <i>interface-id</i> ip-mac ip-only }
Parameter	mac-address: The MAC address of a static binding
Description	vlan-id: The VLAN ID of a static binding. It indicates the outer VLAN ID of a QINQ-termination user. ip-address: The IP address of a static binding <i>interface-id:</i> The Port ID (PID) of a static binding ip-mac: IP-MAC based mode ip-only: IP-based mode
Configuration Mode	Global configuration mode
Usage Guide	Through this command, legitimate users can pass IP Source Guard detection instead of being controlled by DHCP.

↘ Specifying an Exception VLAN for IP Source Guard

Command	ip verify source exclude-vlan <i>vlan-id</i>
Parameter	vlan-id: A VLAN ID exempted from IP Source Guard on a port
Description	
Command	Interface configuration mode
Usage Guide	By using this command, the specified VLANs under a port where IP Source Guard function is enabled can be exempted from check and filtering.

Configuration Example

↘ Enabling IP Source Guard on Port 1

Configuration Steps	<ul style="list-style-type: none"> ● Enable DHCP Snooping. ● Enable IP Source Guard.
	<pre>Ruijie(config)# interface GigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)# ip verify source Ruijie(config-if-GigabitEthernet 0/1)# end</pre>
Verification	Displays the address filtering table of IP Source Guard.
	<pre>Ruijie# show ip verify source</pre>

↘ Specifying an Excluded VLAN

Configuration Steps	<ul style="list-style-type: none"> ● Enable DHCP Snooping. ● Enable IP Source Guard.
	<pre>Ruijie(config)# interface GigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)# ip verify source Ruijie(config-if-GigabitEthernet 0/1)# ip verify source exclude-vlan 1 Ruijie(config-if)# end</pre>
Verification	Display the configuration of excluded VLANs specified on a port.
	<pre>Ruijie# show run</pre>

Common Errors

- Enable IP Source Guard on a trusted port under DHCP Snooping.
- Specify an excluded VLAN before IP Source Guard is enabled.

17.5 Monitoring

Displaying

Description	Command
Displays the address filtering table of IP Source Guard.	show ip verify source [interface <i>interface-id</i>]
Displays the address binding database of IP Source Guard.	show ip source binding

18 Configuring NFPP

18.1 Overview

Network Foundation Protection Policy (NFPP) provides guards for switches.

Malicious attacks are always found in the network environment. These attacks bring heavy burdens to switches, resulting in high CPU usage and operational troubles. These attacks are as follows:

Denial of Service (DoS) attacks may consume lots of memory, entries, or other resources of a switch, which will cause system service termination.

Massive attack traffic is directed to the CPU, occupying the entire bandwidth of the CPU. In this case, normal protocol traffic and management traffic cannot be processed by the CPU, causing protocol flapping or management failure. The forwarding in the data plane will also be affected and the entire network will become abnormal.

A great number of attack packets directed to the CPU consume massive CPU resources, making the CPU highly loaded and thereby influencing device management and performance.

NFPP can effectively protect the system from these attacks. Facing attacks, NFPP maintains the proper running of various system services with a low CPU load, thereby ensuring the stability of the entire network.

18.2 Applications

Application	Description
Attack Rate Limiting	Due to various malicious attacks such as ARP attacks and IP scanning attacks in the network, the CPU cannot process normal protocol and management traffics, causing protocol flapping or management failure. The NFPP attack rate limiting function is used to limit the rate of attack traffic or isolate attack traffic to recover the network.
CentralizedBandwidth Allocation	If normal service traffics are too large, you need to classify and prioritize the traffics. When a large number of packets are directed to the CPU, the CPU will be highly loaded, thereby causing device management or device running failure. The centralized bandwidth distribution function is used to increase the priority of such traffics so that switches can run stably.

18.2.1 Attack Rate Limiting

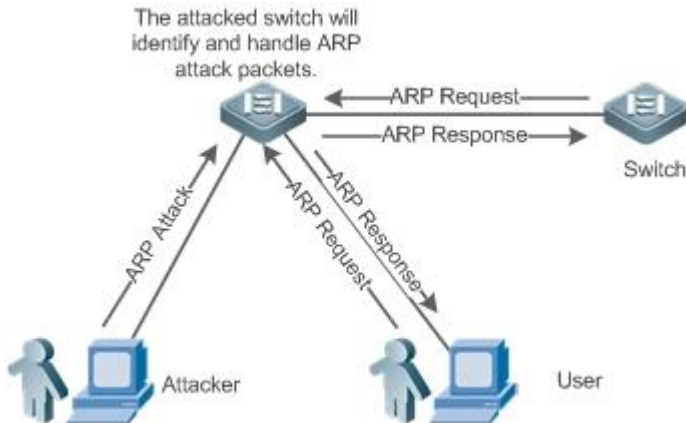

Scenario

NFPP supports attack detection and rate limiting for various types of packets, including Address Resolution Protocol (ARP), Internet Control Message Protocol (ICMP), and Dynamic Host Configuration Protocol (DHCP) packets. It also allows users to define packet matching characteristics and corresponding attack detection and rate limiting policies. The attack rate limiting

function takes effect based on types of packets. This section uses ARP packets as an example scenario to describe the application.

If an attacker floods ARP attack packets while CPU capability is insufficient, most of the CPU resources will be consumed for processing these ARP packets. If the rate of attacker's ARP packet rates exceeds the maximum ARP bandwidth specified in the CPU Protect Policy (CPP) of the switch, normal ARP packets may be dropped. As shown in Figure 18-1, normal hosts will fail to access the network, and the switch will fail to send ARP replies to other devices.

Figure 18-1

Deployment

- By default, the ARP attack detection and rate limiting function is enabled with corresponding policies configured. If the rate of an attacker's ARP packets exceeds the rate limit, the packets are discarded. If it exceeds the attack threshold, a monitoring user is generated and prompt information is exported.
- If the rate of an attacker's ARP packets exceeds the rate limit defined in CPP and affects normal ARP replies, you can enable attack isolation to discard ARP attack packets based on the hardware and recover the network.

i For details about CPP-related configurations, see the *Configuring CPU Protection*.

i To maximize the use of NFPP guard functions, modify the rate limits of various services in CPP based on the application environment or use the configurations recommended by the system. You can run the **show cpu-protect summary** command to display the configurations.

18.2.2 Centralized Bandwidth Allocation

Scenario

A switch classifies services defined in CPP into three types: Manage, Route, and Protocol. Each type of services has an independent bandwidth. Different types of services cannot share their bandwidths. Traffics with bandwidths exceeding the thresholds will be discarded. By such service classification, service packets are processed by orders of precedence.

As shown in Figure 18-2, the switch receives a large number of Telnet packets, OSPF packets, and ARP packets, causing CPU overload. In this case, the CPU cannot process all packets, and a large quantity of packets are backlogged in the queue, causing various problems such as frequent Telnet disconnection, OSPF protocol flapping, and ARP access failure on hosts.

Figure 18-2

Deployment

- By default, CPU centralized bandwidth allocation is enabled to assign an independent bandwidth and bandwidth ratio to each type of services. At the time, the CPU first processes Telnet packets to ensure uninterrupted connection of Telnet service, and then processes OSPF packets to maintain OSPF protocol stability, and finally processes ARP packets.
- If the preceding problems still occur in default configurations, you can accordingly adjust the bandwidths and bandwidth ratios of various types of services.

18.3 Features

Basic Concepts

ARP Guard

In local area networks (LANs), IP addresses are mapped to MAC addresses through ARP, which has a significant role in safeguarding network security. ARP-based DoS attacks mean that a large number of unauthorized ARP packets are sent to the gateway through the network, causing the failure of the gateway to provide services for normal hosts. To prevent such attacks, limit the rate of ARP packets and identify and isolate the attack source.

IP Guard

Many hacker attacks and network virus intrusions start from scanning active hosts in the network. Therefore, many scanning packets rapidly occupy the network bandwidth, causing network communication failure.

To solve this problem, Ruijie Layer-3 switches provide IP guard function to prevent hacker scanning and Blaster Worm viruses and reduce the CPU load. Currently, there are mainly two types of IP attacks:

Scanning destination IP address changes: As the greatest threat to the network, this type of attacks not only consumes network bandwidth and increases device load but also is a prelude of most hacker attacks.

Sending IP packets to non-existing destination IP addresses at high rates: This type of attacks is mainly designed for consuming the CPU load. For a Layer-3 device, if the destination IP address exists, packets are directly forwarded by the switching chip without occupying CPU resources. If the destination IP address does not exist, IP packets are sent to the CPU, which then sends ARP requests to query the MAC address corresponding to the destination IP address. If too many packets are sent to the CPU, CPU resources will be consumed. This type of attack is less destructive than the former one.

To prevent the latter type of attack, limit the rate of IP packets and find and isolate the attack source.

↳ ICMP Guard

ICMP is a common approach to diagnose network failures. After receiving an ICMP echo request from a host, the router or switch returns an ICMP echo reply. The preceding process requires the CPU to process the packets, thereby definitely consuming part of CPU resources. If an attacker sends a large number of ICMP echo requests to the destination device, massive CPU resources on the device will be consumed heavily, and the device may even fail to work properly. This type of attacks is called ICMP flood. To prevent this type of attacks, limit the rate of ICMP packets and find and isolate the attack source.

↳ DHCP Guard

DHCP is widely used in LANs to dynamically assign IP addresses. It is significant to network security. Currently, the most common DHCP attack, also called DHCP exhaustion attack, uses faked MAC addresses to broadcast DHCP requests. Various attack tools on the Internet can easily complete this type of attack. A network attacker can send sufficient DHCP requests to use up the address space provided by the DHCP server within a period. In this case, authorized hosts will fail to request DHCP IP addresses and thereby fail to access the network. To prevent this type of attacks, limit the rate of DHCP packets and find and isolate the attack source.

↳ DHCPv6 Guard

DHCP version 6 (DHCPv6) is widely used in LANs to dynamically assign IPv6 addresses. Both DHCP version 4 (DHCPv4) and DHCPv6 have security problems. Attacks to DHCPv4 apply also to DHCPv6. A network attacker can send a large number of DHCPv6 requests to use up the address space provided by the DHCPv6 server within a period. In this case, authorized hosts will fail to request IPv6 addresses and thereby fail to access the network. To prevent this type of attacks, limit the rate of DHCPv6 packets and find and isolate the attack source.

↳ ND Guard

Neighbor Discovery (ND) is mainly used in IPv6 networks to perform address resolution, router discovery, prefix discovery, and redirection. ND uses five types of packets: Neighbor Solicitation (NS), Neighbor Advertisement (NA), Router Solicitation (RS), Router Advertisement (RA), and Redirect. These packets are called ND packets.

↳ Self-Defined Guard

There are various types of network protocols, including routing protocols such as Open Shortest Path First (OSPF), Border Gateway Protocol (BGP), and Routing Information Protocol (RIP). Various devices need to exchange packets through different protocols. These packets must be sent to the CPU and processed by appropriate protocols. Once the network device runs a protocol, it is like opening a window for attackers. If an attacker sends a large number of protocol packets to a

network device, massive CPU resources will be consumed on the device, and what's worse, the device may fail to work properly.

Since various protocols are being continuously developed, protocols in use vary with the user environments. Ruijie devices hereby provide self-defined guard. Users can customize and flexibly configure guard types to meet guard requirements in different user environments.

Overview

Feature	Description
Host-based Rate Limiting and Attack Identification	Limits the rate according to the host-based rate limit and identify host attacks in the network.
Port-based Rate Limiting and Attack Identification	Limits the rate according to the port-based rate limit and identify port attacks.
Monitoring Period	Monitors host attackers in a specified period.
Isolation Period	Uses hardware to isolate host attackers or port attackers in a specified period.
Trusted Hosts	Trusts a host by not monitoring it.
Centralized BandwidthAllocation	Classifies and prioritizes packets.

18.3.1 Host-based Rate Limiting and Attack Identification

Limit the rate of attack packets of hosts and identify the attacks.

Identify ARP scanning.

Identify IP scanning.

Working Principle

Hosts can be identified in two ways: based on the source IP address, VLAN ID, and port and based on the link-layer source MAC address, VLAN ID, and port. Each host has a rate limit and an attack threshold (also called alarm threshold). The rate limit must be lower than the attack threshold. If the attack packet rate exceeds the rate limit of a host, the host discards the packets beyond the rate limit. If the attack packet rate exceeds the attack threshold of a host, the host identifies and logs the host attacks, and sends traps.

ARP scanning attack may have occurred if ARP packets beyond the scanning threshold received in the configured period meet either of the following conditions:

- The link-layer source MAC address is fixed but the source IP address changes.
- The link-layer source MAC address and source IP address are fixed but the destination IP address continuously changes.

Among IP packets beyond the scanning threshold received in the configured period, if the source IP address remains the same while the destination IP address continuously changes, IP scanning attack may have occurred.

 When NFPP detects a specific type of attack packets under a service, it sends a trap to the administrator. If the attack traffic persists, NFPP will not resend the alarm until 60 seconds later.

-
- i** To prevent CPU resource consumption caused by frequent log printing, NFPP writes attack detection logs to the buffer, obtains them from the buffer at a specified rate, and prints them. NFPP does not limit the rate of traps.
-

Related Configuration

Use ARP guard as an example:

▾ [Configuring the Global Host-based Rate Limit, Attack Threshold, and Scanning Threshold](#)

In NFPP configuration mode:

Run the **arp-guard rate-limit** {**per-src-ip** | **per-src-mac**} *pps* command to configure rate limits of hosts identified based on the source IP address, VLAN ID, and port and hosts identified based on the link-layer source MAC address, VLAN ID, and port.

Run the **arp-guard attack-threshold** {**per-src-ip** | **per-src-mac**} *pps* command to configure attack thresholds of hosts identified based on the source IP address, VLAN ID, and port and hosts identified based on the link-layer source MAC address, VLAN ID, and port.

Run the **arp-guard scan-threshold** *pkt-cnt* command to configure the ARP scanning threshold.

▾ [Configuring Host-based Rate Limit and Attack Threshold, and Scanning Threshold on an Interface](#)

In interface configuration mode:

Run the **nfpp arp-guard policy** {**per-src-ip** | **per-src-mac**} *rate-limit-pps attack-threshold-pps* command to configure rate limits and attack thresholds of hosts identified based on the source IP address, VLAN ID, and port and hosts identified based on the link-layer source MAC address, VLAN ID, and port on an interface.

Run the **nfpp arp-guard scan-threshold** *pkt-cnt* command to configure the scanning threshold on an interface.

-
- i** Only ARP guard and IP guard support anti-scanning at present.
-

18.3.2 Port-based Rate Limiting and Attack Identification

Working Principle

Each port has a rate limit and an attack threshold. The rate limit must be lower than the attack threshold. If the packet rate exceeds the rate limit on a port, the port discards the packets. If the packet rate exceeds the attack threshold on a port, the port logs the attacks and sends traps.

Related Configuration

Use ARP guard as an example:

▾ [Configuring the Global Port-based Rate Limit and Attack Threshold](#)

In NFPP configuration mode:

Run the **arp-guard rate-limit per-port** *pps* command to configure the rate limit of a port.

Run the **arp-guard attack-threshold per-port** *pps* command to configure the attack threshold of a port.

↘ [Configuring Port-based Rate Limit and Attack Threshold on an Interface](#)

In interface configuration mode:

Run the **nfpp arp-guard policy per-port** *rate-limit-pps attack-threshold-pps* command to configure the rate limit and attack threshold of a port.

18.3.3 Monitoring Period

[Working Principle](#)

The monitoring user provides information about attackers in the current system. If the isolation period is 0 (that is, not isolated), the guard module automatically performs software monitoring on attackers in the configured monitoring period. If the isolation period is set to a non-zero value, the guard module automatically isolates the hosts monitored by software.

During software monitoring, if the isolation period is set to a non-zero value, the guard module automatically isolates the attacker and sets the timeout period as the isolation period.

The monitoring period is valid only when the isolation period is 0.

[Related Configuration](#)

Use ARP guard as an example:

↘ [Configuring the Global Monitoring Period](#)

In NFPP configuration mode:

Run the **arp-guard monitor-period** *seconds* command to configure the monitoring period.

18.3.4 Isolation Period

[Working Principle](#)

Isolation is performed by the guard policies after attacks are detected. Isolation is implemented using the filter of the hardware to ensure that these attacks will not be sent to the CPU, thereby ensuring proper running of the device.

Hardware isolation supports two modes: host-based and port-based isolation. At present, only ARP guard supports port-based hardware isolation.

A policy is configured in the hardware to isolate attackers. However, hardware resources are limited. When hardware resources are used up, the system prints logs to notify the administrator.

[Related Configuration](#)

Use ARP guard as an example:

↘ [Configuring the Global Isolation Period](#)

In NFPP configuration mode:

Run the **arp-guard isolate-period** [*seconds* | **permanent**] command to configure the isolation period. If the isolation period is set to 0, isolation is disabled. If it is set to a non-zero value, the value indicates the isolation period. If it is set to **permanent**, ARP attacks are permanently isolated.

↘ **Configuring the Isolation Period on an Interface**

In interface configuration mode:

Run the **nfpp arp-guard isolate-period** [*seconds* | **permanent**] command to configure the isolation period. If the isolation period is set to 0, isolation is disabled. If it is set to a non-zero value, the value indicates the isolation period. If it is set to **permanent**, ARP attacks are permanently isolated.

↘ **Enabling Isolate Forwarding**

In NFPP configuration mode:

Run the **arp-guard isolate-forwarding enable** command to enable isolate forwarding.

↘ **Enabling Port-based Ratelimit Forwarding**

In NFPP configuration mode:

Run the **arp-guard ratelimit-forwarding enable** command to enable port-based ratelimit forwarding.

 At present, only ARP guard supports the configuration of isolate forwarding and ratelimit forwarding.

18.3.5 Trusted Hosts

Working Principle

If you do not want to monitor a host, you can run related commands to trust the host. This trusted host will be allowed to send packets to the CPU.

Related Configuration

Use IP anti-scanning as an example:

↘ **Configuring Trusted Hosts**

In NFPP configuration mode:

Run the **ip-guard trusted-host** *ip mask* command to trust a host.

Run the **trusted-host** {*mac mac_mask* | *ip mask* | *IPv6/prefixlen*} command to trust a host for a self-defined guard.

18.3.6 Centralized Bandwidth Allocation

Working Principle

Services defined in CPP are classified into three types: Manage, Route, and Protocol. (For details, see the following table.) Each type of service has an independent bandwidth. Different types of services cannot share their bandwidths. Traffics

exceeding the bandwidth thresholds are discarded. By such service classification, service packets are processed by orders of precedence.

NFPP allows the administrator to flexibly assign bandwidth for three types of packets based on the actual network environment so that Protocol and Manage packets can be first processed. Prior processing of Protocol packets ensures proper running of protocols, and prior processing of Manage packets ensures proper management for the administrator, thereby ensuring proper running of important device functions and improving the guard capability of the device.

After classified rate limiting, all types of packets are centralized in a queue. When one type of service is processed inefficiently, packets of this service will be backlogged in the queue and may finally use up resources of the queue. NFPP allows the administrator to configure the percentages of these three types of packets in the queue. When the queue length occupied by one type of packets exceeds the value of the total queue length multiplied by the percentage of this packet type, the excessive packets will be discarded. This efficiently prevents one type of packets from exclusively occupying queue resources.

Packet Type	Service Type Defined in CPP
Protocol	tp-guard, dot1x, rldp, rerp, slow-packet, bpdu, isis dhcps, gvrp, ripng, dvmrp, igmp, mpls, ospf, pim, pimv6, rip, vrrp, ospf3, dhcp-relay-s, dhcp-relay-c, option82, tunnel-bpdu, tunnel-gvrp
Route	unknown-ipmc, unknown-ipmcv6, ttl1, ttl0, udp-helper, ip4-packet-other, ip6-packet-other, non-ip-packet-other, arp
Manage	ip4-packet-local, ip6-packet-local

 For the definitions of service types, see the Configuring CPU Protection.

Related Configuration

▾ Configuring the Maximum Bandwidth of Specified Packets

In global configuration mode:

Run the **cpu-protect sub-interface { manage | protocol|route} pps pps_value** command to configure the maximum bandwidth of specified packets.

▾ Configuring the Maximum Percentage of Specified Packets in the Queue

In global configuration mode:

Run the **cpu-protect sub-interface { manage | protocol | route} percent percent_value** command to configure the maximum percentage of specified packets in the queue.

18.4 Configuration

Configuration	Description and Command	
Configuring ARP Guard	arp-guard enable	Enables ARP guard globally.
	arp-guard isolate-period	Configures the global ARP-guard isolation period.
	arp-guard isolate-forwarding enable	Enables ARP-guard isolate forwarding.

Configuration	Description and Command	
	arp-guard ratelimit-forwarding enable	Enables APR-guard ratelimit forwarding.
	arp-guard monitor-period	Configures the global ARP-guard monitoring period.
	arp-guard monitored-host-limit	Configures the maximum number of ARP-guard monitored hosts.
	arp-guard rate-limit	Configures the global ARP-guard rate limit.
	arp-guard attack-threshold	Configures the global ARP-guard attack threshold.
	arp-guard scan-threshold	Configures the global ARP-guard scanning threshold.
	nfpp arp-guard enable	Enables ARP guard on an interface.
	nfpp arp-guard policy	Configures the APR-guard rate limit and attack threshold on an interface.
	nfpp arp-guard scan-threshold	Configures the APR-guard scanning threshold on an interface.
	nfpp arp-guard isolate-period	Configures the APR-guard isolation period on an interface.
Configuring IP Guard	ip-guard enable	Enables IP guard globally.
	ip-guard isolate-period	Configures the global IP-guard isolation period.
	ip-guard monitor-period	Configures the global IP-guard monitoring period.
	ip-guard monitored-host-limit	Configures the maximum number of IP-guard monitored hosts.
	ip-guard rate-limit	Configures the global IP-guard rate limit.
	ip-guard attack-threshold	Configures the global IP-guard attack threshold.
	ip-guard scan-threshold	Configures the global IP-guard scanning threshold.
	ip-guard trusted-host	Configures IP-guard trusted hosts.
	nfpp ip-guard enable	Enables IP guard on an interface.
	nfpp ip-guard policy	Configures the IP-guard rate limit and attack threshold on an interface.
	nfpp ip-guard scan-threshold	Configures the IP-guard scanning threshold on an interface.
nfpp ip-guard isolate-period	Configures the IP-guard isolation period on an interface.	
Configuring ICMP Guard	icmp-guard enable	Enables ICMP guard globally.
	icmp-guard isolate-period	Configures the global ICMP-guard isolation period.

Configuration	Description and Command	
	icmp-guard monitor-period	Configures the global ICMP-guard monitoring period.
	icmp-guard monitored-host-limit	Configures the maximum number of ICMP-guard monitored hosts.
	icmp-guard rate-limit	Configures the global ICMP-guard rate limit.
	icmp-guard attack-threshold	Configures the global ICMP-guard attack threshold.
	icmp-guard trusted-host	Configures ICMP-guard trusted hosts.
	nfpp icmp-guard enable	Enables ICMP guard on an interface.
	nfpp icmp-guard policy	Configures the ICMP-guard rate limit and attack threshold on an interface.
	nfpp icmp-guard isolate-period	Configures the ICMP-guard isolation period on an interface.
Configuring DHCP Guard	dhcp-guard enable	Enables DHCP guard globally.
	dhcp-guard isolate-period	Configures the global DHCP-guard isolation period.
	dhcp-guard monitor-period	Configures the global DHCP-guard monitoring period.
	dhcp-guard monitored-host-limit	Configures the maximum number of DHCP-guard monitored hosts.
	dhcp-guard rate-limit	Configures the global DHCP-guard rate limit.
	dhcp-guard attack-threshold	Configures the global DHCP-guard attack threshold.
	nfpp dhcp-guard enable	Enables DHCP guard on an interface.
	nfpp dhcp-guard policy	Configures the DHCP-guard rate limit and attack threshold on an interface.
Configuring DHCPv6 Guard	dhcpv6-guard enable	Enables DHCPv6 guard globally.
	dhcpv6-guard isolate-period	Configures the global DHCPv6-guard isolation period.
	dhcpv6-guard monitor-period	Configures the global DHCPv6-guard monitoring period.
	dhcpv6-guard monitored-host-limit	Configures the maximum number of DHCPv6-guard monitored hosts.
	dhcpv6-guard rate-limit	Configures the global DHCPv6-guard rate limit.
	dhcpv6-guard attack-threshold { per-src-mac per-port} pps	Configures the global DHCPv6-guard attack threshold.
	nfpp dhcpv6-guard enable	Enables DHCPv6 guard on an interface.

Configuration	Description and Command	
	nfpp dhcpv6-guard policy	Configures the DHCPv6-guard rate limit and attack threshold on an interface.
	nfpp dhcpv6-guard isolate-period	Configures the DHCPv6-guard isolation period on an interface.
Configuring ND Guard	nd-guard enable	Enables ND guard globally.
	nd-guard ratelimit-forwarding enable	Enables ND-guard ratelimit forwarding.
	nd-guard rate-limit per-port	Configures the global ND-guard rate limit.
	nd-guard attack-threshold per-port	Configures the global ND-guard attack threshold.
	nfpp nd-guard enable	Enables ND guard on an interface.
	nfpp nd-guard policy per-port	Configures the ND-guard rate limit and attack threshold on an interface.
Configuring a Self-Defined Guard	define	Configures the name of a self-defined guard.
	match	Configures match fields of a self-defined guard.
	global-policy	Configures the global rate limit and attack threshold of a self-defined guard.
	isolate-period	Configures the global isolation period of a self-defined guard.
	monitor-period	Configures the global monitoring period of a self-defined guard.
	monitored-host-limit	Configures the maximum number of monitored hosts of a self-defined guard.
	trusted-host	Configures trusted hosts of a self-defined guard.
	define name enable	Enables a self-defined guard globally.
	nfpp define name enable	Enables a self-defined guard on an interface.
	nfpp define	Configures the rate limit and attack threshold of a self-defined guard on an interface.
Configuring NFPP Logging	log-buffer entries	Configures the log buffer size.
	log-buffer logs	Configures the log buffer rate.
	logging vlan	Configures VLAN-based logging filtering.
	logging interface	Configures interface-based logging filtering.
	logging enable	Enables log printing.

18.4.1 Configuring ARP Guard

Configuration Effect

- ARP attacks are identified based on hosts or ports. Host-based ARP attack identification supports two modes: identification based on the source IP address, VLAN ID, and port and identification based on the link-layer source MAC address, VLAN ID, and port. Each type of attack identification has a rate limit and an attack threshold. If the ARP packet

rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the ARP packet rate exceeds the attack threshold, the system prints alarm information and sends traps. In host-based attack identification, the system also isolates the attack source.

- ARP guard can also detect ARP scanning attacks. ARP scanning attacks indicate that the link-layer source MAC address is fixed but the source IP address changes, or that the link-layer source MAC address and source IP address are fixed but the destination IP address continuously changes. Due to the possibility of false positive, hosts possibly performing ARP scanning are not isolated and are provided for the administrator's reference only.
- Configure ARP-guard isolation to assign hardware-isolated entries against host attacks so that attack packets are neither sent to the CPU nor forwarded.

Notes

- For a command that is configured both in NFPP configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in NFPP configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy hardware entries of the security module.
- ARP guard prevents only ARP DoS attacks to the switch, but not ARP spoofing or ARP attacks in the network.
- For trusted ports configured for Dynamic ARP Inspection (DAI), ARP guard does not take effect, preventing false positive of ARP traffic over the trusted ports. For details about DAI trusted ports, see the Configuring Dynamic ARP Inspection.

Configuration Steps

▾ Enabling ARP Guard

- (Mandatory) ARP guard is enabled by default.
- This function can be enabled in NFPP configuration mode or interface configuration mode.
- If ARP guard is disabled, the system automatically clears monitored hosts, scanned hosts, and isolated entries on ports.

▾ Configuring the ARP-Guard Isolation Period

- (Optional) ARP-guard isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit defined in CPP, you can configure the isolation period to discard packets and therefore to save bandwidth resources.
- The isolation period can be configured in NFPP configuration mode or interface configuration mode.
- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

▾ Enabling ARP-Guard Isolate Forwarding

- (Optional) ARP-guard isolate forwarding is enabled by default.
- To make isolation valid only at the management plane instead of the forwarding plane, you can enable this function.
- This function can be enabled in NFPP configuration mode.

▾ Enabling ARP-Guard RateLimit Forwarding

- (Optional) This function is enabled by default.
- If the port-based isolation entry takes effect, you can enable this function to pass some of the packets while not discarding all of them.
- This function can be enabled in NFPP configuration mode.

▾ **Configuring the ARP-Guard Monitoring Period**

- (Mandatory) The default ARP-guard monitoring period is 600 seconds.
- If the ARP-guard isolation period is configured, it is directly used as the monitoring period, and the configured monitoring period will lose effect.
- The monitoring period can be configured in NFPP configuration mode.

▾ **Configuring the Maximum Number of ARP-Guard Monitored Hosts**

- (Mandatory) The maximum number of ARP-guard monitored hosts is 20,000 by default.
- Set the maximum number of ARP-guard monitored hosts reasonably. As the number of monitored hosts increases, more CPU resources are used.
- The maximum number of ARP-guard monitored hosts can be configured in NFPP configuration mode.
- If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system prints the log "% NFPP_ARP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.

▾ **Configuring the ARP-Guard Attack Threshold**

- Mandatory.
- To achieve the best ARP-guard effect, you are advised to configure the host-based rate limit and attack threshold based on the following order: Source IP address-based rate limit < Source IP address-based attack threshold < Source MAC address-based rate limit < Source MAC address-based attack threshold.
- The attack threshold can be configured in NFPP configuration mode or interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is less than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_ARP_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source MAC address-based rate limiting takes priority over source IP address-based rate limiting while the latter takes priority over port-based rate limiting.

↘ Configuring the ARP-Guard Scanning Threshold

- Mandatory.
- The scanning threshold can be configured in NFPP configuration mode or interface configuration mode.
- The ARP scanning table stores only the latest 256 records. When the ARP scanning table is full, the latest record will overwrite the earliest record.
- ARP scanning attack may have occurred if ARP packets received within 10 seconds meet either of the following conditions:
 - The link-layer source MAC address is fixed but the source IP address changes.
 - The link-layer source MAC address and source IP address are fixed but the destination IP address continuously changes, and the change times exceed the scanning threshold.

Verification

When a host in the network sends ARP attack packets to a switch configured with ARP guard, check whether these packets can be sent to the CPU.

- If the packets exceed the attack threshold or scanning threshold, an attack log is displayed.
- If an isolated entry is created for the attacker, an isolation log is displayed.

Related Commands

↘ Enabling ARP Guard Globally

Command	arp-guard enable
Parameter	N/A
Description	
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Configuring the Global ARP-Guard Isolation Period

Command	arp-guard isolate-period [<i>seconds</i> permanent]
Parameter	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400.
Description	permanent : Indicates permanent isolation.
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Enabling ARP-Guard Isolate Forwarding

Command	arp-guard isolate-forwarding enable
Parameter	N/A

Description	
Command	NFPP configuration mode
Mode	
Usage Guide	N/A

↘ Enabling ARP-Guard Ratelimit Forwarding

Command	arp-guard ratelimit-forwarding enable
Parameter	N/A
Description	
Command	NFPP configuration mode
Mode	
Usage Guide	N/A

↘ Configuring the Global ARP-Guard Monitoring Period

Command	arp-guard monitor-period <i>seconds</i>
Parameter	<i>seconds</i> : Indicates the monitoring period in the unit of second. The value ranges from 180 to 86,400.
Description	
Command	NFPP configuration mode
Mode	
Usage Guide	N/A

↘ Configuring the Maximum Number of ARP-Guard Monitored Hosts

Command	arp-guard monitored-host-limit <i>number</i>
Parameter	<i>number</i> : Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Description	
Command	NFPP configuration mode
Mode	
Usage Guide	N/A

↘ Configuring the Global ARP-Guard Rate Limit

Command	arp-guard rate-limit { per-src-ip per-src-mac per-port } <i>pps</i>
Parameter	per-src-ip : Limits the rate of each source IP address.
Description	per-src-mac : Limits the rate of each source MAC address. per-port : Limits the rate of each port. <i>pps</i> : Indicates the rate limit, ranging from 1 to 19,999.
Command	NFPP configuration mode
Mode	
Usage Guide	N/A

↘ Configuring the Global ARP-Guard Attack Threshold

Command	arp-guard attack-threshold {per-src-ip per-src-mac per-port} pps
Parameter Description	per-src-ip : Configures the attack threshold of each source IP address. per-src-mac : Configures the attack threshold of each source MAC address. per-port : Configures the attack threshold of each port. <i>pps</i> : Indicates the attack threshold, ranging from 1 to 19,999. The unit is packets per second (pps).
Command Mode	NFPP configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

↘ Configuring the Global ARP-Guard Scanning Threshold

Command	arp-guard scan-threshold pkt-cnt
Parameter Description	<i>pkt-cnt</i> : Indicates the scanning threshold, ranging from 1 to 19,999.
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Enabling ARP Guard on an Interface

Command	nfpp arp-guard enable
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	ARP guard configured in interface configuration mode takes priority over that configured in NFPP configuration mode.

↘ Configuring the ARP-Guard Isolation Period on an Interface

Command	nfpp arp-guard isolate-period [seconds permanent]
Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. permanent : Indicates permanent isolation.
Command Mode	Interface configuration mode
Usage Guide	N/A

↘ Configuring the ARP-Guard Rate Limit and Attack Threshold on an Interface

Command	nfpp arp-guard policy {per-src-ip per-src-mac per-port} rate-limit-pps attack-threshold-pps
Parameter Description	per-src-ip : Configures the rate limit and attack threshold of each source IP address. per-src-mac : Configures the rate limit and attack threshold of each source MAC address. per-port : Configures the rate limit and attack threshold of each port.

	<i>rate-limit-pps</i> : Indicates the rate limit, ranging from 1 to 19,999. <i>attack-threshold-pps</i> : Indicates the attack threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

📌 **Configuring the ARP-Guard Scanning Threshold on an Interface**

Command	nfpp arp-guard scan-threshold <i>pkt-cnt</i>
Parameter Description	<i>pkt-cnt</i> : Indicates the scanning threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

📌 **CPU Protection Based on ARP Guard**

Scenario	<ul style="list-style-type: none"> ARP host attacks exist in the system, and some hosts fail to properly establish ARP connection. ARP scanning exists in the system, causing a very high CPU utilization rate.
Configuration Steps	<ul style="list-style-type: none"> Set the host-based attack threshold to 5 pps. Set the ARP scanning threshold to 10 pps. Set the isolation period to 180 pps.

18.4.2 Configuring IP Guard

Configuration Effect

- IP attacks are identified based on hosts or physical interfaces. In host-based IP attack identification, IP attacks are identified based on the source IP address, VLAN ID, and port. Each type of attack identification has a rate limit and an attack threshold. If the IP packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the IP packet rate exceeds the attack threshold, the system prints alarm information and sends traps. In host-based attack identification, the system also isolates the attack source.
- IP guard can also detect IP scanning attacks. IP anti-scanning applies to IP packet attacks as follows: the destination IP address continuously changes but the source IP address remains the same, and the destination IP address is not the IP address of the local device.
- Configure IP guard isolation to assign hardware-isolated entries against host attacks so that attack packets are neither sent to the CPU nor forwarded.
- IP anti-scanning applies to IP packet attacks where the destination IP address is not the local IP address. The CPP limits the rate of IP packets where the destination IP address is the local IP address.

Notes

- For a command that is configured both in NFPP configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in NFPP configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy hardware entries of the security module.

Configuration Steps

↳ Enabling IP Guard

- (Mandatory) IP guard is enabled by default.
- This function can be enabled in NFPP configuration mode or interface configuration mode.
- If IP guard is disabled, the system automatically clears monitored hosts.

↳ Configuring the IP-Guard Isolation Period

- (Optional) IP-guard isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit defined in CPP, you can configure the isolation period to discard packets and therefore to save bandwidth resources.
- The isolation period can be configured in NFPP configuration mode or interface configuration mode.
- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

↳ Configuring the IP-Guard Monitoring Period

- (Mandatory) The default IP-guard monitoring period is 600 seconds.
- If the IP-guard isolation period is configured, it is directly used as the monitoring period, and the configured monitoring period will lose effect.
- The monitoring period can be configured in NFPP configuration mode.

↳ Configuring the Maximum Number of IP-Guard Monitored Hosts

- (Mandatory) The maximum number of IP-guard monitored hosts is 20,000 by default.
- Set the maximum number of IP-guard monitored hosts reasonably. As the number of monitored hosts increases, more CPU resources are used.
- The maximum number of IP-guard monitored hosts can be configured in NFPP configuration mode.
- If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20,000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system prints the log "% NFPP_IP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.

↳ Configuring the IP-Guard Attack Threshold

- Mandatory.
- The attack threshold can be configured in NFPP configuration mode or interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.

- If the configured attack threshold is less than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_IP_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source IP address-based rate limiting takes priority over port-based rate limiting.

▾ **Configuring the IP-Guard Scanning Threshold**

- Mandatory.
- The scanning threshold can be configured in NFPP configuration mode or interface configuration mode.
- ARP scanning attack may have occurred if ARP packets received within 10 seconds meet the following conditions:
 - The source IP address remains the same.
 - The destination IP address continuously changes and is not the local IP address, and the change times exceed the scanning threshold.

▾ **Configuring IP-Guard Trusted Hosts**

- (Optional) No IP-guard trusted host is configured by default.
- For IP guard, you can only configure a maximum of 500 IP addresses not to be monitored.
- Trusted hosts can be configured in NFPP configuration mode.
- If any entry matching a trusted host (IP addresses are the same) exists in the table of monitored hosts, the system automatically deletes this entry.
- If the table of trusted hosts is full, the system prints the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If a trusted host cannot be deleted, the system prints the log "%ERROR: Failed to delete trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If a host cannot be trusted, the system prints the log "%ERROR: Failed to add trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If the host to trust already exists, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 has already been configured." to notify the administrator.
- If the host to delete from the trusted table does not exist, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 is not found." to notify the administrator.
- If the memory cannot be allocated to a trusted host, the system prints the log "%ERROR: Failed to alloc memory." to notify the administrator.

Verification

When a host in the network sends IP attack packets to a switch configured with IP guard, check whether these packets can be sent to the CPU.

- If the rate of packets from untrusted hosts exceeds the attack threshold or scanning threshold, an attack log is displayed.
- If an isolated entry is created for the attacker, an isolation log is displayed.

Related Commands

↘ Enabling IP Guard Globally

Command	ip-guard enable
Parameter	N/A
Description	
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Configuring the Global IP-Guard Isolation Period

Command	ip-guard isolate-period [<i>seconds</i> permanent]
Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. permanent : Indicates permanent isolation.
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Configuring the Global IP-Guard Monitoring Period

Command	ip-guard monitor-period <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the monitoring period in the unit of second. The value ranges from 180 to 86,400.
Command Mode	NFPP configuration mode
Usage Guide	If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

↘ Configuring the Maximum Number of IP-Guard Monitored Hosts

Command	ip-guard monitored-host-limit <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Configuring the Global IP-Guard Rate Limit

Command	ip-guard rate-limit {per-src-ip per-port} pps
Parameter	per-src-ip : Limits the rate of each source IP address.
Description	per-port : Limits the rate of each port. pps: Indicates the rate limit, ranging from 1 to 19,999.
Command Mode	NFPP configuration mode
Usage Guide	N/A

▾ Configuring the Global IP-Guard Attack Threshold

Command	ip-guard attack-threshold {per-src-ip per-port} pps
Parameter	per-src-ip : Configures the attack threshold of each source IP address.
Description	per-port : Configures the attack threshold of each port. pps: Indicates the attack threshold, ranging from 1 to 19,999. The unit is pps.
Command Mode	NFPP configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

▾ Configuring the Global IP-Guard Scanning Threshold

Command	ip-guard scan-threshold pkt-cnt
Parameter	pkt-cnt: Indicates the scanning threshold, ranging from 1 to 19,999.
Description	
Command Mode	NFPP configuration mode
Usage Guide	N/A

▾ Configuring IP-Guard Trusted Hosts

Command	ip-guard trusted-host ip mask
Parameter	ip: Indicates the IP address.
Description	mask: Indicates the mask of an IP address. all: Used with no to delete all trusted hosts.
Command Mode	NFPP configuration mode
Usage Guide	If you do not want to monitor a host, you can run this command to trust the host. This trusted host can send IP packets to the CPU, without any rate limiting or alarm reporting.

▾ Enabling IP Guard on an Interface

Command	nfpp ip-guard enable
Parameter	N/A
Description	
Command	Interface configuration mode

Mode	
Usage Guide	IP guard configured in interface configuration mode takes priority over that configured in NFPP configuration mode.

▾ Configuring the IP-Guard Isolation Period on an Interface

Command	nfpp ip-guard isolate-period [<i>seconds</i> permanent]
Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. permanent : Indicates permanent isolation.
Command Mode	Interface configuration mode
Usage Guide	N/A

▾ Configuring the IP-Guard Rate Limit and Attack Threshold on an Interface

Command	nfpp ip-guard policy { per-src-ip per-port } <i>rate-limit-pps</i> <i>attack-threshold-pps</i>
Parameter Description	per-src-ip : Configures the attack threshold of each source IP address. per-port : Configures the attack threshold of each port. <i>rate-limit-pps</i> : Indicates the rate limit, ranging from 1 to 19,999. <i>attack-threshold-pps</i> : Indicates the attack threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

▾ Configuring the IP-Guard Scanning Threshold on an Interface

Command	nfpp ip-guard scan-threshold <i>pkt-cnt</i>
Parameter Description	<i>pkt-cnt</i> : Indicates the scanning threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

▾ CPU Protection Based on IP Guard

Scenario	<ul style="list-style-type: none"> ● IP host attacks exist in the system, and packets of some hosts cannot be properly routed and forwarded. ● IP scanning exists in the system, causing a very high CPU utilization rate. ● Packet traffic of some hosts is very large in the system, and these packets need to pass through.
Configuration Steps	<ul style="list-style-type: none"> ● Configure the host-based attack threshold. ● Configure the IP scanning threshold. ● Set the isolation period to a non-zero value.

	<ul style="list-style-type: none"> ● Configure trusted hosts.
	<pre>Ruijie# configure terminal Ruijie(config)# nfpp Ruijie (config-nfpp)#ip-guard rate-limit per-src-ip 20 Ruijie (config-nfpp)#ip-guard attack-threshold per-src-ip 30 Ruijie (config-nfpp)#ip-guard isolate-period 180 Ruijie (config-nfpp)#ip-guard trusted-host 192.168.201.46 255.255.255.255</pre>
Verification	<ul style="list-style-type: none"> ● Run the <code>show nfpp ip-guard summary</code> command to display the configuration.

18.4.3 Configuring ICMP Guard

Configuration Effect

- ICMP attacks are identified based on hosts or ports. In host-based attack identification, ICMP attacks are identified based on the source IP address, VLAN ID, and port. Each type of attack identification has a rate limit and an attack threshold. If the ICMP packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the ICMP packet rate exceeds the attack threshold, the system prints alarm information and sends traps. In host-based attack identification, the system also isolates the attack source.
- Configure ICMP guard isolation to assign hardware-isolated entries against host attacks so that attack packets are neither sent to the CPU nor forwarded.

Notes

- For a command that is configured both in NFPP configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in NFPP configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy hardware entries of the security module.

Configuration Steps

▾ Enabling ICMP Guard

- (Mandatory) ICMP guard is enabled by default.
- This function can be enabled in NFPP configuration mode or interface configuration mode.
- If ICMP guard is disabled, the system automatically clears monitored hosts.

▾ Configuring the ICMP-Guard Isolation Period

- (Optional) ICMP-guard isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit defined in CPP, you can configure the isolation period to discard packets and therefore to save bandwidth resources.
- The isolation period can be configured in NFPP configuration mode or interface configuration mode.
- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

▾ Configuring the ICMP-Guard Monitoring Period

- (Mandatory) The default ICMP-guard monitoring period is 600 seconds.
- If the ICMP-guard isolation period is configured, it is directly used as the monitoring period, and the configured monitoring period will lose effect.
- The monitoring period can be configured in NFPP configuration mode.

▾ Configuring the Maximum Number of ICMP-Guard Monitored Hosts

- (Mandatory) The maximum number of ICMP-guard monitored hosts is 20,000 by default.
- Set the maximum number of ICMP-guard monitored hosts reasonably. As the number of actually monitored hosts increases, more CPU resources are used.
- The maximum number of ICMP-guard monitored hosts can be configured in NFPP configuration mode.

- If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system prints the log "% NFPP_ICMP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.

▾ **Configuring the ICMP-Guard Attack Threshold**

- Mandatory.
- The attack threshold can be configured in NFPP configuration mode or interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is less than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_ICMP_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source IP address-based rate limiting takes priority over port-based rate limiting.

▾ **Configuring ICMP-Guard Trusted Hosts**

- (Optional) No ICMP-guard trusted host is configured by default.
- For ICMP guard, you can only configure a maximum of 500 IP addresses not to be monitored.
- Trusted hosts can be configured in NFPP configuration mode.
- If any entry matching a trusted host (IP addresses are the same) exists in the table of monitored hosts, the system automatically deletes this entry.
- If the table of trusted hosts is full, the system prints the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If a trusted host cannot be deleted, the system prints the log "%ERROR: Failed to delete trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If a host cannot be trusted, the system prints the log "%ERROR: Failed to add trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If the host to trust already exists, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 has already been configured." to notify the administrator.
- If the host to delete from the trusted table does not exist, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 is not found." to notify the administrator.
- If the memory cannot be allocated to a trusted host, the system prints the log "%ERROR: Failed to alloc memory." to notify the administrator.

Verification

When a host in the network sends ICMP attack packets to a switch configured with ICMP guard, check whether these packets can be sent to the CPU.

- If the rate of packets from an untrusted host exceeds the attack threshold, an attack log is displayed.
- If an isolated entry is created for the attacker, an isolation log is displayed.

Related Commands

▾ Enabling ICMP Guard Globally

Command	icmp-guard enable
Parameter Description	N/A
Command Mode	NFPP configuration mode
Usage Guide	N/A

▾ Configuring the Global ICMP-Guard Isolation Period

Command	icmp-guard isolate-period [<i>seconds</i> permanent]
Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. permanent : Indicates permanent isolation.
Command Mode	NFPP configuration mode
Usage Guide	The attacker isolation period falls into two types: global isolation period and port-based isolation period (local isolation period). For a port, if the port-based isolation period is not configured, the global isolation period is used; otherwise, the port-based isolation period is used.

▾ Configuring the Global ICMP-Guard Monitoring Period

Command	icmp-guard monitor-period <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the monitoring period in the unit of second. The value ranges from 180 to 86,400.
Command Mode	NFPP configuration mode
Usage Guide	If the isolation period is 0, the system performs software monitoring on detected attackers. The timeout period is the monitoring period. During software monitoring, if the isolation period is set to a non-zero value, the system automatically performs hardware isolation against monitored attackers and sets the timeout period as the monitoring period. The monitoring period is valid only when the isolation period is 0. If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

▾ Configuring the Maximum Number of ICMP-Guard Monitored Hosts

Command	icmp-guard monitored-host-limit <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Command Mode	NFPP configuration mode
Usage Guide	<p>If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.</p> <p>If the table of monitored hosts is full, the system prints the log "% NFPP_ICMP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.</p>

↘ Configuring the Global ICMP-Guard Rate Limit

Command	icmp-guard rate-limit { per-src-ip per-port } <i>pps</i>
Parameter Description	<p>per-src-ip: Limits the rate of each source IP address.</p> <p>per-port: Limits the rate of each port.</p> <p><i>pps</i>: Indicates the rate limit, ranging from 1 to 19,999.</p>
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Configuring the Global ICMP-Guard Attack Threshold

Command	icmp-guard attack-threshold { per-src-ip per-port } <i>pps</i>
Parameter Description	<p>per-src-ip: Configures the attack threshold of each source IP address.</p> <p>per-port: Configures the attack threshold of each port.</p> <p><i>pps</i>: Indicates the attack threshold, ranging from 1 to 19,999. The unit is pps.</p>
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Configuring ICMP-Guard Trusted Hosts

Command	icmp-guard trusted-host <i>ip mask</i>
Parameter Description	<p><i>ip</i>: Indicates the IP address.</p> <p><i>mask</i>: Indicates the mask of an IP address.</p> <p>all: Used with no to delete all trusted hosts.</p>
Command Mode	NFPP configuration mode
Usage Guide	If you do not want to monitor a host, you can run this command to trust the host. This trusted host can send ICMP packets to the CPU, without any rate limiting or alarm reporting. You can configure the mask so that no host in one network segment is monitored.

	You can configure a maximum of 500 trusted hosts.
--	---

↘ Enabling ICMP Guard on an Interface

Command	nfpp icmp-guard enable
Parameter	N/A
Description	
Command Mode	Interface configuration mode
Usage Guide	ICMP guard configured in interface configuration mode takes priority over that configured in NFPP configuration mode.

↘ Configuring the ICMP-Guard Isolation Period on an Interface

Command	nfpp icmp-guard isolate-period [<i>seconds</i> permanent]
Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. permanent : Indicates permanent isolation.
Command Mode	Interface configuration mode
Usage Guide	N/A

↘ Configuring the ICMP-Guard Rate Limit and Attack Threshold on an Interface

Command	nfpp icmp-guard policy { per-src-ip per-port } <i>rate-limit-pps</i> <i>attack-threshold-pps</i>
Parameter Description	per-src-ip : Configures the rate limit and attack threshold of each source IP address. per-port : Configures the rate limit and attack threshold of each port. <i>rate-limit-pps</i> : Indicates the rate limit, ranging from 1 to 19,999. <i>attack-threshold-pps</i> : Indicates the attack threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

18.4.4 Configuring DHCP Guard

Configuration Effect

- DHCP attacks are identified based on hosts or ports. In host-based attack identification, DHCP attacks are identified based on the link-layer source IP address, VLAN ID, and port. Each type of attack identification has a rate limit and an attack threshold. If the DHCP packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the DHCP packet rate exceeds the attack threshold, the system prints alarm information and sends traps. In host-based attack identification, the system also isolates the attack source.

- Configure DHCP guard isolation to assign hardware-isolated entries against host attacks so that attack packets are neither sent to the CPU nor forwarded.

Notes

- For a command that is configured both in NFPP configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in NFPP configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy hardware entries of the security module.
- For trusted ports configured for DHCP snooping, DHCP guard does not take effect, preventing false positive of DHCP traffic on the trusted ports. For details about trusted ports of DHCP snooping, see "Configuring Basic Functions of DHCP Snooping" in the Configuring DHCP Snooping.

Configuration Steps

↳ Enabling DHCP Guard

- (Mandatory) DHCP guard is enabled by default.
- This function can be enabled in NFPP configuration mode or interface configuration mode.
- If DHCP guard is disabled, the system automatically clears monitored hosts.

↳ Configuring the DHCP-Guard Isolation Period

- (Optional) DHCP-guard isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit defined in CPP, you can configure the isolation period to discard packets and therefore to save bandwidth resources.
- The isolation period can be configured in NFPP configuration mode or interface configuration mode.
- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

↳ Configuring the DHCP-Guard Monitoring Period

- (Mandatory) DHCP-guard monitoring is enabled by default.
- If the DHCP-guard isolation period is configured, it is directly used as the monitoring period, and the configured monitoring period will lose effect.
- The monitoring period can be configured in NFPP configuration mode.

↳ Configuring the Maximum Number of DHCP-Guard Monitored Hosts

- (Mandatory) The maximum number of DHCP-guard monitored hosts is 20,000 by default.
- Set the maximum number of DHCP-guard monitored hosts reasonably. As the number of monitored hosts increases, more CPU resources are used.
- The maximum number of DHCP-guard monitored hosts can be configured in NFPP configuration mode.
- If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is

smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.

- If the table of monitored hosts is full, the system prints the log "% NFPP_DHCP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.

↘ Configuring the DHCP-Guard Attack Threshold

- Mandatory.
- The attack threshold can be configured in NFPP configuration mode or interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is less than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_DHCP_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source MAC address-based rate limiting takes priority over port-based rate limiting.

Verification

When a host in the network sends DHCP attack packets to a switch configured with DHCP guard, check whether these packets can be sent to the CPU.

- If the parameter of the packets exceeds the attack threshold, an attack log is displayed.
- If an isolated entry is created for the attacker, an isolation log is displayed.

- If the DHCPv6-guard isolation period is configured, it is directly used as the monitoring period, and the configured monitoring period does not take effect.
- The DHCPv6-guard monitoring period can be configured in NFPP configuration mode.

▾ Configuring the Maximum Number of DHCPv6-Guard Monitored Hosts

- (Mandatory) The maximum number of DHCPv6-guard monitored hosts is 20,000 by default.
- Set the maximum number of DHCPv6-guard monitored hosts reasonably. As the number of monitored hosts increases, more CPU resources are used.
- The maximum number of DHCPv6-guard monitored hosts can be configured in NFPP configuration mode.
- If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.

- If the table of monitored hosts is full, the system prints the log "% NFPP_DHCPV6_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.

↘ Configuring the DHCPv6-Guard Attack Threshold

- Mandatory.
- The DHCPv6-guard attack threshold can be configured in NFPP configuration mode or interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is less than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_DHCPV6_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source MAC address-based rate limiting takes priority over port-based rate limiting.

Verification

When a host in the network sends DHCPv6 attack packets to a switch configured with DHCPv6 guard, check whether these packets can be sent to the CPU.

- If the parameter of the packets exceeds the attack threshold, an attack log is displayed.
- If an isolated entry is created for the attacker, an isolation log is displayed.

Related Commands

↘ Enabling DHCPv6 Guard Globally

Command	dhcpv6-guard enable
Parameter	N/A
Description	
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Configuring the Global DHCPv6-Guard Isolation Period

Command	dhcpv6-guardisolate-period [<i>seconds</i> permanent]
Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. permanent : Indicates permanent isolation.
Command Mode	NFPP configuration mode
Usage Guide	The attacker isolation period falls into two types: global isolation period and port-based isolation period (local isolation period). For a port, if the port-based isolation period is not configured, the global isolation period is

	used; otherwise, the port-based isolation period is used.
--	---

↘ Configuring the Global DHCPv6-Guard Monitoring Period

Command	dhcpv6-guard monitor-period <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the monitoring period in the unit of second. The value ranges from 180 to 86,400.
Command Mode	NFPP configuration mode
Usage Guide	<p>If the isolation period is 0, the system performs software monitoring on detected attackers. The timeout period is the monitoring period. During software monitoring, if the isolation period is set to a non-zero value, the system automatically performs hardware isolation against monitored attackers and sets the timeout period as the monitoring period. The monitoring period is valid only when the isolation period is 0.</p> <p>If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.</p>

↘ Configuring the Maximum Number of DHCPv6-Guard Monitored Hosts

Command	dhcpv6-guard monitored-host-limit <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Command Mode	NFPP configuration mode
Usage Guide	<p>If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.</p> <p>If the table of monitored hosts is full, the system prints the log "%NFPP_DHCPV6_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.</p>

↘ Configuring the Global DHCPv6-Guard Rate Limit

Command	dhcpv6-guardrate-limit { per-src-mac per-port } <i>pps</i>
Parameter Description	<p>per-src-mac: Limits the rate of each source MAC address.</p> <p>per-port: Limits the rate of each port.</p> <p><i>pps</i>: Indicates the rate limit, ranging from 1 to 19,999.</p>
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Configuring the Global DHCPv6-Guard Attack Threshold

Command	dhcpv6-guard attack-threshold { per-src-mac per-port } <i>pps</i>
----------------	--

Parameter Description	per-src-mac : Configures the attack threshold of each source MAC address. per-port : Configures the attack threshold of each port. <i>pps</i> : Indicates the attack threshold, ranging from 1 to 19,999. The unit is pps.
Command Mode	NFPP configuration mode
Usage Guide	N/A

▾ Enabling DHCPv6 Guard on an Interface

Command	nfpp dhcpv6-guard enable
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	DHCPv6 guard configured in interface configuration mode takes priority over that configured in NFPP configuration mode.

▾ Configuring the DHCPv6-Guard Isolation Period on an Interface

Command	nfpp dhcpv6-guard isolate-period [<i>seconds</i> permanent]
Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. permanent : Indicates permanent isolation.
Command Mode	Interface configuration mode
Usage Guide	N/A

▾ Configuring the DHCP-Guard Rate Limit and Attack Threshold on an Interface

Command	nfpp dhcpv6-guard policy { per-src-mac per-port } <i>rate-limit-pps</i> <i>attack-threshold-pps</i>
Parameter Description	per-src-ip : Configures the rate limit and attack threshold of each source IP address. per-port : Configures the rate limit and attack threshold of each port. <i>rate-limit-pps</i> : Indicates the rate limit, ranging from 1 to 19,999. <i>attack-threshold-pps</i> : Indicates the attack threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Configuration Example

▾ CPU Protection Based on DHCPv6 Guard

Scenario	<ul style="list-style-type: none"> ● DHCPv6 host attacks exist in the system, and DHCPv6 neighbor discovery fails on some hosts.
Configuration Steps	<ul style="list-style-type: none"> ● Configure the host-based attack threshold. ● Set the isolation period to a non-zero value.

	<pre>Ruijie# configure terminal Ruijie(config)# nfpp Ruijie (config-nfpp)#dhcpv6-guard rate-limit per-src-mac 8 Ruijie (config-nfpp)#dhcpv6-guard attack-threshold per-src-mac 16 Ruijie (config-nfpp)#dhcpv6-guard isolate-period 180</pre>
Verification	<ul style="list-style-type: none"> Run the show nfpp dhcpv6-guard summary command to display the configuration.

Common Errors

N/A

18.4.6 Configuring ND Guard

Configuration Effect

- AR ND guard classifies ND packets into three types based on their purposes: 1. NS and NA; 2. RS; 3. RA and Redirect. Type 1 packets are used for address resolution. Type 2 packets are used by hosts to discover the gateway. Type 3 packets are related to routing: RAs are used to advertise the gateway and prefix while Redirect packets are used to advertise a better next hop.
- At present, only port-based ND packet attack identification is supported. You can configure the rate limits and attack thresholds for these three types of packets respectively. If the ND packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the ND packet rate exceeds the attack threshold, the system prints logs and sends traps.

Notes

- For a command that is configured both in NFPP configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in NFPP configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy hardware entries of the security module.

Configuration Steps

↳ Enabling ND Guard

- (Mandatory) ND guard is enabled by default.
- This function can be enabled in NFPP configuration mode or interface configuration mode.

↳ Enabling ND-Guard Ratelimit Forwarding

- (Optional) This function is enabled by default.
- If the port-based isolation entry takes effect, you can enable this function to pass some of the packets while not discarding all of them.
- This function can be enabled in NFPP configuration mode.

↳ Configuring the ND-Guard Attack Threshold

- Mandatory.
- The ND-guard attack threshold can be enabled in NFPP configuration mode or interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is less than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If memories cannot assigned to detected attackers, the system prints the log "%NFPP_ND_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.

Verification

When a host in the network sends ND attack packets to a switch configured with ND guard, check whether these packets can be sent to the CPU.

- If the parameter of the packets exceeds the attack threshold, an attack log is displayed.

Common Errors

N/A

18.4.7 Configuring a Self-Defined Guard

Configuration Effect

- Configure a self-defined guard to resolve network attack problems in special scenarios.

Notes

- For a command that is configured both in self-defined guard configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in self-defined guard configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy hardware entries of the security module.

- A self-defined guard takes priority over basic guards. When configuring the match fields of self-defined guards, see the Configuration Guide.

Configuration Steps

▾ Configuring the Guard Name

- (Mandatory) Configure the name of a self-defined guard to create the self-defined guard.
- The guard name must be unique, and the match fields and values must be different from those of ARP, ICMP, DHCP, IP, and DHCPv6 guards. If the parameters you want to configure already exist, a message is displayed to indicate the configuration failure.

▾ Configuring the Match Fields

- Mandatory.
- Self-defined packets are classified based on the following fields: etype (Ethernet link-layer type), smac (source MAC address), dmac (destination MAC address), protocol (IPv4/IPv6 protocol number), sip (source IPv4/IPv6 address), dip (destination IPv4/IPv6 address), sport (source transport-layer port), and dport (destination transport-layer port).
- **protocol** is valid only when the value of **etype** is **ipv4** or **ipv6**. **src-ip** and **dst-ip** are valid only when the value of **etype** is **ipv4**. **src-ipv6** and **dst-ipv6** are valid only when the value of **etype** is **ipv6**. **src-port** and **dst-port** are valid only when the value of **protocol** is **tcp** or **udp**.
- If the **match** fields and values of a self-defined guard are totally the same as those of an existing guard, the system prints the log "%ERROR: the match type and value are the same with define name (name of an existing guard)." to notify the administrator of the configuration failure.
- If **protocol** is configured but **etype** is IPv4 or IPv6 in the **match** policy, the system prints the log "%ERROR: protocol is valid only when etype is IPv4(0x0800) or IPv6(0x86dd)."
- If **src-ip** and **dst-ip** are configured but **etype** is not IPv4 in the **match** policy, the system prints the log "%ERROR: IP address is valid only when etype is IPv4(0x0800)."
- If **src-ipv6** and **dst-ipv6** are configured but **etype** is not IPv6 in the **match** policy, the system prints the log "%ERROR: IPv6 address is valid only when etype is IPv6(0x86dd)."
- If **src-port** and **dst-port** are configured but **protocol** is not TCP or UDP in the **match** policy, the system prints the log "%ERROR: Port is valid only when protocol is TCP(6) or UDP(17)."
- The following table lists guard policies corresponding to some common network protocols. The rate limits and attack thresholds listed below can meet the requirements in most network scenarios and are for reference only. You can configure valid rate limits and attack thresholds based on actual scenarios.

Protocol	match	policy per-src-ip	policy per-src-mac	policy per-port
RIP	etype 0x0800 protocol 17 dst-port 520	rate-limit 100 attach-threshold 150	Not applicable to this policy	rate-limit 300 attach-threshold 500

Protocol	match	policy per-src-ip	policy per-src-mac	policy per-port
RIPng	etype 0x86dd protocol 17 dst-port 521	rate-limit 100 attach-threshold 150	Not applicable to this policy	rate-limit 300 attach-threshold 500
BGP	etype 0x0800 protocol 6 dst-port 179	rate-limit 1000 attach-threshold 1200	Not applicable to this policy	rate-limit 2000 attach-threshold 3000
BPDU	dst-mac 0180.c200.0000	Not applicable to this policy	rate-limit 20 attach-threshold 40	rate-limit 100 attach-threshold 100
RERP	dst-mac 01d0.f800.0001	Not applicable to this policy	rate-limit 20 attach-threshold 40	rate-limit 100 attach-threshold 100
REUP	dst-mac 01d0.f800.0007	Not applicable to this policy	rate-limit 20 attach-threshold 40	rate-limit 100 attach-threshold 100
BGP	etype 0x0800 protocol 6 dst-port 179	Not applicable to this policy	Not applicable to this policy	Not applicable to this policy
OSPFv2	etype 0x0800 protocol 89	rate-limit 800 attach-threshold 1200	Not applicable to this policy	rate-limit 2000 attach-threshold 3000
OSPFv3	etype 0x86dd protocol 89	rate-limit 800 attach-threshold 1200	Not applicable to this policy	rate-limit 2000 attach-threshold 3000
VRRP	etype 0x0800 protocol 112	rate-limit 64 attach-threshold 100	Not applicable to this policy	rate-limit 1024 attach-threshold 1024
IPv6 VRRP	etype 0x86dd protocol 112	rate-limit 64 attach-threshold 100	Not applicable to this policy	rate-limit 1024 attach-threshold 1024
SNMP	etype 0x0800 protocol 17 dst-port 161	rate-limit 1000 attach-threshold 1200	Not applicable to this policy	rate-limit 2000 attach-threshold 3000
RSVP	etype 0x0800 protocol 46	rate-limit 800 attach-threshold 1200	Not applicable to this policy	rate-limit 1200 attach-threshold 1500
LDP (UDP hello)	etype 0x0800 protocol 17 dst-port 646	rate-limit 10 attach-threshold 15	Not applicable to this policy	rate-limit 100 attach-threshold 150

- To contain as many existing protocol types as possible and facilitate expansion of new protocol types, self-defined guards allow hosts to freely combine type fields of packets. If the configuration is inappropriate, the network may become abnormal. Therefore, the network administrator needs to have a good knowledge of network protocols. As a reference, the following table lists valid configurations of currently known protocols for common self-defined guard policies. For other protocols not listed in the table, configure them with caution.

📌 Configuring the Global Rate Limit and Attack Threshold

- (Mandatory) If these parameters are not configured, the self-defined guard cannot be enabled.

- You must configure one of the `per-src-ip`, `per-src-mac`, and `per-port` fields. Otherwise, the policy cannot take effect.
- `per-src-ip` is valid only when `etype` is IPv4 or IPv6.
- The rate limit configured based on the source MAC address, VLAN ID, and port takes priority over that configured based on the source IP address, VLAN ID, and port.
- The port-based host identification policy of a self-defined guard must be consistent with the global port-based host identification policy.
- If the **`per-src-ip`** policy is not configured globally but configured for a port, the system prints the log `"%ERROR: name (name of a self-defined guard) has not per-src-ip policy."` to notify the administrator of the configuration failure.
- If the **`per-src-mac`** policy is not configured globally but configured for a port, the system prints the log `"%ERROR: name (name of a self-defined guard) has not per-src-mac policy."` to notify the administrator of the configuration failure.
- If the memory cannot be allocated to detected attackers, the system prints the log `"%NFPP_DEFINE_GUARD-4-NO_MEMORY: Failed to allocate memory."` to notify the administrator.
- If the configured rate limit is greater than the attack threshold, the system prints the log `"%ERROR: rate limit is higher than attack threshold 500pps."` to notify the administrator.
- If the configured attack threshold is less than the rate limit, the system prints the log `"%ERROR: attack threshold is smaller than rate limit 300pps."` to notify the administrator.

▾ Configuring the Global Isolation Period

- (Optional) Isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit defined in CPP, you can configure the isolation period to discard packets and therefore to save bandwidth resources.
- The isolation period can be configured in self-defined guard configuration mode or interface configuration mode.
- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

▾ Configuring the Global Monitoring Period

- (Mandatory) The default monitoring period is 600 seconds.
- If the isolation period is configured, it is directly used as the monitoring period, and the configured monitoring period will lose effect.
- The monitoring period can be configured in self-defined guard configuration mode.
- If the isolation period is 0, the system performs software monitoring on detected attackers. The timeout period is the monitoring period. During software monitoring, if the isolation period is set to a non-zero value, the system automatically performs hardware isolation against monitored attackers and sets the timeout period as the monitoring period. The monitoring period is valid only when the isolation period is 0.
- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

▾ Configuring the Maximum Number of Monitored Hosts

- (Mandatory) The maximum number of monitored hosts is 20,000 by default.

- Set the maximum number of monitored hosts reasonably. As the number of monitored hosts increases, more CPU resources are used.
- The maximum number of monitored hosts can be configured in self-defined guard configuration mode.
- If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system prints the log "% NFPP_DEFINE-4-SESSION_LIMIT: Attempt to exceed limit of name's 20000 monitored hosts." to notify the administrator.

▾ Configuring Trusted Hosts

- (Optional) No trusted host is configured by default.
- You can configure a maximum of 500 trusted IP address or MAC address for a self-defined guard.
- Trusted hosts can be configured in self-defined guard configuration mode.
- If you do not want to monitor a host, you can run the following commands to trust the host. This trusted host can send ICMP packets to the CPU, without any rate limiting or alarm reporting. You can configure the mask so that no host in one network segment is monitored.
- You must configure the **match** type before configuring trusted hosts. If the packet type is IPv4 in the **match** policy, you are not allowed to configure trusted IPv6 addresses. If the packet type is IPv6 in the match policy, you are not allowed to configure trusted IPv4 addresses.
- If the **match** type is not configured, the system prints the log "%ERROR: Please configure match rule first."
- If a trusted IPv4 host is added but **etype** is not IPv4 in the **match** policy, the system prints the log "%ERROR: Match type can't support IPv4 trusted host."
- If a trusted IPv6 host is added but **etype** is not IPv6 in the **match** policy, the system prints the log "%ERROR: Match type can't support IPv6 trusted host."
- If the table of trusted hosts is full, the system prints the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If any entry matching a trusted host (IP addresses are the same) exists in the table of monitored hosts, the system automatically deletes this entry.
- If a trusted host cannot be deleted, the system prints the log "%ERROR: Failed to delete trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If a host cannot be trusted, the system prints the log "%ERROR: Failed to add trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If the host to trust already exists, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 has already been configured." to notify the administrator.
- If the host to delete from the trusted table does not exist, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 is not found." to notify the administrator.

- If the memory cannot be allocated to a trusted host, the system prints the log "%ERROR: Failed to allocate memory." to notify the administrator.

▾ Enabling a Self-Defined Guard

- Mandatory.
- You have to configure at least one policy between host-based self-defined guard policy and port-based self-defined guard policy. Otherwise, the self-defined guard cannot be enabled.
- If a self-defined guard is disabled, the system automatically clears monitored hosts.
- Self-defined guards can be configured in self-defined guard configuration mode or interface configuration mode.
- If a self-defined guard policy is not completely configured, the self-defined guard cannot be enabled and a prompt is displayed to notify hosts of the missing policy configurations.
- If the name of a self-defined guard does not exist, the system prints the log "%ERROR: The name is not exist."
- If the match type is not configured for a self-defined guard, the system prints the log "%ERROR: name (name of the self-defined guard) doesn't match any type."
- If no policy is configured for a self-defined guard, the system prints the log "%ERROR: name (name of the self-defined guard) doesn't specify any policy."

Verification

When a host in the network sends packets to a switch configured with a self-defined NFPP guard, check whether these packets can be sent to the CPU.

- If the rate of packets from an untrusted host exceeds the attack threshold, an attack log is displayed.
- If an isolated entry is created for the attacker, an isolation log is displayed.

Related Commands

▾ Configuring the Name of a Self-defined Guard

Command	define <i>name</i>
Parameter	name: Indicates the name of a self-defined guard.
Description	
Command Mode	NFPP configuration mode
Usage Guide	N/A

▾ Configuring Match Fields of a Self-defined Guard

Command	match [<i>etype</i> <i>type</i>] [src-mac <i>smac</i> [src-mac-mask <i>smac_mask</i>]] [dst-mac <i>dmac</i> [dst-mac-mask <i>dst_mask</i>]] [protocol <i>protocol</i>] [src-ip <i>sip</i> [src-ip-mask <i>sip-mask</i>]] [src-ipv6 <i>sipv6</i> [src-ipv6-masklen <i>sipv6-masklen</i>]] [dst-ip <i>dip</i> [dst-ip-mask <i>dip-mask</i>]] [dst-ipv6 <i>dipv6</i> [dst-ipv6-masklen <i>dipv6-masklen</i>]] [src-port <i>sport</i>] [dst-port <i>dport</i>]
Parameter	<i>type</i> : Indicates the type of Ethernet link-layer packets.

Description	<p><i>smac</i>: Indicates the source MAC address.</p> <p><i>smac_mask</i>: Indicates the mask of the source MAC address.</p> <p><i>dmac</i>: Indicates the destination MAC address.</p> <p><i>dst_mask</i>: Indicates the mask of the destination MAC address.</p> <p><i>protocol</i>: Indicates the protocol number of IPv4/IPv6 packets.</p> <p><i>sip</i>: Indicates the source IPv4 address.</p> <p><i>sip-mask</i>: Indicates the mask of the source IPv4 address.</p> <p><i>sipv6</i>: Indicates the source IPv6 address.</p> <p><i>sipv6-masklen</i>: Indicates the mask length of the source IPv6 address.</p> <p><i>dip</i>: Indicates the destination IPv4 address.</p> <p><i>dip-mask</i>: Indicates the mask of the destination IPv4 address.</p> <p><i>dipv6</i>: Indicates the destination IPv6 address.</p> <p><i>dipv6-masklen</i>: Indicates the mask length of the destination IPv6 address.</p> <p><i>sport</i>: Indicates the ID of the source transport-layer port.</p> <p><i>dsport</i>: Indicates the ID of the destination transport-layer port.</p>
Command Mode	Self-defined guard configuration mode
Usage Guide	Create a new self-defined guard and specify the packet fields matched by this guard.

📌 Configuring the Global Rate Limit and Attack Threshold of a Self-defined Guard

Command	global-policy { per-src-ip per-src-mac per-port } <i>rate-limit-pps</i> <i>attack-threshold-pps</i>
Parameter Description	<p>per-src-ip: Collects rate statistics for host identification based on the source IP address, VLAN ID, and port.</p> <p>per-src-mac: Collects rate statistics for host identification based on the source MAC address, VLAN ID, and port.</p> <p>per-port: Collects rate statistics based on each packet receiving port.</p> <p><i>rate-limit-pps</i>: Indicates the rate limit.</p> <p><i>attack-threshold-pps</i>: Indicates the attack threshold.</p>
Command Mode	Self-defined guard configuration mode
Usage Guide	Before creating a self-defined guard type, you must specify rate statistic classification rules for this type, namely, source IP address-based host identification, source MAC address-based host identification, host-based self-defined packet rate statistics, or port-based rate statistics, and specify the rate limits and attack thresholds for the specified rules.

📌 Configuring the Global Isolation Period of a Self-defined Guard

Command	isolate-period [<i>seconds</i> permanent]
Parameter Description	<p><i>seconds</i>: Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation.</p> <p>permanent: Indicates permanent isolation.</p>
Command Mode	Self-defined guard configuration mode

Usage Guide	If the isolation period is not 0, a host is isolated and its packets of the self-defined guard type are discarded when the packet rate of the self-defined guard exceeds the attack threshold.
--------------------	--

↘ Configuring the Global Monitoring Period of a Self-defined Guard

Command	monitor-period <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the monitoring period in the unit of second. The value ranges from 180 to 86,400.
Command Mode	Self-defined guard configuration mode
Usage Guide	N/A

↘ Configuring the Maximum Number of Monitored Hosts of a Self-defined Guard

Command	monitored-host-limit <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Command Mode	Self-defined guard configuration mode
Usage Guide	N/A

↘ Configuring Trusted Hosts of a Self-defined Guard

Command	trusted-host { <i>mac mac_mask</i> <i>ip mask</i> <i>IPv6/prefixlen</i> }
Parameter Description	<i>mac</i> : Indicates the MAC address. <i>mac_mask</i> : Indicates the mask of an MAC address. <i>ip</i> : Indicates the IP address. <i>mask</i> : Indicates the mask of an IP address. <i>IPv6/prefixlen</i> : Indicates the IPv6 address and its mask length. all : Used with no to delete all trusted hosts.
Command Mode	Self-defined guard configuration mode
Usage Guide	N/A

↘ Enabling a Self-Defined Guard Globally

Command	define <i>name</i> enable
Parameter Description	<i>name</i> : Indicates the name of a self-defined guard.
Command Mode	NFPP configuration mode
Usage Guide	The configuration takes effect only after you have configured match , rate-count , rate-limit , and attack-threshold . Otherwise, the configuration fails.

↘ Enabling a Self-defined Guard on an Interface

Command	nfpp define <i>name</i> enable
Parameter	<i>name</i> : Indicates the name of a self-defined guard.
Description	
Command Mode	Interface configuration mode
Usage Guide	The self-defined name must exist. The configuration takes effect only after you have configured match , rate-count , rate-limit , and attack-threshold . Otherwise, the configuration fails.

📌 Configuring the Rate Limit and Attack Threshold of a Self-defined Guard on an Interface

Command	nfpp define <i>name</i> policy {<i>per-src-ip</i> <i>per-src-mac</i> <i>per-port</i>} <i>rate-limit-pps</i> <i>attack-threshold-pps</i>
Parameter	<i>name</i> : Indicates the name of a self-defined guard.
Description	<p>per-src-ip: Configures the rate limit and attack threshold of each source IP address.</p> <p>per-src-mac: Configures the rate limit and attack threshold of each source MAC address.</p> <p>per-port: Configures the rate limit and attack threshold of each port.</p> <p><i>rate-limit-pps</i>: Indicates the rate limit, ranging from 1 to 19,999.</p> <p><i>attack-threshold-pps</i>: Indicates the attack threshold, ranging from 1 to 19,999.</p>
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Configuration Example

📌 CPU Protection Based on a Self-Defined Guard

Scenario	<ul style="list-style-type: none"> ● Basic guards cannot protect the system with RIP attacks.
Configuration Steps	<ul style="list-style-type: none"> ● Configure a self-defined guard, with the key fields matching RIP packets. ● Configure the rate limit. ● Configure the isolation period. ● Configure trusted hosts.
	<pre>Ruijie# configure terminal Ruijie(config)# nfpp Ruijie (config-nfpp)#define rip Ruijie (config-nfpp-define)#match etype 0x0800 protocol 17 dst-port 520 Ruijie (config-nfpp-define)#global-policy per-src-ip 100 150 Ruijie (config-nfpp-define)# isolate-period 180 Ruijie (config-nfpp-define)#trusted-host 192.168.201.46 255.255.255.255 Ruijie (config-nfpp-define)#exit Ruijie (config-nfpp)#define rip enable</pre>
Verification	<ul style="list-style-type: none"> ● Run the show nfpp define summary rip command to display the configuration.

<pre>Define rip summary: match etype 0x800 protocol 17 dst-port 520 Maximum count of monitored hosts: 1000 Monitor period:600s (Format of column Rate-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.) Interface Status Isolate-period Rate-limit Attack-threshold Global Enable 180 100/-/- 150/-/-</pre>
<ul style="list-style-type: none"> ● Run the show nfpp define trusted-host rip command to display the trusted hosts.
<pre>Define rip: IP trusted host number is 1: IP address IP mask ----- 192.168.201.46 255.255.255.255 Total: 1 record(s)Global Enable 180 100/-/- 150/-/-</pre>
<ul style="list-style-type: none"> ● Run the show nfpp define hosts rip command to display the monitored hosts.
<p>If col_filter 1 shows '*', it means "hardware do not isolate host".</p> <pre>VLAN interface IP address remain-time(s) ---- 1 Gi0/5 192.168.201.47 160 Total: 1 host</pre>

Common Errors

N/A

18.4.8 Configuring Centralized Bandwidth Allocation

Configuration Effect

- Configure centralized bandwidth allocation so that Manage and Protocol packets are first processed when the network is busy.

Notes

- The following condition must be met: Valid percentage range of a type of packets ≤ 100% – Percentage of the sum of the other two types

Configuration Steps

Configuring the Maximum Bandwidth of Specified Packets

- (Mandatory) Manage, Route, and Protocol packets share the same default bandwidth.

Configuring the Maximum Percentage of Specified Packets in the Queue

- (Mandatory) By default, Manage packets occupy 30% of the bandwidth, Route packets occupy 25%, and Protocol packets occupy 45%.

Verification

Send a large number of protocol packets such as OSPF packets to a switch, causing high CPU utilization.

- When the host pings the switch, the pinging must be successful and no packet is lost.

Related Commands

Configuring the Maximum Bandwidth of Specified Packets

Command	<code>cpu-protect sub-interface { manage protocol route } pps <i>pps_value</i></code>
Parameter Description	<i>pps_value</i> : Indicates the rate limit, ranging from 1 to 100,000.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Maximum Percentage of Specified Packets in the Queue

Command	<code>cpu-protect sub-interface { manage protocol route } percent <i>percent_value</i></code>
Parameter Description	<i>percent_value</i> : Indicates the percentage of a type of packets in the queue, ranging from 1 to 100.
Command Mode	Global configuration mode
Usage Guide	The following condition must be met: Valid percentage range of a type of packets \leq 100% – Percentage of the sum of the other two types

Configuration Example

Prioritizing Packets Sent to the CPU Through Centralized Bandwidth Allocation

Scenario	<ul style="list-style-type: none"> ● Various types of mass packets exist in the network and belong to different centralized types.
Configuration Steps	<ul style="list-style-type: none"> ● Configure the maximum bandwidth of specified packets. ● Configure the maximum percentage of specified packets in the queue.
	<pre>Ruijie# configure terminal Ruijie(config)# cpu-protect sub-interface manage pps 5000</pre>

	Ruijie(config)# cpu-protect sub-interface manage percent 25
Verification	N/A

Common Errors

N/A

18.4.9 Enabling/Disabling All Guards

Configuration Effect

- Use the (no) all-guard enable command to enable or disable all attack guards so that you do not need to disable or enable them one by one.

Notes

- Only basic guards (ARP, ICMP, IP, DHCP, DHCPv6, and ND) are applied.
- Only the global configuration is applied. Interface-based guard configuration remains the same.
- After the command is executed, basic guards are displayed by using the **show running-config** command.
- The **no all-guard enable** command just packs the **no** commands of all basic guards together. After you run the disabling command, the **no** commands of all basic guards are displayed under the **show running-config** command. After you run the enabling command, the default conditions are displayed under the **show running-config** command.

Configuration Steps

➤ **Running (no) all-guard enable in Global Configuration Mode**

Verification

When a host sends a large number of packets corresponding to basic guards to a switch, such as ARP/ICMP packets, NFPP guard detection takes effect by default.

- Run the **no all-guard enable** command. With the **show cpu-protect** command used, NFPP ratelimit failure is displayed. With the **show nfpp xx-guard host** command used, no attacker is displayed. With the **show nfpp xx-guard summary** command used, the "disabled" status of guards is displayed.

18.4.10 Configuring NFPP Logging

Configuration Effect

- NFPP obtains a log from the dedicated log buffer at a certain rate, generates a system message, and clears this log from the dedicated log buffer.

Notes

- Logs are continuously printed in the log buffer, even if attacks have stopped.

Configuration Steps

▾ Configuring the Log Buffer Size

- Mandatory.
- If the log buffer is full, new logs replace the old ones.
- If the log buffer overflows, subsequent logs replace the previous ones with all attributes marked with a hyphen (-) is displayed in the log buffer. The administrator needs to increase the log buffer size or the system message generation rate.

▾ Configuring the Log Buffer Rate

- Mandatory.
- The log buffer rate depends on two parameters: the time period and the number of system messages generated in the time period.
- If both of the preceding two parameters are set to 0, system messages are immediately generated for logs but are not stored in the log buffer.

▾ Enabling Log Filtering

- (Optional) Log filtering is disabled by default.
- Logs can be filtered based on an interface or VLAN.
- If log filtering is enabled, logs not meeting the filtering rule are discarded.

▾ Enabling Log Printing

- (Mandatory) Logs are stored in the buffer by default.
- If you want to monitor attacks in real time, you can configure logs to be printed on the screen to export the log information in real time.

Verification

Check whether the configuration takes effect based on the log configuration and the number and interval of printed logs.

Related Commands

▾ Configuring the Log Buffer Size

Command	log-buffer entries <i>number</i>
Parameter Description	<i>number</i> : Indicates the buffer size in the unit of the number of logs, ranging from 0 to 1,024.
Command Mode	NFPP configuration mode
Usage Guide	N/A

▾ Configuring the Log Buffer Rate

Command	log-buffer logs <i>number_of_message interval length_in_seconds</i>
Parameter Description	<i>number_of_message</i> : Ranges from 0 to 1,024. The value 0 indicates that all logs are recorded in the log buffer and no system message is generated. <i>length_in_seconds</i> : Ranges from 0 to 86,400 (1 day). The value 0 indicates that logs are not recorded in the log buffer but system messages are instantly generated. This also applies to <i>number_of_message</i> and <i>length_in_seconds</i> . <i>number_of_message/length_in_second</i> indicates the system message generation rate.
Command Mode	NFPP configuration mode
Usage Guide	N/A

▾ Configuring VLAN-based Log Filtering

Command	logging vlan <i>vlan-range</i>
Parameter Description	<i>vlan-range</i> : Records logs in a specified VLAN range. The value format is 1-3,5 for example.
Command Mode	NFPP configuration mode
Usage Guide	Run this command to filter logs so that only logs in the specified VLAN range are recorded. Between interface-based log filtering and VLAN-based log filtering, if either rule is met, logs are recorded in the log buffer.

▾ Configuring Interface-based Log Filtering

Command	logging interface <i>interface-id</i>
Parameter Description	<i>interface-id</i> : Records logs of a specified interface.
Command Mode	NFPP configuration mode
Usage Guide	Run this command to filter logs so that only logs of the specified interface are recorded. Between interface-based log filtering and VLAN-based log filtering, if either rule is met, logs are recorded in the log buffer.

▾ Enabling Log Printing

Command	log-buffer enable
Parameter	N/A
Description	
Command Mode	NFPP configuration mode
Usage Guide	N/A

Configuration Example

Configuring NFPP Logging

Scenario	<ul style="list-style-type: none"> If attackers are too many, log printing will affect the usage of user interfaces, which requires restriction. 														
Configuration Steps	<ul style="list-style-type: none"> Configure the log buffer size. Configure the log buffer rate. Configure VLAN-based log filtering.

19 Configuring DoS Protection

19.1 Overview

Denial of Service (DoS) attacks refer to attacks that cause DoS and aim to put computers or networks out of service.

DoS attacks are diversified in types and can be implemented in many ways, but have one common purpose, that is, prevent victim hosts or networks cannot receive, respond, or process external requests in time. In particular, on a layer-2 (L-2) network, DoS attack packets can be spread in the entire broadcast domain. If hackers maliciously initiate DoS attacks, some operating systems (OSs) may collapse. Ruijie products supports the following anti DoS attack functions:

- Denying land attacks
- Denying invalid TCP packets
- Denying invalid layer-4 (L4) ports

19.2 Applications

Application	Description
Protecting Servers Against DoS Attacks	On a campus network, configure the anti DoS attack function on the devices connected to servers to effectively reduce the negative impacts brought by DoS attacks to servers.

19.2.1 Protecting Servers Against DoS Attacks

As show in Figure 19-1, servers are connected to the core switch. The anti DoS attack function is configured on the core switch to prevent malicious DoS attacks and ensure that servers can provide services normally.

Figure 19-1

Deployment

Enable the function of denying land attacks on the core switch to protect servers against land attacks.

Enable the function of denying invalid TCP packets on the core switch to protect servers against invalid TCP packets.

Enable the function of denying invalid L4 ports on the core switch to protect servers against attacks caused by invalid L4 ports.

19.3 Features

Overview

Feature	Description
Denying Land Attacks	Drop packets with the same source and destination IP addresses or the same L4 source and destination port IDs on the device to prevent these packets from attacking OSs on the network.
Denying Invalid TCP Packets	Drop invalid TCP packets on the device to prevent invalid TCP packets from attacking OSs on the network. (For details about the definition of invalid TCP packets, see "Denying Invalid TCP Packets".)
Denying Invalid L4 Ports	Drop packets with the same L4 source and destination port IDs on the device to prevent these packets from attacking OSs on the network.

19.3.1 Denying Land Attacks

This function protects servers against land attacks.

Working Principle

In a land attack, the attacker sets the source and destination IP addresses or the L4 source and destination port IDs in a SYN packet to the same address of the target host. Consequently, the attacked host will be trapped in an infinite loop or even collapse when attempting to set up a TCP connection with itself.

If the function of denying land attacks is enabled, the device checks packets based on characteristics of land packets (that is, SYN packets with the same source and destination IP addresses), and drops invalid packets.

Related Configuration

📄 Enabling the Function of Denying Land Attacks

By default, the function of denying land attacks is disabled.

Run the **ip deny land** command to enable or disable the function of denying land attacks.

19.3.2 Denying Invalid TCP Packets

This function protects servers against invalid TCP packets.

Working Principle

There are several flag fields in the TCP packet header:

- SYN: Connection establishment flag. The TCP SYN packet is used to set this flag to 1 to request establishment of a connection.
- ACK: Acknowledgement flag. In a TCP connection, this field must be available in every flag (except the first packet, that is, the TCP SYN packet) as the acknowledgement of the previous packet.
- FIN: Finish flag. When a host receives the TCP packet with the FIN flag, the host disconnects the TCP connection.
- RST: Reset flag. When the IP protocol stack receives a TCP packet that contains a non-existent destination port, it responds with a packet with the RST flag.
- PSH: This flag notifies the protocol stack to submit TCP data to the upper-layer program for processing as soon as possible.

In invalid TCP packets, flag fields are set improperly so that the processing resources of hosts are exhausted or even the system collapses. The following lists several common methods for setting flag fields in invalid TCP packets:

- TCP packets with both the SYN and FIN flags

Normally, a TCP packet cannot contain both the SYN and FIN flags. In addition, RFC does not stipulate how the IP protocol stack should process such invalid packets containing both the SYN and FIN flags. Therefore, the protocol stack of each OS may process such packets in different ways when receiving these packets. Attackers can use this feature to send packets containing both the SYN and FIN flags to identify the OS type and initiate attacks on this OS.

- TCP packets without any flag

Normally, a TCP packet contains at least one of the five flags, including SYN, FIN, ACK, RST, and PSH. The first TCP packet (TCP SYN packet) must contain the SYN flag, and the subsequent packets contain the ACK flag. Based on such

assumptions, some protocol stack does not specify the method for processing TCP packets without any flag, and therefore may collapse if such protocol stack receives TCP packets without any flag. Attackers use this feature to initiate attacks on target hosts.

- TCP packets with the FIN flag but without the ACK flag

Normally, except the first packet (TCP SYN packet), all other packets, including the packets with the FIN flag, contain the ACK flag. Some attackers may send TCP packets with the FIN flag but without the ACK flag to the target hosts, causing breakdown of the target hosts.

- TCP packets with the SYN flag and the source port ID set to a value between 0 and 1,023

Port IDs 0 to 1,023 are known port IDs allocated by the Internet Assigned Numbers Authority (IANA). In most systems, these port IDs can be used only by the system (or root) processes or programs run by privileged users. These ports (0–1023) cannot be used as the source port IDs in the first TCP packets (with the SYN flag) sent by clients.

If the function of denying invalid TCP packets is enabled, the device checks packets based on characteristics of invalid TCP packets, and drops invalid TCP packets.

Related Configuration

↘ Enabling the Function of Denying Invalid TCP Packets

By default, the function of denying invalid TCP packets is disabled.

Run the **ip deny invalid-tcp** command to enable or disable the function of denying invalid TCP packets.

19.3.3 Denying Invalid L4 Ports

This function protects servers against invalid L4 ports.

Working Principle

Attackers sends packets in which the IP address of the target host is the same as the L4 port ID of the host to the host target. As a result, the target host sends TCP connection setup requests to itself. Under such attacks, resources of the target host will soon be exhausted and the system will collapse.

If the function of denying invalid L4 ports is enabled, the device checks the L4 source port ID and destination port ID in the packets. If they are the same, the device drops the packets.

Related Configuration

↘ Enabling the Function of Denying Invalid L4 Ports

By default, the function of denying invalid L4 ports is disabled.

Run the **ip deny invalid-l4port** command to enable or disable the function of denying invalid L4 ports.

19.4 Configuration

Configuration Item	Description and Command	
Configuring the Function of Denying Land Attacks	 Optional.	
	ip deny land	Enables the function of denying land attacks.
Configuring the Function of Denying Invalid TCP Packets	 Optional.	
	ipdeny invalid-tcp	Enables the function of denying invalid TCP packets.
Configuring the Function of Denying Invalid L4 Ports	 Optional.	
	ip deny invalid-l4port	Enables the function of denying invalid L4 ports.

19.4.1 Configuring the Function of Denying Land Attacks

Configuration Effect

Enable the function of denying land attacks. Then, the device checks packets based on characteristics of land packets, and drops land packets.

Configuration Steps

▾ Enabling the Function of Denying Land Attacks

- Mandatory.
- Perform this configuration on a device connected to a server.

Verification

- Run the **showipdenyland** command to display the status of the function of denying land attacks.
- After this function is enabled, construct a land attack packet and confirm that this packet cannot be forwarded.

Related Commands

ACL & QoS Configuration

1. Configuring ACL
2. Configuring QoS

1 Configuring ACL

1.1 Overview

Access control list (ACL) is also called access list or firewall. It is even called packet filtering in some documents. The ACL defines rules to determine whether to forward or drop data packets arriving at a network interface.

ACLs are classified by function into two types:

Security ACLs: Used to control data flows that are allowed to pass through a network device.

Quality of service (QoS) ACLs: Used to classify and process data flows by priority.

ACLs are configured for a lot of reasons. Major reasons include:

Network access control: To ensure network security, rules are defined to limit access of users to some services (for example, only access to the WWW and email services is permitted, and access to other services such as Telnet is prohibited), or to allow users to access services in a specified period of time, or to allow only specified hosts to access the network.

QoS: QoS ACLs are used to preferentially classify and process important data flows. For details about the use of QoS ACLs, see the configuration manual related to QoS.

1.2 Applications

Application	Description
Access Control of an Enterprise Network	On an enterprise network, the network access rights of each department, for example, access rights of servers and use permissions of chatting tools (such as QQ and MSN), must be controlled according to requirements.

1.2.1 Access Control of an Enterprise Network

Scenario

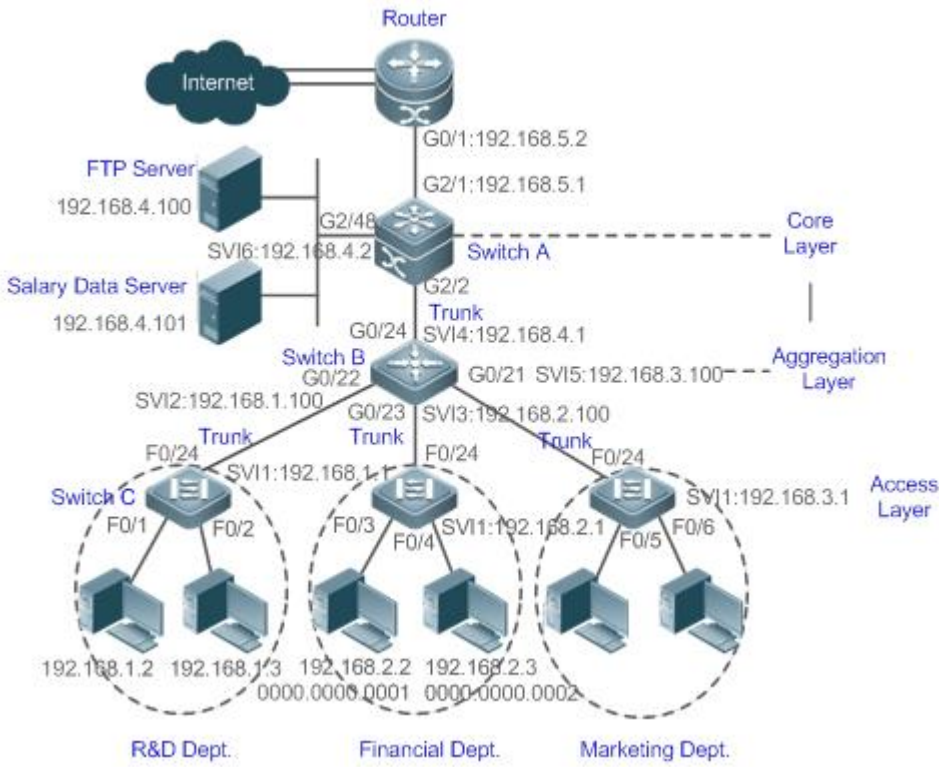

Internet viruses can be found everywhere. Therefore, it is necessary to block ports that are often used by viruses to ensure security of an enterprise network as follows:

Allow only internal PCs to access the server.

Prohibit PCs of a non-financial department from accessing PCs of the financial department, and prohibit PCs of a non-R&D department from accessing PCs of the R&D department.

Prohibit the staff of the R&D department from using chatting tools (such as QQ and MSN) during working hours from 09:00 to 18:00.

Figure 1-1

Remarks	<p>Switch C at the access layer: It is connected to PCs of each department and to Switch B at the aggregation layer through the gigabit optical fiber (trunk mode).</p> <p>Switch B at the aggregation layer: Multiple virtual local area networks (VLANs) are divided. One VLAN is defined for one department. These VLANs are connected to Switch A at the core layer through the 10-gigabit optical fiber (trunk mode).</p> <p>Switch A at the core layer: It is connected to various servers, such as the File Transfer Protocol (FTP) server and Hypertext Transfer Protocol (HTTP) server, and to the Internet through firewalls.</p>
----------------	---

Deployment

Configure an extended ACL on the port G2/1 to filter data packets, thus protecting the network against the viruses. This port is located on a core-layer device (Switch A) and used to connect Switch A to the uplink port G2/1 of a router.

Allow only internal PCs to access servers, and prohibit external PCs from accessing servers. Define and apply the extended IP ACLs on G2/2 or switch virtual interface (SVI) 2 that is used to connect Switch A to an aggregation layer device or server.

Prohibit mutual access between specified departments. Define and apply the extended IP ACLs on G0/22 and G0/23 of Switch B.

Configure and apply the time-based extended IP ACLs on SVI 2 of Switch B to prohibit the R&D department from using chatting tools (such as QQ and MSN) in a specified period of time.

1.3 Features

Basic Concepts

ACL

ACLs include basic ACLs and dynamic ACLs.

You can select basic or dynamic ACLs as required. Generally, basic ACLs can meet the security requirements. However, experienced hackers may use certain software to access the network by means of IP address spoofing. If dynamic ACLs are used, users are requested to pass identify authentication before accessing the network, which prevents hackers from intruding the network. Therefore, you can use dynamic ACLs in some sensitive areas to guarantee network security.

IP address spoofing is an inherent problem of all ACLs, including dynamic ACLs. Hackers may use forged IP addresses to access the network during the validity period of authenticated user identities. Two methods are available to resolve this problem. One is to set the idle time of user access to a smaller value, which increases the difficulty in intruding networks. The other is to encrypt network data using the IPSec protocol, which ensures that all data is encrypted when arriving at a device.

ACLs are generally configured on the following network devices:

Devices between the internal network and the external network (such as the Internet)

Devices on the border of two network segments

Devices connected to controlled ports

ACL statements must be executed in strict compliance with their sequence in the ACL. Comparison starts from the first statement. Once the header of a data packet matches a statement in the ACL, the subsequent statements are ignored and no longer checked.

Input/Output ACLs, Filtering Field Template, and Rules

When receiving a packet on an interface, the device checks whether the packet matches any access control entry (ACE) in the input ACL of this interface. Before sending a packet through a interface, the device checks whether the packet matches any ACE in the output ACL of this interface.

When different filtering rules are defined, all or only some rules may be applied simultaneously. If a packet matches an ACE, this packet is processed according to the action policy (permit or deny) defined in this ACE. ACEs in an ACL identify Ethernet packets based on the following fields in the Ethernet packets:

Layer 2 (L2) fields:

48-bit source MAC address (containing all 48 bits)

48-bit destination MAC address (containing all 48 bits)

16-bit L2 type field

Layer 3 (L3) fields:

Source IP address field (All source IP address values can be specified, or the subnet can be used to define a type of data flows.)

Destination IP address field (All destination IP address values can be specified, or the subnet can be used to define a type of data flows.)

Protocol type field

Layer 4 (L4) fields:

Either a TCP source or destination port is specified, or both are specified, or the range of the source or destination port is specified.

Either a UDP source or destination port is specified, or both are specified, or the range of the source or destination port is specified.

Filtering fields refer to the fields in packets that can be used to identify or classify packets when an ACE is generated. A filtering field template is a combination of these fields. For example, when an ACE is generated, packets are identified and classified based on the destination IP address field in each packet; when another ACE is generated, packets are identified and classified based on the source IP address field and UDP source port field in each packet. The two ACEs use different filtering field templates.

Rules refer to values of fields in the filtering field template of an ACE. For example, the content of an ACE is as follows:

```
permit tcp host 192.168.12.2 any eq telnet
```

In this ACE, the filtering field template is a combination of the following fields: source IP address field, IP protocol field, and TCP destination port field. The corresponding values (rules) are as follows: source IP address = Host 192.168.12.2; IP protocol = TCP; TCP destination port = Telnet.

Figure 1-2 Analysis of the ACE: permit tcp host 192.168.12.2 any eq telnet

A filtering field template can be a combination of L3 and L4 fields, or a combination of multiple L2 fields. The filtering field template of a standard or an extended ACL, however, cannot be a combination of L2 and L3 fields, a combination of L2 and L4 fields, or a combination of L2, L3, and L4 fields. To use a combination of L2, L3, and L4 fields, you can use the expert ACLs.

An SVI associated with ACLs in the outgoing direction supports the IP standard, IP extended, MAC extended, and expert ACLs.

If an MAC extended or expert ACL is configured to match the destination MAC address and is applied to the outgoing direction of the SVI, the related ACE can be configured but cannot take effect. If an IP extended or expert ACL is configured to match the destination IP address, but the destination IP address is not in the subnet IP address range of the associated SVI, the configured ACL cannot take effect. For example, assume that the address of VLAN 1 is **192.168.64.1 255.255.255.0**, an IP extended ACL is created, and the ACE is **deny udp any 192.168.65.1 0.0.0.255 eq 255**. If this ACL is applied to the outgoing interface of VLAN 1, the ACL cannot take effect because the destination IP address is not in the subnet IP address range of VLAN 1. If the ACE is **deny udp any 192.168.64.1 0.0.0.255 eq 255**, the ACL can take effect because the destination IP address is in the subnet IP address range of VLAN 1.

On a switch, if ACLs are applied to the outgoing direction of a physical port or an aggregate port (AP), the ACLs can filter only well-known packets (unicast or multicast packets), but not unknown unicast packets. That is, for unknown or broadcast packets, ACLs configured in the outgoing direction of a port does not take effect.

On a switch, if the input ACL and DOT1X, global IP+MAC binding, port security, and IP source guard are shared among all ports, the permit and default deny ACEs do not take effect, but other deny ACEs take effect.

On a switch, if the input ACL and QoS are shared, the permit ACEs do not take effect, other deny ACEs take effect, and the default deny ACE takes effect after the QoS ACE takes effect.

On a switch, you can run the **no rgos-security compatible** command to make the permit and deny ACEs take effect at the same time when the port-based input ACL and DOT1X, global IP+MAC binding, port security, and IP source guard are shared.

If ACEs are added to an ACL and then the switch is restarted after an ACL is applied to the incoming direction of multiple SVIs, the ACL may fail to be configured on some SVIs due to the limited hardware capacity.

If an expert ACL is configured and applied to the outgoing direction of an interface, and some ACEs in this ACL contain the L3 matching information (e.g. the IP address and L4 port), non-IP packets sent to the device from this interface cannot be controlled by the permit and deny ACEs in this ACL.

If ACEs of an ACL (IP ACL or expert extended ACL) are configured to match non-L2 fields (such as SIP and DIP), the ACL does not take effect on tagged MPLS packets.

ACL Logging

To allow users better learn the running status of ACLs on a device, you can determine whether to specify the ACL logging option as required when adding ACEs. If this option is specified, logs are output when packets matching ACEs are found. ACL logs are displayed based on ACEs. That is, the device periodically displays ACEs with matched packets and the number of matched packets. An example of the log is as follows:

```
*Sep 9 16:23:06: %ACL-6-MATCH: ACL 100 ACE 10 permit icmp any any, match 78 packets.
```

To control the amount of logs and output frequency, you can configure the log update interval respectively for the IPv4 ACL and the IPv6 ACL.

An ACE containing the ACL logging option consumes more hardware resources. If all configured ACEs contain this option, the ACE capacity of a device will be reduced by half.

By default, the log update interval is 0, that is, no log is output. After the ACL logging option is specified in an ACE, you need to configure the log update interval to output related logs.

For an ACE containing the ACL logging option, if no packet is matched in the specified interval, no packet matching log related to this ACE will be output. If matched packets are found in the specified interval, packet matching logs related to this ACE will be output when the interval expires. The number of matched packets is the total number of packets that match the ACE during the specified interval, that is, the period from the previous log output to the current log output.

Only switches support the ACL logging function.

ACL Packet Matching Counters

To implement network management, users may want to know whether an ACE has any matched packets and how many packets are matched. ACLs provide the ACE-based packet matching counters. You can enable or disable packet matching counters for all ACEs in an ACL, which can be an IP ACL, MAC ACL, expert ACL, or IPv6 ACL. In addition, you can run the **clear counters access-list** [*acl-id* | *acl-name*] command to reset ACL counters for a new round of statistics.

Enabling ACL counters requires more hardware entries. In an extreme case, this will reduce by half the number of ACEs that can be configured on a device.

Only switches support the ACL packet matching counters.

Overview

Feature	Description
IP ACL	Control incoming or outgoing IPv4 packets of a device based on the L3 or L4 information in the IPv4 packet header.
MAC Extended ACL	Control incoming or outgoing L2 packets of a device based on the L2 information in the Ethernet packet header.
Expert Extended ACL	Combine the IP ACL and MAC extended ACL into an expert extended ACL, which controls (permits or denies) incoming or outgoing packets of a device using the same rule based on the L2, L3, and L4 information in the packet header.
IPv6 ACL	Control incoming or outgoing IPv6 packets of a device based on the L3 or L4 information in the IPv6 packet header.
ACL80	Customize the matching fields and mask for scenarios where fixed matching fields cannot meet the requirements.
ACL Redirection	Redirect incoming packets of a device that match ACEs to a specified outgoing interface.
Global Security ACL	Make an ACL take effect in the incoming direction of all interfaces, instead of applying the ACL on every interface.
Security Channel	Allow packets to bypass the check of access control applications, such as DOT1X and Web authentication, to meet requirements of some special scenarios.
SVI Router ACL	Enable users in the same VLAN to communicate with each other.
ACL Logging	Output ACL packet matching logs at a specified interval according to requirements. The logs help users learn the packet matching result of a specified ACE.

1.3.1 IP ACL

The IP ACL implements refined control on incoming and outgoing IPv4 packets of a device. You can permit or deny the entry of specific IPv4 packets to a network according to actual requirements to control access of IP users to network resources.

Working Principle

Define a series of IP access rules in the IP ACL, and then apply the IP ACL either in the incoming or outgoing direction of an interface or globally. The device checks whether the incoming or outgoing IPv4 packets match the rules and accordingly forwards or blocks these packets.

To configure an IP ACL, you must specify a unique name or ID for the ACL of a protocol so that the protocol can uniquely identify each ACL. The following table lists the protocols that can use IDs to identify ACLs and the range of IDs.

Protocol	ID Range
Standard IP	1–99, 1300–1999
Extended IP	100–199, 2000–2699

Basic ACLs include the standard IP ACLs and extended IP ACLs. Typical rules defined in an ACL contain the following matching fields:

Source IP address

Destination IP address

IP protocol number

L4 source port ID or ICMP type

L4 destination port ID or ICMP code

The standard IP ACL (ID range: 1–99, 1300–1999) is used to forward or block packets based on the source IP address, whereas the extended IP ACL (ID range: 100–199, 2000–2699) is used to forward or block packets based on a combination of the preceding matching fields.

For an individual ACL, multiple independent ACL statements can be used to define multiple rules. All statements reference the same ID or name so that these statements are bound with the same ACL. However, more statements mean that it is increasingly difficult to read and understand the ACL.

For routing products, the ICMP code matching field in an ACL rule is ineffective for ICMP packets whose ICMP type is 3. If the ICMP code of ICMP packets to be matched is configured in an ACL rule, the ACL matching result of incoming ICMP packets of a device whose ICMP type is 3 may be different from the expected result.

Implicit "Deny All Traffic" Rule Statement

At the end of every IP ACL is an implicit "deny all traffic" rule statement. Therefore, if a packet does not match any rule, the packet will be denied.

For example:

```
access-list 1 permit host 192.168.4.12
```

This ACL permits only packets sent from the source host 192.168.4.12, and denies packets sent from all other hosts. This is because the following statement exists at the end of this ACL: **access-list 1 deny any**.

If the ACL contains only the following statement:

```
access-list 1 deny host 192.168.4.12
```

Packets sent from any host will be denied when passing through this port.

When defining an ACL, you must consider the routing update packets. As the implicit "deny all traffic" statement exists at the end of an ACL, all routing update packets may be blocked.

Input Sequence of Rule Statements

Every new rule is added to the end of an ACL and in front of the default rule statement. The input sequence of statements in an ACL is very important. It determines the priority of each statement in the ACL. When determining whether to forward or block packets, a device compares packets with rule statements based on the sequence that rule statements are created. After locating a matched rule statement, the device does not check any other rule statement.

If a rule statement is created and denies all traffic, all subsequent statements will not be checked.

For example:

```
access-list 101 deny ip any any
access-list 101 192.168.12.0 0.0.0.255 eq telnet any
```

The first rule statement denies all IP packets. Therefore, Telnet packets from the host on the network 192.168.12.0/24 will be denied. After the device finds that packets match the first rule statement, it does not check the subsequent rule statements any more.

Related Configuration

Configuring an IP ACL

By default, no IP ACL is configured on a device.

Run the **ip access-list { standard | extended } {acl-name | acl-id}** command in global configuration mode to create a standard or an extended IP ACL and enter standard or extended IP ACL mode.

Adding ACEs to an IP ACL

By default, a newly created IP ACL contains an implicit ACE that denies all IPv4 packets. This ACE is hidden from users, but takes effect when the ACL is applied to an interface. That is, all IPv4 packets will be discarded. Therefore, if you want the device to receive or send some specific IPv4 packets, add some ACEs to the ACL.

For a standard IP ACL, add ACEs as follows:

No matter whether the standard IP ACL is a named or number ACL, you can run the following command in standard IP ACL mode to add an ACE:

```
[ sn ] { permit | deny } { host source | any | source source-wildcard } [ time-range time-range-name ] [ log ]
```

For a numbered standard IP ACL, you can also run the following command in global configuration mode to add an ACE:

```
access-list acl-id { permit | deny } { host source | any | source source-wildcard } [ time-range tm-rng-name ] [ log ]
```

For an extended IP ACL, you can add ACEs as follows:

No matter whether the extended IP ACL is a named or numbered ACL, you can run the following command in extended IP ACL mode to add an ACE:

```
[ sn ] { permit | deny } protocol { host source | any | source source-wildcard } { host destination | any | destination destination-wildcard } [ precedence precedence [ tos tos ] ] [ dscp dscp ] [ fragment ] [ time-range time-range-name ] [ log ]
```

For a numbered extended IP ACL, you can also run the following command in global configuration mode to add an ACE:

```
access-list acl-id { permit | deny } protocol { host source | any | source source-wildcard } { host destination | any | destination destination-wildcard } [ precedence precedence [ tos tos ] ] dscp dscp [ fragment ] [ time-range time-range-name ] [ log ]
```

Applying an IP ACL

By default, the IP ACL is not applied to any interface, that is, the IP ACL does not filter incoming or outgoing IP packets of the device.

Run the **ip access-group { acl-id | acl-name } { in | out } [reflect]** command in interface configuration mode to apply a standard or an extended IP ACL to a specified interface. By default, a reflexive ACL is disabled on a router. You can run the **reflect** command to enable the reflexive ACL. The working principle of the reflexive ACL is as follows:

1.3.2 MAC Extended ACL

The MAC extended ACL implements refined control on incoming and outgoing packets based on the L2 header of packets. You can permit or deny the entry of specific L2 packets to a network, thus protecting network resources against attacks or control users' access to network resources.

Working Principle

Define a series of MAC access rules in the MAC extended ACL, and then apply the ACL to the incoming or outgoing direction of an interface. The device checks whether the incoming or outgoing packets match the rules and accordingly forwards or blocks these packets.

To configure an MAC extended ACL, you must specify a unique name or ID for this ACL to uniquely identify the ACL. The following table lists the range of IDs that identify MAC extended ACLs.

Protocol	ID Range
MAC extended ACL	700–799

Typical rules defined in an MAC extended ACL include:

Source MAC address

Destination MAC address

Ethernet protocol type

The MAC extended ACL (ID range: 700–799) is used to filter packets based on the source or destination MAC address and the Ethernet type in the packets.

For an individual MAC extended ACL, multiple independent ACL statements can be used to define multiple rules. All statements reference the same ID or name so that these statements are bound with the same ACL. However, more statements mean that it is increasingly difficult to read and understand the ACL.

If ACEs in a MAC extended ACL are not defined specifically for IPv6 packets, that is, the Ethernet type is not specified or the value of the Ethernet type field is not 0x86dd, the MAC extended ACL does not filter IPv6 packets. If you want to filter IPv6 packets, use the IPv6 extended ACL.

Implicit "Deny All Traffic" Rule Statement

At the end of every MAC extended ACL is an implicit "deny all traffic" rule statement. Therefore, if a packet does not match any rule, the packet will be denied.

For example:

```
access-list 700 permit host 00d0.f800.0001 any
```

This ACL permits only packets from the host with the MAC address 00d0.f800.0001, and denies packets from all other hosts. This is because the following statement exists at the end of this ACL: **access-list 700 deny any any**.

Related Configuration

Configuring an MAC Extended ACL

By default, no MAC extended ACL is configured on a device.

Run the **mac access-list extended {acl-name | acl-id}** command in global configuration mode to create an MAC extended ACL and enter MAC extended ACL mode.

Adding ACEs to an MAC Extended ACL

By default, a newly created MAC extended ACL contains an implicit ACE that denies all L2 packets. This ACE is hidden from users, but takes effect when the ACL is applied to an interface. That is, all L2 packets will be discarded. Therefore, if you want the device to receive or send some specific L2 packets, add some ACEs to the ACL.

You can add ACEs to an MAC extended ACL as follows:

No matter whether the MAC extended ACL is a named or numbered ACL, you can run the following command in MAC extended ACL mode to add an ACE:

```
[sn] { permit | deny } { any | host src-mac-addr } { any | host dst-mac-addr } [ethernet-type] [cos cos ] [inner cos ]  
[ time-range tm-rng-name ]
```

For a numbered MAC extended ACL, you can also run the following command in global configuration mode to add an ACE:
access-list acl-id { permit | deny } { any | host src-mac-addr } { any | host dst-mac-addr } [ethernet-type] [cos cos] [inner cos] [time-range time-range-name]

Applying an MAC Extended ACL

By default, the MAC extended ACL is not applied to any interface, that is, the created MAC extended ACL does not filter incoming or outgoing L2 packets of a device.

Run the **mac access-group { acl-id | acl-name } { in| out }** command in interface configuration mode to apply an MAC extended ACL to a specified interface.

1.3.3 Expert Extended ACL

You can create an expert extended ACL to match the L2 and L3 information in packets using the same rule. The expert extended ACL can be treated as a combination and enhancement of the IP ACL and the MAC extended ACL because the expert extended ACL can contain ACEs in both the IP ACL and the MAC extended ACL. In addition, the VLAN ID can be specified in the expert extended ACL to filter packets.

Working Principle

Define a series of access rules in the expert extended ACL, and then apply the ACL in the incoming or outgoing direction of an interface. The device checks whether incoming or outgoing packets match the rules and accordingly forwards or blocks these packets.

To configure an expert extended ACL, you must specify a unique name or ID for this ACL so that the protocol can uniquely identify each ACL. The following table lists the ID range of the expert extended ACL.

Protocol	ID Range
Expert extended ACL	2700–2899

When an expert extended ACL is created, defined rules can be applied to all packets. The device determines whether to forward or block packets by checking whether packets match these rules.

Typical rules defined in an expert extended ACL include:

All information in the basic ACL and MAC extended ACL

VLAN ID

The expert extended ACL (ID range: 2700–2899) is a combination of the basic ACL and MAC extended ACL, and can filter packets based on the VLAN ID.

For an individual expert extended ACL, multiple independent statements can be used to define multiple rules. All statements reference the same ID or name so that these statements are bound with the same ACL.

If rules in an expert extended ACL are not defined specifically for IPv6 packets, that is, the Ethernet type is not specified or the value of the Ethernet type field is not 0x86dd, the expert extended ACL does not filter IPv6 packets. If you want to filter IPv6 packets, use the IPv6 extended ACL.

Implicit "Deny All Traffic" Rule Statement

At the end of every expert extended ACL is an implicit "deny all traffic" rule statement. Therefore, if a packet does not match any rule, the packet will be denied.

For example:

```
access-list 2700 permit 0x0806 any any any any any
```

This ACL permits only ARP packets whose Ethernet type is 0x0806, and denies all other types of packets. This is because the following statement exists at the end of this ACL: **access-list 2700 deny any any any any.**

Related Configuration

Configuring an Expert Extended ACL

By default, no expert extended ACL is configured on a device.

Run the **expert access-list extended {acl-name | acl-id}** command in global configuration mode to create an expert extended ACL and enter expert extended ACL mode.

Adding ACEs to an Expert Extended ACL

By default, a newly created expert extended ACL contains an implicit ACE that denies all packets. This ACE is hidden from users, but takes effect when the ACL is applied to an interface. That is, all L2 packets will be discarded. Therefore, if you want the device to receive or send some specific L2 packets, add some ACEs to the ACL.

You can add ACEs to an expert extended ACL as follows:

No matter whether the expert extended ACL is a named or numbered ACL, you can run the following command in expert extended ACL mode to add an ACE:

```
[sn] { permit | deny } [protocol | [ ethernet-type ] [ cos [ out ] [ inner in ] ] [ [ VID [ out ] [ inner in ] ] ] { source source-wildcard | host source | any } { host source-mac-address | any } { destination destination-wildcard | host destination | any } { host destination-mac-address | any } [ precedence precedence ] [ tos tos ] [ fragment ] [ range lower upper ] [ time-range time-range-name ]]
```

For a numbered expert extended ACL, you can also run the following command in expert extended ACL mode to add an ACE:

```
access-list acl-id { permit | deny } [[protocol | [ ethernet-type ] [ cos [ out ] [ inner in ] ] [ [ VID [ out ] [ inner in ] ] ] { source source-wildcard | host source | any } { host source-mac-address | any } { destination destination-wildcard | host destination | any } { host destination-mac-address | any } [ precedence precedence ] [ tos tos ] [ fragment ] [ range lower upper ] [ time-range time-range-name ]]
```

Applying an Expert Extended ACL

By default, the expert extended ACL is not applied to any interface, that is, the created expert extended ACL does not filter incoming or outgoing L2 or L3 packets of a device.

Run the **expert access-group { acl-id | acl-name } { in | out }** command in interface configuration mode to apply an expert extended ACL to a specified interface.

1.3.4 IPv6 ACL

The IPv6 ACL implements refined control on incoming and outgoing IPv6 packets of a device. You can permit or deny the entry of specific IPv6 packets to a network according to actual requirements to control access of IPv6 users to network resources.

Working Principle

Define a series of IPv6 access rules in the IPv6 ACL, and then apply the ACL in the incoming or outgoing direction of an interface. The device checks whether the incoming or outgoing IPv6 packets match the rules and accordingly forwards or blocks these packets.

To configure an IPv6 ACL, you must specify a unique name for this ACL.

Unlike the IP ACL, MAC extended ACL, and expert extended ACL, you can specify only a name but not an ID for the IPv6 ACL created.

Only one IP ACL, or one MAC extended ACL, or one expert extended ACL can be applied to the incoming or outgoing direction of an interface. Besides, one more IPv6 ACL can be applied.

Implicit "Deny All Traffic" Rule Statement

At the end of every IPv6 ACL is an implicit "deny all IPv6 traffic" rule statement. Therefore, if a packet does not match any rule, the packet will be denied.

For example:

```
ipv6 access-list ipv6_acl
10 permit ipv6 host 200::1 any
```

This ACL permits only IPv6 packets from the source host 200::1, and denies IPv6 packets from all other hosts. This is because the following statement exists at the end of this ACL: deny ipv6 any any.

Although the IPv6 ACL contains the implicit "deny all IPv6 traffic" rule statement by default, it does not filter ND packets.

Input Sequence of Rule Statements

Every new rule is added to the end of an ACL and in front of the default rule statement. The input sequence of statements in an ACL is very important. It determines the priority of each statement in the ACL. When determining whether to forward or block packets, a device compares packets with rule statements based on the sequence that rule statements are created. After locating a matched rule statement, the device does not check any other rule statement.

If a rule statement is created and permits all IPv6 traffic, all subsequent statements will not be checked.

For example:

```
ipv6 access-list ipv6_acl
10 permit ipv6 any any
20 deny ipv6 host 200::1 any
```

As the first rule statement permits all IPv6 packets, all IPv6 packets sent from the host 200::1 does not match the subsequent deny rule with the serial number of 20, and therefore will not be denied. After the device finds that packets match the first rule statement, it does not check the subsequent rule statements any more.

Related Configuration

Configuring an IPv6 ACL

By default, no IPv6 ACL is configured on a device.

Run the **ipv6 access-list *acl-name*** command in global configuration mode to create an IPv6 ACL and enter IPv6 ACL mode.

Adding ACEs to an IPv6 ACL

By default, a newly created IPv6 ACL contains an implicit ACE that denies all IPv6 packets. This ACE is hidden from users, but takes effect when the ACL is applied to an interface. That is, all IPv6 packets will be discarded. Therefore, if you want the device to receive or send some specific IPv6 packets, add some ACEs to the ACL.

Run the following command in IPv6 ACL mode to add an ACE:

```
[sn] {permit | deny } protocol {src-ipv6-prefix/prefix-len | host src-ipv6-addr | any} {dst-ipv6-pfix/pfix-len | host dst-ipv6-addr | any} [range lower upper] [dscp dscp] [flow-label flow-label] [fragment] [time-range tm-rng-name][log]
```

Applying an IPv6 ACL

By default, the IPv6 ACL is not applied to any interface, that is, the IPv6 ACL does not filter incoming or outgoing IPv6 packets of a device.

Run the **ipv6 traffic-filter *acl-name* { in | out }** command in interface configuration mode to apply an IPv6 ACL to a specified interface.

1.3.5 ACL80

ACL80 refers to the expert advanced ACL, and is also called custom ACL. It filters packets based on the first 80 bytes of every packet. Among these 80 bytes, the SMAC, DMAC, SIP, DIP, and ETYPE fields in a packet are mandatory, and you can specify the remaining 16 bytes.

Working Principle

A packet consists of a number of bytes. ACL80 allows you to match the specified 16 bytes by bit in the first 80 bytes of a packet. Any bit of a 16-byte field can be set to a value (**0** or **1**), indicating whether the bit is compared. When any byte is filtered, three factors are considered: content of the matching field, mask of the matching field, and the start position for matching. Bits of the matching field content are in one-to-one mapping relationship with bits of the matching field mask. The filtering rule specifies the value of the field to be filtered. The filtering field template specifies whether the corresponding field in the filtering rule should be filtered. (**1** indicates that the bit specified in the filtering rule should be matched; **0** indicates that the bit specified in the filtering rule is not matched.) Therefore, when it is required to match a specific bit, you must set the corresponding bit to 1 in the filtering field template. For example, if the bit is set to **0** in the filtering field template, no bit is matched no matter which bit is specified in the filtering rule.

For example,

```
Ruijie(config)# expert access-list advanced name
Ruijie(config-exp-dacl)# permit 00d0f8123456 ffffffff 0
Ruijie(config-exp-dacl)# deny 00d0f8654321 ffffffff 6
```

The custom ACL matches any byte of the first 80 bytes in a L2 data frame according to user' definition, and filters packets accordingly. To properly use a custom ACL, you must have an in-depth understanding about the structure of a L2 data frame. The following shows the first 64 bytes of a L3 data frame (every letter represents a hexadecimal number, and every two letters represent one byte):

```
AA AA AA AA AA AA BB BB BB BB BB BB CC CC DD DD
DD DD EE FF GG HH HH HH II II JJ KK LL LL MM MM
```

NN NN OO PP QQ QQ RR RR RR RR SS SS SS SS TT TT

UU UU VV VV VV VV WW WW WW WW XY ZZ aa aa bb bb

The following table describes the meaning and offset of each letter:

Letter	Meaning	Offset	Letter	Meaning	Offset
A	Destination MAC address	0	O	Time To Live (TTL) field	34
B	Source MAC address	6	P	Protocol number	35
C	VLAN tag field	12	Q	IP checksum	36
D	Data frame length	16	R	Source IP address	38
E	Destination service access point (DSAP) field	18	S	Destination IP address	42
F	Source service access point (SSAP) field	19	T	TCP source port	46
G	Cntl field	20	U	TCP destination port	48
H	Org Code field	21	V	Serial number	50
I	Encapsulated data type	24	W	Acknowledgment field	54
J	IP version number	26	XY	IP header length and reserved bit	58
K	TOS field	27	Z	Reserved bit and flags bit	59
L	IP packet length	28	a	Windows size field	60
M	ID	30	b	Miscellaneous	62
N	Flags field	32			

In the above table, the offset of each field is the offset of this field in the tagged 802.3 SNAP packet. In a custom ACL, you can use the rule mask and offset jointly to extract any byte from the first 80 bytes of a data frame, compare the byte with the rule customized in the ACL, and then filter matched data frames for further processing. Customized rules may be some fixed attributes of data. For example, to obtain all TCP packets, you can define the rule as "06", rule mask as "FF", and offset as "35". Then, the device can use the rule mask and offset jointly to extract the content of TCP protocol number field in a received data frame, and compare the extracted content with the rule to obtain all TCP packets.

Only switches support the ACL80.

The ACL80 supports filtering of the Ethernet, 803.3 SNAP, and 802.3 LLC packets. If the values of the fields from DSAP to cntl are set to AAAA03, the ACL is used to filter the 803.3 SNAP packets. If the values of the fields from DSAP to cntl are set to E0E003, the ACL is used to filter the 803.3 LLC packets. The value of the cntl field cannot be configured to filter Ethernet packets.

The ACL80 can be configured to compare packets with any of the 16 bytes. If the 16 bytes are already used, no ACE can be configured to compare packets with fields in any other bytes.

Related Configuration

Configuring an Expert Advanced ACL

By default, no expert advanced ACL is configured on a device.

Run the **expert access-list advanced *acl-name*** command in global configuration mode to create an expert advanced ACL and enter expert advanced ACL mode.

Adding ACEs to an Expert Advanced ACL

By default, a newly created expert advanced ACL contains an implicit ACE that denies all packets. This ACE is hidden from users, but takes effect when the ACL is applied to an interface. That is, all L2 packets will be discarded. Therefore, if you want the device to receive or send some specific L2 packets, add some ACEs to the ACL.

Run the `[sn] { permit | deny } hex hex-mask offset` command in expert advanced ACL mode to add an ACE to the expert advanced ACL.

Applying an Expert Advanced ACL

By default, the expert advanced ACL is not applied to any interface, that is, the created expert advanced ACL does not filter incoming or outgoing packets of a device.

Run the **expert access-group *acl-name* { in | out }** command in interface configuration mode to apply an expert advanced ACL to a specified interface.

1.3.6 ACL Redirection

ACL redirection allows a device to analyze received packets and redirect the packets to a specified port for forwarding. To analyze specific incoming packets of a device, you can configure the ACL redirection function to redirect packets meeting rules to a specified port and capture packets on this port for analysis.

Working Principle

Bind different ACL policy to an interface and specify an output destination interface for each policy. When receiving packets on this interface, the device searches ACL policies bound to this interface one by one. If packets match criteria described in a certain policy, the device forwards packets on the destination interface specified by the policy, thus redirecting packets based on traffic.

Only switches support the ACL redirection function.

ACL redirection takes effect only in the incoming direction of an interface.

Related Configuration

Configuring an ACL

Before configuring ACL redirection, configure an ACL. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

Configuring ACL Redirection

By default, ACL redirection is not configured on a device.

Run the **redirect destination interface** *interface-name* **acl** {*acl-id* | **acl-name** } **in** command in interface configuration mode to configure ACL redirection.

You can configure the ACL redirection function only on an Ethernet interface, AP, or SVI.

1.3.7 Global Security ACL

To meet the requirements of security deployment, the port-based ACL is often configured to filter out virus packets and obtain packets with certain characteristics, for example, packets that attack the TCP port. Various virus packets exist in a global network environment, and the identification features of virus packets under each port are identical or similar. Therefore, an ACL is generally created. After the deny ACE for matching virus signatures is added to the ACL, the port-based ACL is applied to each port on the switch to filter out virus packets.

For two reasons, it is not convenient to use the port-based ACLs in antivirus scenarios such as virus filtering. The first reason is that the port-based ACL must be configured on every port, which results in repeated configuration, poor operation performance, and over-consumption of ACL resources. The second reason is that the access control function of the ACL is weakened. As the port-based ACL is used for virus filtering, basic functions of the ACL, such as route update restriction and network access restriction, cannot be used properly. The global security ACL can be used for global antivirus deployment and defense without affecting the port-based ACL. By running only one command, you can make the global security ACL takes effect on all L2 interfaces. In contrast, the port-based ACL must be configured on every interface.

Working Principle

The global security ACL takes effect on all L2 interfaces. When both the global security ACL and the port-based ACL are configured, both take effect. Packets that match the global security ACL are directly filtered out as virus packets. Packets that do not match the global security ACL are still controlled by the port-based ACL. You can disable the global security ACL on some ports so that these ports are not controlled by the global security ACL.

The global security ACL is mainly used for virus filtering. Therefore, in an ACL associated with the global security ACL, only the deny ACEs take effect, and the permit ACEs do not take effect.

Unlike the secure ACL applied to a port, the global security ACL does not contain the default "deny all traffic" ACE, that is, all packets that do not match the ACL are permitted.

A global secure ACL can take effect either on a L2 port or a routed port. That is, it takes effect on all the following types of ports: access port, trunk port, hibird port, routed port, and AP (L2 or L3). The global secure ACL does not take effect on an SVI.

You can disable the global security ACL on an individual physical port or AP, but not on a member port of an AP.

The global secure ACL supports only the associated IP standard ACL, IP extended ACL, MAC extended ACL and Expert extended ACL.

Related Configuration

Configuring an ACL

Before configuring the global security ACL, configure an ACL. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL.

Configuring a Global Security ACL

By default, no global security ACL is configured on a device.

Run the `{ip | mac | Expert } access-group acl-id { in | out }` command in global configuration mode to enable the global security ACL.

Configuring an Exclusive Interface of the Global Security ACL

By default, no exclusive interface is configured for the global security ACL on a device.

Run the `no global ip access-group` command in interface configuration to disable the global security ACL on a specified interface.

1.3.8 Security Channel

In some application scenarios, packets meeting some characteristics may need to bypass the checks of access control applications. For example, before DOT1X authentication, users are allowed to log in to a specified website to download the DOT1X authentication client. The security channel can be used for this purpose. When the security channel configuration command is executed to apply a secure ACL globally or to an interface or, this ACL becomes a security channel.

Working Principle

The security channel is also an ACL, and can be configured globally or for a specified interface or. When arriving at an interface, packets are check on the security channel. If meeting the matching conditions of the security channel, packets directly enters a switch without undergoing the access control, such as port security, Web authentication, 802.1x, and IP+MAC binding check. A globally applied security channel takes effect on all interfaces except exclusive interfaces.

The deny ACEs in an ACL that is applied to a security channel do not take effect. In addition, this ACL does not contain an implicit "deny all traffic" rule statement at the end of the ACL. If packets do not meet matching conditions of the security channel, they are checked according to the access control rules in compliance with the relevant process.

You can configure up to eight exclusive interfaces for the global security channel. In addition, you cannot configure interface-based security channel on these exclusive interfaces.

If a security channel is applied to an interface while a global security channel exists, this global security channel does not take effect on this interface.

If both port-based migratable authentication mode and security channel are applied to an interface, the security channel does not take effect.

An IPv6 ACL cannot be configured as a security channel.

Only switches support the security channel.

The configuration mode does not support the exclusive Interface of security channel.

Related Configuration

Configuring an ACL

Before configuring the security channel, configure an ACL. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, or expert extended ACL.

Configuring a Security Channel on an Interface

By default, no security channel is configured on an interface of a device.

Run the **security access-group** *{acl-id | acl-name}* command in interface configuration mode to configure the security channel on an interface.

Configuring a Security Channel

By default, no security channel is configured on a device.

Run the **security access-group** *{acl-id | acl-name}* command in VXLAN configuration mode to configure a VXLAN security channel.

Configuring a Global Security Channel

By default, no global security channel is configured on a device.

Run the **security global access-group** *{acl-id | acl-name}* command in global configuration mode to configure a global security channel.

Configuring an Exclusive Interface for the Global Security Channel

By default, no exclusive interface is configured for the global security channel on a device.

Run the **security uplink enable** command in interface configuration mode to configure a specified interface as the exclusive interface of the global security channel.

1.3.9 SVI Router ACL

By default, an ACL that is applied to an SVI also takes effect on L2 packets forwarded within a VLAN and L3 packets forwarded between VLANs. Consequently, users in the same VLAN may fail to communicate with each other. Therefore, a switchover method is provided so that the ACL that is applied to an SVI takes effect only on routing packets between VLANs.

Working Principle

By default, the SVI router ACL function is disabled, and an SVI ACL takes effect on L3 packets forwarded between VLANs and L2 packets forwarded within a VLAN. After the SVI router ACL function is enabled, the SVI ACL takes effect only on L3 packets forwarded between VLANs.

Only switches support the SVI router ACL.

Related Configuration

Configuring an ACL

Before configuring the SVI router ACL, configure and apply an ACL. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

Applying an ACL

For details about how to apply an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL. Apply the ACL in SVI configuration mode.

Configuring the SVI Router ACL

Run the **svi router-acls enable** command in global configuration mode to enable the SVI router ACL so that the ACL that is applied to an SVI takes effect only on packets forwarded at L3, and not on packets forwarded at L2 within a VLAN.

1.3.10 ACL Logging

ACL logging is used to monitor the running status of ACEs in an ACL and provide essential information for routine network maintenance and optimization.

Working Principle

To better learn the running status of ACLs on a device, you can determine whether to specify the ACL logging option as required when adding ACEs. If this option is specified, logs are output when packets matching ACEs are found. ACL logs are displayed based on ACEs. That is, the device periodically displays ACEs with matched packets and the number of matched packets. An example of the log is as follows:

```
*Sep 9 16:23:06: %ACL-6-MATCH: ACL 100 ACE 10 permit icmp any any, match 78 packets.
```

To control the amount of logs and output frequency, you can configure the log update interval.

An ACE containing the ACL logging option consumes more hardware resources. If all configured ACEs contain this option, the ACE capacity of a device will be reduced by half.

By default, the log update interval is 0, that is, no log is output. After the ACL logging option is specified in an ACE, you need to configure the log update interval to output related logs; otherwise, logs are not output.

For an ACE containing the ACL logging option, if no packet is matched in the specified interval, no packet matching log related to this ACE will be output. If matched packets are found in the specified interval, packet matching logs related to this ACE will be output when the interval expires. The number of matched packets is the total number of packets that match the ACE during the specified interval, that is, the period from the previous log output to the current log output.

Only switches support the ACL logging function.

You can configure the ACL logging option only for an IP ACL or an IPv6 ACL.

Related Configuration

Configuring an ACL

Configure an ACL before configuring ACEs containing the ACL logging option. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL and IPv6 ACL. Note that the ACL logging option must be configured.

Configuring the Log Update Interval

Run the `{ip | ipv6} access-list log-update interval time` command in the configuration mode to configure the interval at which the ACL logs are output.

Applying an ACL

For details about how to apply an ACL, see the earlier descriptions about the IP ACL and IPv6 ACL.

1.3.11 Packet Matching Counters

In addition to ACL logs, packet matching counters provide another choice for routine network maintenance and optimization.

Working Principle

To implement network management, users may want to know whether an ACE has any matched packets and how many packets are matched. ACLs provide the ACE-based packet matching counters. You can enable or disable packet matching counters for all ACEs in an ACL. When a packet matches the ACE, the corresponding counter increments by 1. You can run the `clear counters access-list [acl-id | acl-name]` command to reset counters of all ACEs in an ACL for a new round of statistics.

Enabling ACL counters requires more hardware entries. In an extreme case, this will reduce by half the number of ACEs that can be configured on a device.

You can enable packet matching counters on an IP ACL, MAC ACL, expert ACL, or IPv6 ACL.

Only switches support the ACL packet matching counters.

Related Configuration

Configuring an ACL

Configure an ACL before configuring ACEs containing the ACL logging option. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL and IPv6 ACL. Note that the ACL logging option must be configured.

Enabling Packet Matching Counters

To enable packet matching counters on an IP ACL, MAC ACL, or expert ACL, run the **{mac |expert |ip} access-list counter {acl-id | acl-name}** command in global configuration mode.

To enable packet matching counters on an IPv6 ACL, run the **ipv6 access-list counter acl-name** command in global configuration mode.

Applying an ACL

For details about how to apply an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

Clearing Packet Matching Counters

Run the **clear counters access-list [acl-id | acl-name]** command in privileged EXEC mode to reset packet matching counters.

1.3.12 Fragmented Packet Matching Mode

In fragmented packet matching mode, an ACL can implement more refined control on fragmented packets.

Working Principle

IP packets may be fragmented when transmitted on the network. When fragmentation occurs, only the first fragment of the packet contains the L4 information, such as the TCP/UDP port number, ICMP type, and ICMP code, and other fragmented packets do not contain the L4 information. By default, if an ACE contains the fragment flag, fragmented packets except the first fragments are filtered. If an ACE does not contain the fragment flag, all fragmented packets (including the first fragments) are filtered. In addition to this default fragmented packet matching mode, a new fragmented packet matching mode is provided. You can switch between the two fragmented packet matching modes as required on a specified ACL. In the new fragmented packet matching mode, if an ACE does not contain the fragment flag and packets are fragmented, the first fragments are compared with all the matching fields (including L3 and L4 information) defined in the ACE, and other fragmented packets are compared with only the non-L4 information defined in the ACE.

In the new fragmented packet matching mode, if an ACE does not contain the fragment flag and the action is Permit, this type of ACE occupies more hardware entries. In an extreme case, this will reduce by half the number of hardware entries. If Established is configured for filter the TCP flag in an ACE, more hardware entries will be occupied.

The ACL will be temporarily ineffective during switchover of the fragmented packet matching mode.

In the new fragmented packet matching mode, if an ACE does not contain the fragment flag, the L4 information of packets needs to be compared, and the action is Permit, the ACE checks the L3 and L4 information of the first fragments of packets, and checks only the L3 information of other fragmented packets. If the action is Deny, the ACE checks only the first fragments of packets, and ignores other fragmented packets.

In the new fragmented packet matching mode, if an ACE contains the fragment flag, the ACE checks only fragmented packets but not the first fragments of packets no matter whether the action in the ACE is Permit or Deny.

Only the IP extended ACL and the expert extended ACL support switching between the two fragmented packet matching modes.

Only switches support filtering of fragmented packets.

Related Configuration

Configuring an ACL

For details about how to configure an ACL, see the earlier descriptions about the IP ACL and expert extended ACL.

Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL and expert extended ACL. Note that the fragment option must be added.

Switching the Fragmented Packet Matching Mode

Run the [**no**] {**ip** | **expert**} **access-list new-fragment-mode** { *acl-id* | *acl-name* } command in global configuration mode to switch the fragmented packet matching mode.

Applying an ACL

For details about how to apply an ACL, see the earlier descriptions about the IP ACL and expert extended ACL.

1.4 Configuration

Configuration Item	Description and Command	
Configuring an IP ACL	(Optional) It is used to filter IPv4 packets.	
	ip access-list standard	Configures a standard IP ACL.
	ip access-list extended	Configures an extended IP ACL.
	permit host any time-range log	Adds a permit ACE to a standard IP ACL.
	deny host any time-range log	Adds a deny ACE to a standard IP ACL.
	permit host any host any tos dscp precedence fragment time-range log	Adds a permit ACE to an extended IP ACL.
	deny host any host any tos dscp precedence fragment time-range log	Adds a deny ACE to an extended IP ACL.
	ip access-group in out	Applies a standard or an extended IP ACL.

Configuration Item	Description and Command	
Configuring a MAC Extended ACL	(Optional) It is used to filter L2 packets.	
	mac access-list extended	Configures a MAC extended ACL.
	permit any host any host cos inner time-range	Adds a permit ACE to a MAC extended ACL.
	deny any host any host cos inner time-range	Adds a deny ACE to a MAC extended ACL.
	mac access-group in out	Applies a MAC extended ACL.
Configuring an Expert Extended ACL	(Optional) It is used to filter L2 and L3 packets.	
	expert access-list extended	Configures an expert extended ACL.
	permit cos inner VID inner host any host any host any precedence tos fragment range time-range	Adds a permit ACE to an expert extended ACL.
	deny cos inner VID inner host any host any host any precedence tos fragment range time-range	Adds a deny ACE to an expert extended ACL.
	expert access-group in out	Applies an expert extended ACL.
Configuring an IPv6 Extended ACL	(Optional) It is used to filter IPv6 packets.	
	ipv6 access-list	Configures an IPv6 ACL.
	permit host any host any range dscp flow-label fragment time-range log	Adds a permit ACE to an IPv6 ACL.
	deny host any host any range dscp flow-label fragment time-rangelog	Adds a deny ACE to an IPv6 ACL.
	ipv6 traffic-filter in out	Applies an IPv6 ACL.
Configuring an ACL80	(Optional) It is used to customize the fields for filter L2 and L3 packets.	
	expert access-list advanced	Configures an expert advanced ACL.
	permit	Adds a permit ACE to an expert advanced ACL.
	deny	Adds a deny ACE to an expert advanced ACL.
	expert access-group in out	Applies an expert advanced ACL.
Configuring ACL Redirection	(Optional) It is used to redirect packets meeting the rules to a specified interface.	
	redirect destination interface acl in	Configures ACL redirection.
Configuring a Global Security ACL	(Optional) It is used to make an ACL take effect globally.	

Configuration Item	Description and Command	
	ip access-group in out	Applies a global security ACL in global configuration mode.
	no global ip access-group	Configures an interface as the exclusive interface of the global security ACL in interface configuration mode.
Configuring a Security Channel	(Optional) It is used to enable packets meeting some characteristics to bypass the checks of access control applications, such as the DOT1X and Web authentication.	
	security access-group	Enables the security channel in interface configuration mode.
	security global access-group	Enables the security channel in global configuration mode.
	security uplink enable	Configures an interface as the exclusive interface of the global security channel in interface configuration mode.
Configuring Comments for ACLs	(Optional) It is used to configure comments for an ACL or ACE so that users can easily identify the functions of the ACL or ACE.	
	list-remark	Configures a comment for an ACL in ACL configuration mode.
	access-list list-remark	Configures a comment for an ACL in global configuration mode.
	remark	Configures a comment for an ACE in ACL configuration mode.

1.4.1 Configuring an IP ACL

Configuration Effect

Configure and apply an IP ACL to an interface/VXLAN to control all incoming and outgoing IPv4 packets of this interface/VXLAN. You can permit or deny the entry of specific IPv4 packets to a network to control access of IP users to network resources.

Notes

N/A

Configuration Steps

Configuring an IP ACL

(Mandatory) Configure an IP ACL if you want to control access of IPv4 users to network resources.

You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The IP ACL takes effect only on the local device, and does not affect other devices on the network.

Adding ACEs to an IP ACL

(Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, all incoming IPv4 packets of the device are denied by default.

Applying an IP ACL

(Mandatory) Apply an IP ACL to a specified interface/VXLAN if you want this ACL take effect.

You can apply an IP ACL on a specified interface/VXLAN of an access, an aggregate, or a core device based on the distribution of users.

Verification

Use the following methods to verify the configuration effects of the IP ACL:

Run the **ping** command to verify that the IP ACL takes effect on the specified interface. For example, if an IP ACL is configured to prohibit a host with a specified IP address or hosts in a specified IP address range from accessing the network, run the **ping** command to verify that the host(s) cannot be successfully pinged.

Access related network resources to verify that the IP ACL takes effect on the specified interface. For example, access the Internet or access the FTP resources on the network through FTP.

Related Commands

Configuring an IP ACL

Command	ip access-list { standard extended } {acl-name acl-id }
Parameter Description	<p>standard: Indicates that a standard IP ACL is created.</p> <p>extended: Indicates that an extended IP ACL is created.</p> <p><i>acl-name:</i> Indicates the name of a standard or an extended IP ACL. If this option is configured, a named ACL is created. The name is a string of 1 to 99 characters. The ACL name cannot start with numbers (0–9), "in", or "out".</p> <p><i>acl-id:</i> Indicates the ID that uniquely identifies a standard or extended IP ACL. If this option is configured, a numbered ACL is created. If a standard IP ACL is created, the value range of <i>acl-id</i> is 1–99 and 1300–1999. If an extended IP ACL is created, the value range of <i>acl-id</i> is 100–199 and 2000–2699.</p>
Command Mode	Global configuration mode
Usage Guide	Run this command to configure a standard or an extended IP ACL and enter standard or extended IP ACL configuration mode. If you want to control access of users to network resources by checking the source IP address of each packet, configure a standard IP ACL. If you want to control access of users to network resources by checking the source or destination IP address, protocol number, and TCP/UDP source or destination port, configure an extended IP ACL.

Adding ACEs to an IP ACL

Add ACEs to a standard IP ACL.

Use either of the following methods to add ACEs to a standard IP ACL:

Command	[<i>sn</i>] { permit deny } { host <i>source</i> any <i>source source-wildcard</i> } [time-range <i>time-range-name</i>] [log]
Parameter Description	<p><i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p>permit: Indicates that the ACE is a permit ACE.</p> <p>deny: Indicates that the ACE is a deny ACE.</p> <p>host source: Indicates that IP packets sent from a host with the specified source IP address are filtered.</p> <p>any: Indicates that IP packets sent from any host are filtered.</p> <p><i>source source-wildcard</i>: Indicates that IP packets sent from hosts in the specified IP network segment are filtered.</p> <p>time-range <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p> <p>log: Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.</p>
Command Mode	Standard IP ACL configuration mode
Usage Guide	Run this command to add ACEs in standard IP ACL configuration mode. The ACL can be a named or numbered ACL.

Command	access-list <i>acl-id</i> { permit deny } { host <i>source</i> any <i>source source-wildcard</i> } [time-range <i>tm-rng-name</i>] [log]
Parameter Description	<p><i>acl-id</i>: Indicates the ID of a numbered ACL. It uniquely identifies an ACL. The value range of <i>acl-id</i> is 1–199 and 1300–1999.</p> <p>permit: Indicates that the ACE is a permit ACE.</p> <p>deny: Indicates that the ACE is a deny ACE.</p> <p>host source: Indicates that IP packets sent from a host with the specified source IP address are filtered.</p> <p>any: Indicates that IP packets sent from any host are filtered.</p> <p><i>source source-wildcard</i>: Indicates that IP packets sent from hosts in the specified IP network segment are filtered.</p> <p>time-range <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p> <p>log: Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.</p>
Command	Standard IP ACL configuration mode

Mode	
Usage Guide	Run this command to add ACEs to a numbered IP ACL in global configuration mode. It cannot be used to add ACEs to a named IP ACL.

Add ACEs to an extended IP ACL.

Use either of the following methods to add ACEs to an extended IP ACL:

Command	[<i>sn</i>] { permit deny } <i>protocol</i> { host <i>source</i> any <i>source source-wildcard</i> } { host <i>destination</i> any <i>destination destination-wildcard</i> } [[precedence <i>precedence</i> [tos <i>tos</i>]] dscp <i>dscp</i>] [fragment] [time-range <i>time-range-name</i>] [log]
Parameter Description	<p><i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p>permit: Indicates that the ACE is a permit ACE.</p> <p>deny: Indicates that the ACE is a deny ACE.</p> <p><i>protocol</i>: Indicates the IP protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations to replace the specific IP protocol numbers, including eigrp, gre, icmp, igmp, ip, ipinip, nos, ospf, tcp, and udp.</p> <p>host source: Indicates that IP packets sent from a host with the specified source IP address are filtered.</p> <p><i>source source-wildcard</i>: Indicates that IP packets sent from hosts in the specified IP network segment are filtered.</p> <p>host destination: Indicates that IP packets sent to a host with the specified destination IP address are filtered. If the any keyword is configured, IP packets sent to any host are filtered.</p> <p><i>destination destination-wildcard</i>: Indicates that IP packets sent to hosts in a specified IP network segment are filtered.</p> <p>any: Indicates that IP packets sent to or from any host are filtered.</p> <p>precedence precedence: Indicates that IP packets with the specified precedence field in the header are filtered.</p> <p>tos tos: Indicates that IP packets with the specified the type of service (TOS) field in the header are filtered.</p> <p>dscp dscp: Indicates that IP packets with the specified the dscp field in the header are filtered.</p> <p>fragment: Indicates that only fragmented IP packets except the first fragments are filtered.</p> <p>time-range time-range-name: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p> <p>log: Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.</p>
Command Mode	Extended IP ACL configuration mode
Usage Guide	Run this command to add ACEs in extended IP ACL configuration mode. The ACL can be a named or

	numbered ACL.
--	---------------

Command	access-list <i>acl-id</i> { permit deny } <i>protocol</i> { host <i>source</i> any <i>source source-wildcard</i> } { host <i>destination</i> any <i>destination destination-wildcard</i> } [[precedence <i>precedence</i> [tos <i>tos</i>]]] [dscp <i>dscp</i>] [fragment] [time-range <i>time-range-name</i>] [log]
Parameter Description	<p><i>acl-id</i>: Indicates the ID of a numbered ACL. It uniquely identifies an ACL. The value range of <i>acl-id</i> is 100–199 and 2000–1999.</p> <p><i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p>permit: Indicates that the ACE is a permit ACE.</p> <p>deny: Indicates that the ACE is a deny ACE.</p> <p><i>protocol</i>: Indicates the IP protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations to replace the specific IP protocol numbers, including eigrp, gre, icmp, igmp, ip, ipinip, nos, ospf, tcp, and udp.</p> <p>host source: Indicates that IP packets sent from a host with the specified source IP address are filtered.</p> <p><i>source source-wildcard</i>: Indicates that IP packets sent from hosts in the specified IP network segment are filtered.</p> <p>host destination: Indicates that IP packets sent to a host with the specified destination IP address are filtered. If the any keyword is configured, IP packets sent to any host are filtered.</p> <p><i>destination destination-wildcard</i>: Indicates that IP packets sent to hosts in a specified IP network segment are filtered.</p> <p>any: Indicates that IP packets sent to or from any host are filtered.</p> <p>precedence precedence: Indicates that IP packets with the specified precedence field in the header are filtered.</p> <p>tos tos: Indicates that IP packets with the specified the type of service (TOS) field in the header are filtered.</p> <p>dscp dscp: Indicates that IP packets with the specified the dscp field in the header are filtered.</p> <p>fragment: Indicates that only fragmented IP packets except the first fragments are filtered.</p> <p>time-range time-range-name: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p> <p>log: Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.</p>
Command Mode	Extended IP ACL configuration mode
Usage Guide	Run this command to add ACEs to a numbered IP ACL in extended IP ACL configuration mode. It cannot be used to add ACEs to a named extended IP ACL.

Applying an IP ACL

Command	<code>ip access-group { acl-id acl-name } { in out } [reflect]</code>
Parameter Description	<p><i>acl-id</i>: Indicates that a numbered standard or extended IP ACL will be applied to the interface.</p> <p><i>acl-name</i>: Indicates that a named standard or extended IP ACL will be applied to the interface.</p> <p>in: Indicates that this ACL controls incoming IP packets of the interface.</p> <p>out: Indicates that this ACL controls outgoing IP packets of the interface.</p> <p>reflect: Indicates that the reflexive ACL is enabled.</p>
Command Mode	Interface/VXLAN configuration mode
Usage Guide	This command makes an IP ACL take effect on the incoming or outgoing packets of a specified interface/VXLAN.

Configuration Example

The following configuration example describes only ACL-related configurations.

Configuring an IP ACL to Prohibit Departments Except the Financial Department from Accessing the Financial Data Server

Scenario Figure 1-3	
Configuration Steps	<p>Configure an IP ACL.</p> <p>Add ACEs to the IP ACL.</p> <p>Apply the IP ACL to the outgoing direction of the interface connecting the financial data server.</p>
SW1	<pre>sw1(config)#ip access-list standard 1 sw1(config-std-nacl)#permit 10.1.1.0 0.0.0.255 sw1(config-std-nacl)#deny 11.1.1.1 0.0.0.255 sw1(config-std-nacl)#exit</pre>

	<pre>sw1(config)#int gigabitEthernet 0/3 sw1(config-if-GigabitEthernet 0/3)#ip access-group 1 out</pre>

1.4.2 Configuring an MAC Extended ACL

Configuration Effect

Configure and apply an MAC extended ACL to an interface to control all incoming and outgoing IPv4 packets of this interface. You can permit or deny the entry of specific L2 packets to a network to control access of users to network resources based on L2 packets.

Notes

N/A

Configuration Steps

Configuring an MAC Extended ACL

(Mandatory) Configure an MAC extended ACL if you want to control users' access to network resources based on the L2 packet header, for example, the MAC address of each user's PC.

You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The MAC extended ACL takes effect only on the local device, and does not affect other devices on the network.

Adding ACEs to an MAC Extended ACL

(Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, all incoming L2 Ethernet packets of the device are denied by default.

Applying an MAC extended ACL

(Mandatory) Apply an MAC extended ACL to a specified interface if you want this ACL take effect.

You can apply an MAC extended ACL on a specified interface of an access, an aggregate, or a core device based on the distribution of users.

Verification

Use the following methods to verify the configuration effects of the MAC extended ACL:

If an MAC extended ACL is configured to permit or deny some IP packets, run the **ping** command to check whether ACEs of this ACL takes effect on the specified interface. For example, an MAC extended ACL is configured to prevent a device interface from receiving IP packets (Ethernet type is 0x0800), run the **ping** command for verification.

If an MAC extended ACL is configured to permit or deny some non-IP packets (e.g. ARP packets), also run the **ping** command to check whether ACEs of this ACL takes effect on the specified interface. For example, to filter out ARP packets, run the **ping** command for verification.

You can also construct L2 packets meeting some specified characteristics to check whether the MAC extended ACL takes effect. Typically, prepare two PCs, construct and send L2 packets on one PC, enable packet capturing on another PC, and check whether packets are forwarded as expected (forwarded or blocked) according to the action specified in the ACEs.

Related Commands

Configuring an MAC Extended ACL

Command	mac access-list extended { <i>acl-name</i> <i>acl-id</i> }
Parameter Description	<i>acl-name</i> : Indicates the name of an MAC extended ACL. If this option is configured, a named ACL is created. The name is a string of 1 to 99 characters. The ACL name cannot start with numbers (0–9), "in", or "out". <i>acl-id</i> : Indicates the ID that uniquely identifies an MAC extended ACL. If this option is configured, a numbered ACL is created. The value range of <i>acl-id</i> is 700–799.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure an MAC extended ACL and enter MAC extended ACL configuration mode. You can configure an MAC extended ACL to control users' access to network resources by checking the L2 information of Ethernet packets.

Adding ACEs to an MAC Extended ACL

Use either of the following methods to add ACEs to an MAC extended ACL:

Add ACEs in MAC extended ACL configuration mode.

Command	[<i>sn</i>] { permit deny } { any host <i>src-mac-addr</i> <i>src-mac-addr mask</i> } { any host <i>dst-mac-addr</i> <i>dst-mac-addr mask</i> } [<i>ethernet-type</i>] [cos <i>cos</i> [inner <i>cos</i>]] [time-range <i>tm-rng-name</i>]
Parameter Description	<i>sn</i> : Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher

	<p>priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p>permit: Indicates that the ACE is a permit ACE.</p> <p>deny: Indicates that the ACE is a deny ACE.</p> <p>any: Indicates that L2 packets sent from any host are filtered.</p> <p>host <i>src-mac-addr</i>: Indicates that IP packets sent from a host with the specified source MAC address are filtered.</p> <p><i>src-mac-addr mask:</i> Indicates that the source MAC address is reversed.</p> <p>any: Indicates that L2 packets sent to any host are filtered.</p> <p>host <i>dst-mac-addr</i>: Indicates that IP packets sent to a host with the specified destination MAC address are filtered.</p> <p><i>dst-mac-addr mask:</i> Indicates that the destination MAC address is reversed.</p> <p><i>ethernet-type:</i> Indicates that L2 packets of the specified Ethernet type are filtered.</p> <p>cos <i>cos</i>: Indicates that L2 packets with the specified class of service (cos) field in the outer tag are filtered.</p> <p>inner <i>cos</i>: Indicates that L2 packets with the specified cos field in the inner tag are filtered.</p> <p>time-range <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p>
Command Mode	MAC extended ACL configuration mode
Usage Guide	Run this command to add ACEs in MAC extended ACL configuration mode. The ACL can be a named or numbered ACL.

Add ACEs to an MAC extended ACL in global configuration mode.

Command	access-list <i>acl-id</i> { permit deny } { any host <i>src-mac-addr</i> <i>src-mac-addr mask</i> } { any host <i>dst-mac-addr</i> <i>dst-mac-addr mask</i> } [<i>ethernet-type</i>] [cos <i>cos</i> [inner <i>cos</i>]] [time-range <i>tm-rng-name</i>]
Parameter Description	<p><i>acl-id:</i> Indicates the ID of a numbered ACL. It uniquely identifies an ACL. The value range of <i>acl-id</i> is 700–799.</p> <p>permit: Indicates that the ACE is a permit ACE.</p> <p>deny: Indicates that the ACE is a deny ACE.</p> <p>host <i>src-mac-addr</i>: Indicates that IP packets sent from a host with the specified source MAC address are filtered.</p> <p><i>src-mac-addr mask:</i> Indicates that the source MAC address is reversed.</p> <p>any: Indicates that L2 packets sent to any host are filtered.</p> <p>host <i>dst-mac-addr</i>: Indicates that IP packets sent to a host with the specified destination MAC address are filtered.</p> <p><i>dst-mac-addr mask:</i> Indicates that the destination MAC address is reversed.</p> <p><i>ethernet-type:</i> Indicates that L2 packets of the specified Ethernet type are filtered.</p> <p>cos <i>cos</i>: Indicates that L2 packets with the specified cos field in the outer tag are filtered.</p>

	<p>inner cos: Indicates that L2 packets with the specified cos field in the inner tag are filtered.</p> <p>time-range <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p>
Command Mode	Global configuration mode
Usage Guide	Run this command to add ACEs to a numbered MAC extended ACL in global configuration mode. It cannot be used to add ACEs to a named MAC extended ACL.

Applying an MAC Extended ACL

Command	mac access-group { <i>acl-id</i> <i>acl-name</i> } { in out }
Parameter Description	<p><i>acl-id</i>: Indicates that a numbered MAC extended IP ACL will be applied to the interface.</p> <p><i>acl-name</i>: Indicates that a named MAC extended IP ACL will be applied to the interface.</p> <p>in: Indicates that this ACL controls incoming L2 packets of the interface.</p> <p>out: Indicates that this ACL controls outgoing L2 packets of the interface.</p>
Command Mode	Interface configuration mode
Usage Guide	This command makes an MAC extended ACL take effect on the incoming or outgoing packets of a specified interface.

Configuration Example

The following configuration example describes only ACL-related configurations.

Configuring an MAC Extended ACL to Restrict Resources Accessible by Visitors

<p>Scenario Figure 1-4</p>	<p>The diagram shows a central switch labeled SW1. It has four interfaces: Gi 0/1, Gi 0/2, Gi 0/3, and Gi 0/4. Gi 0/3 is connected to a group of Servers, which includes a Financial Data Server (MAC:00e0.f800.000d) and a Public Server (MAC:00e0.f800.000c). Gi 0/1 is connected to a group of Employees, represented by PC1 and PC2. Gi 0/2 is connected to a group of Visitors, also represented by PC1 and PC2. Gi 0/4 is connected to the Internet, represented by a cloud icon.</p>
<p>Configuration Steps</p>	<p>Configure an MAC extended ACL.</p> <p>Add ACEs to the MAC extended ACL.</p> <p>Apply the MAC extended ACL to the outgoing direction of the interface connected to the visitor area so that</p>

1.4.3 Configuring an Expert Extended ACL

Configuration Effect

Configure and apply an expert extended ACL to an interface to control incoming and outgoing packets of the interface based on the L2 and L3 information, and allow or prohibit the entry of specific packets to the network. In addition, you can configure an expert extended ACL to control all L2 packets based on the VLAN to permit or deny the access of users in some network segments to network resources. Generally, you can use an expert extended ACL if you want to incorporate ACEs of the IP ACL and MAC extended ACL into one ACL.

Configuration Steps

Configuring an Expert Extended ACL

(Mandatory) Configure an expert extended ACL if you want to control users' access to network resources based on the L2 packet header, for example, the VLAN ID.

You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The expert extended ACL takes effect only on the local device, and does not affect other devices on the network.

Adding ACEs to an Expert Extended ACL

(Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, all incoming packets of the device are denied by default.

Applying an Expert Extended ACL

(Mandatory) Apply an expert extended ACL to a specified interface if you want this ACL take effect.

You can apply an expert extended ACL in the incoming or outgoing direction of a specified interface of an access, an aggregate, or a core device based on the distribution of users.

Verification

Use the following methods to verify the configuration effects of the expert extended ACL:

If IP-based access rules are configured in an expert extended ACL to permit or deny some IP packets, run the **ping** command to verify whether these rules take effect.

If MAC-based access rules are configured in an expert extended ACL to permit or deny some L2 packets (e.g. ARP packets), also run the **ping** command to check whether ACEs of this ACL takes effect on the specified interface. For example, to filter out ARP packets, run the **ping** command for verification.

If VLAN ID-based access rules are configured in an expert extended ACL to permit or deny some L2 packets in some network segments (e.g., to prevent communication between VLAN 1 users and VLAN 2 users), ping PCs of VLAN 2 on a PC of VLAN 1. If the ping operation fails, the rules take effect.

Related Commands

Configuring an Expert Extended ACL

Command	expert access-list extended { <i>acl-name</i> <i>acl-id</i> }
Parameter Description	<i>acl-name</i> : Indicates the name of an expert extended ACL. If this option is configured, a named ACL is created. The name is a string of 1 to 99 characters. The ACL name cannot start with numbers (0–9), "in", or "out". <i>acl-id</i> : Indicates the ID of an expert extended ACL. If this option is configured, a numbered ACL is created. The value range of <i>acl-id</i> is 2700-2899.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure an expert extended ACL and enter expert extended ACL configuration mode.

Adding ACEs to an Expert Extended ACL

Use either of the following methods to add ACEs to an expert extended ACL:

Add ACEs in expert extended ACL configuration mode.

Command	<pre>[sn] { permit deny } [protocol] [ethernet-type] [cos [out] [inner in]] [[VID [out] [inner in]]] { source source-wildcard host source any } { host source-mac-address any } { destination destination-wildcard host destination any } { host destination-mac-address any } [precedence precedence] [tos tos] [fragment] [range lower upper] [time-range time-range-name]</pre>
Parameter Description	<p>sn: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p>permit: Indicates that the ACE is a permit ACE.</p> <p>deny: Indicates that the ACE is a deny ACE.</p> <p>protocol: Indicates the IP protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations to replace the specific IP protocol numbers, including eigrp, gre, icmp, igmp, ip, ipinip, nos, ospf, tcp, and udp.</p> <p>ethernet-type: Indicates that L2 packets of the specified Ethernet type are filtered.</p> <p>cos out: Indicates that L2 packets with the specified cos field in the outer tag are filtered.</p> <p>cos inner in: Indicates that L2 packets with the specified cos field in the inner tag are filtered.</p> <p>VID out: Indicates that L2 packets with the specified VLAN ID field in the outer tag are filtered.</p> <p>VID inner in: Indicates that L2 packets with the specified VLAN ID field in the inner tag are filtered.</p> <p>source source-wildcard: Indicates that IP packets sent from hosts in the specified IP network segment are filtered.</p> <p>host source: Indicates that IP packets sent from a host with the specified source IP address are filtered.</p> <p>any: Indicates that IP packets sent from any host are filtered.</p> <p>host source-mac-address: Indicates that IP packets sent from a host with the specified source MAC address are filtered.</p> <p>any: Indicates that L2 packets sent to any host are filtered.</p> <p>destination destination-wildcard: Indicates that IP packets sent to hosts in a specified IP network segment are filtered.</p> <p>host destination: Indicates that IP packets sent to a host with the specified destination IP address are filtered.</p> <p>any: Indicates that IP packets sent to any host are filtered.</p> <p>host destination-mac-address: Indicates that IP packets sent to a host with the specified destination MAC address are filtered.</p> <p>any: Indicates that L2 packets sent to any host are filtered.</p> <p>precedence precedence: Indicates that IP packets with the specified precedence field in the header are filtered.</p> <p>tos tos: Indicates that IP packets with the specified the TOS field in the header are filtered.</p> <p>dscp dscp: Indicates that IP packets with the specified the dscp field in the header are filtered.</p> <p>fragment: Indicates that only fragmented IP packets except the first fragments are filtered.</p>

	time-range <i>time-range-name</i> : Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.
Command Mode	Expert extended ACL configuration mode
Usage Guide	Run this command to add ACEs in expert extended ACL configuration mode. The ACL can be a named or numbered ACL.

Add ACEs to an expert extended ACL in global configuration mode.

Command	access-list <i>acl-id</i> { permit deny } [<i>protocol</i> [<i>ethernet-type</i>] [cos [<i>out</i>] [<i>inner in</i>]] [[VID [<i>out</i>] [<i>inner in</i>]]] { <i>source source-wildcard</i> host source any } { host source-mac-address any } { <i>destination destination-wildcard</i> host destination any } { host destination-mac-address any } [precedence precedence] [tos tos] [fragment] [range lower upper] [time-range time-range-name]
Parameter Description	<p><i>acl-id</i>: Indicates the ID of a numbered ACL. It uniquely identifies an ACL. The value range of <i>acl-id</i> is 2700-2899.</p> <p>permit: Indicates that the ACE is a permit ACE.</p> <p>deny: Indicates that the ACE is a deny ACE.</p> <p><i>protocol</i>: Indicates the IP protocol number. The value ranges from 0 to 255. 1.4.4 Configuring an IPv6 Extended ACL

Configuration Effect

Configure and apply an IPv6 ACL to an interface/VXLAN to control all incoming and outgoing IPv5 packets of this interface/VXLAN. You can permit or deny the entry of specific IPv6 packets to a network to control access of IPv6 users to network resources.

Configuration Steps

Configuring an IPv6 ACL

(Mandatory) Configure an IP ACL if you want to access of IPv4 users to network resources.

You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The IPv6 ACL takes effect only on the local device, and does not affect other devices on the network.

Adding ACEs to an IPv6 ACL

(Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, all incoming IPv6 packets of the device are denied by default.

Applying an IPv6 ACL

(Mandatory) Apply an IPv6 ACL to a specified interface on a device if you want this ACL take effect.

You can apply an IPv6 ACL on a specified interface/VXLAN of an access, an aggregate, or a core device based on the distribution of users.

Verification

Use the following methods to verify the configuration effects of the IPv6 ACL:

Run the **ping** command to verify that the IPv6 ACL takes effect on the specified interface. For example, if an IPv6 ACL is configured to prohibit a host with a specified IP address or hosts in a specified IPv6 address range from accessing the network, run the **ping** command to verify that the host(s) cannot be successfully pinged.

Access network resources, for example, visit an IPv6 website, to check whether the IPv6 ACL takes effect on the specified interface.

Related Commands

Configuring an IPv6 ACL

Command	ipv6 access-list <i>acl-name</i>
Parameter	<i>acl-name</i> : Indicates the name of a standard or an extended IP ACL. The name is a string of 1 to 99 characters. The ACL name cannot start with numbers (0–9), "in", or "out".
Description	
Command Mode	Global configuration mode
Usage Guide	Run this command to configure an IPv6 ACL and enter IPv6 configuration mode.

Adding ACEs to an IPv6 ACL

To filter TCP or UDP packets, add ACEs to an IPv6 ACL as follows:

Command	[<i>sn</i>] {permit deny } <i>protocol</i> {<i>src-ipv6-prefix/prefix-len</i> host <i>src-ipv6-addr</i> any} {<i>dst-ipv6-pfx/pfx-len</i> host <i>dst-ipv6-addr</i> any} [<i>op dstport</i> range <i>lower upper</i>] [dscp <i>dscp</i>] [flow-label <i>flow-label</i>] [fragment] [time-range <i>tm-rng-name</i>][log]
Parameter Description	<p><i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p>permit: Indicates that the ACE is a permit ACE.</p> <p>deny: Indicates that the ACE is a deny ACE.</p> <p><i>protocol</i>: Indicates the IPv6 protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations of IPv6 protocol numbers to replace the specific IP protocol numbers, including icmp, ipv6, tcp, and udp.</p> <p><i>src-ipv6-prefix/prefix-len</i>: Indicates that IP packets sent from hosts in the specified IPv6 network segment are filtered.</p> <p>host <i>src-ipv6-addr</i>: Indicates that IPv6 packets sent from a host with the specified source IP address are filtered.</p> <p>any: Indicates that IPv6 packets sent from any host are filtered.</p> <p><i>dst-ipv6-pfx/pfx-len</i>: Indicates that IPv6 packets sent from hosts in the specified IPv6 network segment are filtered.</p> <p>host <i>dst-ipv6-addr</i>: Indicates that IPv6 packets sent to a host with the specified destination IP address are filtered.</p> <p>any: Indicates that IPv6 packets sent to any host are filtered.</p> <p><i>op dstport</i>: Indicates that TCP or UDP packets are filtered based on the L4 destination port number. The value of the op parameter can be eq (equal to), neq (not equal to), gt (greater than), or lt (smaller than).</p> <p>range <i>lower upper</i>: Indicates that TCP or UDP packets with the L4 destination port number in the specified range are filtered.</p> <p>dscp <i>dscp</i>: Indicates that IPv6 packets with the specified the dscp field in the header are filtered.</p>

	<p>flow-label <i>flow-label</i>: Indicates that IPv6 packets with the specified the flow label field in the header are filtered.</p> <p>fragment: Indicates that only fragmented IPv6 packets except the first fragments are filtered.</p> <p>time-range <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p> <p>log: Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.</p>
Command Mode	IPv6 ACL configuration mode
Usage Guide	Run this command to add ACEs in IPv6 ACL configuration mode.

To filter IPv6 packets except for the TCP or UDP packets, add ACEs to an IPv6 ACL as follows:

Command	<pre>[sn] { permit deny } protocol { src-ipv6-prefix/prefix-len host src-ipv6-addr any } { dst-ipv6-pfix/pfix-len host dst-ipv6-addr any } [dscp dscp] [flow-label flow-label] [fragment] [time-range tm-rng-name] [log]</pre>
Parameter Description	<p><i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p>permit: Indicates that the ACE is a permit ACE.</p> <p>deny: Indicates that the ACE is a deny ACE.</p> <p><i>protocol</i>: Indicates the IPv6 protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations of IPv6 protocol numbers to replace the specific IP protocol numbers, including icmp, ipv6, tcp, and udp.</p> <p><i>src-ipv6-prefix/prefix-len</i>: Indicates that IP packets sent from hosts in the specified IPv6 network segment are filtered.</p> <p>host <i>src-ipv6-addr</i>: Indicates that IPv6 packets sent from a host with the specified source IP address are filtered.</p> <p>any: Indicates that IPv6 packets sent from any host are filtered.</p> <p><i>dst-ipv6-pfix/pfix-len</i>: Indicates that IPv6 packets sent from hosts in the specified IPv6 network segment are filtered.</p> <p>host <i>dst-ipv6-addr</i>: Indicates that IPv6 packets sent to a host with the specified destination IP address are filtered.</p> <p>any: Indicates that IPv6 packets sent to any host are filtered.</p> <p>dscp <i>dscp</i>: Indicates that IPv6 packets with the specified the dscp field in the header are filtered.</p> <p>flow-label <i>flow-label</i>: Indicates that IPv6 packets with the specified the flow label field in the header are filtered.</p> <p>fragment: Indicates that only fragmented IPv6 packets except the first fragments are filtered.</p>

	<p>time-range <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p> <p>log: Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.</p>
Command Mode	IPv6 ACL configuration mode
Usage Guide	Run this command to add ACEs in IPv6 ACL configuration mode.

Applying an IPv6 ACL

Command	ipv6 traffic-filter <i>acl-name</i> { in out }
Parameter Description	<p><i>acl-name</i>: Indicates the name of an IPv6 ACL.</p> <p>in: Indicates that this ACL controls incoming IPv6 packets of the interface.</p> <p>out: Indicates that this ACL controls outgoing IPv6 packets of the interface.</p>
Command Mode	Interface configuration mode
Usage Guide	This command makes an IPv6 ACL take effect on the incoming or outgoing packets of the specified interface.

Configuration Example

Configuring an IPv6 ACL to Prohibit the R&D Department from Accessing the Video Server

<p>Scenario Figure 1-6</p>	
Configuration Steps	<p>Configure an IPv6 ACL.</p> <p>Add an ACE to the IPv6 ACL to prevent access to the video server.</p> <p>Add an ACE to the IPv6 ACL to permit all IPv6 packets.</p> <p>Apply the IPv6 ACL to the incoming direction of the interface connected to the R&D department.</p>
SW1	<pre>sw1(config)#ipv6 access-list dev_deny_ipv6video sw1(config-ipv6-nacl)#deny ipv6 any host 200::1 sw1(config-ipv6-nacl)#permit ipv6 any any</pre>

	<pre>sw1(config-ipv6-nacl)#exit sw1(config)#int gigabitEthernet 0/2 sw1(config-if-GigabitEthernet 0/2)# ipv6 traffic-filter dev_deny_ipv6video in</pre>
Verification	On a PC of the R&D department, ping the video server. Verify that the ping operation fails.
SW1	<pre>sw1(config)#show access-lists ipv6 access-list dev_deny_ipv6video 10 deny ipv6 any host 200::1 20 permit ipv6 any any sw1(config)#show access-group ipv6 traffic-filter dev_deny_ipv6video in Applied On interface GigabitEthernet 0/2</pre>

1.4.5 Configuring an ACL80

Configuration Effect

When the IP ACL, MAC extended ACL, expert extended ACL, and IPv6 ACL with fixed matching fields cannot meet requirements, configure the ACL80 to customize the packet fields that need to be matched.

Configuration Steps

Configuring an Expert Advanced ACL

(Mandatory) Configure an expert advanced ACL if you want to implement the ACL80 function. For details about how to configure the expert advanced ACL, see the related descriptions.

You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The expert advanced ACL takes effect only on the local device, and does not affect other devices on the network.

Adding ACEs to an Expert Advanced ACL

(Mandatory) Add ACEs to an expert advanced ACL to customize matching fields. If no ACE is added to the expert advanced ACL, the deny ACEs will drop all packets by default. For details about how to add an ACE to an expert advanced ACL, see the related descriptions.

Applying an Expert Advanced ACL

(Mandatory) Apply an expert advanced ACL to a specified interface if you want this ACL take effect.

You can apply an expert advanced ACL on a specified interface of an access, an aggregate, or a core device based on the distribution of users.

Verification

Use the following methods to verify the configuration effects of the expert advanced ACL:

Run the **ping** command to check whether the configurations take effect.

Construct packets matching the ACEs to check whether ACEs take effect.

Related Commands

Configuring an Expert Advanced ACL

Command	expert access-list advanced <i>acl-name</i>
Parameter Description	<i>acl-name</i> : Indicates the name of an expert advanced ACL. The name is a string of 1 to 99 characters. The ACL name cannot start with numbers (0–9), "in", or "out".
Command Mode	Global configuration mode
Usage Guide	Run this command to configure an expert advanced ACL and enter expert advanced ACL configuration mode.

Adding ACEs to an Expert Advanced ACL

Command	[<i>sn</i>] { permit deny } <i>hex hex-mask offset</i>
Parameter Description	<p><i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p>permit: Indicates that the ACE is a permit ACE.</p> <p>deny: Indicates that the ACE is a deny ACE.</p> <p><i>hex</i>: Indicates the customized matching rule expressed in hexadecimal format, for example, 00d0f800.</p> <p><i>hex-mask</i>: Indicates the matching mask.</p> <p><i>offset</i>: Indicates the start position of matching. For example, if the matching content is 00d0f800, the matching mask is 00ff0000, and start position is 6, the destination MAC address of each packet is compared. All packets whose second byte of the destination MAC address is d0 match this ACE.</p>
Command Mode	Expert advanced ACL configuration mode
Usage Guide	Run this command to add ACEs in expert advanced ACL configuration mode.

Applying an Expert Advanced ACL

Command	<code>expert access-group <i>acl-n</i> { in out }</code>
Parameter Description	<p><i>acl-id</i>: Indicates that a numbered expert advanced ACL will be applied to the interface.</p> <p><i>acl-name</i>: Indicates that a named expert advanced ACL will be applied to the interface.</p> <p>in: Indicates that this ACL controls incoming L2 packets of the interface.</p> <p>out: Indicates that this ACL controls outgoing L2 packets of the interface.</p>
Command Mode	Interface configuration mode
Usage Guide	This command makes an expert advanced ACL take effect on the incoming or outgoing packets of a specified interface.

Configuration Example

The following configuration example describes only ACL-related configurations.

Configuring an ACL80 to Restrict Resources Accessible by Visitors (It is required that visitors and employees cannot communicate with each other, visitors can access the public resource server but not the financial data server of the company.)

<p>Scenario Figure 1-7</p>	<p>The diagram illustrates a network topology. At the center is a switch labeled SW1. SW1 has four interfaces: Gi 0/1, Gi 0/2, Gi 0/3, and Gi 0/4. Gi 0/3 is connected to a group of servers, which includes a Financial Data Server (IP 10.1.1.1/24) and a Public Server (IP 10.1.1.2/24). Gi 0/1 and Gi 0/2 are connected to two separate VLANs. VLAN 2, labeled 'Employees', has an IP segment of 192.168.1.0/24 and a gateway of 192.168.1.1/24. VLAN 3, labeled 'Visitors', has an IP segment of 192.168.2.0/24 and a gateway of 192.168.2.1/24. Gi 0/4 is connected to the Internet, represented by a cloud icon.</p>
<p>Configuration Steps</p>	<p>Configure an expert advanced ACL.</p> <p>Add an ACE to deny packets sent from PCs in the visitor area (VLAN 3) to employee PCs in VLAN 2.</p> <p>Add an ACE to prevent visitors from accessing the financial data server of the company.</p> <p>Add an ACE to permit all packets.</p> <p>Apply the ACL to the incoming direction of the interface of the switch that connects to the visitor area.</p>

SW1	<pre>sw1(config)#expert access-list advanced acl80-guest sw1(config-exp-dacl)#deny C0A801 FFFFFFFF 42 sw1(config-exp-dacl)#deny 0A010101 FFFFFFFF 42 sw1(config-exp-dacl)#permit 0806 FFFF 24 sw1(config-exp-dacl)#permit 0800 FFFF 24 sw1(config-exp-dacl)#exit sw1(config)#int gigabitEthernet 0/2 sw1(config-if-GigabitEthernet 0/2)#expert access-group acl80-guest in</pre>
Verification	<p>On a visitor's PC, ping the financial data server. Verify that the ping operation fails.</p> <p>On a visitor's PC, ping the public resource server. Verify that the ping operation succeeds.</p> <p>On a visitor's PC, ping the gateway address 192.168.1.1 of an employee. Verify that the ping operation fails.</p> <p>On a visitor's PC, access the Internet, for example, visit the Baidu website. Verify that the webpage can be opened.</p>
SW1	<pre>sw1(config)#show access-lists expert access-list advanced sss 10 deny C0A801 FFFFFFFF 42 20 deny 0A010101 FFFFFFFF 42 30 permit 0806 FFFF 24 40 permit 0800 FFFF 24 expert access-group acl80-guest in Applied On interface GigabitEthernet 0/2</pre>

1.4.6 Configuring ACL Redirection

Configuration Effect

Configure the ACL redirection function on a specified interface to directly redirect specified packets on the interface to a specified port for further forwarding.

Configuration Steps

Configuring an ACL

(Mandatory) To implement ACL redirection, you must first configure an ACL, for example, an IP, MAC extended, or expert extended ACL. For details about how to configure an ACL, see the related descriptions.

You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The IPv6 ACL takes effect only on the local device, and does not affect other devices on the network.

Adding ACEs to an ACL

(Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, the ACL redirection function is not available. For details about how to add an ACE to an ACL, see the related descriptions.

Configuring ACL Redirection

(Mandatory) Enable ACL redirection on a specified interface if you want to implement ACL redirection.

You can configure the ACL redirection function on a specified interface of an access, an aggregate, or a core device based on the distribution of users.

Verification

Send packets matching ACEs on the port where ACL redirection is enabled, and then use the packet capturing software on the destination port to check whether the ACL redirection function takes effect.

Related Commands

Configuring an ACL

For details about how to configure an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

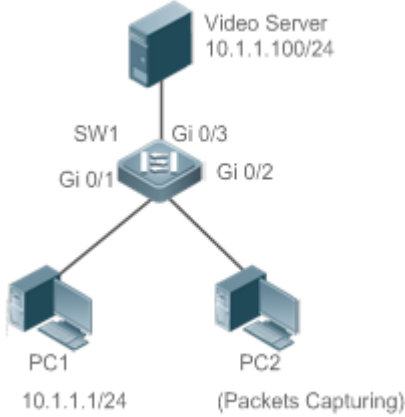

Configuring ACL Redirection

Command	redirect destination interface <i>interface-name</i> acl { <i>acl-id</i> <i>acl-name</i> } in
Parameter Description	<p>interface <i>interface-name</i>: Indicates the name of the destination port for redirection.</p> <p><i>acl-id</i>: Indicates the ID of an ACL.</p> <p><i>acl-name</i>: Indicates the name of an ACL.</p> <p>in: Indicates that incoming packets of the interface are redirected.</p>
Command Mode	Interface configuration mode
Usage Guide	Run this command to redirect incoming packets of the interface that match ACEs to the destination port for further forwarding.

Configuration Example

The following configuration example describes only ACL-related configurations.

Enabling ACL Redirection to Redirect Packets Sent from the Host 10.1.1.1 to the Packet Capturing Device for Analysis

<p>Scenario Figure 1-8</p>	
<p>Configuration Steps</p>	<p>Configures an IP ACL. Add an ACE to the IP ACL to permit packets sent from the host 10.1.1.1. Enable ACL redirection on the port GI 0/1, and set the destination port to Gi 0/2.</p>
<p>SW1</p>	<pre>sw1(config)#ip access-list standard 1 sw1 (config-std-nacl)#permit host 10.1.1.1 sw1(config-std-nacl)#exit sw1(config)#int gigabitEthernet 0/1 sw1(config-if-GigabitEthernet 0/1)# redirect destination interface gigabitEthernet 0/2 acl 1</pre>
<p>Verification</p>	<p>Capture packets on PC 2. Ping the video server on PC 1. Verify that ICMP requests sent from PC 1 are captured on PC 2.</p>
<p>SW1</p>	<pre>sw1#show access-lists ip access-list standard 1 10 permit host 10.1.1.1 sw1#show redirect interface gigabitEthernet 0/1 acl redirect configuration on interface gigabitEthernet 0/1 redirect destination interface gigabitEthernet 0/2 acl 1 in</pre>

1.4.7 Configuring a Global Security ACL

Configuration Effect

Configure a global security ACL to prevent internal PCs of a company from accessing illegal websites or prevent virus from attacking the company's internal network. You can also configure exclusive interfaces to allow specified departments of the company to access external websites.

Configuration Steps

Configuring an ACL

(Mandatory) Configure an ACL if you want to protect the internal network globally. For details about the configuration method, see the earlier descriptions about the ACL.

You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The configurations take effect only on the local device, and do not affect other devices on the network.

Adding ACEs to an ACL

(Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, it is equivalent that the global security ACL does not exist. For details about how to add an ACE to an ACL, see the related descriptions.

Configuring a Global Security ACL

(Mandatory) Enable the global security function if you want to make the global security ACL take effect.

You can configure a global security ACL on an access, an aggregate, or a core device based on the distribution of users.

Verification

On the internal network protected by the global security ACL, ping the website or device that are denied by ACEs to check whether the global security ACL takes effect.

Related Commands

Configuring an ACL

For details about the configuration method, see the earlier descriptions about the ACL.

Adding ACEs to an ACL

For details about the configuration method, see the earlier descriptions about the ACL.

Configuring a Global Security ACL

Command	{ ip mac expert } access-group <i>acl-id</i> { in out }
Parameter Description	<i>acl-id</i> : Indicates the ID of an ACL. in : Filters the incoming packets of the device. out : Filters the outgoing packets of the device.
Command Mode	Global configuration mode
Usage Guide	Run this command to enable the global security ACL so that the ACL takes effect on all L2 interfaces of the device.

Configuring an Exclusive Interface of the Global Security ACL

Command	no global ip access-group
Parameter	N/A
Description	
Command Mode	Interface configuration mode
Usage Guide	Run this command to invalidate a global security ACL on a specified interface.

Configuration Example

The following configuration example describes only ACL-related configurations.

Configuring a Global Security ACL to Prevent the R&D Department From Accessing the Server of the Sales Department but Allow the Sales Department to Access This Server

<p>Scenario Figure 1-9</p>	
<p>Configuration Steps</p>	<p>Configure an extended IP ACL "ip_ext_deny_dst_sale_server".</p> <p>Add the ACE that prevents the device to forward packets to the destination host 10.1.1.3/24.</p> <p>Configure the ACL "ip_ext_deny_dst_sale_server" as a global security ACL.</p> <p>Configure the interface directly connected to the sales department as the exclusive interface of the global security ACL.</p>
<p>SW1</p>	<pre>sw1(config)#ip access-list extended ip_ext_deny_dst_sale_server sw1(config-ext-nacl)# deny ip any host 10.1.1.3 sw1(config-ext-nacl)#exit sw1(config)#ip access-group ip_ext_deny_dst_sale_server in sw1(config)#int gigabitEthernet 0/1</pre>

	<pre>sw1(config-if-GigabitEthernet 0/1)# no global ip access-group</pre>
<p>Verification</p>	<p>On a PC of the sales department, ping the server of the sales department. Verify that the ping operation succeeds.</p> <p>On the PCs of R&D department 1 and R&D department 2, ping the server of the sales department. Verify that the ping operations fail.</p>
	<pre>sw1#show access-lists ip access-list extended ip_ext_deny_dst_sale_server 10 deny ip any host 10.1.1.3 sw1#show running ! ip access-group ip_ext_deny_dst_sale_server in ! ! ! ! ! ! ! ! ! ! interface GigabitEthernet 0/1 no global ip access-group !</pre>

1.4.8 Configuring a Security Channel

Configuration Effect

Configure a security channel to enable packets meeting the security channel rules to bypass the checks of access control applications. Configure the security channel if an access control application (such as DOT1X) is enabled on an uplink interface of a user, but the user should be allowed to log in to a website to download some resources (for example, downloading the Ruijie SU client) before the DOT1X authentication.

Configuration Steps

Configuring an ACL

(Mandatory) Configure an ACL before configuring the security channel. For details about the configuration method, see the earlier descriptions.

You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The configurations take effect only on the local device, and do not affect other devices on the network.

Adding ACEs to an ACL

(Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured for an ACL, it is equivalent that the security channel does not take effect. For details about how to add an ACE to an ACL, see the related descriptions.

Configuring a Security Channel on a Specified Interface, Globally

Configure a security channel on an interface if you want this security channel to take effect on the interface. Configure a global security channel if you want this security channel to take effect globally. You must configure either the interface-based security channel or the global security channel.

You can configure a security channel on an access, an aggregate, or a core device based on the distribution of users.

Configuring an Exclusive Interface for the Global Security Channel

(Optional) Configure an interface as the exclusive interface for the global security channel if you do not want the global security channel to take effect on this interface.

Configuring an Access Control Application

(Optional) You can enable the DOT1X or Web authentication function to verify the security channel function.

You can configure the access control function on an access, an aggregate, or a core device based on the distribution of users.

Verification

On a PC that is subject to the control of an access control application, ping the resources (devices or servers) that are allowed to bypass the check of the access control application to verify the configuration of the security channel.

Related Commands

Configuring an ACL

For details about how to configure an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

Configuring a Security Channel on an Interface

Command	security access-group { <i>acl-id</i> <i>acl-name</i> }
Parameter Description	<i>acl-id</i> : Indicates that ID of the ACL that is configured as the security channel. <i>acl-name</i> : Indicates that name of the ACL that is configured as the security channel.
Command Mode	Interface configuration mode
Usage Guide	Run this command to configure a specified ACL as the security channel on the specified interface.

Configuring a Global Security Channel

Command	security global access-group { <i>acl-id</i> <i>acl-name</i> }
Parameter Description	<i>acl-id</i> : Indicates that ID of the ACL that is configured as the security channel. <i>acl-name</i> : Indicates that name of the ACL that is configured as the security channel.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure the specified ACL as the global security channel.

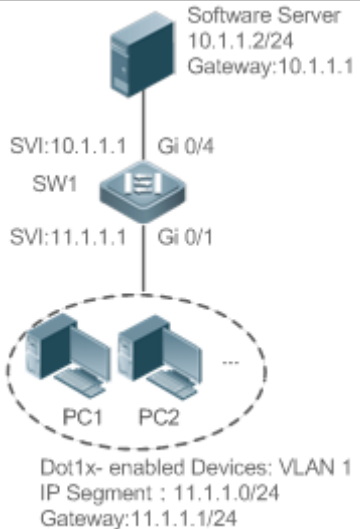

Configuring an Exclusive Interface for the Global Security Channel

Command	security uplink enable
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Run this command to configure the specified interface as the exclusive interface of the global security channel.

Configuration Example

The following configuration example describes only ACL-related configurations.

Enabling DOT1X Authentication and Configuring a Security Channel to Allow Users to Download the SU Software From the Server Before Authentication

<p>Scenario Figure 1-10</p>	 <p>Software Server 10.1.1.2/24 Gateway:10.1.1.1</p> <p>SVI:10.1.1.1 Gi 0/4 SW1</p> <p>SVI:11.1.1.1 Gi 0/1</p> <p>PC1 PC2</p> <p>Dot1x- enabled Devices: VLAN 1 IP Segment : 11.1.1.0/24 Gateway:11.1.1.1/24</p>
<p>Configuration Steps</p>	<p>Configure an expert extended ACL "exp_ext_esc".</p> <p>Add an ACE to allow forwarding packets to the destination host 10.1.1.2.</p> <p>Add an ACE to permit the DHCP packets.</p> <p>Add an ACE to permit the ARP packets.</p> <p>On the interface where DOT1X authentication is enabled, configure the ACL "exp_ext_esc" as the security channel.</p>
<p>SW1</p>	<pre>sw1(config)#expert access-list extended exp_ext_esc sw1(config-exp-nacl)# permit ip any any host 10.1.1.2 any sw1(config-exp-nacl)# permit 0x0806 any any any any any sw1(config-exp-nacl)# permit tcp any any any any eq 67 sw1(config-exp-nacl)# permit tcp any any any any eq 68 sw1(config)#int gigabitEthernet 0/1 sw1(config-if-GigabitEthernet 0/1)# security access-group exp_ext_esc</pre>
<p>Verification</p>	<p>On a PC of the sales department, ping the server of the sales department. Verify that the ping operation succeeds.</p> <p>On the PCs of R&D department 1 and R&D department 2, ping the server of the sales department. Verify that the ping operations fail.</p>
	<pre>sw1#show access-lists expert access-list extended exp_ext_esc 10 permit ip any any host 10.1.1.2 any 20 permit arp any any any any 30 permit tcp any any any any eq 67</pre>

```
40 permit tcp any any any any eq 68.....

sw1#show running-config interface gigabitEthernet 0/1

Building configuration...

Current configuration : 59 bytes

interface GigabitEthernet 0/1
 security access-group exp_ext_esc
```

1.4.9 Configuring the Time Range-Based ACEs

Configuration Effect

Configure the time range-based ACEs if you want some ACEs to take effect or to become invalid in a specified period of time, for example, in some time ranges during a week.

Configuration Steps

Configuring an ACL

(Mandatory) Configure an ACL if you want ACEs to take effect in the specified time range. For details about the configuration method, see the earlier descriptions.

You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The configurations take effect only on the local device, and do not affect other devices on the network.

Adding an ACE with the Time Range Specified

(Mandatory) Specify the time range when adding an ACE. For details about how to configure the time range, see the configuration manual related to the time range.

Applying an ACL

(Mandatory) Apply the ACL to a specified interface if you want to make ACEs take effect in the specified time range.

You can apply an IP ACL on a specified interface of an access, an aggregate, or a core device based on the distribution of users.

Verification

In the time range that the configured ACE takes effect or becomes invalid, run the **ping** command or construct packets matching the ACE to check whether the ACE takes effect or becomes invalid.

Related Commands

Configuring an ACL

For details about the ACL configuration commands, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

Adding an ACE with the Time Range Specified

For details about the ACE configuration commands, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

Applying an ACL

For details about the command for applying an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

Configuration Example

The following configuration example describes only ACL-related configurations.

Adding an ACE With the Time Range Specified to Allow the R&D Department to Access the Internet Between 12:00 and 13:30 Every Day

<p>Scenario Figure 1-11</p>	<p>R&D Dept.: VLAN 1 IP Segment: 10.1.1.0/24 Gateway: 10.1.1.1</p>
<p>Configuration Steps</p>	<p>Configure a time range named "access-internet", and add an entry of the time range between 12:00 and 13:30 every day.</p> <p>Configure an IP ACL "ip_std_internet_acl".</p> <p>Add an ACE to allow packets with the source IP address in the network segment 10.1.1.0/24, and associate this ACE with the time zone "access-internet".</p> <p>Add an ACE to deny packets with the source IP address the network segment 10.1.1.0/24. Access to the Internet is not allowed except in the specified time range.</p> <p>Add an ACE to permit all packets.</p> <p>Apply the ACL to the outgoing direction of the interface connected to the breakout gateway.</p>

SW1	<pre> Ruijie(config)# time-range access-internet Ruijie(config-time-range)# periodic daily 12:00 to 13:30 Ruijie(config-time-range)# exit sw1(config)# ip access-list standard ip_std_internet_acl sw1(config-std-nacl)# permit 10.1.1.0 0.0.0.255 time-range access-internet sw1(config-std-nacl)# deny 10.1.1.0 0.0.0.255 sw1(config-std-nacl)# permit any sw1(config-std-nacl)# exit sw1(config)#int gigabitEthernet 0/2 sw1(config-if-GigabitEthernet 0/2)# ip access-group ip_std_internet_acl out </pre>
Verification	<p>Within the time range between 12:00 and 13:30, visit the Baidu website on a PC of the R&D department. Verify that the website can be opened normally.</p> <p>Beyond the time range between 12:00 and 13:30, visit the Baidu website on a PC of the R&D department. Verify that the website cannot be opened.</p>

1.4.10 Configuring Comments for ACLs

Configuration Effect

During network maintenance, if a lot of ACLs are configured without any comments, it is difficult to distinguish these ACLs later on. You can configure comments for ACLs to better understand the intended use of ACLs.

Configuration Steps

Configuring an ACL

(Mandatory) Configure an ACL before configuring the security channel. For details about the configuration method, see the earlier descriptions.

You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The configurations take effect only on the local device, and do not affect other devices on the network.

Configuring Comments for ACLs

(Optional) Configure comments for ACLs so that it is easy to manage and understand the configured ACLs.

Adding ACEs to an ACL

(Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, it is equivalent that the security channel does not take effect. For details about how to add an ACE to an ACL, see the related descriptions.

Configuring Comments for ACEs

(Optional) To facilitate understanding of a configured ACL, you can configure comments for ACEs in addition to comments for the ACL.

Verification

Run the **show access-lists** command on the device to display the comments configured for ACLs.

Related Commands

Configuring an ACL

For details about how to configure an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

Configuring a Comment for an ACL

Use either of the following two methods to configure a comment for an ACL:

Command	<code>list-remark <i>comment</i></code>
Parameter Description	<i>comment</i> : Indicates the comment. The value is a string of 1 to 100 characters. A comment longer than 100 characters will be truncated to 100 characters.
Command	ACL configuration mode

Mode	
Usage Guide	Run this command to configure the comment for a specified ACL.

Command	access-list <i>acl-id</i> list-remark <i>comment</i>
Parameter Description	<i>acl-id</i> : Indicates the ID of an ACL. <i>comment</i> : Indicates the comment. The value is a string of 1 to 100 characters. A comment longer than 100 characters will be truncated to 100 characters.
Command Mode	Configuration mode
Usage Guide	Run this command to configure the comment for a specified ACL.

Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

Configuring Comments for ACEs

Use either of the following two methods to configure a comment for an ACE:

Command	remark <i>comment</i>
Parameter Description	<i>comment</i> : Indicates the comment. The value is a string of 1 to 100 characters. A comment longer than 100 characters will be truncated to 100 characters.
Command Mode	ACL configuration mode
Usage Guide	Run this command to configure the comment for a specified ACE.

Command	access-list <i>acl-id</i> remark <i>comment</i>
Parameter Description	<i>acl-id</i> : Indicates the ID of an ACL. <i>comment</i> : Indicates the comment. The value is a string of 1 to 100 characters. A comment longer than 100 characters will be truncated to 100 characters.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure the comment for a specified ACE.

1.5 Monitoring

Clearing

Description	Command
Clears the ACL packet matching counters.	clear counters access-list [<i>acl-id</i> <i>acl-name</i>]
Clears the counters of packets matching the deny ACEs.	clear access-list counters [<i>acl-id</i> <i>acl-name</i>]

Displaying

Description	Command
Displays the basic ACLs.	show access-lists [<i>acl-id</i> <i>acl-name</i>] [summary]
Displays the redirection ACEs bound to a specified interface. If the interface is not specified, redirection ACEs bound to all interfaces are displayed.	show redirect [interface <i>interface-name</i>]
Displays the ACL configurations applied to an interface.	show access-group [interface <i>interface-name</i>]
Displays the IP ACL configurations applied to an interface.	show ip access-group [interface <i>interface-name</i>]
Displays the MAC extended ACL configurations applied to an interface.	show mac access-group [interface <i>interface-name</i>]
Displays the expert extended ACL configurations applied to an interface.	show expert access-group [interface <i>interface-name</i>]
Displays the IPv6 ACL configurations applied to an interface.	show ipv6 traffic-filter [interface <i>interface-name</i>]

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the ACL running process.	debug acl acl-id event
Debugs the ACL clients.	debug acl acl-id client-show
Debugs the ACLs created by all ACL clients.	debug acl acl-id acl-show

2 Configuring QoS

2.1 Overview

Quality of Service (QoS) indicates that a network can provide a good service capability for specified network communication by using various infrastructure technologies.

When the network bandwidth is sufficient, all data streams can be properly processed; when network congestion occurs, all data streams may be discarded. To meet users' requirements for different applications and different levels of service quality, a network must be able to allocate and schedule resources based on users' requirements and provide different levels of service quality for different data streams. To be specific, the network can process real-time and important data packets in higher priorities, and process non-real-time and common data packets in lower priorities and even discard the data packets upon network congestion.

The "doing the best" forwarding mechanism used by traditional networks cannot meet the requirements any longer and then QoS comes into being. QoS-enabled devices provide transmission QoS quality service. A transmission priority can be assigned to data streams of a type to identify the importance of the data streams. Then, the devices provide forwarding policies for different priorities, congestion mitigation and other mechanisms to provide special transmission services for these data streams. A network environment configured with QoS can provide predictability for network performance, effectively allocate network bandwidth, and reasonably utilize network resources.

2.2 Applications

Application	Description
Interface Rate Limit + Priority Relabeling	Based on different service requirements for a campus network, provide rate control and priority-based processing for outgoing traffic of the teaching building, laboratories and dormitory building.
Priority Relabeling + Queue Scheduling	Provide priority-based processing and bandwidth control for traffic of internal access to servers of an enterprise.

2.2.1 Interface Rate Limit + Priority Relabeling

Scenario

To meet the service requirements of normal teaching, a school puts forwards the following requirements:

Control the Internet access traffic under 100M and discard packets out of control.

Control the outgoing traffic of the dormitory building under 50M and discard packets out of control.

Control the rate of packets with DSCP priority 7 sent from laboratories under 20M, and change the DSCP priorities of these packets whose rates exceed 20M to 16.

Control the outgoing traffic of the teaching building under 30M and discard packets out of control.

Figure 2-1

Remarks	A school connects GigabitEthernet 0/24 of Switch A to the Internet in the uplink and connects GigabitEthernet 0/1, GigabitEthernet 0/2 and GigabitEthernet 0/3 of Switch A to the teaching building, laboratory and dormitory building in the downlink respectively.
----------------	--

Deployment

Configure the QoS interface rate limit for the interface G0/24 of Switch A for connecting the Internet. Configure the QoS rate limit for packets sent from the dormitory building on Switch A.

Set the rate limit for packets with the DSCP priority 7 sent from the laboratory to 20M and relabel the DSCP priority of packets out of the rate limit to 16.

Configure the QoS rate limit for packets sent from the teaching building on Switch A.

2.2.2 Priority Relabeling + Queue Scheduling

Scenario

Configure priority relabeling and queue scheduling to meet the following requirements:

When the R&D department and market department access servers, the priorities of the server packets are as follows: mail server > file server > salary query server.

No matter when the HR management department accesses the Internet or servers, the switch processes the corresponding packets in the highest priority.

Since network congestion often occurs in switch running, in order to ensure smooth business operation, WRR queue scheduling must be used to schedule IP packets for the R&D and market departments to access the mail database, file database, and salary query database based on the ratio of 6:2:1.

Figure 2-2

Remarks	The R&D, market and HR management departments access the interfaces GigabitEthernet 0/1, GigabitEthernet 0/2 and GigabitEthernet 0/3 of Switch A respectively. The salary query server, mail server and file server are connected to GigabitEthernet 0/23 of Switch A.
----------------	--

Deployment

Configure the CoS values of data streams for accessing different servers to ensure that the switch processes packets for different servers in different priorities.

Set the default CoS value of the interface to a specific value to ensure that the switch processes packets sent by the HR management department in the highest priority.

Configure WRR queue scheduling to ensure that data packets are transmitted in a specific quantity ratio.

2.3 Features

Basic Concept

DiffServ

The Differentiated Services (DiffServ) Mode is an IETF system based on which QoS is implemented in Ruijie products. The DiffServ system classifies all packets transmitted in a network into different types. The classification information is included in layer-2/3 packet headers, including 802.1P, IP and IP DSCP priorities.

In a DiffServ-compliant network, all devices apply the same transmission service policy to packets containing the same classification information and apply different transmission service policies to packets containing different classification information. Classification information of packets is either assigned by hosts or other devices in the network or assigned based on different application policies or different packet contents. Based on the classification information carried by packets, a device may provide different transmission priorities for different packet streams, reserve bandwidth for a kind of packet streams, discard certain packets with lower priorities, or take some other actions.

802.1P(PRI) priority

The 802.1 P priority is located at the header of a layer-2 packet with the 802.1Q header, and is used in scenarios where layer-3 headers do not need to be analyzed and QoS needs to be implemented at layer 2. Figure 2-3 shows the structure of a layer-2 packet.

Figure 2-3

As shown in Figure 2-3, the 4-byte 802.1Q header contains 2-byte Tag Protocol Identifier (TPID) whose value is 0x8100 and 2-byte Tag Control Information (TCI). The first three bits of the TCI indicate the 802.1P priority.

IP priority (IP PRE) and DSCP priority

The priorities of IP packets are identified by the IP PRE and DSCP priority. The Type Of Service (ToS) field of the IPv4 header comprises 8 bits; where the first three bits indicate the IP precedence (IP PRE), ranging from 0 to 7. RFC 2474 redefines the ToS field of the IPv4 header, which is called the Differentiated Services (DS) field. The Differentiated Services Code Point (DSCP) priority is identified by the first 6 bits (bits 0 to 5) of the DS field, and by the first 6 bits of the Traffic Class field in the IPv6 header. Figure 2-4 shows the locations of the IP PRE and DSCP priorities in IPv4/IPv6 packets.

Figure 2-4

CoS

Class of Service (COS). Ruijie products convert packet priorities into CoS values to identify the local priorities of the packets and determine the input queue ID when packets are sent from the output interface.

Overview

Feature	Description
Stream Classification	Stream classification uses certain rules to identify packets with same characteristics and is the prerequisite and basis for distinguishing network services.
Priority Labeling and Mapping	Label packet priorities with specified values and map the values to corresponding CoS values.
Traffic Supervision	Supervise the specification of traffic flowing into a network, limit the traffic within a reasonable range, and discard the traffic out of the limit or modify the priority of the traffic.
Congestion Management	Determine the sequence of data packets sent from an interface based on the priorities of the data packets and ensure that key services can be processed in time when congestion occurs.
Congestion Mitigation	Monitor the usage of the output interface queue and reduce the network load by actively discarding packets and adjusting the network traffic when network congestion occurs.

2.3.1 Stream Classification

Stream classification uses certain rules to identify packets with same characteristics and is the prerequisite and basis for distinguishing network services. Stream classification rules are used to distinguish different packets in the network and specify different QoS parameters for packets at different service levels.

Working Principle

Stream classification rules can be matching the PRE or DSCP priorities of IP packets or classifying packets by identifying packet content through an ACL. You can define the binding between multiple streams and stream behaviors by using commands to form policies which can be applied to interfaces for stream classification and processing.

QoS policy

A QoS policy comprises three elements: class, stream behavior and policy.

Class

A class identifies streams and comprises the class name and class rules. You can define the class rules by using commands to classify packets.

Stream behavior

Stream behaviors define the QoS actions taken for packets, including priority labeling and traffic supervision for packets.

Policy

A policy binds a specific class and specific stream behaviors and comprises the policy name, names of the classes bound, and stream behaviors. You can bind a specified class and stream behaviors by using a QoS policy and apply the policy to one or more interfaces.

QoS logical interface group

You can specify a series of interfaces as a QoS logical interface group (including both APs and Ethernet interfaces) and associate policies with the logical interface group for QoS processing. Take rate limit for stream behaviors for example. For

packets that meet the rate limit conditions, all interfaces in the same logical interface group share the bandwidth specified by the policy.

Related Configuration

Creating a class

No class is defined by default.

You can run the **class-map** command to create a class and enter the class configuration mode.

Matching an ACL

No rules are defined for a class by default.

In the class configuration mode, you can run the **match access-group** command to define a class rule as matching an ACL. You need to create ACL rules first.

Matching PRE priorities of IP packets

No rules are defined for a class by default.

In the class configuration mode, you can run the **match ip precedence** command to define a class rule as matching PRE priorities of IP packets. The value range of IP PRE is 0 to 7.

Matching DSCP priorities of IP packets

No rules are defined for a class by default.

In the class configuration mode, you can run the **match ip dscp** command to define a class rule as matching DSCP priorities of IP packets. The value range of DHCP priorities is 0 to 63.

Creating a policy

No policy is defined by default.

You can run the **policy-map** command to create a policy and enter the policy configuration mode.

Associating a class

A policy is not associated with any class by default.

In the policy configuration mode, you can run the **class** command to associate a class and enter the policy-class configuration mode.

Binding a stream behavior

A class is not bound to any stream behavior by default.

In the policy-class configuration mode, you can run the **set** command to modify the CoS, DSCP or VID values of a specified stream; where, the CoS value ranges from 0 to 7, the DSCP value ranges from 0 to 63 and the VID value ranges from 1 to 4094. You can run the **police** command to limit the bandwidth and process streams out of the limit for specified streams. The bandwidth limit ranges are determined by products.

Configuring a logical interface group

No logical interface group is defined and an interface is not added to any logical interface group by default.

In the global configuration mode, you can run the **virtual-group** command to create a logical interface group. In the interface configuration mode, you can run the **virtual-group** command to add an interface to a logical interface group. If this logical interface group is not created, you can create the logical interface group and add the interface to the group. You can create 128 logical interface groups, ranging from 1 to 128.

Applying a policy to an interface

No policy is applied to an interface by default.

In the interface configuration mode, you can run the **service-policy** command to apply a policy in the input/output directions of the interface.

2.3.2 Priority Labeling and Mapping

Priorities are used to label the scheduling weights of packets or the priorities of the packets in forwarding. Different packet types have different priority types including 802.1P(PRI), IP PRE and DSCP priorities. Priority labeling and mapping refer to labeling packet priorities with specified values and mapping the values to corresponding CoS values.

Working Principle

After data streams of packets enter a device interface, the device assigns priorities to the packets based on the trust mode configured for the interface. The following describes several trust modes:

When the interface trust mode is untrust, which means not trusting the priority information carried in packets:

Modify the CoS value according to the default CoS value (0, which is configurable), COS-DSCP mapping table and DSCP-COS mapping table of the interface and put the packets into queues based on the final CoS value. For output packets carrying the 802.1Q tag, the packet priority will be modified to the corresponding CoS value.

When the interface trust mode is trusting CoS:

For packets carrying the 802.1Q tag, modify the CoS value according to the PRI value, CoS-DSCP mapping table, and DSCP-CO mapping table, and put the packets into queues based on the final CoS value. For output packets carrying the 802.1Q tag, the packet priority will be modified to the corresponding CoS value.

For packets not carrying the 802.1Q tag, modify the CoS value according to the default CoS value (0, which is configurable), COS-DSCP mapping table and DSCP-COS mapping table of the interface, and put the packets into queues based on the final CoS value. For output packets carrying the 802.1Q tag, the packet priority will be modified to the corresponding CoS value.

When the interface trust mode is trusting DSCP:

For non-IP packets, the processing is the same as that for trusting CoS.

For IP packets, modify the CoS value according to the DSCP value of the packets and the DSCP-CoS mapping table and put the packets into queues based on the final CoS value.

When the interface trust mode is trusting IP PRE:

For non-IPv4 packets, the processing is the same as that for trusting CoS.

For IPv4 packets, obtain and modify the DSCP priority of the packets according to the IP PRE value of the packets and the IP-PRE-DSCP mapping table, obtain the CoS value according to the DSCP-CoS mapping table, and then put the packets into queues based on the final CoS value.

When the trust mode and the applied policy of an interface work together:

When the trust mode and the applied policy of an interface work together, the trust mode has a lower priority than the policy and the CoS priority can be obtained according to the DSCP-CoS mapping table.

If a policy is applied to the interface but the policy does not have a configuration for modifying the DSCP and CoS values, the processing will be performed based on the trust mode of the interface.

Related Configuration

Configuring the trust mode of an interface

The default trust mode of an interface is untrust.

In the interface configuration mode, run the **mls qos trust** command to modify the trust mode. The trust mode can be trusting CoS, trusting DSCP or trusting IP PRE.

Configuring the default CoS value of an interface

The default CoS value of an interface is 0.

In the interface configuration mode, run the **mls qos cos** command to modify the default CoS value of the interface, which ranges from 0 to 7.

Labeling the priority of streams

The priorities of streams are not relabeled by default.

In the policy-class configuration mode, run the **set** command to modify the CoS, DSCP and VID values of streams. The CoS value ranges from 0 to 7; the DSCP value ranges from 0 to 63; the VID value ranges from 1 to 4094.

Configuring CoS-to-DSCP Map

By default, the CoS values 0, 1, 2, 3, 4, 5, 6 and 7 are mapped to the DSCP values 0, 8, 16, 24, 32, 40, 48 and 56 respectively.

Run the **mls qos map cos-dscp** command to configure the COS-DSCP mapping. The DSCP value ranges from 0 to 63.

Configuring DSCP-to-CoS Map

By default, DSCP 0 to 7 are mapped to CoS 0, DSCP 8 to 15 mapped to CoS 1, DSCP 16 to 23 mapped to CoS 2, DSCP 24 to 31 mapped to CoS 3, DSCP 32 to 39 mapped to CoS 4, DSCP 40 to 47 mapped to CoS 5, DSCP 48 to 55 mapped to CoS 6, and DSCP 56 to 63 mapped to CoS 7.

Run the **mls qos map dscp-cos** command to configure the DSCP-CoS mapping. The CoS value ranges from 0 to 7 and the DSCP value ranges from 0 to 63.

Configuring IP-PRE-to-DSCP Map

By default, the IP PRE values 0, 1, 2, 3, 4, 5, 6 and 7 are mapped to the DSCP values 0, 8, 16, 24, 32, 40, 48 and 56 respectively.

Run the **mls qos map ip-prec-dscp** command to configure the IP PRE-DSCP mapping. The DSCP value ranges from 0 to 63.

2.3.3 Traffic Supervision

Supervise the specification of traffic flowing into a network, limit the traffic within a reasonable range, and discard the traffic out of the limit or modify the priority of packets. In addition, the total traffic of an interface can be monitored and the traffic out of the limit will be discarded.

Working Principle

Traffic supervision is used to monitor the specification of traffic flowing into a network and conduct preset supervision actions based on different assessment results. These actions can be:

Forwarding: Normally forward packets within the traffic limit.

Discarding: discard packets out of the traffic limit.

Changing the priority and forwarding: modify the priorities of packets out of the traffic limit and then forward the packets.

Directly discard packets out of the total traffic limit of an interface.

Related Configuration

Configuring the action to be conducted for traffic out of limit

No action to be conducted for traffic out of limit is configured by default.

In the policy-class configuration mode, run the **police** command to configure the action to be conducted for traffic out of limit to discarding traffic out of limit, or modifying the CoS value or DSCP value. The traffic limit range is determined by products. When the traffic is out of the limit, you can modify the CoS value in the range of 0 to 7 and the DSCP value in the range of 0 to 63.

Configuring the total traffic limit for an interface

The total traffic limit for an interface is not configured by default.

In the interface configuration mode, run the **rate-limit** command to configure the total traffic limit for an interface in the input and output directions. The traffic limit range is determined by products.

2.3.4 Congestion Management

When the receiving rate of packets exceeds the sending rate of packets, congestion will occur on the sending interface. If no sufficient buffer is provided to store these packets, the packets may be lost. The congestion management mechanism determines the sequence of data packets to be sent from an interface based on the priorities of the data packets. The congestion management function allows for congestion control by increasing the priorities of important data packets. When congestion occurs, the important data packets are sent in higher priorities to ensure that key services are implemented in time.

Working Principle

A queue scheduling mechanism is used for congestion management and the process is as follows:

After each packet passes all QoS processing in a switch, the packet will obtain a CoS value finally.

At the output interface, the device classifies the packets into corresponding sending queues based on the CoS values.

The output interface selects packets in a queue for sending based on various scheduling policies (SP, WRR, DRR, WFQ, SP+WRR, SP+DRR and SP+WFQ).

Scheduling policy

The queue scheduling policies include SP, WRR, DRR, WFQ, SP+WRR, SP+DRR, and SP+WFQ.

Strict-Priority (SP) scheduling means scheduling packets strictly following queue IDs. Before sending packets each time, check whether a queue with the first priority has packets to be sent. If yes, the packets in this queue are sent first. If not, check whether a queue with the second priority has packets. Follow the same rules for packets in other queues.

Weighted Round Robin (WRR) scheduling means scheduling queues in turn to ensure that all queues have certain service time. For example, a 1000 Mbps interface has 8 output queues. The WRR configures a weighted value (5, 5, 10, 20, 20, 10, 20 and 10, which indicate the proportions of obtained resources) for each queue. This scheduling method ensures that a queue with the lowest priority is assigned with at least 50 Mbps bandwidth, which avoids that packets in the queue with the lowest priority are not served for long time when the SP scheduling method is used.

Deficit Round Robin (DRR) scheduling is similar to the WRR, but applies weight values based on bytes, but not based on time slices.

Weighted Fair Queueing (WFQ) scheduling provides dynamic and fair queuing and applies weighted values based on bytes, similar to the DRR. When encountering an empty queue, the DRR will shift to the next queue for transmission immediately. If a queue misses its transmission time, the queue must wait for the next time, which is the difference between the WFQ and DRR; therefore, the WFQ is more suitable for processing data packets with variable lengths than the DRR.

SP+WRR scheduling means configuring the SP scheduling for one or more sending queues and configuring the WRR scheduling for the other queues. Among SP queues, only after all packets in the SP queue with the first priority are sent, the packets in the SP queue with the second priority can be sent. Among SP and WRR queues, only after the packets in all SP queues are sent, the packets in WRR queues can be sent.

SP+DRR scheduling means configuring the SP scheduling for one or more sending queues and configuring the DRR scheduling for the other queues. Among SP queues, only after all packets in the SP queue with the first priority are sent, the packets in the SP queue with the second priority can be sent. Among SP and DRR queues, only after the packets in all SP queues are sent, the packets in DRR queues are sent.

SP+WFQ scheduling means configuring the SP scheduling for one or more sending queues and configuring the WFQ scheduling for the other queues. Among SP queues, only after all packets in the SP queue with the first priority are sent, the packets in the SP queue with the second priority can be sent. Among SP and WFQ queues, only after the packets in all SP queues are sent, the packets in WFQ queues can be sent.

QoS multicast queue

On some products, interface queues are classified into unicast queues and multicast queues. There are 8 unicast queues. All known unicast packets enter corresponding unicast queues for forwarding based on their priorities. There are 1 to 8 multicast queues (depending on products. Certain products do not support multicast queues). Except for known unicast packets, all packets (such as broadcast packets, multicast packets, unknown unicast packets, and mirroring packets) enter corresponding multicast queues for forwarding based on their priorities. Similar to unicast queues, you can configure priority mappings and scheduling algorithms for multicast queues. The **Cos-to-Mc-Queue** command can be used to configure mapping from priorities to multicast queues. At present, multicast queues support the SP, WRR and SP+WRR scheduling algorithms.

Scheduling policy and round robin weight for output queues on an interface

The scheduling policies and round robin weight for output queues are based on global configurations. Some products support both global configurations and interface-based configurations. Interface-based configurations have higher priorities than global configurations. The global scheduling policy works with the corresponding global round robin weight whereas the interface scheduling policy works with the interface round robin weight. If only the global scheduling policy or interface scheduling policy is configured but no corresponding round robin weights are configured, the default round robin weights will work with the scheduling policy.

Queue bandwidth

Some products allow for configuring the guaranteed minimum bandwidth and the limited maximum bandwidth for a queue. A queue configured with the guaranteed minimum bandwidth ensures that the bandwidth for this queue is not smaller than the configured value. A queue configured with the limited maximum bandwidth ensures that the bandwidth for this queue is not greater than the configured value and packets out of the bandwidth limit will be discarded. The bandwidth limits for unicast and multicast queues are configured together on some products whereas configured separately on some other products. In addition, some products allow for configuring bandwidth only for unicast queues.

Related Configuration

Configuring CoS-to-Queue Map

By default, the CoS values 0, 1, 2, 3, 4, 5, 6 and 7 are mapped to the queues 1, 2, 3, 4, 5, 6, 7 and 8 respectively.

Run the **priority-queue cos-map** command to configure the CoS-to-queue mapping. The CoS value ranges from 0 to 7 and the queue value ranges from 1 to 8.

Configuring the scheduling policy for an output queue

By default, the scheduling policy for a output queue is WRR.

Run the **mls qos scheduler** command to configure the output scheduling policy for a queue. Configurable scheduling policies include SP, RR, WRR, DRR and WFQ. You can also run the **priority-queue** command to configure the scheduling policy as SP.

Configuring the round robin weight corresponding to the WRR scheduling policy for an output queue

By default, the weight of a global queue is 1:1:1:1:1:1:1:1.

Run the **wrr-queue bandwidth** command to configure the round robin weight corresponding to the WRR scheduling policy for an output queue. The configurable weight range is determined by products.

A higher weight means longer output time.

Configuring the round robin weight corresponding to the DRR scheduling policy for an output queue

By default, the weight of a global queue is 1:1:1:1:1:1:1.

Run the **dr-queue bandwidth** command to configure the round robin weight corresponding to the DRR scheduling policy for an output queue. The configurable weight range is determined by products.

A higher weight means more packet bytes that can be sent.

Configuring the round robin weight corresponding to the WFQ scheduling policy for an output queue

By default, the weight of a global queue is 1:1:1:1:1:1:1.

Run the **wfq-queue bandwidth** command to configure the round robin weight corresponding to the WFQ scheduling policy for an output queue. The configurable weight range is determined by products.

A higher weight means more packet bytes that can be sent.

Configuring the bandwidth for a queue

Run the **qos queue** command to configure the guaranteed minimum bandwidth and the limited maximum bandwidth for each queue. The queue value ranges from 1 to 8 and the guaranteed minimum bandwidth and limited maximum bandwidth value ranges are determined by products. Supported queue types (unicast, multicast, or both unicast and multicast) are determined by products.

2.3.5 Congestion Mitigation

Monitor the usage of the output interface queue and reduce the network load by actively discarding packets and adjusting the network traffic when network congestion occurs.

Working Principle

Mitigate congestion by effectively monitoring the network traffic and forecasting occurrence of congestion. Packets need to be discarded to mitigate congestion. Discarding policies include Tail-Drop, Random Early Detection (RED), and Weighted Random Early Detection (WRED).

Tail-Drop

Traditional packet loss policies include Tail-Drop. Tail-Drop is effective for all traffic and cannot distinguish service levels. When congestion occurs, data packets at the tail of a queue will be discarded until the congestion is removed.

RED and WRED

Hosts running TCP will decrease the rate of sending packets to respond to massive packet loss. After congestion is removed, the hosts increase the rate of sending packets. In this way, Tail-Drop may cause TCP Global Synchronization. When a queue discards multiple TCP packets simultaneously, multiple TCP connections enter the congestion mitigation and slow startup

state simultaneously, and the traffic is reduced and adjusted. When congestion is removed, traffic peaks may appear. The process repeats constantly, the network traffic goes up and down suddenly, and the line traffic always fluctuates between the lowest quantity and the highest quantity. When TCP global synchronization occurs, the connection bandwidth cannot be adequately used, which causes bandwidth waste.

To avoid this circumstance, you can use the RED/WRED packet discarding policy. This policy provides a mechanism for discarding packets in random, which avoids TCP global synchronization. When packets of a TCP connection are discarded and sent at a lower rate, packets of other TCP connections are still sent at higher rates. In this way, there are always some TCP connections whose packets are sent at higher rates, which increases the utilization of line bandwidth.

When WRED is used, you can set the lower threshold value and maximum discarding probability for a queue. When the queue length is smaller than the lower threshold value (value range: 1 to 100), WRED does not discard packets. When the queue length is between the higher (100) and lower threshold values, WRED discards packets in random (the longer the queue length, the higher probability of packet discarding. There is a maximum discarding probability). When the queue length is greater than the higher threshold value, WRED discards packets at the maximum discarding probability.

Different from RED, WRED uses priorities to distinguish discarding policies. RED is a special example of WRED. When all CoS values of an interface are mapped to the same lower and higher threshold values, WRED becomes RED.

Related Configuration

Enabling the WRED function

The default packet discarding policy is Tail-Drop.

You can run the **queueing wred** command to enable the WRED function.

Configuring the lower threshold value

When 2 groups of lower threshold values are supported, the default values are 100 and 80 (the number of threshold value groups are determined by products).

In the interface configuration mode, you can run the **wrr-queue random-detect min-threshold** command to configure the lower threshold values for packets discarded by WRED in each queue. The queue value ranges from 1 to 8. The lower threshold value ranges from 1 to 100.

When the queue length is smaller than the lower threshold value, WRED does not discard packets. When the queue length is between the lower and higher threshold values, WRED discards packets in random.

Configuring the maximum discarding probability

When 2 groups of maximum discarding probabilities are supported, the default values are 100 and 80 (the number of threshold value groups are determined by products).

In the interface configuration mode, you can run the **wrr-queue random-detect probability** command to configure the maximum discarding probabilities for packets discarded by WRED in each queue. The queue value ranges from 1 to 8. The maximum discarding probability ranges from 1 to 100.

When the queue length is between the lower and higher threshold value, WRED discards packets in random. The longer the queue, the higher the discarding probability will be. The maximum discarding probability cannot be exceeded. When the queue length is greater than the higher threshold value, WRED discards packets at the maximum discarding probability.

Configuring the CoS-to-threshold mapping

By default, all CoS values are mapped to the first group of threshold values (the number of threshold groups is determined by products).

In the interface configuration mode, you can run the **wrr-queue cos-map** command to configure the CoS-to-threshold group mapping. The CoS value ranges from 0 to 7 and the number of threshold groups is determined by products. Multiple groups of lower threshold values and maximum discarding probabilities can be configured. By configuring the CoS-to-threshold group mapping, you can select the effective threshold group mapped to a CoS value, for example, CoS 0 mapped to the first threshold group, and CoS 1 mapped to the second threshold group. If the packets of CoS 0 and 1 are added to queue 1 for scheduling, the packets of CoS 0 are processed based on the lower threshold values and maximum discarding probabilities in the first group and the packets of CoS 1 are processed based on the lower threshold values and maximum discarding probabilities of the second group.

When all CoS values of an interface are mapped to the same group of threshold values, the enabled WRED becomes RED.

2.4 Configuration

Configuration	Description and Command	
Configuring Stream Classification_	(Optional) It is used to create stream classification information.	
	class-map	Creates a class.
	match access-group	Matches ACL rules.
	match ip precedence	Matches the PRE priorities of IP packets.
	match ip dscp	Matches the DSCP priorities of IP packets.
	policy-map	Creates a policy.
	class	Associates a class.
	police	Binds the bandwidth limit for streams and the action for processing packets out of the limit.
	set	Binds the behaviors for modifying the CoS, DSCP and VID values of streams.
	virtual-group	Creates a logical interface group and adds interfaces to the logical interface group.
service-policy	Applies a policy to an interface.	
Configuring Priority Labeling and Mapping for Packets	(Optional) It is used to configure the trust mode, default CoS value and various mappings for an interface.	
	mls qos trust	Modifies the trust mode of an interface.

Configuration	Description and Command	
	mls qos cos	Modifies the default CoS value of the interface.
	mls qos map cos-dscp	Configures the CoS-to-DSCP mapping.
	mls qos map dscp-cos	Configures the DSCP-to-CoS mapping.
	mls qos map ip-precedence-dscp	Configures the IP PRE-to-DSCP mapping.
Configuring Interface Rate Limit	(Optional) It is used to configure the rate limit for an interface.	
	rate-limit	Configures the traffic limit for an interface.
Configuring Congestion Management	(Optional) It is used to configure the CoS-to-queue mapping, queue scheduling policies and round robin weight.	
	priority-queue cos-map	Configures the CoS-to-queue mapping.
	priority-queue	Configures the output scheduling policy for a queue to SP.
	mls qos scheduler	Configures the output scheduling policy for a queue.
	wrr-queue bandwidth	Configures the round robin weight corresponding to the WRR scheduling policy for an output queue.
	drr-queue bandwidth	Configures the round robin weight corresponding to the DRR scheduling policy for an output queue.
	wfq-queue bandwidth	Configures the round robin weight corresponding to the WFQ scheduling policy for an output queue.
	qos mc-queue cos-map	Configures the CoS-to-multicast queue mapping.
	qos mc-queue scheduler mode	Configures the output scheduling policy for a multicast queue.
	qos mc-queue scheduler weight	Configures the round robin weight corresponding to the WRR scheduling policy for a multicast output queue.
qos queue bandwidth	Configures the guaranteed minimum bandwidth and limited maximum bandwidth for a queue.	
	qos queue ecn	Enables the queue ECN function.
Configuring Congestion Mitigation	(Optional) It is used to prevent network congestion by setting packet discarding.	
	queueing wred	Enables the WRED function.

Configuration	Description and Command	
	wrr-queue random-detect min-threshold	Configures the lower threshold value for packets discarded by WRED.
	wrr-queue random-detect probability	Configures the maximum discarding probability for packets discarded by WRED.
	wrr-queue cos-map	Configures the threshold-to-CoS mapping.

2.4.1 Configuring Stream Classification

Configuration Effect

Create a class and match classification rules.

Create a policy, bind a class and stream behaviors, and associate with an interface.

Notes

The class and policy names cannot comprise more than 31 characters.

Interface configurations allow for only AP and Ethernet interface configurations. Certain products support policies applied to SVI interfaces through the **service-policy** command. When both physical interfaces and SVI interfaces are configured with policies, the priority of the physical interfaces is higher than that of the SVI interfaces.

Configuration Steps

Creating a class and matching ACL rules

Optional.

Create a class. In the class configuration mode, match ACL, IP PRE or DSCP.

Creating a policy

Optional.

Create a policy. In the policy configuration mode, bind the class and stream behaviors.

Creating a logical interface group and adding interfaces to the logical interface group

Optional.

Create a logical interface group and add interfaces to the logical interface group.

Applying a policy to an interface

Optional.

Associate a configured policy with a specified interface or logical interface group.

Verification

Run the **show class-map** command to check whether the class is successfully created and whether rules are successfully matched.

Run the **show policy-map** command to check whether the policy is successfully created and whether the class and stream behaviors are successfully bound.

Run the **show mls qos interface** command to check whether the interface is associated with the policy.

Run the **show virtual-group** command to check the interfaces in the logical interface group.

Run the **show mls qos virtual-group** command to check whether the logical interface group is associated with the policy.

Related Commands

Creating a class

Command	class-map <i>class-map-name</i>
Parameter Description	<i>class-map-name</i> : Indicates the name of a class to be created. The name cannot comprise more than 31 characters.
Command Mode	Global configuration mode
Usage Guide	-

Matching an ACL

Command	match access-group <i>access-list-number</i>
Parameter Description	<i>access-list-number</i> : Indicates the number of the ACL to be matched.
Command Mode	Class configuration mode
Usage Guide	-

Matching PRE of IP packets

Command	match ip precedence <i>precedence-value... [precedence-value...]</i>
Parameter Description	<i>precedence -value</i> : Indicates the IP PRE to be matched, ranging from 0 to 7.
Command Mode	Class configuration mode
Usage Guide	-

Matching DSCP of IP packets

Command	match ip dscp <i>dscp-value... [dscp-value...]</i>
Parameter Description	<i>dscp -value</i> : Indicates the DSCP to be matched, ranging from 0 to 63.
Command Mode	Class configuration mode
Usage Guide	-

Creating a policy

Command	policy-map <i>policy-map-name</i>
Parameter Description	<i>policy-map-name</i> : Indicates the name of a policy to be created. The name cannot comprise more than 31 characters.
Command Mode	Global configuration mode
Usage Guide	-

Associating a class

Command	class <i>class-map-name</i>
Parameter Description	<i>class-map-name</i> : Indicates the name of a class to be associated.
Command Mode	Policy configuration mode
Usage Guide	-

Binding the behaviors for modifying the CoS, DSCP and VID values of streams

Command	set { ip dscp <i>new-dscp</i> cos <i>new-cos</i> vid <i>new-vid</i> }
Parameter Description	ip dscp <i>new-dscp</i> : Changes the DSCP value of streams to <i>new-dscp</i> , ranging from 0 to 63. cos <i>new-cos</i> : Changes the CoS value of streams to <i>new-cos</i> , ranging from 0 to 7. vid <i>new-vid</i> : Changes the VLAN ID of streams to <i>new-vid</i> , ranging from 1 to 4094.
Command Mode	Class configuration mode
Usage Guide	-

Binding the bandwidth limit for streams and the action for processing packets out of the limit

Command	police <i>rate-bps</i> <i>burst-byte</i> [exceed-action { drop dscp <i>new-dscp</i> cos <i>new-cos</i> [none-tos] }]
Parameter Description	<i>rate-bps</i> : Indicates the bandwidth limit per second (KBits). The value range is determined by products. <i>burst-byte</i> : Indicates the burst traffic limit (Kbytes). The value range is determined by products. drop : Discards packets out of the bandwidth limit. dscp <i>new-dscp</i> : Changes the DSCP value of packets out of the bandwidth limit to <i>new-dscp</i> , ranging from 0 to 63. cos <i>new-cos</i> : Changes the CoS value of packets out of the bandwidth limit to <i>new-cos</i> , ranging from 0 to 7. none-tos : Does not change the DSCP value of packets when changing the CoS value of the packets.
Command Mode	Class configuration mode
Usage Guide	-

Creating a logical interface group and adding interfaces to the logical interface group

Command	virtual-group <i>virtual-group-number</i>
Parameter	<i>virtual-group-number</i> : Indicates the logical interface group number, ranging from 1 to 128.

Description	
Command Mode	Create the logical interface group in the global configuration mode, add the interface to the logical interface group in the interface configuration mode. If no logical interface group exists, you need to create a logical interface group first and then add interfaces to the logical interface group.
Usage Guide	-

Applying a policy to an interface

Command	service-policy { input output } <i>policy-map-name</i>
Parameter Description	input: Indicates the input direction of the interface. output: Indicates the output direction of the interface. <i>policy-map-name:</i> Indicates the name of the policy applied to the interface.
Command Mode	Interface configuration mode
Usage Guide	-

Configuration Example

Creating four stream classes and matching ACL, IP PRE and DSCP

Configuration Steps	Create ACL rules. Create four stream classes and match ACL, IP PRE and DSCP.
	<pre>Ruijie# configure terminal Ruijie(config)# access-list 11 permit host 192.168.23.61</pre>
	<pre>Ruijie(config)# class-map cmap1 Ruijie(config-cmap)# match access-group 11 Ruijie(config-cmap)# exit Ruijie(config)# class-map cmap2 Ruijie(config-cmap)# match ip dscp 21 Ruijie(config-cmap)# exit Ruijie(config)# class-map cmap3 Ruijie(config-cmap)# match ip precedence 5 Ruijie(config-cmap)# exit</pre>
Verification	Check whether the created ACL rules and stream class rules are successful.
	<pre>Ruijie# show access-lists ip access-list standard 11 10 permit host 192.168.23.61</pre>

```
Ruijie# show class-map
Class Map cmap1
  Match access-group 11
Class Map cmap2
  Match ip dscp 21
Class Map cmap3
  Match ip precedence 5
```

Creating a policy, binding a class and stream behaviors, and associating with an interface

<p>Configuration Steps</p>	<p>Create the stream class cmap1, and match packets whose DSCP value is 18. Create cmap2 and match packets whose IP PRE is 7.</p> <p>Create the policy pmap1, associate the policy with cmap1, and bind the behavior of changing the CoS value of the stream to 6. Associate the policy with cmap2, bind the behavior of changing the DSCP value of the stream to 16, limiting the traffic per second within 10,000 Kbits and trigger traffic within 1024 Kbits per second, and changing the DSCP value for traffic out of limit to 7.</p> <p>Apply the policy pmap1 to the output direction of the interface gigabitEthernet 0/0.</p> <p>Create virtual logical group 1, add the interfaces gigabitEthernet 0/1 and gigabitEthernet 0/2 to the group, and apply the policy pmap1 to the input interface of the virtual logical group.</p>
	<pre>Ruijie# configure terminal Ruijie(config)# class-map cmap1 Ruijie(config-cmap)# match ip dscp 18 Ruijie(config-cmap)# exit Ruijie(config)# class-map cmap2 Ruijie(config-cmap)# match ip precedence 7 Ruijie(config-cmap)# exit</pre>
	<pre>Ruijie(config)# policy-map pmap1 Ruijie(config-pmap)# class cmap1 Ruijie(config-pmap-c)# set cos 6 Ruijie(config-pmap-c)# exit Ruijie(config-cmap)# class cmap2 Ruijie(config-pmap-c)# set ip dscp 15 Ruijie(config-pmap-c)# police 10000 1024 exceed-action dscp 7 Ruijie(config-pmap-c)# exit</pre>

	<pre>Ruijie(config-pmap)# exit</pre>
	<pre>Ruijie(config)# interface gigabitEthernet 0/0 Ruijie(config-if-GigabitEthernet 0/0)# service-policy output pmap1 Ruijie(config-if-GigabitEthernet 0/0)# exit</pre>

Verification	<p>Check whether the stream class rules are successfully created.</p> <p>Check whether the policy is successfully created, and whether the stream and stream behaviors are successfully bound.</p> <p>Check whether the policy is applied to the interface.</p> <p>Check whether the logical interface group is successfully created, whether interfaces are successfully associated and whether the policy is successfully applied to the interface.</p>
	<pre>Ruijie# show class-map Class Map cmap1 Match ip dscp 18 Class Map cmap2 Match ip precedence 7</pre>
	<pre>Ruijie# show policy-map Policy Map pmap1 Class cmap1 set cos 6 Class cmap2 set ip dscp 15 police 10000 1024 exceed-action dscp 7</pre>

<pre>Ruijie# show mls qos interface gigabitEthernet 0/0 Interface: GigabitEthernet 0/0 Ratelimit input: Ratelimit output: Attached input policy-map: Attached output policy-map: pmap1 Default trust: none Default cos: 0</pre>
<pre>Ruijie# show virtual-group 1 virtual-group member ----- - 1 Gi0/1 Gi0/2 Ruijie# show mls qos virtual-group 1 Virtual-group: 1 Attached input policy-map: pmap1</pre>

2.4.2 Configuring Priority Labeling and Mapping for Packets

Configuration Effect

Configure the trust mode and default CoS value of an interface.

Configure the CoS-to-DSCP, DSCP-to-CoS, and IP-PRE-to-DSCP mappings.

Notes

Interface configurations allow for only AP and Ethernet interface configurations.

Configuration Steps

Configuring the trust mode and default CoS value of an interface

Optional.

In the interface configuration mode, configure the trust mode and default CoS value of an interface.

Configuring the CoS-to-DSCP, DSCP-to-CoS, and IP-PRE-to-DSCP mappings

Optional.

Configure various mappings.

Verification

Run the **show mls qos interface** command to display the trust mode and default CoS value of the interface.

Run the **show mls qos maps** command to display the CoS-to-DSCP, DSCP-to-CoS and IP-PRE-to-DSCP mappings.

Related Commands

Configuring the trust mode of an interface

Command	mls qos trust { cos ip-precedence dscp }
Parameter	cos: Configures the trust mode of an interface to CoS.
Description	ip-precedence: Configures the trust mode of an interface to IP PRE. dscp: Configures the trust mode of an interface to DSCP.
Command Mode	Interface configuration mode
Usage Guide	-

Configuring the default CoS value of an interface

Command	mls qos cos default-cos
Parameter	<i>default-cos:</i> Configures the default CoS value, ranging from 0 to 7. The default value is 0.
Description	
Command Mode	Interface configuration mode
Usage Guide	-

Configuring CoS-to-DSCP MAP

Command	mls qos map cos-dscp dscp1...dscp8
Parameter	<i>dscp1...dscp8:</i> Indicates the DSCP values mapped to the CoS values. The default CoS values 0~7 are mapped to DSCP 0, 8, 16, 24, 32, 40, 48 and 56 respectively. The DSCP value ranges from 0 to 63.
Description	
Command Mode	Global configuration mode
Usage Guide	-

Configuring DSCP-to-CoS MAP

Command	mls qos map dscp-cos dscp-list to cos
Parameter	<i>dscp-list:</i> Indicates the DSCP list mapped to the CoS values. The default DSCP 0~7 are mapped to CoS 0, DSCP 8~15 mapped to CoS 1, DSCP 16~23 mapped to CoS 2, DSCP 24~31 mapped to CoS 3, DSCP 32~39 mapped to CoS 4, DSCP 40~47 mapped to CoS 5, DSCP 48~55 mapped to CoS 6, and DSCP 56~63 mapped to CoS 7. The DSCP value ranges from 0 to 63.
Description	<i>cos:</i> Indicates the CoS values mapped to the dscp-list, ranging from 0 to 7.
Command Mode	Global configuration mode
Usage Guide	-

Configuring IP-PRE-to-DSCP MAP

Command	<code>mls qos map ip-prec-dscp dscp1...dscp8</code>
Parameter	<i>dscp1...dscp8</i> : Indicates the DSCP values mapped to the IP PRE values. The default IP PRE 0~7 are mapped to DSCP 0, 8, 16, 24, 32, 40, 48 and 56 respectively. The DSCP value ranges from 0 to 63.
Description	
Command Mode	Global configuration mode
Usage Guide	-

Configuration Example

Configuring the trust mode and default CoS value of an interface

Configuration Steps	<p>Modify the trust mode of the interface gigabitEthernet 0/0 to DSCP.</p> <p>Change the default CoS value of the interface gigabitEthernet 0/1 to 7.</p>

2.4.3 Configuring Interface Rate Limit

Configuration Effect

Configure the traffic limit for an interface.

Notes

The configuration is supported only by Ethernet and aggregate interfaces.

Configuration Steps

Configuring the traffic limit for an interface

Optional.

Configure the limit on the traffic and burst traffic for an interface.

Verification

Run the **show mls qos rate-limit** command to display the rate limit information about the interface.

Related Commands

Configuring the traffic limit for an interface

Command	rate-limit { input output } bps burst-size
Parameter Description	input: Indicates the input direction of the interface. output: Indicates the output direction of the interface. <i>bps:</i> Indicates the bandwidth limit per second (Kbits). The value range is determined by products. <i>burst-size:</i> Indicates the burst traffic limit (Kbytes). The value range is determined by products.
Command Mode	Interface configuration mode
Usage Guide	-

Configuration Example

Typical application – Interface rate limit + priority relabeling

Configuration Steps	<p>For Internet access by using the output interface, configure the output traffic limit on the interface G0/24, and set the bandwidth limit to 102,400 Kbits per second and burst traffic limit to 256 Kbytes per second.</p> <p>For the dormitory building, configure the input traffic limit on the interface G0/3, and set the bandwidth limit to 51,200 Kbits per second and burst traffic limit to 256 Kbytes per second.</p> <p>For the teaching building, configure the input traffic limit on the interface G0/1, and set the bandwidth limit to 30,720 Kbits per second and burst traffic limit to 256 Kbytes per second.</p> <p>For the laboratory, create the class cmap_dscp7 to match DSCP priority 7, create the policy pmap_shiyan to associate with cmap_dscp7, bind the stream behavior of changing the DSCP value for packets whose rates exceed 20M to 16, apply pmap_shiyan to the interface G0/2, and configure the interface to trusting DSCP.</p>
	<pre>Ruijie# configure terminal Ruijie(config)# interface gigabitEthernet 0/24 Ruijie(config-if-GigabitEthernet 0/24# rate-limit output 102400 256</pre>

2.4.4 Configuring Congestion Management

Configuration Effect

Configure the CoS-to-queue mapping.

Configure the scheduling policy and round robin weight for an output queue.

Configure the guaranteed minimum bandwidth and limited maximum bandwidth for a queue.

Notes

Interface configurations allow for only AP and Ethernet interface configurations.

Configuration Steps

Configuring the guaranteed minimum bandwidth and limited maximum bandwidth for a queue

Optional.

Configure the guaranteed minimum bandwidth and limited maximum bandwidth for a queue.

Verification

Run the **show mls qos queueing** command to display the output queue information.

Run the **show mls qos scheduler** command to display the scheduling policy for the output queue.

	value 0 indicates that the queue uses the SP scheduling algorithm. The default weight for global/interface queues is 1:1.
Command Mode	Global configuration mode
Usage Guide	-

Configuring the guaranteed minimum bandwidth and limited maximum bandwidth for a queue

Command	qos queue <i>queue-id</i> bandwidth { minimum maximum } <i>bandwidth</i>
Parameter Description	<i>queue-id</i> : Indicates the queue ID to be configured, ranging from 1 to 8. minimum bandwidth : Indicates the guaranteed minimum bandwidth Kbps. The value range is determined by products. It is not configured by default. maximum bandwidth : Indicates the limited maximum bandwidth Kbps. The value range is determined by products. It is not configured by default.
Command Mode	Interface configuration mode
Usage Guide	-

Configuration Example

Configuring the CoS-to-queue mapping and modifying the scheduling policy and its round robin weight

Configuration Steps	Configure the CoS-to-queue mapping to the mapping from the CoS values 0, 1, 2, 3, 4, 5, 6, and 7 to queues 1, 2, 5, 5, 5, 5, 7, and 8. Configure the output scheduling policy for a queue to DRR and the round robin weight to 2:1:1:1:6:6:6:8.
	<pre>Ruijie# configure terminal Ruijie(config)# priority-queue cos-map 5 2 3 4 5 Ruijie(config)# mls qos scheduler drr Ruijie(config)# drr-queue bandwidth 2 1 1 1 6 6 6 8</pre>
Verification	Check whether the CoS-to-queue mapping is successfully created, and whether the output scheduling policy and round robin weight are successfully configured for the queue.

Configuring the guaranteed minimum bandwidth and limited maximum bandwidth for a queue

Configuration Steps	Configure the limited maximum bandwidth to 10M and guaranteed minimum bandwidth to 5M for queue 1 on the interface gigabitEthernet 0/1. Configure the guaranteed minimum bandwidth to 2M for queue 2.
	<pre> Ruijie# configure terminal Ruijie(config)# interface gigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)# qos queue 1 bandwidth maximum 10240 Ruijie(config-if-GigabitEthernet 0/1)# qos queue 1 bandwidth minimum 5120 Ruijie(config-if-GigabitEthernet 0/1)# qos queue 2 bandwidth minimum 2048 Ruijie(config-if-GigabitEthernet 0/1)# exit </pre>
Verification	Check whether the guaranteed minimum bandwidth and limited maximum bandwidth are successfully configured for the interface.

Typical application – Priority relabeling + queue scheduling

Configuration Steps	<p>Create ACLs for accessing various servers and create classes for matching these ACLs.</p> <p>Create policies for associating with the classes and specify new CoS values for packets accessing various servers. Associate the CoS values with the input interfaces for the R&D and market departments and configure the interfaces to trusting CoS.</p> <p>Configure the default CoS value for the HR management department interface to the highest priority 7 to ensure that packets from the HR management department are sent in the highest priority.</p>
----------------------------	---

	<p>Configure the output scheduling policy to WR and the round robin weight to 1:1:1:2:6:1:1:0 for the queues. This means that the SP scheduling algorithm is used for packets of the HR management department, and the packets of the R&D and market departments for accessing the mail database, file database and salary query database are scheduled based on the ratio of 6:2:1.</p>

2.4.5 Configuring Congestion Mitigation

Configuration Effect

Configure the lower threshold value for WRED. When the length of packets in a queue is smaller than the lower threshold value, WRED does not discard packets.

Configure the maximum discarding probability. When the length of packets in the queue is between the lower and higher threshold values, WRED discards packets in random. The maximum probability for discarding packets is configured.

Configure the CoS-to-threshold mapping.

Notes

Interface configurations allow for only AP and Ethernet interface configurations.

Configuration Steps

Enabling the WRED function

Optional.

Enable the WRED function if necessary.

Configuring the lower threshold value

Optional.

Configure the lower threshold value if necessary.

Configuring the maximum discarding probability

Optional.

Configure the maximum discarding probability if necessary.

Configuring the CoS-to-threshold mapping

Optional.

Configure the CoS-to-threshold mapping if necessary.

Verification

Run the **show queueing wred interface** command to display the WRED configuration.

1 Configuring REUP

1.1 Overview

The Rapid Ethernet Uplink Protection Protocol (REUP) provides a rapid uplink protection function.

In the dual uplink networking, REUP is used to ensure normal communication between links, block redundant links, avoid link loops, and implement fast backup.

The upstream interfaces of REUP are configured in pairs. If both interfaces are normal, an interface works in the backup state. The interface in the backup state does not forward data packets. When the interface in the forward state is faulty, the backup interface switches to the forward state immediately, and provides data transmission. In addition, REUP also sends address update packets to upstream devices so that the upstream devices can update their MAC addresses immediately. This function of REUP ensures that layer-2 data streams can be restored within 50 ms after a link is faulty.

REUP is mutually exclusive with the Spanning Tree Protocol (STP) based on interfaces. In this case, a device runs STP downward and runs REUP upward to implement backup and fault protection for the upstream link. REUP ensures that basic link redundancy is provided when STP is disabled and that millisecond-level fault recovery faster than STP is also provided.

Protocols and Standards

- REUP is a proprietary protocol of Ruijie Network, and there is no standard and protocol for reference.

1.2 Applications

Application	Description
Communication in Dual Uplink Networking	Forward packets in the dual-uplink networking.

1.2.1 Communication in Dual Uplink Networking

Scenario

For communication in dual uplink networking, the access switch has two uplink paths, as shown in Figure 1-1.

Figure 1-1 Dual uplink networking

Deployment

- Enable REUP on interface1 and interface2 of the access switch D/E to implement fast switching when a link is faulty.
- Enable MAC address update message receiving of REUP on the interfaces connected to switches A/B/C to rapidly clear the MAC addresses on the interfaces when a link is faulty.

1.3 Features

Basic Concepts

↘ REUP Pair

Specify an interface as the backup interface of another interface to configure an REUP pair. One interface is the active interface and the other interface is the backup interface. When the two interfaces are normal, an interface is configured as the forward interface whereas the other interface is configured as the backup interface. You can determine the interface to be configured as the backup interface. See the related information in the section "Configuring the Preemption Mode and Delay Time of REUP".

↘ MAC Address Update Message

MAC address update messages refer to FLUSH packets sent by Ruijie Network to uplink devices through private multicast. When an uplink device of Ruijie Network enables the function for receiving MAC address update messages and receives MAC address update messages, the device updates the MAC addresses of corresponding interfaces.

↘ MAC Address Update Group

Multiple interfaces are added to a group. If one interface in the group receives a MAC address update message, the MAC addresses of other interfaces in the group will be updated. In this case, the group is called MAC address update group.

↘ MAC Address Update Packet

Packets sent to update MAC addresses in order to support uplink devices are called MAC address update packets.

↘ Link Tracking Group

The uplink and downstream interfaces of a device are added to a group. If all upstream interfaces in the group are down, all downstream interfaces in this group are forced down. In this case, this group is called a link tracing group.

Overview

Feature	Description
Dual Link Backup of REUP	When a link is faulty, the other link can rapidly switch to the forward state.
Preemption Mode and Delay Time of REUP	When both links are normal, the preemption mode can be used to determine the link that is used for forwarding data and the delay time that is used to determine the waiting time before switching.
MAC Address Update	During link switching, the MAC address of an interface is updated to make packet convergence faster.
VLAN Load Balance	When the two links are normal, the utilization of link bandwidth can be maximized.
Link State Tracking	When the upstream link is faulty, the downstream link is switched.

1.3.1 Dual Link Backup of REUP

When an active link is faulty, the link in the backup state will rapidly switch to the forward state and start forwarding data, minimizing the service interruption caused by link failure.

Working Principle

Specify an interface as the backup interface of another interface to configure an REUP pair. When the two interfaces are normal, a link is in the forward state (forwarding data packets) and the other link is in the backup state (not forwarding data). When the active link is faulty, the link in the backup state rapidly switches to the forward state and starts forwarding data. When the faulty link is recovered, the link enters the backup state and does not forward data packets. Of course, you can configure the preemption mode to specify whether a link recovered from failure preempts the link that is in the forward state currently.

Figure 1-2 A topology with two normal links

As shown in Figure 1-2, connect interfaces 1 and 2 of switch D (E) to the uplink switches B and C (C and B) and configure REUP on interfaces 1 and 2. When the links are normal, interface 1 is in the forward state and forwards data packets and interface 2 is in the backup state and does not forward data packets.

Figure 1-3 A topology with interface 1 of switch D (E) faulty

Once interface 1 is faulty, interface 2 immediately starts forwarding data packets and recovers the uplink transmission of the switch. In the non-preemption mode, when the link of interface 1 is recovered, interface 1 is in the backup state and does not forward data packets whereas interface 2 continues forwarding data packets.

Related Configuration

↳ Enabling Dual Link Backup on an interface

By default, dual link backup on an interface is disabled.

You can run the **switchport backup interface** command to configure a layer-2 physical interface (or layer-2 AP interface) as a backup interface and enable the dual link backup function of REUP.

You must enable the dual link backup function of REUP on an interface. The function involves the link switching of REUP only when an interface is faulty.

- ❗ REUP, ERPS, and RERP do not share interfaces.
- ❗ Devices enabled with REUP must disable the storm control function of all layer-2 interfaces.

1.3.2 Preemption Mode and Delay Time of REUP

Working Principle

You can determine which link should be used first by configuring the preemption mode of REUP. If the preemption mode is set to bandwidth first, REUP selects a link with a high bandwidth first. You can also set the preemption mode to forced to select a stable and reliable link first forcibly.

To avoid frequent active/backup link switching caused by abnormal faults, REUP provides a preemption delay function. When the two links are recovered, link switching is performed when the faulty link becomes stable after a delay (35s by default).

Related Configuration

📄 Configuring the Preemption Mode and Delay Time of REUP

By default, the preemption mode is disabled and the delay time is 35s.

You can run the **switchport backup interface preemption mode** command to configure the preemption mode.

You can run the **switchport backup interface preemption delay** command to configure the delay time.

A smaller delay means more frequent preemption switching after the faulty link is recovered.

- i** REUP uses the value of the **Bandwidth** attribute for an AP interface as the actual bandwidth of the AP interface, which is equal to the value of the **Speed** attribute (the number of link up member interfaces x the number of member interfaces).
- i** When an uplink enables STP, the preemption delay time of REUP is greater than 35s.

1.3.3 MAC Address Update

During link switching, the MAC address of an interface is updated to make packet convergence faster.

Working Principle

As shown in Figure 1-2, interface 1 and interface 2 of switch D (E) are enabled with dual link backup of REUP. Interface 1 works as the active interface. During normal communication, switch A learns the MAC addresses of users 1 and 2 (users 3 and 4) from the interfaces connecting to switch B (C).

When interface 1 of switch D (E) is faulty, interface 2 rapidly switches to the forward state and starts forwarding data packets. In this case, switch A does not learn the MAC addresses of users 1 and 2 (users 3 and 4) on the interfaces connecting to switch B (C). The data packets sent by the server to users 1 and 2 (users 3 and 4) are forwarded to switch C (B) by switch A, causing that the packets from the server to users 1 and 2 (users 3 and 4) are lost.

To avoid the preceding problems, you can enable the MAC address update function on switch D (E). When interface 2 starts forwarding packets, switch D (E) sends a MAC address update message to interface 2. After receiving the MAC address update message, switch A updates the MAC address on the interface of switch A. In this way, switch A forwards the packets sent by the server to the users to the interfaces of switch B (C) to make packet convergence faster.

In addition, import the setting of a MAC address update group, that is, classify multiple interfaces into the same group. When an interface in this group receives a MAC address update message, the MAC addresses on other interfaces in the group are updated to reduce the side effect of flooding caused by MAC address update.

To be compatible with upstream devices not supporting MAC address update messages, switch D (E) will send MAC address update packets for users 1 and 2 (users 3 and 4) upward when interface 2 switches to the forward state. In this way, switch A can update the MAC addresses of users 1 and 2 (users 3 and 4) to the corresponding interfaces and recover the downlink data transmission of switch A.

Related Configuration

📌 Enabling Sending of MAC Address Update Messages on an interface

By default, sending of MAC address update messages is disabled on an interface.

You can run the **mac-address-table move update transit** command to enable sending of MAC address updates on all interfaces of a device.

If sending of MAC address update messages is not enabled, MAC address update messages will not be sent when dual link backup switching of REUP is performed.

📌 Enabling Receiving of MAC Address Update Messages on an interface

By default, receiving of MAC address update messages is disabled on an interface.

You can run the **mac-address-table move update receive** command to enable receiving of MAC address updates on all interfaces of a device.

If receiving of MAC address update messages is not enabled, a device cannot receive MAC address update messages from downlink devices during dual link backup switching of REUP and will not update the MAC addresses.

📌 Configuring a VLAN for Sending MAC Address Update Messages

By default, a VLAN for sending MAC address update messages is the default VLAN to which an interface belongs.

You can run the **mac-address-table move update transit vlan** command to configure the VLAN in which interfaces send MAC address update messages.

If the VLAN in which interfaces send MAC address update messages is configured, the messages are sent in the configured VLAN; otherwise, the messages are sent in the default VLAN to which the interface belongs.

📌 Configuring a VLAN for Receiving MAC Address Update Messages

By default, MAC address update messages are received in all VLANs.

You can run the **no mac-address-table move update receive vlan** command to configure a VLAN in which interfaces do not receive MAC address update messages. MAC address update messages are received in remaining VLANs.

If no VLAN in which interfaces receive MAC address update messages is configured, MAC address update messages are received in all the configured VLANs; otherwise, MAC address update messages are received in the remaining VLANs.

📌 Configuring a MAC Address Update Group

By default, there is no MAC address update group.

You can run the **mac-address-table update group** command to add an interface to the MAC address update group. The interface is added to the first update group by default.

If no MAC address update group is configured, MAC address update will not be performed when MAC address update packets are received.

📌 **Configuring the Maximum Number of MAC Address Update Packets Sent Per Second**

By default, the maximum number of MAC address update packets sent per second is 150.

You can run the **mac-address-table move updatemax-update-rate** command to configure the maximum number of MAC address update packets sent per second.

The larger the number of packets, the more CPU time used for sending the packets, and the fewer downlink packets are lost.

1.3.4 VLAN Load Balance

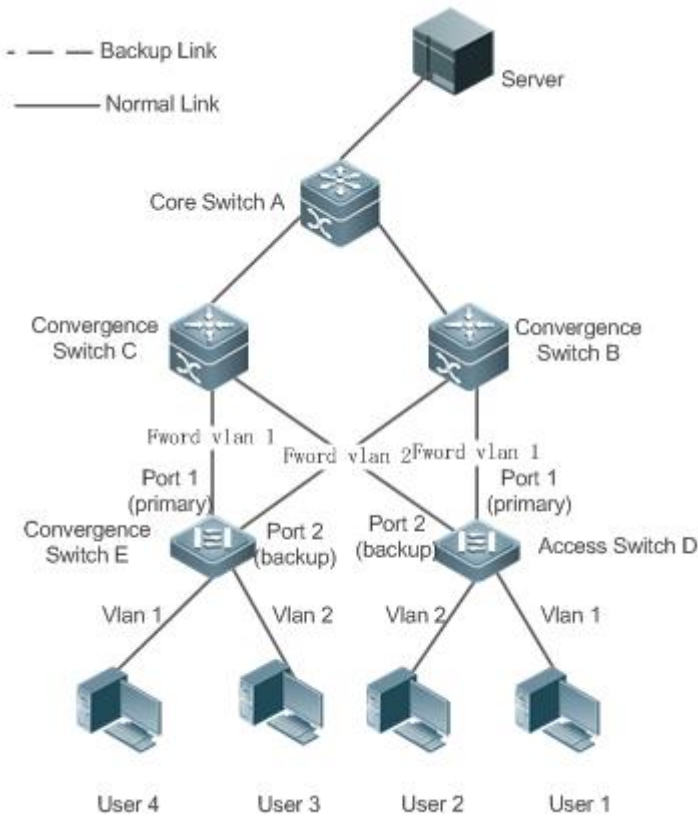

Working Principle

The VLAN load balance function allows REUP to forward data packets of mutually exclusive VLANs for two interfaces to make full use of the link bandwidth.

As shown in Figure 1-4, configure dual link backup of REUP and enable VLAN load balance of REUP on interface 1 and interface 2 of switch D, and map VLAN 1 to instance 1 and VLAN 2 to instance 2. Data of VLAN 1 (instance 1) is transmitted through interface 1 and all the other data of VLAN 2 (instance 2) is transmitted through interface 2. Perform the same processing on switch E.

When an interface is faulty, the other interface takes over the transmission of all VLANs. When the faulty interface is recovered and does not become faulty within the preemption delay, the transmission of VLANs is switched back to the recovered interface.

Figure 1-4 A topology with two normal links of load balance

Related Configuration

Enabling VLAN Load Balance on an interface

By default, the VLAN load balance function on an interface is disabled.

You can run the **switchport backup interface prefer instance** command to enable the VLAN load balance function.

If this function is not enabled, the link bandwidth cannot be fully used when packets are forwarded when the two links are normal. You must enable the VLAN load balance function on a port so that the interface can be involved in VLAN load balance.

i The instance mapping of REUP VLAN load balance is controlled by the MSTP module in a unified manner. For details about how to configure the instances, see the description in the *Configuring MSTP*.

! The VLAN load balance function can be configured only on trunk, uplink or hybrid interfaces.

1.3.5 Link State Tracking

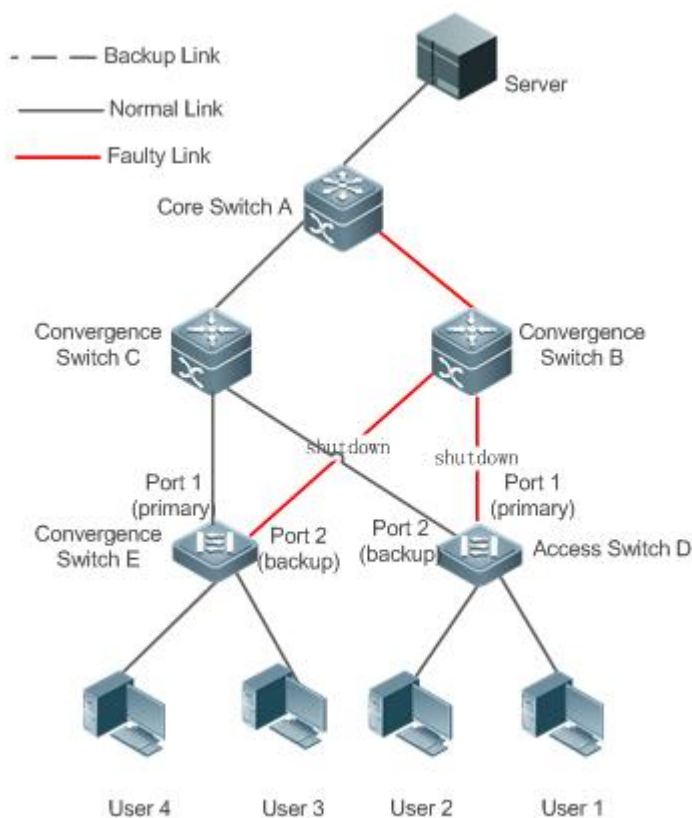

Link tracking means that when the upstream link is faulty, services are switched to the downstream link so that the backup interface can continue forwarding packets.

Working Principle

Link state tracking provides the function of notifying downlink devices for link switching when the upstream link is faulty. You can configure the uplink and downstream interfaces of a link state tracking group and bind the link status of multiple downstream interfaces to the interfaces of multiple upstream links to implement link status synchronization. When all upstream links in a tracking group are faulty, the interfaces of the downstream links are shut down forcibly to ensure that the transmission of the downstream links is switched from the active link to the backup link.

As shown in Figure 1-5, when the upstream link of switch B is faulty, link state tracking rapidly shuts down the downstream interface of switch B so that the uplink transmission of switch D is switched to switch C.

Figure 1-5 A topology where the upstream link of the active link is faulty

Related Configuration

Enabling Link Tracking

Link tracking is disabled by default.

You can run the **link state track [number]** command to enable a link tracking group. The value of **number** ranges from 1 to 2. The first link tracking group is enabled by default (the default value of **number** is 1).

If link tracking is not enabled, the status of a corresponding upstream interface cannot be detected and packet forwarding switching cannot be implemented in time.

➤ **Enabling the Downlink Delay Up Function for a Link Tracking Group**

By default, the downlink delay for link tracking is 0s.

You can run the **link state track *number* up-delay *timer*** command to enable a link tracking group. The value of **number** ranges from 1 to 2. The first link tracking group is enabled by default (the default value of **number** is 1). The value of **timer** ranges from 0 to 300s, which is 0s by default.

By enabling the downlink delay up function, you can avoid frequent downlink switching caused by uplink flapping in a link tracking group. That is, when the upstream link becomes up, the downstream link becomes up after a delay.

➤ **Adding an interface to a Link Tracking Group**

By default, an interface is not added to a link tracking group.

You can run the **link state group [*number*] {upstream | downstream}** command to set upstream interfaces and downstream interfaces of the link tracking group. The value of **number** ranges from 1 to 2. An interface is added to the first link tracking group by default (the default value of **number** is 1).

If an interface is not added to a tracking group, the status of a corresponding upstream interface cannot be detected and packet forwarding switching cannot be implemented in time.

1.4 Configuration

Configuration	Description and Command
Configuring Basic Functions of REUP	 (Mandatory) It is used to enable dual link backup of REUP.
	switchport backup interface Enables dual link backup of REUP.
Configuring the Preemption Mode and Delay Function of REUP	 (Optional) It is used to determine the preemption mode and delay time. The default values are used if they are not configured.
	switchport backup interface preemption mode Sets the preemption mode.
	switchport backup interface preemption delay Sets the delay time for preemption.
Configuring MAC Address Update	 (Optional) It is used to enable rapid update of MAC addresses.

Configuration	Description and Command	
	mac-address-table update group	Sets the MAC address update group ID of a switch.
	mac-address-table move update transit	Enables sending of MAC address update messages.
	mac-address-table move update transit vlan	Enables sending of the VLAN ID of MAC address update messages.
	mac-address-table move update	Configures the maximum number of MAC address update packets sent per second. The value ranges from 0 to 32000. The default value is 150.
	mac-address-table move update receive	Enables receiving of MAC address update messages.
	mac-address-table move update receive vlan	Configures the VLAN range for processing MAC address update messages.
	Configuring VLAN Load Balance	 (Optional) It is used to enable VLAN load balance.
switchport backup interface prefer instance		Configures the link VLAN load balance of REUP.
Configuring Link Tracking	 (Optional) It is used to enable link tracking.	
	link state track up-delay	Enables the downlink delay up for a link state tracking group.
	link state track	Enables a link state tracking group.
	link state group	Add an interface as an upstream interface or a downstream interface of a specified link state tracking group.

1.4.1 Configuring Basic Functions of REUP

Configuration Effect

- When a link is faulty, the other normal link is switched to the forward state immediately for forwarding packets.

Notes

- An interface belongs to only one REUP pair. Each active link has only one backup link. A backup link can be used as the backup link of only one active link. The active and backup links must use different interfaces.
- REUP supports layer-2 physical interfaces and AP interfaces, but does not support AP member interfaces.
- The active and backup interfaces may be of different types and have different rates. For example, an AP interface can be used as the active interface whereas a physical interface is configured as the backup interface.
- Interfaces configured with REUP are not involved in STP calculation.

- Each device can be configured with a maximum of 16 REUP pairs.
- Interfaces successfully configured with REUP cannot change interfaces to layer-3 interfaces or be added to an AP.

Configuration Steps

↳ Enabling Dual Link Backup of REUP

- Mandatory.
- If there is no special requirement, dual link backup of REUP should be enabled on an interface of the receiving switch.

Verification

Run the **show interfaces switchport backup [detail]** command to check whether dual link backup of REUP is configured.

Related Commands

↳ Enabling Dual Link Backup of REUP

Command	switchport backup interface <i>interface-id</i>
Parameter Description	<i>interface-id</i> : Indicates the backup interface ID.
Command Mode	Interface configuration mode
Usage Guide	If the interface where the mode resides is the active interface, the interface corresponding to the interface-id parameter is the backup interface. When the active link is faulty, rapidly recover the transmission of the backup link.

Configuration Example

↳ Enabling Dual Link Backup of REUP

Scenario Figure 1-6 Dual uplink networking	As shown in Figure 1-6, there are two upstream links from switch D to switch A, which are switch D > switch B > switch A and switch D > switch C > switch A. There are two upstream links from switch E to switch A, which are switch E > switch B > switch A and switch E > switch C > switch A.
---	---

Configuration Steps

- Configure dual link backup (the interface Gi0/1 is the active interface and Gi0/2 is the backup interface) of REUP on the access switch D (E).

D

```
SwitchD> enable
SwitchD# configure terminal
SwitchD(config)# interface GigabitEthernet 0/1
SwitchD(config-if-GigabitEthernet 0/1)# switchport mode trunk
SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface GigabitEthernet 0/2
SwitchD(config-if-GigabitEthernet 0/1)# exit
```

E

```
SwitchE> enable
SwitchE# configure terminal
SwitchE(config)# interface GigabitEthernet 0/1
SwitchE(config-if-GigabitEthernet 0/1)# switchport mode trunk
SwitchE(config-if-GigabitEthernet 0/1)#switchport backup interface GigabitEthernet 0/2
SwitchD(config-if-GigabitEthernet 0/1)# exit
```

Verification

- Check the dual link backup information configured for switch D (E).

D

```
SwitchD#show interfaces switchport backup detail
Switch Backup Interface Pairs:
```

	<pre> Active Interface Backup Interface State ----- Gi0/1 Gi0/2 Active Up/Backup Standby Interface Pair : Gi0/1, Gi0/2 Preemption Mode : off Preemption Delay : 35 seconds Bandwidth : Gi0/1(100000 Mbits), Gi0/2(100000 Mbits) </pre>
E	<pre> SwitchE#show interfaces switchport backup detail Switch Backup Interface Pairs: Active Interface Backup Interface State ----- Gi0/1 Gi0/2 Active Up/Backup Standby Interface Pair : Gi0/1, Gi0/2 Preemption Mode : off Preemption Delay : 35 seconds Bandwidth : Gi0/1(100000 Mbits), Gi0/2(100000 Mbits) </pre>

Common Errors

- Other REUP pairs are configured on a configured interface.
- A configured interface is not a layer-2 physical interface or AP interface.

1.4.2 Configuring the Preemption Mode and Delay Function of REUP

Configuration Effect

- Restrict the preemption mode and preemption delay time for REUP link switching.

Notes

- Dual link backup of REUP must be configured.

Configuration Steps

- Optional.
- If the active link needs to always forward packets or the link bandwidth needs to be used to determine the link for forwarding packets, the corresponding preemption mode and delay time must be configured.

Verification

Run the **show interfaces switchport backup [detail]** command to check whether the preemption mode and delay time are consistent with the configurations.

Related Commands

Configuring the Preemption Mode of REUP

Command	switchport backup interface <i>interface-id</i> preemption mode {forced bandwidth off}
Parameter Description	<i>interface-id</i> : Indicates the backup interface ID. mode : Sets the preemption mode: forced : Indicates the forced mode. bandwidth : Indicates the bandwidth mode. off : Indicates that the preemption mode is off.
Command Mode	Interface configuration mode
Usage Guide	The preemption modes include forced, bandwidth and off. In the bandwidth mode, an interface with a high bandwidth is selected first to transmit data; in the forced mode, the active interface is selected first to transmit data; in the off mode, no preemption is performed. The default mode is off.

Configuring the Delay Time of REUP

Command	switchport backup interface <i>interface-id</i> preemption delay <i>delay-time</i>
Parameter Description	<i>interface-id</i> : Indicates the backup interface ID. <i>delay-time</i> : Indicates the delay time.
Command Mode	Interface configuration mode
Usage Guide	Preemption delay indicates the delay time after a faulty link is recovered to the time when link switching is performed again.

Configuration Example

Configuring the Preemption Mode and Delay Time of REUP

Scenario	As shown in Figure 1-6, there are two upstream links from switch D to switch A, which are switch D > switch B > switch A and switch D > switch C > switch A. There are two upstream links from switch E to switch A, which are switch E > switch B > switch A and switch E > switch C > switch A.
Configuration Steps	<ul style="list-style-type: none"> Configure the preemption mode to bandwidth on the access switch D (E) and the delay time to 40s.
D	<pre>SwitchD> enable SwitchD# configure terminal SwitchD(config)# interface GigabitEthernet 0/1</pre>

	<pre>SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface gi 0/2 preemption mode bandwidth SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface gi 0/2 preemption delay 40 SwitchD(config-if-GigabitEthernet 0/1)# exit</pre>
E	<pre>SwitchE> enable SwitchE# configure terminal SwitchD(config)# interface GigabitEthernet 0/1 SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface gi 0/2 preemption mode bandwidth SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface gi 0/2 preemption delay 40 SwitchD(config-if-GigabitEthernet 0/1)# exit</pre>
Verification	<ul style="list-style-type: none"> ● Check the dual link backup information configured for switch D (E).
D	<pre>SwitchD#show interfaces switchport backup detail Switch Backup Interface Pairs: Active Interface Backup Interface State ----- Gi0/1 Gi0/2 Active Up/Backup Standby Interface Pair : Gi0/1, Gi0/2 Preemption Mode : bandwidth Preemption Delay : 40 seconds Bandwidth : Gi0/1(100000 Mbits), Gi0/2(100000 Mbits)</pre>
E	<pre>SwitchE#show interfaces switchport backup detail Switch Backup Interface Pairs: Active Interface Backup Interface State ----- Gi0/1 Gi0/2 Active Up/Backup Standby Interface Pair : Gi0/1, Gi0/2 Preemption Mode : bandwidth</pre>

Preemption Delay : 40 seconds
Bandwidth : Gi0/1(100000 Mbits), Gi0/2(100000 Mbits)

Common Errors

- A configured interface is not a layer-2 physical interface or AP interface.

1.4.3 Configuring MAC Address Update

Configuration Effect

- Rapidly delete and update MAC addresses of an interface during link switching to make packet convergence faster.

Notes

- Dual link backup of REUP must be configured.
- Each device can be configured with a maximum of 8 address update groups. Each address update group can have a maximum of 8 member interfaces and an interface can belong to multiple address update groups.

Configuration Steps

- Mandatory.
- If there is no special requirement, the MAC address update function should be configured.

Verification

Run the **show mac-address-table update group [detail]** command to view the update group configuration.

Related Commands

▾ Configuring the MAC Address Update Group ID of a Switch

Command	mac-address-table update group [group-num]
Parameter Description	<i>group-num</i> : Indicates the MAC address update group ID.
Command Mode	Interface configuration mode
Usage Guide	In order to reduce large flooding caused by MAC address update which may affect normal data transmission of the switch, we add a setting of a MAC address update group. Only after all interfaces on a switching path are added to the same MAC address update group, transmission of downlink data can be rapidly recovered.

▾ Enabling Sending of MAC Address Update Messages

Command	mac-address-table move update transit
Parameter	-

Description	
Command Mode	Command Mode
Usage Guide	To reduce link switching and loss of downlink data streams, you need to enable sending of MAC address update messages on a switch that performs switching.

▾ Enabling Sending of the VLAN ID of MAC Address Update Messages

Command	mac-address-table move update transit vlan <i>vid</i>
Parameter Description	<i>vid</i> : Indicates the VLAN ID for sending MAC address update messages.
Command Mode	Interface configuration mode
Usage Guide	After sending of MAC address update messages is enabled, MAC address update messages can be sent to uplink devices during link switching.

Configure the maximum number of MAC address update packets sent per second.

▾ Configuring the Maximum Number of MAC Address Update Packets Sent Per Second

Command	mac-address-table move update max-update-rate <i>pkts-per-second</i>
Parameter Description	<i>pkts-per-second</i> : Indicates the maximum number of MAC address update packets sent per second. The value ranges from 0 to 32000. The default value is 150.
Command Mode	Configuration mode
Usage Guide	During link switching, REUP sends MAC address update packets of a specified quantity to uplink devices per second to recover the downlink data transmission of the uplink device.

▾ Enabling Receiving of MAC Address Update Messages

Command	mac-address-table move update receive
Parameter Description	-
Command Mode	Configuration mode
Usage Guide	During switching of dual link backup, downlink data streams may be lost since the MAC address table of the uplink switch is not updated in real time. In order to reduce loss of layer-2 data streams, you need to update the MAC address table of the uplink switch. In this case, you need to enable receiving of MAC address update messages on the uplink switch.

▾ Configuring the VLAN Range for Processing MAC Address Update Messages

Command	mac-address-table move update receive vlan <i>vlan-range</i>
Parameter Description	<i>vlan-range</i> : Indicates the VLAN range for processing MAC address update messages.

Command Mode	Configuration mode
Usage Guide	This command is used to disable the function for processing MAC address update messages on certain VLANs. For a VLAN disabled with the function for processing MAC address update messages, MAC address update packets can be used to recover the downlink transmission of uplink devices; however, the convergence performance for link faults will be decreased.

Configuration Example

Configuring MAC Address Update

Scenario	As shown in Figure 1-6, there are two upstream links from switch D to switch A, which are switch D > switch B > switch A and switch D > switch C > switch A. There are two upstream links from switch E to switch A, which are switch E > switch B > switch A and switch E > switch C > switch A.
Configuration Steps	<ul style="list-style-type: none"> ● Enable sending of MAC address update messages on the access switch D (E). ● Enable receiving of MAC address update packets on switch B (C). ● Add all interfaces on the REUP switching path to the same MAC address update group. ● In the environment, Gi0/1 and Gi0/3 of switch B are the interfaces on the switching path of switch D's uplink, and Gi0/3 and Gi0/2 are the interfaces on the switching path of switch E's uplink. You can add interfaces Gi0/1, Gi0/2 and Gi0/3 to the same address update group. Similarly, you can obtain the configuration of switch C. ● Enable receiving of MAC address update packets on switch A. ● Add all interfaces on the REUP switching path of switch A to the same MAC address update group.
D	<pre>SwitchD> enable SwitchD# configure terminal SwitchD(config)# mac-address-table move update transit SwitchD(config)# exit</pre>

C	<pre> SwitchC# show mac-address-table update group detail Mac-address-table Update Group:1 Received mac-address-table update message count:0 Group member Receive Count Last Receive Switch-ID Receive Time ----- Gi0/1 0 0000.0000.0000 Gi0/2 0 0000.0000.0000 Gi0/3 0 0000.0000.0000 </pre>
A	<pre> SwitchA# show mac-address-table update group detail Mac-address-table Update Group:1 Received mac-address-table update message count:0 Group member Receive Count Last Receive Switch-ID Receive Time ----- Gi0/1 0 0000.0000.0000 Gi0/2 0 0000.0000.0000 </pre>

Common Errors

- A configured interface is not a layer-2 physical interface or AP interface.

1.4.4 Configuring VLAN Load Balance

Configuration Effect

- Maximize the utilization of link bandwidth.

Notes

- Dual link backup of REUP must be configured.
- The Access interface cannot be shared by VLAN load balance and STP.
- For interfaces successfully configured with VLAN load balance, you cannot modify the attributes of the interfaces but can modify the VLAN attributes of the interfaces.

Configuration Steps

- If maximizing bandwidth utilization is not required, this configuration is optional.
- If there is a requirement for VLAN load balance, corresponding configuration must be performed.

Verification

Run the **show interfaces switchport backup [detail]** command to check whether VLAN load balance is configured.

Related Commands

Configuring VLAN Load Balance

Command	switchport backup interface <i>interface-id</i> prefer instance <i>instance-range</i>
Parameter	<i>interface-id</i> : Indicates the backup interface ID.
Description	<i>instance-range</i> : Indicates the load instance range of the backup interface.
Command Mode	Interface configuration mode
Usage Guide	You can modify the mapping between instances and VLANs by using the instance mapping function of MSTP.

Configuration Example

Configuring VLAN Load Balance

Scenario	As shown in Figure 1-6, there are two upstream links from switch D to switch A, which are switch D > switch B > switch A and switch D > switch C > switch A. There are two upstream links from switch E to switch A, which are switch E > switch B > switch A and switch E > switch C > switch A.
Configuration Steps	<ul style="list-style-type: none"> ● Configure instance mappings on switch D (E) to map VLAN 1 to instance 1, VLAN 2 to instance 2, VLAN 3 to instance 3, and VLAN 4 to instance 4. For details, see the <i>MSTP Configuration Guide</i>. ● Configure the VLAN load balance function on switch D (E).
D	<pre>SwitchD> enable SwitchD# configure terminal SwitchD(config)# interface GigabitEthernet 0/1 SwitchD(config-if-GigabitEthernet 0/1)# switchport mode trunk SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface gi0/2 prefer instance 2 SwitchD(config-if-GigabitEthernet 0/1)# exit</pre>

--	--

Common Errors

- The mappings between VLAN IDs and instances are not configured.

1.4.5 Configuring Link Tracking

Configuration Effect

- After detecting that the upstream link is disconnected, forcibly disconnect the downstream link so that link switching can be performed.

Notes

- Dual link backup of REUP must be configured.
- For the link state tracking function, each interface belongs to only one link state tracking group and each device can be configured with up to 2 link state tracking groups. Each link state tracking group can have 8 upstream interfaces and 256 downstream interfaces.

Configuration Steps

- Mandatory.
- If there is no special requirement, the uplink tracking function should be configured.

Verification

Run the **show link state group** command to view the configured link tracking information.

Related Commands

↘ Enabling a Link State Tracking Group

Command	link state track [num]
Parameter	<i>num</i> : Indicates the ID of a link state tracking group.
Description	

Command Mode	Configuration mode
Usage Guide	You can create a link tracking group and then add an interface to the specified tracking group.

📌 **Enabling the Downlink Delay Up for a Link State Tracking Group**

Command	link state track <i>num</i> up-delay <i>timer</i>
Parameter	<i>num</i> : Indicates the ID of a link state tracking group.
Description	<i>Timer</i> : Indicates the downlink delay up time, which is 0s by default.
Command Mode	Configuration mode
Usage Guide	You must enable the delay function so that the downstream link can be up after the delay.

📌 **Adding an interface to a Link Tracking Group**

Command	ink stategroup <i>num</i> {upstream downstream}
Parameter	<i>num</i> : Indicates the ID of a link state tracking group.
Description	upstream : Adds the interface as an upstream interface of the tracking group. downstream : Adds the interface as a downstream interface of the tracking group.
Command Mode	Interface configuration mode
Usage Guide	You can create a link tracking group and then add an interface to the specified tracking group.

Configuration Example

📌 **Configuring a Link Tracking Group**

Scenario	As shown in Figure 1-6, there are two upstream links from switch D to switch A, which are switch D > switch B > switch A and switch D > switch C > switch A. There are two upstream links from switch E to switch A, which are switch E > switch B > switch A and switch E > switch C > switch A.
Configuration Steps	<ul style="list-style-type: none"> ● Create link tracking group 1 on switch B (C). ● On switch B (C), add the interfaces Gi0/1 and Gi0/2 as downstream interfaces of the link tracking group and add the interface Gi0/3 as an upstream interface of the link tracking group.

<p>B</p>	<pre>SwitchB> enable SwitchB# configure terminal SwitchB(config)# link state track 1 SwitchB(config)# interface GigabitEthernet 0/1 SwitchB(config-if-GigabitEthernet 0/1)#link state group 1 downstreamSwitchB(config-if-GigabitEthernet 0/1)#exit SwitchB(config)# interface GigabitEthernet 0/2 SwitchB(config-if-GigabitEthernet 0/2)# link state group 1 downstream SwitchB(config-if-GigabitEthernet 0/2)#exit SwitchB(config)# interface GigabitEthernet 0/3 SwitchB(config-if-GigabitEthernet 0/3)#link state group 1 upstream SwitchB(config-if-GigabitEthernet 0/3)#exit</pre>

<p>B</p>	<pre>SwitchB#show link state group Link State Group:1 Status: enabled, Down Upstream Interfaces :Gi0/3(Down)</pre>

	Downstream Interfaces : Gi0/2(Down)
--	-------------------------------------

Common Errors

- Interfaces are added to a link tracking group when the link tracking group is not enabled.

1.5 Monitoring

Displaying

Description	Command
Displays the dual link backup information of REUP.	show interfaces [<i>interface-id</i>] switchport backup [detail]
Displays the configurations of an MAC address update group.	show mac-address-table update group [detail]
Displays the REUP statistics about sent MAC address update messages.	show mac-address-table move update
Displays the information about a link state tracking group.	show link state group

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Enables all REUP debugging.	debug reup all
Debugs the normal running process of REUP.	debug reup process
Debugs MAC address update messages of REUP.	debug reup packet
Debugs MAC address update packets of REUP.	debug reup macupdt
Debugs hot backup.	debug reup ha
Debugs errors occurring in REUP running.	debug reup error
Debugs received events.	debug reup evnet
Debugs statistics when show operations are performed.	debug reup status

2 Configuring RLDP

2.1 Overview

The Rapid Link Detection Protocol (RLDP) achieves rapid detection of unidirectional link failures, directional forwarding failures and downlink loop failures of an Ethernet. When a failure is found, relevant ports will be closed automatically according to failure treatment configuration or the user will be notified to manually close the ports to avoid wrong flow forwarding or an Ethernet layer-2 loop.

2.2 Applications

Application	Description
Unidirectional Link Detection	Detect a unidirectional link failure.
Bidirectional Forwarding Detection	Detect a bidirectional link failure.
Downlink Loop Detection	Detect a link loop.

2.2.1 Unidirectional Link Detection

Scenario

As shown in the following figure, A is connected to B via optical fiber. The two lines are the Tx and Rx lines of optical fiber. Unidirectional link detection is enabled on A and B. If any of the Tx of Port A, Rx of Port B, Tx of Port B and Rx of Port A fails, a unidirectional failure will be detected and treated under the RLDP. If the failure is eliminated, the administrator may manually restore the RLDP on A and B and resume detection.

Figure 2-1

Remarks	<p>A and B are layer-2 or layer-3 switches.</p> <p>The Tx of Port A of A is connected to the Rx of Port B of B.</p> <p>The Rx of Port A of A is connected to the Tx of Port B of B.</p>
----------------	---

Deployment

- Global RLDP is enabled.
- Configure unidirectional link detection under Port A and Port B and define a method for failure treatment.

2.2.2 Bidirectional Forwarding Detection

Scenario

As shown in the following figure, A is connected to B via optical fiber, and the two lines are Tx and Rx lines of optical fiber. Unidirectional link detection is enabled on A and B. If the Tx of Port A, Rx of Port B, Rx of Port A and Tx of Port B all fail, a bidirectional failure will be detected and treated under the RLDP. If the failure is eliminated, the administrator may manually restore the RLDP on A and B and resume detection.

Figure 2-2

Remarks	A and B are layer-2 or layer-3 switches. The Tx of Port A of A is connected to the Rx of Port B of B. The Rx of Port A of A is connected to the Tx of Port B of B.
----------------	--

Deployment

- Global RLDP is enabled.
- Configure BFD under Port A and Port B and define a method for failure treatment.

2.2.3 Downlink Loop Detection

Scenario

As shown in the following figure, A, B and C are connect into a loop. Downlink loop detection is enabled on A, and a loop is detected and treated.

Figure 2-3

Remarks	A, B and C are layer-2 or layer-3 switches. A, B and C are interconnected via exchange ports.
----------------	--

Deployment

- Global RLDP is enabled on A.
- Configure downlink loop detection on the Gi 2/0/1 and Gi 2/0/9 ports of A, and define a method for failure treatment.

2.3 Features

Most Ethernet link detection mechanisms detect link connectivity through automatic physical-layer negotiation. However, in some cases devices are connected on the physical layer and operate normally but layer-2 link communication is disabled or abnormal. The RLDP recognizes a neighbor device and detects a link failure through exchanging Prob packets, Echo packets or Loop packets with the device.

Basic Concepts

↘ Unidirectional Link Failure

A unidirectional link failure occurs in case of a cross-connected optical fiber, a disconnected optical fiber, an open-circuit optical fiber, one open-circuit line in a twisted-pair cable, or unidirectional open circuit of an intermediate device between two devices. In such cases, one end of a link is connected and the other disconnected so that flow is forwarded wrongly or a loop guard protocol (for example, the STP) fails.

↘ Bidirectional Link Failure

A bidirectional link failure occurs in case of two optical fibers, two open-circuit lines in a twisted-pair cable, or bidirectional open circuit of an intermediate device between two devices. In such cases, the both ends of a link are disconnected so that flow is forwarded wrongly.

↘ Loop Failure

A downlink device is wrongly connected to form a loop, resulting in a broadcast storm.

↘ RLDP Packet

The RLDP defines three types of packets: Prob packets, Echo packets and Loop packets.

- Prob packets are layer-2 multicast packets for neighbor negotiation, and unidirectional or bidirectional link detection. The default encapsulation format is SNAP, which changes automatically to EthernetII if a neighbor sends EthernetII packets.
- Echo packets are layer-2 unicast packets as response to Prob packets and used for unidirectional or bidirectional link detection. The default encapsulation format is SNAP, which changes automatically to EthernetII if a neighbor sends EthernetII packets.
- Loop packets are layer-2 multicast packets for downlink loop detection. They can only be received. The default encapsulation format is SNAP.

↘ RLDP Detection Interval and Maximum Detection Times

A detection interval and the maximum detection times can be configured for the RLDP. A detection interval determines the period of sending Prob packets and Loop packets. When a device receives a Prob packet, it replies with an Echo packet immediately. A detection interval and the maximum detection times determine the maximum detection time (equal to a detection interval × the maximum detection times + 1) for unidirectional or bidirectional link detection. If neither Prob nor Echo packet from a neighbor can be received within the maximum detection time, the treatment of unidirectional or bidirectional failure will be triggered.

↘ RLDP Neighbor Negotiation

When configured with unidirectional or bidirectional link detection, a port can learn a peer-end device as its neighbor. One port may learn one neighbor, which is variable. If negotiation is enabled, unidirectional or bidirectional link detection starts after a port finds a neighbor through negotiation, which succeeds when a port receives a Prob packet from the neighbor. However, if the RLDP is enabled under a failure, the port cannot learn a neighbor so that detection cannot start. In this case, recover the link state before enabling the RLDP.

↘ Treatment for Failed Port under RLDP

- Warning: Only print Syslog to indicate a failed port and a failure type.
- Shutdown SVI: Print Syslog, and then inquire an SVI according to the Access VLAN or Native VLAN of a port and shut down the SVI if the port is a physical exchange port or layer-2 AP member port.
- Port violation: Print Syslog, and configure a failed port as in violation state, and the port will enter Linkdown state physically.
- Block: Print Syslog, and configure the forward state of a port as Block, and the port will not forward packets.

↘ Recovery of Failed Port under RLDP

- Manual reset: Manually reset all failed ports to initialized state and restart link detection.
- Manual or automatic errdisable recovery: Recover all failed ports to initialized state manually or regularly (30s by default and configurable) and restart link detection.
- Automatic recovery: Under unidirectional or bidirectional link detection, if the treatment for failed ports is not specified as port violation, recover ports to initialized state based on Prob packets and restart link detection.

↘ Port State under RLDP

- normal: Indicates the state of a port after link detection is enabled.
- error: Indicates the state of a port after a unidirectional or bidirectional link failure or a loop failure is detected.

↘ Overview

Feature	Description
---------	-------------

Deploying RLDP Detection	Enable unidirectional or bidirectional link detection or downlink loop detection for failures and implement treatment.
--	--

2.3.1 Deploying RLDP Detection

The RLDP provides unidirectional link detection, bidirectional forwarding detection and downlink loop detection.

Working Principle

↘ Unidirectional Link Detection

When this function is enabled, a port sends Prob packets and receives Echo packets from a neighbor regularly as well as receiving Prob packets from a neighbor and replying with Echo packets. Within the maximum detection time, if the port receives Prob packets but no Echo packets, or none of them, treatment for a unidirectional failure will be triggered and detection will stop.

↘ Bidirectional Forwarding Detection

When this function is enabled, a port sends Prob packets and receives Echo packets from a neighbor regularly as well as receiving Prob packets from a neighbor and replying with Echo packets. Within the maximum detection time, if the port receives neither Prob packets nor Echo packets from a neighbor, treatment for a bidirectional failure will be triggered and detection will stop.

↘ Downlink Loop Detection

When this function is enabled, a port sends Loop packets regularly. In the following cases, a loop failure will be triggered after the same port or a different port receives the packets: in one case, the egress and ingress ports are the same routed port or layer-3 AP member port; in another case, the egress and ingress ports are exchange ports or layer-2 AP member ports in a same default VLAN and in Forward state. Treatment for the failure will be implemented and detection will stop.

Related Configuration

- Configuring RLDP Detection

By default, RLDP detection is disabled.

You may run the global command **rldp enable** or the interface command **rldp port** to enable RLDP detection and specify a detection type and treatment.

You may run the **rldp neighbor-negotiation** command to neighbor negotiation, the **rldp detect-interval** to specify a detection interval, the **rldp detect-max** to specify detection times, or the **rldp reset** to recover a failed port.

2.4 Configuration

Configuration	Description and Command	
Configuring Basic RLDP Functions	 (Mandatory) It is used to enable RLDP detection under global configuration mode.	
	rldp enable	Enables global RLDP detection on all ports.

 (Mandatory) It is used to specify under interface configuration mode a detection type and failure treatment for an interface.	
rldp port	Enables RLDP detection on a port and specifies a detection type and failure treatment.
 (Optional) It is used to configure a detection interval, detection times and neighbor negotiation under global configuration mode.	
rldp detect-interval	Modifies global RLDP parameters on all ports, such as the detection interval, maximum detection times and neighbor negotiation.
rldp detect-max	
rldp neighbor-negotiation	
 (Optional) It is used under privileged mode.	
rldp reset	Recovers all ports.

2.4.1 Configuring Basic RLDP Functions

Configuration Effect

- Enable RLDP unidirectional link detection, bidirectional forwarding detection, or downlink loop detection to discover failures.

Notes

- Loop detection is effective to all member ports of an AP when configured on one of the ports. Unidirectional link detection and bidirectional forwarding detection are effective only on an AP member port.
- The loop detection on a physical port added to an AP shall be configured the same as that of the other member ports. There are three cases. First, if loop detection is not configured on a newly-added port but on the existing member ports, the new port adopts the configuration and detection results of the existing ports. Second, if a newly-added port and the existing member ports have different loop detection configuration, the new port adopts the configuration and detection results of the existing ports.
- When configuring the RLDP on an AP port, you may configure failure treatment only as "shutdown-port", to which other configurations will be modified.
- When "shutdown-port" is configured on a port, RLDP detection cannot be restored in case of a failure. After troubleshooting, you may run the **rldp reset** or **errdisable recovery** command to restore the port and resume detection. For configuration of the **errdisable recovery** command, please refer to the *SWITCH-INTF-SCG.doc*.

Configuration Steps

▾ Enabling RLDP

- Mandatory.
- Enable RLDP detection on all ports under global configuration mode.

▾ Enabling Neighbor Negotiation

- Optional.
- Enable the function under global configuration mode, and port detection will be started under successful neighbor negotiation.

▾ Configuring Detection Interval

- Optional.
- Specify a detection interval under global configuration mode.

▾ Configuring Maximum Detection Times

- Optional.
- Specify the maximum detection times under global configuration mode.

▾ Configuring Detection under Port

- Mandatory.
- Configure unidirectional RLDP detection, bidirectional RLDP detection or downlink loop detection under interface configuration mode, and specify failure treatment.

▾ Restoring All Failed Ports

- Optional.
- Enable this function under privileged mode to restore all failed ports and resume detection.

Verification

- Display the information of global RLDP, port and neighbor.

Related Commands

▾ Enabling Global RLDP Detection

Command	rldp enable
Parameter	N/A
Description	
Command Mode	Global configuration mode

Usage Guide	Enable global RLDP detection.
--------------------	-------------------------------

↘ Enabling RLDP Detection on Interface

Command	rldp port { unidirection-detect bidirection-detect loop-detect } { warning shutdown-svi shutdown-port block }
Parameter Description	<p>unidirection-detect: Indicates unidirectional link detection.</p> <p>bidirection-detect: Indicates bidirectional forwarding detection.</p> <p>loop-detect: Indicates downlink loop detection.</p> <p>warning: Indicate the failure treatment is warning.</p> <p>shutdown-svi: Indicate the failure treatment is closing the SVI that the interface is on.</p> <p>shutdown-port: Indicates the failure treatment is port violation.</p> <p>block: Indicates the failure treatment is disabling learning and forwarding of a port.</p>
Command Mode	Interface configuration mode
Usage Guide	The interfaces include layer-2 switch ports, layer-3 routed ports, layer-2 AP member ports, and layer-3 AP member ports.

↘ Modifying Global RLDP Detection Parameters

Command	rldp {detect-interval <i>interval</i> detect-max <i>num</i> neighbor-negotiation }
Parameter Description	<p>detect-interval <i>interval</i>: Indicates a detection interval.</p> <p>detect-max <i>num</i>: Indicates detection times.</p> <p>neighbor-negotiation: Indicates neighbor negotiation.</p>
Command Mode	Global configuration mode
Usage Guide	Modify all RLDP parameters on all ports when necessary.

↘ Recovering Failed Port

Command	rldp reset
Parameter Description	N/A
Command Mode	Privileged mode
Usage Guide	Recover all failed ports to initialized state and resume detection.

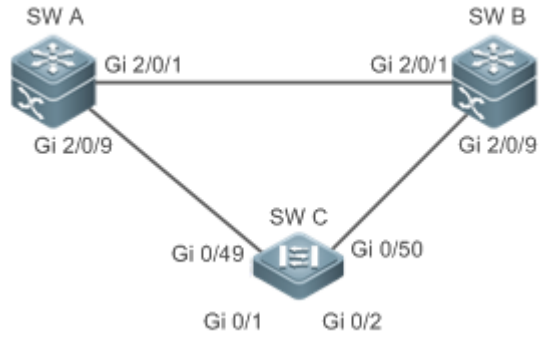

↘ Displaying RLDP State Information

Command	show rldp [interface <i>interface-name</i>]
Parameter Description	<i>interface-name</i> : Indicates the interface to display information of.
Command	Privileged mode, global configuration mode, or interface configuration mode

Mode	
Usage Guide	Display RLDP state information.

Configuration Example

Enabling RLDP Detection in Ring Topology

<p>Scenario</p> <p>Figure 2-4</p>	<p>As shown in the following figure, the aggregation and access sections are in a ring topology. The STP is enabled on all devices to prevent loop and provide redundancy protection. To avoid a unidirectional or bidirectional link failure resulting in STP failure, RLDP unidirectional and bidirectional link detection is enabled between aggregation devices as well as between an aggregation device and the access device. To avoid loop due to wrong downlink connection of the aggregation devices, enable RLDP downlink loop detection on the downlink ports of the aggregation devices and of the access device. To avoid loop due to wrong downlink connection of the access device, enable RLDP downlink loop detection on the downlink ports of the access device.</p> 
<p>Configuration Steps</p>	<ul style="list-style-type: none"> SW A and SW B are aggregation devices, and SW C is an access device. Users connected to SW C. SW A, SW B and SW C are structured in a ring topology, and the STP is enabled on each of them. For STP configuration, refer to relevant configuration guide. Enable the RLDP on SW A, enable unidirectional and bidirectional link detection on the two ports, and enable loop detection on the downlink port. Enable the RLDP on SW B, enable unidirectional and bidirectional link detection on the two ports, and enable loop detection on the downlink port. Enable the RLDP on SW C, enable unidirectional and bidirectional link detection on the two uplink ports, and enable loop detection on the two downlink ports.
<p>A</p>	<pre>A#configure terminal A(config)#rldp enable A(config)#interface GigabitEthernet 2/0/1 A(config-if-GigabitEthernet 2/0/1)#rldp port unidirection-detect shutdown-port A(config-if-GigabitEthernet 2/0/1)#rldp port bidirection-detect shutdown-port A(config-if-GigabitEthernet 2/0/1)# exit</pre>

	<pre>A(config)#interface GigabitEthernet 2/0/9 A(config-if-GigabitEthernet 2/0/1)#rldp port unidirection-detect shutdown-port A(config-if-GigabitEthernet 2/0/1)#rldp port bidirection-detect shutdown-port A(config-if-GigabitEthernet 2/0/1)#rldp port loop-detect shutdown-port A(config-if-GigabitEthernet 2/0/1)#exit</pre>
B	<p>Apply the configuration on SW A.</p>
C	<pre>C#configure terminal C(config)#rldp enable C(config)#interface GigabitEthernet 0/49 C(config-if-GigabitEthernet 0/49)#rldp port unidirection-detect shutdown-port C(config-if-GigabitEthernet 0/49)#rldp port bidirection-detect shutdown-port C(config-if-GigabitEthernet 0/49)# exit C(config)#interface GigabitEthernet 0/50 C(config-if-GigabitEthernet 0/50)#rldp port unidirection-detect shutdown-port C(config-if-GigabitEthernet 0/50)#rldp port bidirection-detect shutdown-port C(config-if-GigabitEthernet 0/50)#exit C(config)#interface GigabitEthernet 0/1 C(config-if-GigabitEthernet 0/1)# rldp port loop-detect shutdown-port C(config-if-GigabitEthernet 0/1)#exit C(config)#interface GigabitEthernet 0/2 C(config-if-GigabitEthernet 0/2)# rldp port loop-detect shutdown-port C(config-if-GigabitEthernet 0/2)#exit</pre>
Verification	<ul style="list-style-type: none"> ● Check the RLDP information on SW A, SW B and SW C. Take SW A for example.
A	<pre>A#show rldp rldp state : enable rldp hello interval: 3 rldp max hello : 2 rldp local bridge : 00d0.f822.33aa ----- Interface GigabitEthernet 2/0/1 port state : normal</pre>

```
neighbor bridge : 00d0.f800.51b1
neighbor port   : GigabitEthernet 2/0/1
unidirection detect information:
    action: shutdown-port
    state  : normal
bidirection detect information:
    action: shutdown-port
    state  : normal

Interface GigabitEthernet 2/0/9
port state      : normal
neighbor bridge : 00d0.f800.41b0
neighbor port   : GigabitEthernet 0/49
unidirection detect information:
    action: shutdown-port
    state  : normal
bidirection detect information:
    action: shutdown-port
    state  : normal
loop detect information:
    action: shutdown-port
    state  : normal
```

Common Errors

- RLDP functions and private multicast address authentication or TPP are enabled at the same time.
- Neighbor negotiation is not enabled when configuring unidirectional or bidirectional link detection. The RLDP should be enabled on a neighbor device, or otherwise a unidirectional or bidirectional failure will be detected.
- If RLDP detection is configured to be implemented after neighbor negotiation while configuring unidirectional or bidirectional link detection, detection cannot be implemented as no neighbor can be learned due to a link failure. In this situation, you are suggested to recover the link state first.
- You are suggested not to specify the failure treatment as Shutdown SVI under a routed port.
- You are suggested not to specify the failure treatment as Block for a port, on which a loop protection protocol is enabled, for example, the STP.

Common Errors

- When the RLDP loop detection configurations are modified, the **no exec-cmd** command is not executed to delete the original configurations or the **exec-cmd** command is not re-executed to cancel the configurations.

2.5 Monitoring

Displaying

3 Configuring DLDP

3.1 Overview

The Data Link Detection Protocol (DLDP) is a protocol used to quickly detect faulty Ethernet links.

A typical Ethernet link detection mechanism detects physical link connectivity through autonegotiation at the physical layer. Such a mechanism has limitations when detecting Layer-3 data communication exceptions despite normal physical connections.

DLDP provides reliable Layer-3 link detection information. After detecting a faulty link, DLDP shuts down the logical state of Layer-3 ports to realize fast Layer-3 protocol convergence.

3.2 Applications

Application	Description
Intra-Network Segment DLDP Detection	The source IP address of the detected port and the detected IP address are in the same network segment.
Inter-Network Segment DLDP Detection	The source IP address of the detected port and the detected IP address are in different network segments.

3.2.1 Intra-Network Segment DLDP Detection

Scenario

This section describes the basic DLDP application scenario where the source IP address of the detected port and the detected IP address are in the same network segment.

In Figure 3-1, the Gi 0/1 Layer-3 port on Switch A and the Gi 0/2 Layer-3 port on Switch C are in the same network segment. To detect the Layer-3 link connectivity from Gi 0/1 to Gi 0/2, enable DLDP on Gi 0/1 or Gi 0/2.

Figure 3-1

Remarks	Device A and Device C are switches. Gi 0/1 and Gi 0/2 are Layer-3 ports in the same network segment. B is a network in the same network segment as Gi 0/1 and Gi 0/2.
----------------	---

Deployment

- Enable DLDP on Gi 0/1 or Gi 0/2.

3.2.2 Inter-Network Segment DLDP Detection

Scenario

This section describes the DLDP application scenario where the source IP address of the detected port and the detected IP address are in different network segments.

In Figure 3-2, the Gi 0/1 Layer-3 port on Switch A and the Gi 0/4 Layer-3 port on Switch D are in different network segments. To detect the Layer-3 link connectivity from Gi 0/1 to Gi 0/4, enable DLDP on Gi 0/1 and configure the DLDP next-hop IP address (IP address of the Gi 0/2 port on Switch B).

Figure 3-2

Remarks	Device A, Device B, and Device D are switches. Gi 0/1 and Gi 0/4 are Layer-3 ports in different network segments.
----------------	--

Deployment

- Enable DLDP on Gi 0/1 and configure the DLDP next-hop IP address.

3.3 Features

Basic Concepts

DLDP Detection Interval and Retransmission Times

Detection interval: Indicates the interval at which DLDP detection packets (ICMP echo) are transmitted.

Retransmission times: Indicate the maximum times DLDP detection packets can be retransmitted in the case of a DLDP detection failure.

When a network device does not receive a reply packet from the peer end within the period of the detection interval multiplied by the retransmission times, the device determines that a Layer-3 link failure occurs and shuts down the logical state of its Layer-3 port (despite the normal physical link connection). When Layer-3 link connectivity is recovered, the device restores its Layer-3 port to Up logical state.

DLDP Detection Modes

Active mode and passive mode are two DLDP detection modes.

Active mode (default): ICMP detection packets are sent actively.

Passive mode: ICMP detection packets are received passively.

DLDP Next Hop

Next hop: Indicates the next node connected to the detected IP address in inter-network segment DLDP detection.

In some cases, DLDP needs to detect IP reachability in non-directly connected network segments. You need to configure the next-hop IP address for the detected port to allow DLDP to obtain the next-hop MAC address through an ARP packet before sending a correct ICMP packet.

In this situation, you need to avoid the return of the reply packet from another link; otherwise, DLDP will misjudge that the detected port does not receive an ICMP reply.

DLDP Recovery Times

Recovery times: Indicate the times DLDP needs to receive consecutive reply packets (ICMP reply) before it can determine link failure recovery.

In some cases, link detection may be unstable. For example, a link is only intermittently pingable. In this case, DLDP repeatedly changes the link status between Up and Down, which may further destabilize the ring network.

Recovery times indicate the times DLDP needs to receive consecutive reply packets before DLDP can set the link in Down state to Up. The default recovery times are three times, indicating that the link needs to be successfully pinged three times before it is set to Up. The recovery times setting reduces link detection sensitivity but increases stability. Related parameters are adjustable according to the network condition.

DLDP Bound MAC Address

Bound MAC address: Indicates the MAC address bound to the detected IP address.

In a complex network environment, DLDP may obtain an invalid MAC address if the detected link has abnormal ARP packets transmitted (causing ARP spoofing), which will make DLDP detection abnormal.

To address this problem, you can bind the detected IP address (or next-hop IP address) to a static MAC address to avoid a DLDP failure in the case of ARP spoofing.

Overview

Feature	Description
DLDP Detection	Detects Layer-3 link connectivity. When a Layer-3 link is abnormal, DLDP shuts down the Layer-3 port.
MAC Address Binding	Binds the detected IP address to the MAC address of the detected device to avoid DLDP exceptions otherwise caused by ARP spoofing.
Passive DLDP Detection	When both ends of the detected link are enabled with DLDP, you can configure one end in passive mode to save bandwidth and CPU resources.

3.3.1 DLDP Detection

DLDP detects Layer-3 link connectivity. When a Layer-3 link is abnormal, DLDP shuts down the corresponding Layer-3 port.

Working Principle

After DLDP detection is enabled, DLDP sends an ARP packet to obtain the MAC address and outbound port of the detected device or the next-hop device. Then DLDP periodically sends IPv4 ICMP echo packets to the MAC address and outbound port to detect link connectivity. If DLDP does not receive an IPv4 ICMP reply packet from the detected device within a specific period, DLDP determines that the link is abnormal and sets the Layer-3 port to Down.

Related Configuration

- Enabling DLDP Detection

By default, DLDP detection is disabled on ports.

Run the **lldp** command with the detected IP address specified to enable DLDP detection.

You can configure the next-hop IP address, MAC address of the detected device, transmission interval, retransmission times, and recovery times based on the actual environment.

3.3.2 MAC Address Binding

The MAC address binding feature is used to bind the detected IP address (or next-hop IP address) to the MAC address of the detected device (or next-hop device) to avoid DLDP exceptions otherwise caused by ARP spoofing

Working Principle

You can bind the detected IP address (or next-hop IP address) to a static MAC address to avoid a DLDP failure in the case of ARP spoofing.

Related Configuration

By default, no MAC address is bound in DLDP detection.

Bind the MAC address of the detected device when you run the **lldp** command to enable DLDP detection. If the next-hop IP address is specified, bind the MAC address of the next-hop device.

After DLDP detection is enabled, DLDP sends ARP packets and ICMP packets with a fixed destination IP address and a fixed destination MAC address. If the source IP address and MAC address in the received packet do not match the bound IP address and MAC address, DLDP will not process the packet.

3.3.3 Passive DLDP Detection

When both ends of the detected link are enabled with DLDP, you can configure one end in passive mode to save bandwidth and CPU resources.

Working Principle

After the device at the local end sends an ICMP echo packet, the peer device determines link connectivity according to the packet reception time by using specific detection parameters, which are the same as those at the local end, thus saving bandwidth and CPU resources.

Related Configuration

By default, passive DLDP detection is disabled.

Run the **dldp passive** command to enable passive DLDP detection.

After passive DLDP detection is enabled, DLDP will return an ICMP reply packet upon receiving an ICMP echo packet, instead of actively sending ICMP echo packets to the peer end. If DLDP does not receive an ICMP echo packet within a specific period, it determines that the link to the peer port is abnormal.

3.4 Configuration

Configuration	Description and Command	
Enabling DLDP Detection	 (Mandatory) It is used to enable DLDP detection in interface configuration mode.	
	dldp Enables DLDP detection.	
	 (Mandatory) It is used to enable passive DLDP detection in interface configuration mode.	
	dldp passive Enables passive DLDP detection.	
	 (Optional) It is used to configure the detection interval, retransmission times, and recovery times of DLDP detection in global configuration mode.	
	dldp interval	Modifies the DLDP parameters globally to apply the modifications to DLDP detection on all ports.
	dldp retry	
dldp resume		

3.4.1 Enabling DLDP Detection

Configuration Effect

- Detect Layer-3 link connectivity. When a Layer-3 link is abnormal, DLDP shuts down the Layer-3 port.

Notes

- DLDP supports the configuration of multiple IP addresses on a Layer-3 port. DLDP sets the port to Down when none of the IP addresses receives an ICMP reply. If one IP address resumes communication, DLDP sets the port to Up again.
- DLDP uses the first IP address of the Layer-3 port as the source IP address of detection packets.

Configuration Steps

- [Enabling DLDP Detection](#)

- Mandatory.
- When you enable DLDP detection in interface configuration mode, you can configure the next-hop IP address, MAC address, transmission interval, retransmission times, and recovery times based on the actual environment.

▾ Configuring a DLDP Detection Mode

- Optional.
- You can configure active or passive DLDP detection in interface configuration mode based on the actual environment.
- If DLDP detection needs to be enabled at both ends of a Layer-3 link, you can configure passive DLDP detection at one end to save bandwidth and CPU resources.

▾ Configuring DLDP Parameters Globally

- Optional.
- You can modify the parameters of DLDP detection on all ports in global configuration mode based on requirements. The parameters include the packet transmission interval, packet retransmission times, and recovery times.

Verification

- Display the device DLDP information, including the status and statistics of DLDP detection on all ports.

Related Commands

▾ Enabling DLDP Detection

Command	dldp <i>ip-address</i> [<i>next-hop-ip</i>] [mac-address <i>mac-addr</i>] [interval <i>tick</i>] [retry <i>retry-num</i>] [resume <i>resume-num</i>]
Parameter Description	<p><i>ip-address</i>: Indicates the detected IP address.</p> <p>next-hop-ip: Indicates the next-hop IP address.</p> <p><i>mac-addr</i>: Indicates the MAC address of the detected device to be bound. If the next-hop IP address is specified, bind the MAC address of the next-hop device.</p> <p><i>tick</i>: Indicates the interval at which detection packets are transmitted. The value ranges from 5 to 6,000 ticks (1 tick = 10 ms). The default value is 100 ticks (1s).</p> <p><i>retry-num</i>: The value ranges from 1 to 3,600. The default value is 4.</p> <p><i>resume-num</i>: Indicates the recovery times. The value ranges from 1 to 200. The default value is 3.</p>
Command Mode	Interface configuration mode
Usage Guide	The port to be enabled with DLDP detection must be a Layer-3 port, such as a router port, L3AP port, and SVI port.

▾ Configuring a DLDP Detection Mode

Command	dldp passive
----------------	---------------------

Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	You need to enable DLDP detection before configuring a DLDP detection mode.

↘ **Modifying DLDP Detection Parameters Globally**

Command	dlldp { interval tick retry retry-num resume resume-num }
Parameter Description	<p><i>tick</i>: Indicates the interval at which detection packets are transmitted. The value ranges from 5 to 6,000 ticks (1 tick = 10 ms). The default value is 100 ticks (1s).</p> <p><i>retry-num</i>: Indicates the interval at which detection packets are retransmitted. The value ranges from 5 to 3,600. The default value is 4.</p> <p><i>resume-num</i>: Indicates the recovery times. The value ranges from 1 to 200. The default value is 3.</p>
Command Mode	Global configuration mode
Usage Guide	Use this command to quickly modify the parameters of DLDP detection on all ports when the actual environment is changed.

↘ **Displaying the DLDP Status**

Command	show dldp statistic [interface interface-name]
Parameter Description	<i>interface-name</i> : Indicates the Layer-3 port on which the DLDP status will be displayed.
Command Mode	Privileged mode, global configuration mode, and interface configuration mode
Usage Guide	Use this command to display the DLDP status on a specific port. You can also use this command to display the DLDP status on all ports.

Configuration Example

↘ **Enabling DLDP Detection on Layer-3 Ports on Device A and Device B in a Layer-3 Network**

Verification	<ul style="list-style-type: none"> ● Enable DLDP detection on the Gi 0/1 and Gi 0/2 router ports on Device A to detect the Layer-3 link connectivity between Device A and Device B and that between Device A and Device D. ● To control the Gi 0/2 router port of Device B, enable passive DLDP detection on the port.

Common Errors

- An unreachable IPv4 unicast route is misjudged as a DLDP detection failure.
- DLDP detection fails because the peer device does not support ARP/ICMP replies.
- No next-hop IP address is configured in inter-network segment DLDP detection.

Displays the DLDP statistics on the Up/Down port sates.	show dldp statistic

4 Configuring PCAP

4.1 Overview

Packet Capture (PCAP) is a maintenance function commonly used in network devices.

Similar to the packet capture software running on a personal computer, the PCAP function can capture, save, or display the packets sent from and received by the network device.

4.2 Applications

Application	Description
Capturing Packets	

4.2.1 Capturing Packets

[Scenario](#)

During routine maintenance, if you find packet sending or receiving failures in the network, specify the capture point and capture direction, enter the packet feature, and start the packet capture to check whether the packets arrives at the device or are sent from the device.

[Deployment](#)

Perform packet capture as follows:

- Create a capture feature rule and name it.
- Create a capture point and specify the capture point name, capture location (physical port, VLAN, and control plane), capture direction, and capture feature.
- Specify the name of the file to be saved.
- Enable packet capture at the capture point.
- Wait until the capture ends.
- Upload the file to the PC.
- Enable the capture software on the PC to check the captured packets.

4.3 Features

[Overview](#)

Feature	Description
---------	-------------

Capturing Packets	Captures packets sent and received on a specified physical port, VLAN, and control plane.
-----------------------------------	---

4.3.1 Capturing Packets

Clients can define the capture point and specify the capture location and direction, matching rule information, number of captured packets, and file name; and then enable the capture procedure.

Working Principle

Clients can define the capture rules by defining capture points. To capture multiple types of packets at the same time, a client is allowed to define multiple capture points and distinguish them by their names. The capture rules are as follows:

- 1) The capture location can be selected from the certain physical port, VLAN port, and system control plane. Each capture point can only have one capture location.
- 2) The available capture directions can be the outgoing direction, incoming direction, and bidirectional.
- 3) The 7-tuple information can match the source MAC address, destination MAC address, layer-2 protocol type, source IP address, destination IP address, layer-3 protocol type, and TCP/UDP port information.
- 4) The number of captured packets or size of the captured packet can be specified.
- 5) The file name can be specified. The captured packet will be saved in PCAP file format. The file will be output in the form of system log by default on the console unless otherwise specified.

A client enables capture via commands after the rules are configured. The capture will automatically stop when the number of captured packets or the file size reaches the specified value. The client can also stop the capture after commands are entered manually.

Due to too many packets displayed, only 30 packets will be displayed in the form of system log on the console by default if the file name is not specified.

4.4 Configuration

Configuration	Description and Command	
Capturing Packets	packet capture rule <i>rule-name</i> [src-mac <i>smac</i>] [dst-mac <i>dmac</i>] [etype <i>type</i> ip arp] [src-ip <i>sip sip-mask</i>] [dst-ip <i>dip dip-mask</i>] [src-ipv6 <i>sipv6 sipv6-prefix</i>] [dst-ipv6 <i>dipv6 dipv6-prefix</i>] [protocol <i>protocol</i> tcp udp] [src-port <i>sport</i>] [dst-port <i>dport</i>]	Defines capture matching rule.
	packet capture point <i>capture-point-name</i> rule <i>rule-name</i> location { interface <i>interface-name</i> vlan <i>vlan-id</i> control-plane } {in out both}	Creates the capture point and specifies the capture location, matching rule, and capture direction.

	packet capture file <i>filename</i> [buffer-size <i>buf-size</i>] [packet-num <i>pkt-num</i>]	Specifies the name of the file to be saved.
	packet capture { start stop }	Starts/Stops packet capture.

4.4.1 Capturing Packets

Configuration Effect

- Define the capture matching rule.
- Create the capture point.
- Specify the name of the file to be saved.
- Start packet capture.
- Stop packet capture.

Configuration Steps

▾ Defining Capture Matching Rule

- (Mandatory) Run this command to define the packet capture rule.

Command	packet capture rule <i>rule-name</i> [src-mac <i>smac</i>] [dst-mac <i>dmac</i>] [etype type ip arp] [src-ip <i>sip sip-mask</i>] [dst-ip <i>dip dip-mask</i>] [src-ipv6 <i>sipv6 sipv6-prefix</i>] [dst-ipv6 <i>dipv6 dipv6-prefix</i>][protocol <i>protocol</i> tcp udp] [src-port <i>sport</i>] [dst-port <i>dport</i>]
Parameter Description	<i>rule-name</i> : Indicates the matching rule name. <i>smac</i> : Indicates the source MAC address. <i>dmac</i> : Indicates the destination MAC address. type ip arp : Indicates the layer-2 protocol type. <i>sip</i> : Indicates the source IP address. <i>sip-mask</i> : Indicates the source IP address mask. <i>dip</i> : Indicates the destination IP address. <i>dip-mask</i> : Indicates the destination IP address mask. <i>sipv6</i> : Indicates the source IPv6 address. <i>sipv6-prefix</i> : Indicates the source IPv6 prefix. <i>dipv6</i> : Indicates the destination IPv6 address. <i>sipv6-prefix</i> : Indicates the destination IPv6 prefix. protocol tcp udp : Indicates the layer-3 protocol type. <i>sport</i> : Indicates the TCP/UDP protocol source port. <i>dport</i> : Indicates the TCP/UDP protocol destination port.
Defaults	-
Command Mode	Privileged EXEC mode
Usage Guide	1. The user can define multiple capture rules and distinguish them by different names. After a rule is defined, the rule needs to be referenced by the packet capture point to actually take effect.

2. Before deleting the capture rule, all the packet capture points referencing the rule need to be deleted.

↳ **Creating Capture Point**

- (Mandatory) Run this command to create the capture point.

Command	packet capture point <i>capture-point-name</i> rule <i>rule-name</i> location { <i>interface interface-name</i> vlan <i>vlan-id</i> control-plane } { in out both }
Parameter Description	<i>capture-point-name</i> : Indicates the capture point name. <i>rule-name</i> : Indicates the matching rule name, which is defined by running the packet capture rule command. <i>interface-name</i> : Indicates the name of the port on which packets are captured. <i>vlan-id</i> : Indicates the ID of the VLAN in which packets are captured. <i>control-plane</i> : Indicates the control plane on which packets are captured. in out both : Indicates the capture direction (incoming, outgoing, or bidirectional).
Defaults	-
Command Mode	Privileged EXEC mode
Usage Guide	1. The user can define multiple capture points at the same location as required to match different capture rules or packet directions. The capture points can work simultaneously without affecting each other. 2. If the capture point is modified during packet capture, the modification will not take effect immediately and will take effect next time packet capture is enabled.

↳ **Specifying Name of File to Be Saved**

- (Optional) Run this command to specify the name of the file to be saved.

Command	packet capture file <i>filename</i> [buffer-size <i>buf-size</i>] [packet-num <i>pkt-num</i>]
Parameter Description	<i>filename</i> : Indicates the name of the file to be saved. <i>buf-size</i> : Indicates the buffer size. The buffer size is 2 MB by default if not specified. Packet capture automatically stops when the buffer is full. <i>pkt-num</i> : Indicates the number of captured packets. Packet capture automatically stops when the number of captured packets reaches the specified number. Packets will be captured continually by default unless otherwise specified.
Defaults	N/A
Command Mode	Privileged EXEC mode
Usage Guide	1. The file name setting takes effect next time packet capture is enabled.

↳ **Starting/Stopping Packet Capture**

- (Mandatory) Enter this command to start or stop packet capture.

Command	packet capture { start stop }
Parameter Description	start stop : Starts/Stops packet capture.

Defaults	N/A
Command Mode	Privileged EXEC mode
Usage Guide	<ol style="list-style-type: none"> 1. If the packet capture stop command is not entered after packet capture starts, the packet capture automatically stops at the capture point when the number of captured packets reaches the specified number. If the packet capture stop condition is not met, run this command to immediately stop the packet capture. 2. Run the packet capture start command to capture packets at all packet capture points simultaneously.

Verification

Run the **show packet capture status** command to display packet capture information.

Command	show packet capture status
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	Run this command to display the packet capture status.
Command Presentation	<pre> Ruijie#show packet capture status Capture rules: Capture rules tcp: etype: 0x0800 source MAC: 2222.2222.2222 destination MAC: 1111.1111.1111 protocol: 0x6 source IP: 10.10.10.3 destination IP: 10.10.10.10 source port: 5 destination port: 10 Capture points: Capture point controlplane: Capture rules: tcp location: control-plane </pre>

```
direction: all
status: stopped
packets captured(in): 200

Displaying

Description	Command
Displays the packet capture status.	show packet capture status

5 Configuring VRRP

5.1 Overview

Virtual Router Redundancy Protocol (VRRP) is a fault-tolerant routing protocol.

VRRP adopts the master-backup design to ensure migration of functions from a Master router to a Backup one when the Master failed, without influencing internal and external data communication or modifying Local Area Network (LAN) configuration. A VRRP group maps multiple routers into a virtual router. VRRP ensures only one router at a moment on behalf of a virtual router transfers packets, which is the elected Master. If the Master fails, one of the Backup routers will replace it. Under VRRP, it seems that a host in a LAN uses only one router and the routing remains functional even when the first-hop router fails.

- VRRP is applicable to LAN scenarios which require the redundancy of routing egresses.

Protocols and Standards

- RFC2338: Virtual Router Redundancy Protocol
- RFC3768: Virtual Router Redundancy Protocol (VRRP)
- RFC5798: Virtual Router Redundancy Protocol (VRRP) Version 3 for IPv4 and IPv6

5.2 Applications

Application	Description
Routing Redundancy	Configure routers in a LAN as one VRRP group to achieve simple routing redundancy.
Load Balancing	Configure routers in a LAN as multiple VRRP groups to achieve traffic load balancing.

5.2.1 Routing Redundancy

Scenario

Configure routers in a LAN as one VRRP group, where hosts take the virtual IP address of this group as the default gateway address.

- Packets from Host 1, Host 2 and Host 3 to other networks are forwarded by the elected Master router (Router A in Figure 5-1).
- If Router A fails, the Master will be re-elected between Router B and Router C to forward packets, achieving simple routing redundancy.

Figure 5-1

Deployment

- Router A, Router B and Router C are connected to the LAN via Ethernet interfaces.
- On Router A, Router B and Router C, VRRP is configured on the Ethernet interfaces connected to the LAN.
- These Ethernet interfaces are in the same VRRP group whose virtual IP address is 192.168.12.1.
- The gateway address for Host 1, Host 2 and Host 3 is the IP address of the VRRP group, namely 192.168.12.1.

5.2.2 Load Balancing

Scenario

Configure routers in a LAN as multiple VRRP groups. Hosts in the LAN take virtual IP addresses of the groups as their gateways, and each router backs up for other routers in different group.

- Packets from Host 1 and Host 2 to other networks with the default gateway address as the virtual IP address of virtual router 1 are forwarded by the Master of virtual router 1 (Router A in Figure 5-2).
- Packets from Host 3 and Host 4 to other networks with the default gateway address as the virtual IP address of virtual router 2 are forwarded by the Master of virtual router 2 (Router B in Figure 5-2).
- Routing redundancy is achieved on Router A and Router B, and the LAN traffic is shared to achieve load balancing.

Figure 5-2

Deployment

- Router A and Router B are connected to the LAN via Ethernet interfaces.
- On Router A and Router B, two virtual routers are configured on the Ethernet interfaces connected to the LAN.

Router A takes the IP address 192.168.12.1 of Ethernet interface Gi0/0 as the IP address of virtual router 1. Thus for virtual router 1, Router A becomes the Master and Router B becomes the Backup.

- Router B takes the IP address 192.168.12.2 of Ethernet interface Gi0/0 as the IP address of virtual router 2. Thus for virtual router 2, Router B becomes the Master and Router A becomes the Backup.
- In the LAN, Host 1 and Host 2 take the IP address 192.168.12.1 of virtual router 1 as the default gateway address, while Host 3 and Host 4 take the IP address 192.168.12.2 of virtual router 2 as the default gateway address.

5.3 Features

Basic Concepts

Virtual Router

A virtual router, also called a VRRP group, is regarded as a default gateway for hosts in a LAN. A VRRP group contains a Virtual Router Identifier (VRID) and a set of virtual IP addresses.

Virtual IP Address

Indicates the IP address of a virtual router. A virtual router can be configured with one or multiple IP addresses.

IP Address Owner

If a VRRP group has the virtual IP address as that of an Ethernet interface on one real router, the router is regarded as the virtual IP address owner. In such case, the router priority is 255. If the owned Ethernet interface is available, the VRRP group will be in Master state automatically. The IP address owner receives and processes the packets with the destination IP address as that of the virtual router.

Virtual MAC Address

The virtual MAC address of a VRRP group is an IEEE 802 MAC address, formatted as **00-00-5E-00-01-{VRID}** with the first five octets assigned and the last two as a group VRID. A VRRP group responds to an Address Resolution Protocol (ARP) request with its virtual MAC address instead of a real MAC address.

➤ **Master Router**

In a VRRP group, only the Master router answers ARP requests and forwards IP packets. If a real router is the IP Address Owner, it becomes the Master router.

➤ **Backup Router**

In a VRRP group, Backup routers only monitor the state of the Master but do not respond to ARP requests or forward IP packets. When the Master fails, Backup routers will take the chance to compete for the position.

➤ **Preemption Mode**

If a VRRP group runs in Preemption mode, a higher priority Backup router will replace the lower priority Master router.

Overview

Feature	Description
VRRP	VRRP achieves redundancy for the default gateways of terminals on a multi-access media (for example, Ethernet). It enables a Backup router to forward packets when the Master router is down, providing transparent routing switch and promoting network service quality.

5.3.1 VRRP

In case that the Master router is faulty, VRRP achieves migration of functions from the Master router to a Backup one without influencing internal and external data communication or modifying LAN configuration.

Working Principle

Figure 5-3 Working Principle of VRRP

➤ **Working Mode of VRRP**

The RFC2338, RFC3768 and RFC5798 protocols define the format and operating mechanism of VRRP packets. Multicast VRRP packets are sent periodically with specified destination addresses by the Master router to advertise normal operation or for Master election. VRRP allows a router in a LAN to automatically replace the Master who forwards IP packets when the latter fails. This helps achieve hot backup and fault tolerance of IP-based routing as well as ensure communication continuity and reliability for hosts in the LAN. A VRRP group achieves redundancy through multiple real routers. However, only one router acts as the Master to forward packets while the others are Backup routers. Router switching in a VRRP group is completely transparent to hosts in a LAN.

📌 Master Election Process

The RFC standards stipulate the master election process as follows:

- VRRP provides a simple mechanism for Master election. First, compare the VRRP priorities configured on the interfaces of the routers in a VRRP group. The router with the highest priority is elected as the Master. If these priorities are equal, compare the primary IP addresses of these routers. The router with the biggest IP address is elected as the Master.
- After the Master router is elected, the other routers become Backup routers (and enter the **Backup** state) and monitor the state of the master router through the VRRP packets the master router sends. If the master router is operational, it regularly sends VRRP multicast packets known as Advertisement packets to notify the Backup routers of its status. If the Backup routers do not receive such packets within a set period, all of them will enter the Master state. In such case, the previous step of Master election is repeated. In this way, a router with the highest priority will be elected as a new master, achieving VRRP backup.

Once the Master router of a VRRP group is elected, it is responsible to forward packets for hosts in a LAN.

📌 Communication Process

The VRRP communication process can be explained by Figure 5-3. The routers R1 and R2 are connected to the LAN segment 192.168.12.0/24 via the VRRP-enabled Ethernet interfaces Gi0/0. Hosts in the LAN take the virtual IP address of the VRRP group as the default gateway address. Only the virtual router is recognized by the hosts. The Master router in the group, however, is unknown. For example, when PC 1 plan to communicate with PC 2, PC 1 sends packets to the default gateway with the virtual IP address; The Master router in the group receives the packets and forwards them to PC 2. In this process, PC 1 only senses the virtual router instead of R1 or R2. The Master router in the group is elected between R1 and R2. When the Master fails, it will be replaced automatically by the other router.

Related Configuration

📌 Enabling VRRP

By default, VRRP is disabled on an interface.

In the interface configuration mode, run the `vrrp group ip ipaddress [secondary]` or `vrrp group ipv6 ipv6-address` command to set the VRID and virtual IP address to enable VRRP.

VRRP must be enabled on an interface.

📌 Configuring the IPv4 VRRP Authentication String

By default, VRRP is in non-authentication mode.

Run the **vrrp group authentication *string*** command to set an authentication string in MD5 authentication mode or a plain text password in plain text mode for an IPv4 VRRP group. In the plain text authentication mode, a password contains 8 bytes at most.

Members of a VRRP group can communicate with each other only when they are in the same authentication mode. In the plain text authentication mode, all routers in a VRRP group should have the same authentication password. The plain text authentication password cannot guarantee security but only prevents/prompts wrong VRRP configurations.

▾ Configuring the VRRP Advertisement Interval

By default, the advertisement interval of the Master router is 1 second.

Run the **vrrp [ipv6] group timers advertise { *advertise-interval* | **csec** *centisecond-interval* }** command to change the interval.

When VRRP learning timer is not configured, the same advertisement interval should be set for a VRRP group, otherwise routers in **Backup** state will discard received VRRP packets.

▾ Configuring the VRRP Preemption Mode

By default, a VRRP group operates in the Preemption mode.

To enable the Preemption mode for a VRRP group, run the **vrrp [ipv6] group preempt [**delay** *seconds*]** command. The optional parameter **delay** *seconds* is 0 by default.

If a VRRP group operates in the Preemption mode, a router will become the Master of the group when it finds that its priority is higher than that of the current Master. If a VRRP group operates in Non-preemption mode, a router will not become the Master even when it finds that its priority is higher than that of the current Master. It makes little sense to configure the Preemption mode when the VRRP group uses the IP address of an Ethernet interface, in which case the group has the highest priority and automatically becomes the Master in the group. The optional parameter **Delay Seconds** defines the delay before a backup VRRP router declares its Master identity.

▾ Enabling the IPv6 VRRP Accept Mode

By default, the Accept mode is disabled for an IPv6 VRRP group.

To enable the Accept mode, run the **vrrp ipv6 group accept_mode** command.

After the Accept mode is enabled, an IPv6 VRRP virtual router in **Master** state receives and processes packets with the virtual router IP address as the destination; when the Accept mode is disabled, the virtual router discards such packets except Neighbor Advertisement (NA) packets and Neighbor Solicitation (NS) packets. Besides, an IPv6 VRRP master virtual router in **Owner** state receives and processes packets with the virtual router IP address as the destination by default no matter whether the Accept mode is configured or not.

▾ Configuring the VRRP Router Priority

By default, the router priorities in a VRRP group are all 100.

To adjust the priority, run the **vrrp [ipv6] group priority *level*** command.

If a router in the Preemption mode owns the group's virtual IP address and the highest priority, it becomes the group Master, while the other routers with lower priorities in the group become Backup (or monitoring) routers.

↘ Configuring the VRRP Tracked Interface

By default, no interface is tracked by a VRRP group.

To configure such an interface, run the **vrrp group track** { *interface-type interface-number* | **bfd** *interface-type interface-number ipv4-address* } [*priority*] or **vrrp ipv6 group track** *interface-type interface-number* [*priority*] command.

After an interface is configured for a VRRP group to monitor, the router priority will be adjusted dynamically based on the interface state. Once the interface becomes unavailable, the priority of the router in the group will be reduced by a set value, and another functional and higher priority router in this group will become the Master.

↘ Configuring the VRRP Tracked IP Address

By default, no IP address is tracked by a VRRP group.

To configure such an address, run the **vrrp group track** *ip-address* [**interval** *interval-value*] [**timeout** *timeout-value*] [**retry** *retry-value*] [*priority*] or **vrrp ipv6 group track** { *ipv6-global-address* | { *ipv6-linklocal-address interface-type interface-number* } } [**interval** *interval-value*] [**timeout** *timeout-value*] [**retry** *retry-value*] [*priority*] command.

After an IP address is configured for a VRRP group to monitor, the router priority will be adjusted dynamically based on the address accessibility. Once the address is inaccessible (the **ping** command fails), the priority of the router in the group will be reduced by a set value, and another higher priority router in this group will become the Master.

↘ Configuring the VRRP Learning Timer

By default, the learning timer is disabled for a VRRP group.

To enable it, run the **vrrp** [**ipv6**] *group timers learn* command.

After the learning timer is configured, a VRRP Backup router learns the advertisement interval of NA packets from the Master. Based on this instead of a locally set interval, the Backup router calculates the interval for determining a failure of the Master. This command achieves the synchronization of advertisement intervals between Backup routers and the Master.

↘ Configuring the VRRP Group Description

By default, no description is configured for a VRRP group.

To configure such a string, run the **vrrp** [**ipv6**] *group description text* command.

A VRRP description helps distinguishing VRRP groups. A description has 80 bytes at most, otherwise wrong configuration is prompted.

↘ Configuring the VRRP Delay

By default, no delay is configured for a VRRP group.

To enable it, run the **vrrp delay** { **minimum** *min-seconds* | **reload** *reload-seconds* } command. The two types of delay range from 0 to 60 seconds.

The command configures the delay of starting a VRRP group on an interface. There are two types of VRRP delay: the delay after system startup and the delay after an interface resumes. You may configure them respectively or simultaneously. After the delay is configured for a VRRP group on an interface, the VRRP group starts after the delay instead of immediately upon system startup or the interface's resumption, ensuring non-preemption. If the interface receives a VRRP packet during the delay, the delay will be canceled and the VRRP will be started immediately. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface.

↘ Configuring the IPv4 VRRP Version

By default, IPv4 adopts the VRRPv2 standard.

To specify the version for IPv4 VRRP, run the **vrrp group version { 2 | 3 }** command.

When the parameter value is set to 2, VRRPv2 is adopted; when the parameter value is set to 3, VRRPv3 is adopted.

↘ Specifying a Sub VLAN of a Super VLAN to Receive the IPv4 VRRP Packets

By default, IPv4 VRRP packets are sent to the first **Up** Sub VLAN interface of a Super VLAN.

To specify the first Sub VLAN in Up state of a Super VLAN to receive IPv4 VRRP packets, run the **vrrp detection-vlan first-subvlan** command; to specify a Sub VLAN, run the **vrrp detection-vlan subvlan-id** command. If VRRP and VRRP Plus are enabled simultaneously on a Super VLAN interface, VRRP packets are sent to all Up interfaces of the Sub VLANs under the Super VLAN.

Both the above configurations reduce VRRP packets and avoids influencing router performance and occupying network bandwidth. Yet the routers constituting an IPv4 VRRP group should be interconnected within the first UP Sub VLAN interface or a specified Sub VLAN of the Super VLAN.

↘ Configuring the BFD Support for IPv4 VRRP on an Interface

By default, the Bidirectional Forwarding Detection (BFD) protocol support for VRRP is not enabled on an interface.

To enable it, run the **vrrp group bfd ip-address** command.

For a Backup router, run this command to correlate an IPv4 VRRP group with BFD without caring the configured IP address. For the Master, as the primary IP address of a Backup router is not known, the router IP address can only be specified by the administrator.

To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.

After the BFD support is enabled for a specified IPv4 VRRP group, when the Master fails, a Backup router may detect it within one second.

↘ Configuring Global IPv4 VRRP BFD

By default, the VRRP does not adopt the global IPv4 VRRP BFD mode in detecting the state of the Master.

To enable global IPv4 VRRP BFD, run the **vrrp bfd interface-type interface-number ip-address** command.

After global IPv4 VRRP BFD is enabled, multiple IPv4 VRRP groups may share BFD sessions, achieving fast detection and master-backup failover.

To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.

5.4 Configuration

Configuration	Description and Command
Configuring IPv4 VRRP	 (Mandatory) It is used to enable IPv4 VRRP.
	vrrp group ip <i>ipaddress</i> [secondary] Enables IPv4 VRRP.
	 (Optional) It is used to configure IPv4 VRRP parameters.
	vrrp group authentication <i>string</i> Configures the IPv4 VRRP authentication string.
	vrrp group timers advertise { <i>advertise-interval</i> csec <i>centisecond-interval</i> } Configures the IPv4 VRRP advertisement interval.
	vrrp group preempt [delay <i>seconds</i>] Configures the IPv4 VRRP Preemption mode.
	vrrp group priority <i>level</i> Configures the IPv4 VRRP router priority.
	vrrp group track { <i>interface-type</i> <i>interface-number</i> bfd <i>interface-type</i> <i>interface-number ip4-address</i> } [<i>priority</i>] Configures the IPv4 VRRP tracked interface.
	vrrp group track <i>ip-address</i> [interval <i>interval-value</i>] [timeout <i>timeout-value</i>] [retry <i>retry-value</i>] [<i>priority</i>] Configures the IPv4 VRRP tracked IP address.
	vrrp group timers learn Configures the IPv4 VRRP learning timer.
	vrrp group description <i>text</i> Configures the IPv4 VRRP group description.
	vrrp delay { minimum <i>min-seconds</i> reload <i>reload-seconds</i> } Configures the IPv4 VRRP delay.
	vrrp group version { 2 3 } Configures the IPv4 VRRP version.
	vrrp detection-vlan { first-subvlan <i>subvlan-id</i> } Specifies a sub VLAN of a super VLAN to receive the IPv4 VRRP packets.
	vrrp group bfd <i>ip-address</i> Configures the BFD support for IPv4 VRRP on an Interface.
vrrp bfd <i>interface-type interface-number</i> <i>ip-address</i> Configures global IPv4 VRRP BFD.	
Configuring IPv6 VRRP	 (Mandatory) It is used to enable IPv6 VRRP.
vrrp group ipv6 <i>ipv6-address</i> Enables IPv6 VRRP in interface configuration mode.	
 (Optional) It is used to configure IPv6 VRRP parameters.	

Configuration	Description and Command
	vrrp ipv6 group timers advertise { <i>advertise-interval</i> csec <i>centisecond-interval</i> } Configures the IPv6 advertisement interval.
	vrrp ipv6 group preempt [delay seconds] Configures the IPv6 VRRP Preemption mode.
	vrrp ipv6 group accept_mode Enables the Accept mode for an IPv6 VRRP group.
	vrrp ipv6 group priority level Configures the IPv6 VRRP router priority.
	vrrp ipv6 group track interface-type interface-number [interface-priority] Configures the IPv6 VRRP tracked interface.
	vrrp ipv6 group track { ipv6-global-address { ipv6-linklocal-address interface-type interface-number } } [interval interval-value] [timeout timeout-value] [retry retry-value] [priority] Configures the IPv6 VRRP tracked IP address.
	vrrp ipv6 group timers learn Configures the IPv6 VRRP learning timer.
	vrrp ipv6 group description text Configures the IPv6 VRRP group description.
	vrrp delay { minimum min-seconds reload reload-seconds } Configures the IPv6 VRRP delay.
Configuring VRRP-MSTP	 The configuration is the same as IPv4 VRRP configuration.

5.4.1 Configuring IPv4 VRRP

Configuration Effect

- Configure a VRRP group on an interface of a specific LAN segment by setting the VRID and virtual IP address.
- Configure multiple VRRP groups on an interface to achieve load balancing and offer more stable and reliable network services.
- Configure the VRRP tracked interfaces to monitor real-time failures, change interface priorities and realize master-backup failover dynamically.

Notes

- To achieve VRRP, the routers in a VRRP group should be configured with the same virtual IPv4 address.
- To achieve mutual backup between multiple IPv4 VRRP groups, configure multiple IPv4 VRRP groups with identical VRRP configuration on different interface and configure different priorities for them so that they act as the master and backup groups mutually.
- Enable VRRP on Layer-3 interfaces.

Configuration Steps

↳ Enabling IPv4 VRRP

- By default, IPv4 VRRP is disabled on an interface. You can enable it based on your demand.

↳ Configuring the IPv4 VRRP Authentication String

- By default, VRRP is in non-authentication mode. You can enable plain text authentication mode based on your demand.

↳ Configuring the IPv4 VRRP Advertisement Interval

- By default, the Master router sends advertisement packets every one second. You can modify the interval based on your demand.

↳ Configuring the IPv4 VRRP Preemption Mode

- By default, a VRRP group operates in Preemption mode with a zero-second delay.

↳ Configuring the IPv4 VRRP Router Priority

- The default router priority for a VRRP group is 100. You can modify the priority based on your demand.

↳ Configuring the IPv4 VRRP Tracked Interface

- By default, an IPv4 VRRP group monitors no interface and the value of priority change is 10. To achieve fault monitoring through interface monitoring, please configure this item.

↳ Configuring the IPv4 VRRP Learning Timer

- By default, the learning timer is disabled for a VRRP group. Enable this function if the Backup routers need to learn the Master's advertisement interval.

↳ Configuring the IPv4 VRRP Group Description

- By default, no description is configured for a VRRP group. To distinguish VRRP groups clearly, configure descriptions.

↳ Configuring the IPv4 VRRP Delay

- By default, the IPv6 VRRP delay is not configured. To guarantee an effective non-preemption mode, configure the delay.

↳ Configuring the IPv4 VRRP Version

- By default, IPv4 adopts the VRRPv2 standard. To change it, use the corresponding command.

↳ Specifying a Sub VLAN of a Super VLAN to Receive the IPv4 VRRP Packets

- By default, IPv4 VRRP packets are only sent to the first **UP** Sub VLAN interface of a Super VLAN, but you may configure a specific Sub VLAN.

↳ Configuring the BFD Support for IPv4 VRRP on an Interface

- By default, the BFD support is not configured on an interface. To configure it, use the corresponding command.

↘ Configuring Global IPv4 VRRP BFD

- By default, global IPv4 VRRP BFD is not enabled. To implement it, use the corresponding command.

Verification

- Run the **show vrrp** command to verify the configuration.

Related Commands

↘ Enabling IPv4 VRRP

Command	vrrp group ip <i>ipaddress</i> [secondary]
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group, the range of which varies with product models. <i>ipaddress</i> : Indicates the IP address of a VRRP group. secondary : Indicates the secondary IP address of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	If no virtual IP address is specified, routers cannot join a VRRP group. If no secondary IP address is applied, the configured IP address will be the primary IP address of a VRRP group.

↘ Configuring the IPv4 VRRP Authentication String

Command	vrrp group authentication <i>string</i>
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group. <i>string</i> : Indicates the authentication string of a VRRP group (a plain text password consists of 8 bytes at most).
Command Mode	Interface configuration mode
Usage Guide	In a VRRP group, the same authentication password should be configured for routers. The plain text authentication password cannot guarantee security but only prevents/prompts wrong VRRP configurations. This command is only applicable to VRRPv2 instead of VRRPv3. Authentication is abolished for VRRPv3 (IPv4 VRRP and IPv6 VRRP) packets. If VRRPv2 is chosen for an IPv4 VRRP group, the command is effective; if VRRPv3 is chosen, the command is ineffective.

↘ Configuring the IPv4 VRRP Advertisement Interval

Command	vrrp group timers advertise { <i>advertise-interval</i> csec <i>centisecond-interval</i> }
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group. <i>advertise-interval</i> : Indicates the advertisement interval of a VRRP group (unit: second). csec centisecond-interval : An interval for a master router in a backup group to send VRRP packets. It is an integer from 50 to 99. The unit is centisecond. No default value is provided. The command is only effective for VRRPv3 packets. If it is configured for VRRPv2 packets, the default interval is one second.

Command Mode	Interface configuration mode
Usage Guide	<p>If a router is elected as the Master in a VRRP group, it sends VRRP advertisement packets at the set interval to announce its VRRP state, priority and other information.</p> <p>According to the RFC standards, if an IPv4 VRRP group adopts VRRPv3 for sending multicast packets, the maximum advertisement interval is 40 seconds. Therefore, if the interval is set longer than 40 seconds, this maximum interval will be applied, though the configuration is effective.</p>

↘ Configuring the IPv4 VRRP Preemption Mode

Command	vrrp group preempt [delay seconds]
Parameter Description	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p>delay seconds: Indicates the preemption delay for the Master router to claim its status. The default value is 0 second.</p>
Command Mode	Interface configuration mode
Usage Guide	<p>If a VRRP group runs in Preemption mode, a higher priority router will take the place of the lower priority Master. If a VRRP group runs in Non-preemption mode, a router with the priority higher than that of the Master remains Backup. It makes little sense to configure the Preemption mode when the VRRP group uses the IP address of an Ethernet interface, in which case the group has the highest priority and automatically becomes the Master in the group.</p>

↘ Configuring the IPv4 VRRP Router Priority

Command	vrrp group priority level
Parameter Description	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p><i>level</i>: Indicates the priority of an interface in a VRRP group.</p>
Command Mode	Interface configuration mode
Usage Guide	This command is used to manually configure the VRRP router priority.

↘ Configuring the IPv4 VRRP Tracked Interface

Command	vrrp group track { interface-type interface-number bfd interface-type interface-number ipv4-address } [priority]
Parameter Description	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p><i>interface-type interface-number</i>: Indicates the interface to be tracked.</p> <p>bfd interface-type interface-number ipv4-address: A specified adjacent IP address tracked through BFD.</p> <p><i>priority</i>: Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.</p>
Command Mode	Interface configuration mode
Usage Guide	A tracked interface must be a routable Layer-3 logic interface (for example, a Routed port, an SVI interface, a Loopback interface, or a Tunnel interface).

	The priority of the router owns the virtual IP address associated with a VRRP group must be 255, and no tracked interface can be configured on it.
--	--

▾ Configuring the IPv4 VRRP Tracked IP Address

Command	vrrp group track <i>ipv4-address</i> [interval <i>interval-value</i>] [timeout <i>timeout-value</i>] [retry <i>retry-value</i>] [<i>priority</i>]
Parameter Description	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p><i>ipv4-address</i>: Indicates the IPv4 address to be tracked.</p> <p>interval <i>interval-value</i>: Indicates the probe interval. The unit is second. Unless configured manually, the value is 3 seconds by default.</p> <p>timeout <i>timeout-value</i>: Indicates the probe timeout of waiting for responses. If no response is received when the timeout is up, it is regarded that the destination is inaccessible. The unit is second. Unless configured manually, the value is 1 second by default.</p> <p>retry <i>retry-value</i>: Indicates the probe retries. If the probe packet is sent continually for <i>retry-value</i> times but no response is received, it is regarded that the destination is inaccessible. The unit is times. Unless configured, the value is 3 times by default.</p> <p><i>priority</i>: Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.</p>
Command Mode	Interface configuration mode
Usage Guide	To monitor a host, specify its IPv4 address for an IPv4 VRRP group. If a VRRP group owns the actual IP address of an Ethernet interface, the group priority is 255, and no monitored IP address can be configured.

▾ Configuring the IPv4 VRRP Learning Timer

Command	vrrp group timers learn
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	Once the learning timer is enabled on a VRRP router, a Backup router learns the advertisement interval of the Master during the timer. Based on this, the Backup router calculates the interval for determining the Master router as failed instead of using the locally configured advertisement interval. This command achieves synchronization with the learning timer between the Master and Backup routers.

▾ Configuring the IPv4 VRRP Group Description

Command	vrrp group description <i>text</i>
Parameter Description	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p><i>text</i>: Indicates the description of a VRRP group.</p>
Command Mode	Interface configuration mode

Usage Guide	A VRRP description helps distinguishing VRRP groups. A description has 80 bytes at most, otherwise wrong configuration is prompted.
--------------------	---

↘ Configuring the IPv4 VRRP Delay

Command	vrrp delay { minimum <i>min-seconds</i> reload <i>reload-seconds</i> }
Parameter	minimum <i>min-seconds</i> : Indicates the VRRP delay after an interface state changes.
Description	reload <i>reload-seconds</i> : Indicates the VRRP delay after the system starts.
Command Mode	Interface configuration mode
Usage Guide	After the delay is configured for a VRRP group on an interface, the VRRP group starts after the delay instead of immediately upon system startup or the interface's resumption, ensuring non-preemption. If the interface receives a VRRP packet during the delay, the delay will be canceled and the VRRP will be started immediately. The two types of delay share a value range of 0 to 60 seconds. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface.

↘ Configuring the IPv4 VRRP Version

Command	vrrp group version { 2 3 }
Parameter	2 : Indicates VRRPv2.
Description	3 : Indicates VRRPv3.
Command Mode	Interface configuration mode
Usage Guide	Considering the compatibility between VRRPv2 and VRRPv3, specify a standard for IPv4 VRRP based on the actual network condition. VRRPv2 is developed in RFC3768, while VRRPv3 is described in RFC5798. This command is only applicable to IPv4 VRRP.

↘ Specifying a Sub VLAN of a Super VLAN to Receive the IPv4 VRRP Packets

Command	vrrp detection-vlan { first-subvlan <i>subvlan-id</i> }
Parameter	first-subvlan : Sends IPv4 VRRP packets only to the first UP Sub VLAN interface in a Super VLAN.
Description	<i>subvlan-id</i> : Sends IPv4 VRRP packets to a specified Sub VLAN.
Command Mode	Interface configuration mode
Usage Guide	This command is used to specify a Sub VLAN of a Super VLAN to receive the IPv4 VRRP packets. IPv4 VRRP packets are sent in a Super VLAN using the following three methods. Packets are sent to the first UP Sub VLAN interface in a Super VLAN, or to a specified Sub VLAN interface in a Super VLAN, or to all the Sub VLAN interfaces in a Super VLAN. If VRRP and VRRP Plus are enabled simultaneously on a Super VLAN interface, VRRP packets are sent to all Up interfaces of the Sub VLANs under the Super VLAN. This command is configured on a VLAN interface and effective only to Super VLAN interfaces.

↘ Configuring the BFD Support for IPv4 VRRP on an Interface

Command	vrrp group bfd <i>ip-address</i>
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.

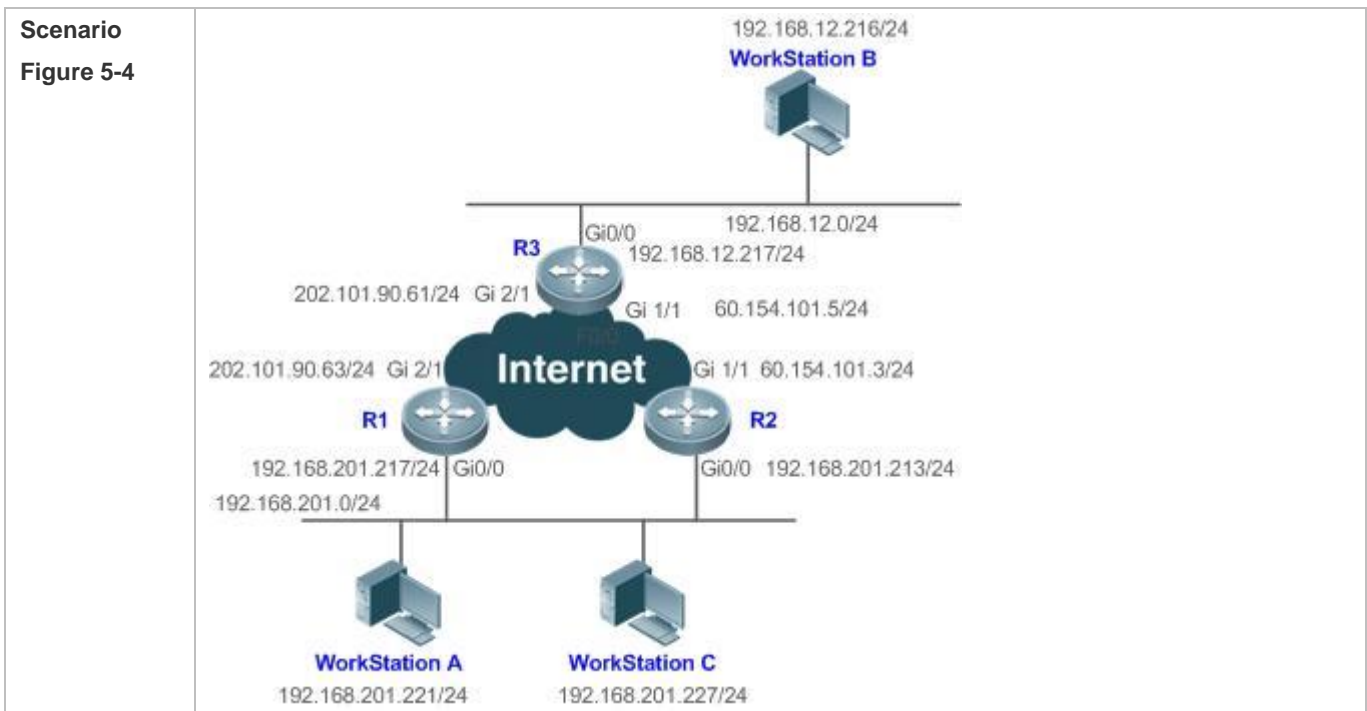

Description	<i>ip-address</i> : Indicates the interface IP address.
Command Mode	Interface configuration mode
Usage Guide	For a Backup router, run this command to correlate an IPv4 VRRP group with BFD without caring the configured IP address. For the Master, as the primary IP address of a Backup router is not known, the router IP address can only be specified by the administrator. If global IPv4 VRRP BFD is configured, this configuration cannot be performed. To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.

↘ **Configuring Global IPv4 VRRP BFD**

Command	<code>vrrp bfd interface-type interface-number ip-address</code>
Parameter	<i>interface-type interface-number</i> : Indicates interface type and ID.
Description	<i>ip-address</i> : Indicates the interface IP address.
Command Mode	Global configuration mode
Usage Guide	If global IPv4 VRRP BFD is configured, the configured BFD support will be deleted. To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface. A global IPv4 VRRP BFD session is only applicable to an IPv4 VRRP group consisting of two routers.

Configuration Example

↘ **Configuring an IPv4 VRRP Group and Tracked Interface**

Configuration Steps	<ul style="list-style-type: none"> ● The cluster of Work Station A and Work Station B (192.168.201.0/24) uses the virtual IP address 192.168.201.1 of the VRRP group constituted by the routers R1 and R2 as the gateway address to communicate with Work Station B (192.168.12.0/24). ● GigabitEthernet 2/1 on R1 is configured as the tracked interface. ● No VRRP but an ordinary routing function is configured on R3.
R3	<pre> R3#configure terminal R3(config)#interface GigabitEthernet 0/0 // The command “no switchport” is only required for a switch. R3(config-if-GigabitEthernet 0/0)#no switchport R3(config-if-GigabitEthernet 0/0)#ip address 192.168.12.217 255.255.255.0 R3(config-if-GigabitEthernet 0/0)#exit R3(config)#interface GigabitEthernet 1/1 // The command “no switchport” is only required for a switch. R3(config-if-GigabitEthernet 1/1)#no switchport R3(config-if-GigabitEthernet 1/1)#ip address 60.154.101.5 255.255.255.0 R3(config-if-GigabitEthernet 1/1)#exit R3(config)#interface GigabitEthernet 2/1 // The command “no switchport” is only required for a switch. R3(config-if-GigabitEthernet 2/1)#no switchport R3(config-if-GigabitEthernet 2/1)#ip address 202.101.90.61 255.255.255.0 R3(config-if-GigabitEthernet 2/1)#exit R3(config)#router ospf R3(config-router)#network 202.101.90.0 0.0.0.255 area 10 R3(config-router)#network 192.168.12.0 0.0.0.255 area 10 R3(config-router)#network 60.154.101.0 0.0.0.255 area 10 </pre>
R1	<pre> R1#configure terminal R1(config)#interface GigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)#ip address 192.168.201.217 255.255.255.0 R1(config-if-GigabitEthernet 0/0)#vrrp 1 priority 120 R1(config-if-GigabitEthernet 0/0)#vrrp 1 version 3 R1(config-if-GigabitEthernet 0/0)#vrrp 1 timers advertise 3 </pre>

	<pre> R1(config-if-GigabitEthernet 0/0)#vrrp 1 ip 192.168.201.1 R1(config-if-GigabitEthernet 0/0)#vrrp 1 track GigabitEthernet 2/1 30 R1(config-if-GigabitEthernet 0/0)#exit R1(config)#interface GigabitEthernet 2/1 R1(config-if-GigabitEthernet 2/1)#ip address 202.101.90.63 255.255.255.0 R1(config-if-GigabitEthernet 2/1)#exit R1(config)#router ospf R1(config-router)#network 202.101.90.0 0.0.0.255 area 10 R1(config-router)#network 192.168.201.0 0.0.0.255 area 10 </pre>
R2	<pre> R2#configure terminal R2(config)#interface GigabitEthernet 0/0 R2(config-if-GigabitEthernet 0/0)#ip address 192.168.201.213 255.255.255.0 R2(config-if-GigabitEthernet 0/0)#vrrp 1 ip 192.168.201.1 R2(config-if-GigabitEthernet 0/0)#vrrp 1 version 3 R2(config-if-GigabitEthernet 0/0)#vrrp 1 timers advertise 3 R2(config-if-GigabitEthernet 0/0)#exit R2(config)#interface GigabitEthernet 1/1 // The command "no switchport" is only required for a switch. R2(config-if-GigabitEthernet 1/1)#no switchport R2(config-if-GigabitEthernet 1/1)#ip address 60.154.101.3 255.255.255.0 R2(config-if-GigabitEthernet 1/1)#exit R2(config)#router ospf R2(config-router)#network 60.154.101.0 0.0.0.255 area 10 R2(config-router)#network 192.168.201.0 0.0.0.255 area 10 </pre>
Verification	<p>Run the show vrrp command to verify the configuration.</p> <ul style="list-style-type: none"> ● Check whether R1, which acts as the Master, reduces its VRRP priority from 120 to 90 when GigabitEthernet2/1 connected to the Wide Area Network (WAN) is unavailable. If yes, R2 becomes the Master. ● Check whether R1 resumes its VRRP priority from 30 to 120 when GigabitEthernet 2/1 connected to the WAN recovers. If yes, R1 is re-elected as the Master.
R1	<pre> R1#show vrrp GigabitEthernet 0/0 - Group 1 </pre>

	<pre>State is Master Virtual IP address is 192.168.201.1 configured Virtual MAC address is 0000.5e00.0101 Advertisement interval is 3 sec Preemption is enabled min delay is 0 sec Priority is 120 Master Router is 192.168.201.217 (local), priority is 120 Master Down interval is 10.59 sec Tracking state of 1 interface, 1 up: up GigabitEthernet 2/1 priority decrement=30</pre>
R2	<pre>R2#show vrrp GigabitEthernet 0/0 - Group 1 State is Backup Virtual IP address is 192.168.201.1 configured Virtual MAC address is 0000.5e00.0101 Advertisement interval is 3 sec Preemption is enabled min delay is 0 sec Priority is 100 Master Router is 192.168.201.217 , priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.82 sec</pre>

Common Errors

- Different virtual IP addresses are configured on the routers in a VRRP group, resulting in multiple Master routers in the group.
- Different VRRP advertisement intervals are configured on the routers in a VRRP group and the learning timer is not configured, resulting in multiple Master routers in the group.
- Different VRRP versions are configured on the routers in a VRRP group, resulting in multiple Master routers in the group.
- For VRRPv2, the Ethernet interfaces of the routers in a VRRP group are all in plain text authentication mode but inconsistent in authentication strings, resulting in multiple Master routers in the group.

Configuration Example

Configuring Multiple IPv4 VRRP Groups

<p>Scenario Figure 5-5</p>	<p>The diagram illustrates a network topology for configuring multiple IPv4 VRRP groups. It features three routers: R1, R2, and R3. R1 and R2 are connected to a central cloud labeled 'Internet'. R1 is connected to the Internet via its Gi 2/1 interface (202.101.90.63/24), and R2 is connected via its Gi 1/1 interface (60.154.101.3/24). R3 is connected to the Internet via its Gi 0/0 interface (192.168.12.217/24). R3 is also connected to a LAN containing WorkStation B (192.168.12.216/24) via its Gi 1/1 interface (60.154.101.5/24). R1 and R2 are connected to another LAN containing WorkStation A (192.168.201.221/24) and WorkStation C (192.168.201.227/24) via their Gi 0/0 interfaces (192.168.201.217/24 and 192.168.201.213/24, respectively). This LAN is configured with two VRRP groups: 'Virtual Gateway 1' with virtual IP 192.168.201.1 and 'Virtual Gateway 2' with virtual IP 192.168.201.2.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● The user workstation cluster (192.168.201.0/24) uses the backup group constituted by the routers R1 and R2. The gateway for partial workstations (A for example) points to the virtual IP address 192.168.201.1 of the backup group 1, while that for other partial workstations (C for example) points to the virtual IP address 192.168.201.2 of the backup group 2. IPv4 multicast routing is enabled on all the routers. ● R1 acts as the master router in the group 2 and as a backup router in the group 1. ● R2 acts as a backup router in the group 2 and as a master router in the group 1.
<p>R3</p>	<pre>R3#configure terminal R3(config)#interface GigabitEthernet 0/0 // The command "no switchport" is only required for a switch. R3(config-if-GigabitEthernet 0/0)#no switchport R3(config-if-GigabitEthernet 0/0)#ip address 192.168.12.217 255.255.255.0 R3(config-if-GigabitEthernet 0/0)#exit R3(config)#interface GigabitEthernet 1/1</pre>

	<pre>// The command "no switchport" is only required for a switch. ```

5.4.2 Configuring IPv6 VRRP

Configuration Effect

- Configure an IPv6 VRRP group on an interface of a specific LAN segment by setting the VRID and virtual IPv6 address.
- Configure multiple IPv6 VRRP groups on an interface to achieve load balance and achieve more stable and reliable network services.
- Configure the VRRP tracked interfaces to monitor real-time failures, change interface priorities and realize master-backup failover dynamically.

Notes

- To achieve VRRP, the routers in a VRRP group should be configured with the same virtual IPv6 address.
- To achieve mutual backup for multiple IPv6 VRRP backup groups, you need to configure multiple IPv6 VRRP groups with identical VRRP configuration on an interface and configure different priorities for them to make routers master and backup mutually.
- VRRP must be enabled on Layer-3 interfaces.

Configuration Steps

↳ Enabling IPv6 VRRP in Interface Configuration Mode

- By default, IPv6 VRRP is not enabled on an interface. You can enable it based on your demand.

↳ Configuring the IPv6 VRRP Advertisement Interval

- By default, the Master router sends advertisement packets every one second. You can modify the interval based on your demand.

↳ Configuring the IPv6 VRRP Preemption Mode

- By default, a VRRP group operates in Preemption mode with a zero-second delay.

↳ Enabling the Accept Mode for an IPv6 VRRP Group

- By default, the Accept mode is disabled for an IPv6 VRRP group. To require an IPv6 VRRP VRRP group in Master state to receive and process packets with the destination IP address as that of the virtual router, enable Accept mode.

↳ Configuring the IPv6 VRRP Router Priority

- The default router priority for a VRRP group is 100. You can modify the priority based on your demand.
- ↳ **Configuring the IPv6 VRRP Tracked Interface**
- By default, no tracked interface is configured. You can modify the interval based on your demand.
- ↳ **Configuring the IPv6 VRRP Tracked IP Address**
- By default, no tracked IPv6 address is configured and the value of priority change is 10. You can configure this function based on your demand.
- ↳ **Configures the IPv6 VRRP Learning Timer**
- By default, the learning timer is disabled for a VRRP group. Enable this function if the Backup routers need to learn the Master's advertisement interval.
- ↳ **Configuring the IPv6 VRRP Group Description**
- By default, no description is configured for a VRRP group. To distinguish VRRP groups clearly, configure descriptions.
- ↳ **Configuring the IPv4 VRRP Delay**
- By default, the IPv6 VRRP delay is not configured. To guarantee an effective non-preemption mode, configure the delay.

Verification

- Run the **show vrrp** command to verify the configuration.

Related Commands

↳ Enabling IPv6 VRRP

Command	vrrp group ipv6 <i>ipv6-address</i>
Parameter	<i>group</i> : Indicates the VRID of a VRRP group, the range of which varies with product models.
Description	<i>ipv6-address</i> : Indicates the IPv6 address of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	IPv6 VRRP groups and IPv4 VRRP groups share a VRID range from 1 to 255. One VRID is applicable to an IPv4 VRRP group and an IPv6 VRRP group at the same time. The first configured address should be a link-local address, which can be deleted only after other virtual addresses.

↳ Configuring the IPv6 VRRP Advertisement Interval

Command	vrrp ipv6 group timers advertise { <i>advertise-interval</i> csec <i>centisecond-interval</i> }
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<i>advertise-interval</i> : Indicates the advertisement interval of a VRRP group (unit: second). csec centisecond-interval : An interval for a master router in a backup group to send VRRP packets. It is an

	integer from 50 to 99. The unit is centisecond. No default value is provided. The command is only effective for VRRPv3 packets. If it is configured for VRRPv2 packets, the default interval is one second.
Command Mode	Interface configuration mode
Usage Guide	<p>If a router is elected as the Master in a VRRP group, it sends VRRP advertisement packets at the set interval to announce its VRRP state, priority and other information.</p> <p>According to the RFC standards, if an IPv6 VRRP group adopts VRRPv3 for sending multicast packets, the maximum advertisement interval is 40 seconds. Therefore, if the interval is set longer than 40 seconds, this maximum interval will be applied, though the configuration is effective.</p>

↘ Configuring the Preemption Mode

Command	vrrp ipv6 group preempt [delay seconds]
Parameter Description	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p>delay seconds: Indicates the preemption delay for the Master router to claim its status. The default value is 0 second.</p>
Command Mode	Interface configuration mode
Usage Guide	<p>If a VRRP group runs in Preemption mode, a higher priority router will take the place of the lower priority Master. If a VRRP group runs in Non-preemption mode, a router with the priority higher than that of the Master remains Backup. It makes little sense to configure the Preemption mode when the VRRP group uses the IP address of an Ethernet interface, in which case the group has the highest priority and automatically becomes the Master in the group.</p>

↘ Enabling the Accept Mode for an IPv6 VRRP Group

Command	vrrp ipv6 group accept_mode
Parameter Description	<p><i>group</i>: Indicates the VRID of a VRRP group.</p>
Command Mode	Interface configuration mode
Usage Guide	<p>By default, an IPv6 VRRP group in Master state is not permitted to receive packets with the destination IPv6 address as that of the VRRP group. However, it receives NA and NS packets no matter whether Accept mode is configured. Besides, the IP Address Owner in Master state receives and processes the packets with the destination IPv6 address as that of the VRRP group no matter whether Accept mode is configured or not.</p>

↘ Configuring the IPv6 VRRP Router Priority

Command	vrrp ipv6 group priority level
Parameter Description	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p><i>level</i>: Indicates the priority of a VRRP router.</p>
Command Mode	Interface configuration mode

Usage Guide	This command is used to manually configure the VRRP router priority.
--------------------	--

▾ Configuring the IPv6 VRRP Tracked Interface

Command	<code>vrrp ipv6 group track interface-type interface-number [priority]</code>
Parameter Description	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p><i>interface-type interface-number</i>: Indicates the interface to be tracked.</p> <p><i>priority</i>: Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.</p>
Command Mode	Interface configuration mode
Usage Guide	<p>A tracked interface must be a routable Layer-3 logic interface (for example, a Routed port, an SVI interface, a Loopback interface, or a Tunnel interface).</p> <p>The priority of the router owns the virtual IP address associated with a VRRP group must be 255, and no tracked interface can be configured on it.</p>

▾ Configuring the IPv6 VRRP Tracked IP Address

Command	<code>vrrp ipv6 group track { ipv6-global-address ipv6-linklocal-address interface-type interface-number } [interval interval-value] [timeout timeout-value] [retry retry-value] [priority]</code>
Parameter Description	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p><i>ipv6-global-address</i>: Indicates the IPv6 global unicast address.</p> <p><i>ipv6-linklocal-address</i>: Indicates the IPv6 link-local address.</p> <p><i>interface-type interface-number</i>: Indicates the interface to be tracked.</p> <p>interval interval-value: Indicates the probe interval. The unit is second. Unless configured manually, the value is 3 seconds by default.</p> <p>timeout timeout-value: Indicates the probe timeout of waiting for responses. If no response is received when the timeout is up, it is regarded that the destination is inaccessible. The unit is second. Unless configured manually, the value is 1 second by default.</p> <p>retry retry-value: Indicates the probe retries. If the probe packet is sent continually for <i>retry-value</i> times but no response is received, it is regarded that the destination is inaccessible. The unit is times. Unless configured, the value is 3 times by default.</p> <p><i>priority</i>: Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.</p>
Command Mode	Interface configuration mode
Usage Guide	<p>To monitor a host, specify its IPv6 address for an IPv6 VRRP group.</p> <p>If the host IP address being tracked is a link-local address, specify a network interface.</p> <p>If a VRRP group owns the actual IP address of an Ethernet interface, the group priority is 255, and no monitored IP address can be configured.</p>

▾ Configures the IPv6 VRRP Learning Timer

Command	<code>vrrp ipv6 group timers learn</code>
----------------	---

Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	Once the learning timer is enabled on a VRRP router, a Backup router learns the advertisement interval of the Master during the timer. Based on this, the Backup router calculates the interval for determining the Master router as failed instead of using the locally configured advertisement interval. This command achieves synchronization with the learning timer between the Master and Backup routers.

📌 Configuring the IPv6 VRRP Group Description

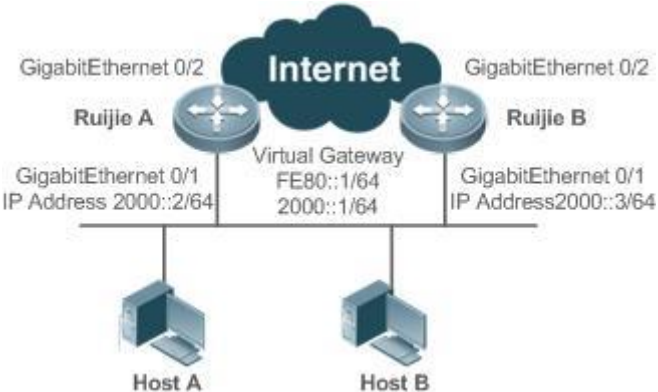

Command	vrrp ipv6 <i>group</i> description <i>text</i>
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group. <i>text</i> : Indicates the description of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	A VRRP description helps distinguishing VRRP groups. A description has 80 bytes at most, otherwise wrong configuration is prompted.

📌 Configuring the IPv4 VRRP Delay

Command	vrrp delay { minimum <i>min-seconds</i> reload <i>reload-seconds</i> }
Parameter Description	minimum <i>min-seconds</i> : Indicates the VRRP delay after an interface state changes. reload <i>reload-seconds</i> : Indicates the VRRP delay after the system starts.
Command Mode	Interface configuration mode
Usage Guide	After the delay is configured for a VRRP group on an interface, the VRRP group starts after the delay instead of immediately upon system startup or the interface's resumption, ensuring non-preemption. If the interface receives a VRRP packet during the delay, the delay will be canceled and the VRRP will be started immediately. The two types of delay share a value range of 0 to 60 seconds. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface.

Configuration Example

📌 Configuring an IPv6 VRRP Group and Tracked Interface

<p>Scenario Figure 5-6</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Host A and Host B access the Internet resources through the default gateway 2000::1/64. ● Ruijie A and Ruijie B belong to the IPv6 VRRP group 1, and their virtual addresses are 2000::1/64 and FE80::1 respectively. ● Ruijie A tracks the interface GigabitEthernet 0/2 connected to the Internet. When GigabitEthernet 0/2 is unavailable, Ruijie A reduces its priority and Ruijie B acts as a gateway.
<p>RuijieA</p>	<pre>RuijieA#configure terminal RuijieA(config)#interface GigabitEthernet 0/1 RuijieA(config-if-GigabitEthernet 0/1)#no switchport RuijieA(config-if-GigabitEthernet 0/1)#ipv6 address 2000::2/64 RuijieA(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 FE80::1 RuijieA(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2000::1 RuijieA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 priority 120 RuijieA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 timers advertise 3 RuijieA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 track GigabitEthernet 0/2 50 RuijieA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 accept_mode</pre>
<p>RuijieB</p>	<pre>RuijieB#configure terminal RuijieB(config)#interface GigabitEthernet 0/1 RuijieB(config-if-GigabitEthernet 0/1)#no switchport RuijieB(config-if-GigabitEthernet 0/1)#ipv6 address 2000::3/64 RuijieB(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 FE80::1 RuijieB(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2000::1 RuijieB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 priority 100 RuijieB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 timers advertise 3 RuijieB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 accept_mode</pre>

<p>Verification</p>	<p>Run the show vrrp command to verify the configuration.</p> <ul style="list-style-type: none"> ● Check whether Ruijie A, which acts as the Master router, reduces its VRRP group priority from 120 to 70 when it finds that the interface GigabitEthernet 0/2 connected to WAN is unavailable. If yes, Ruijie B becomes the Master. ● Check whether Ruijie A increases its VRRP group priority from 50 to 120 when it finds the interface GigabitEthernet 0/2 connected to WAN becomes available again. If yes, Ruijie A becomes the Master again.
<p>RuijieA</p>	<pre>RuijieA#show ipv6 vrrp 1 GigabitEthernet 0/1 - Group 1 State is Master Virtual IPv6 address is as follows: FE80::1 2000::1 Virtual MAC address is 0000.5e00.0201 Advertisement interval is 3 sec Accept_Mode is enabled Preemption is enabled min delay is 0 sec Priority is 120 Master Router is FE80::1234 (local), priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.59 sec Tracking state of 1 interface, 1 up: up GigabitEthernet 0/2 priority decrement=50</pre>
<p>RuijieB</p>	<pre>RuijieB#show ipv6 vrrp 1 GigabitEthernet 0/1 - Group 1 State is Backup Virtual IPv6 address is as follow: FE80::1 2000::1 Virtual MAC address is 0000.5e00.0201 Advertisement interval is 3 sec</pre>

```

Accept_Mode is enabled

Preemption is enabled

    min delay is 0 sec

Priority is 100

Master Router is FE80::1234, priority is 120

Master Advertisement interval is 3 sec

Master Down interval is 10.82 sec
    
```

Configuration Example

Multiple VRRP Backup Groups (under IPv6)

<p>Scenario Figure 5-7</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> Host A and Host B access the Internet resources through the gateways 2000::1/64 and 2000::100/64 respectively. Ruijie A and Ruijie B belong to the IPv6 VRRP group 1, and their virtual addresses are 2000::1/64 and FE80::1 respectively. Ruijie A and Ruijie B belong to the backup group 2 of a virtual IPv6 router, and their virtual addresses are 2000::100/64 and FE80::100 respectively. Ruijie A and Ruijie B act as gateways and forward flows, being a backup router to each other.
<p>RuijieA</p>	<pre> RuijieA#configure terminal RuijieA(config)#interface GigabitEthernet 0/1 RuijieA(config-if-GigabitEthernet 0/1)#no switchport RuijieA(config-if-GigabitEthernet 0/1)#ipv6 address 2000::2/64 RuijieA(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 FE80::1 RuijieA(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2000::1 </pre>

	<pre> RuijieA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 priority 120 RuijieA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 timers advertise 3 RuijieA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 accept_mode RuijieA(config-if-GigabitEthernet 0/1)#vrrp 2 ipv6 FE80::100 RuijieA(config-if-GigabitEthernet 0/1)# vrrp 2 ipv6 2000::100 RuijieA(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 priority 100 RuijieA(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 timers advertise 3 RuijieA(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 accept_mode </pre>
RuijieB	<pre> RuijieB#configure terminal RuijieB(config)#interface GigabitEthernet 0/1 RuijieB(config-if-GigabitEthernet 0/1)#no switchport RuijieB(config-if-GigabitEthernet 0/1)#ipv6 address 2000::3/64 RuijieB(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 FE80::1 RuijieB(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2000::1 RuijieB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 priority 100 RuijieB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 timers advertise 3 RuijieB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 accept_mode RuijieB(config-if-GigabitEthernet 0/1)#vrrp 2 ipv6 FE80::100 RuijieB(config-if-GigabitEthernet 0/1)# vrrp 2 ipv6 2000::100 RuijieB(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 priority 120 RuijieB(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 timers advertise 3 RuijieB(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 accept_mode </pre>
Verification	Run the show vrrp command to verify the configuration.
RuijieA	<pre> RuijieA#show ipv6 vrrp GigabitEthernet 0/1 - Group 1 State is Master Virtual IPv6 address is as follows: FE80::1 2000::1 Virtual MAC address is 0000.5e00.0201 </pre>

	<pre>Advertisement interval is 3 sec Accept_Mode is enabled Preemption is enabled min delay is 0 sec Priority is 120 Master Router is FE80::1234 (local), priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.59 sec GigabitEthernet 0/1 - Group 2 State is Backup Virtual IPv6 address is as follows: FE80::100 2000::100 Virtual MAC address is 0000.5e00.0202 Advertisement interval is 3 sec Accept_Mode is enabled Preemption is enabled min delay is 0 sec Priority is 100 Master Router is FE80::5678, priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.82 sec</pre>

Master Down interval is 10.82 sec

GigabitEthernet 0/1 - Group 2

State is Master

Virtual IPv6 address is as follows:

  FE80::100
  2000::100

Virtual MAC address is 0000.5e00.0202

Advertisement interval is 3 sec

Accept_Mode is enabled

Preemption is enabled
  min delay is 0 sec

Priority is 120

Master Router is FE80::5678(local), priority is 120

Master Advertisement interval is 3 sec

Master Down interval is 10.59 sec
```

5.4.3 Configuring VRRP-MSTP

Configuration Effect

- Link-level and gateway-level backup are achieved and network robustness is improved greatly when MSTP and VRRP are applied simultaneously.

Notes

- configure the routers in a VRRP backup group with the same virtual IPv4 address.
- Enabled VRRP on a Layer 3 interface.

Configuration Steps

▾ Enabling IPv4 VRRP

- By default, IPv4 VRRP is not enabled on an interface. To enable IPv4 VRRP, please configure this item.

↘ **Configuring the IPv4 VRRP Authentication String**

- By default, VRRP is in a non-authentication mode. To enable plain text password authentication for VRRP, please configure this item.

↘ **Configuring the IPv4 VRRP Advertisement Interval**

- By default, a master router sends VRRP GWADV packets at an interface of one second. To manually set a value, please configure this item.

↘ **Configuring the IPv4 VRRP Preemption Mode**

- By default, VRRP groups work in the preemption mode with zero-second delay.

↘ **Configuring the IPv4 VRRP Router Priority**

- The default router priority for a VRRP group is 100. You can modify the priority based on your demand.

↘ **Configuring the IPv4 VRRP Tracked Interface**

- By default, an IPv4 VRRP group monitors no interface. To achieve fault monitoring through monitoring an interface, please configure this item.

↘ **Configuring the IPv4 VRRP Learning Timer**

- By default, timed learning is not enabled for a VRRP backup group. To enable backup routers to learn the VRRP GWADV packets from a master router, please configure this item.

↘ **Configuring the IPv4 VRRP Group Description**

- By default, no description is configured for a VRRP group. To distinguish VRRP groups conveniently, please configure this item.

↘ **Configuring the IPv4 VRRP Delay**

- By default, the VRRP delay for a VRRP group is not configured. Configure the delay to guarantee a stable transition from Non-preemption mode to Preemption mode.

↘ **Configuring the IPv4 VRRP Version**

- By default, the VRRPv2 standard is adopted for IPv4 VRRP packets. To modify it manually, please configure this item.

↘ **Specifying a Sub VLAN of a Super VLAN to Receive the IPv4 VRRP Packets**

- By default, IPv4 VRRP packets are only sent to the first UP Sub VLAN interface in a Super VLAN, but you may configure a specific Sub VLAN interface to send such packets.

↘ **Configuring the BFD Support for IPv4 VRRP on an Interface**

- By default, the linkage between an IPv4 VRRP and BFD is not configured on an interface. To enable such linkage, please configure this item.

↘ Configuring Global IPv4 VRRP BFD

- By default, global IPv4 VRRP BFD is not used to detect whether a master router is active. To enable this, please configure this item.

Verification

- Run the **show vrrp** command to verify the configuration.

Related Commands

↘ Enabling IPv4 VRRP

Command	vrrp group ip <i>ipaddress</i> [secondary]
Parameter	<i>group</i> : Indicates the VRID of a VRRP group, the range of which varies with product models.
Description	<i>ipaddress</i> : The IP address of a VRRP group. secondary : Indicates the secondary IP address of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	If no virtual IP address is specified, routers cannot join a VRRP group. If no secondary IP address is applied, the configured IP address will be the primary IP address of a VRRP group.

↘ Configuring the IPv4 VRRP Authentication String

Command	vrrp group authentication <i>string</i>
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<i>string</i> : Indicates the authentication string of a VRRP group (a plain text password consists of 8 bytes at most).
Command Mode	Interface configuration mode
Usage Guide	In a VRRP group, the same authentication password should be configured for routers. The plain text authentication password cannot guarantee security but only prevents/prompts wrong VRRP configurations. This command is only applicable to VRRPv2 instead of VRRPv3. Authentication is abolished for VRRPv3 packets. If VRRPv2 is chosen for an IPv4 VRRP group, the command is effective; if VRRPv3 is chosen, the command is ineffective.

↘ Configuring the IPv4 VRRP Advertisement Interval

Command	vrrp group timers advertise { <i>advertise-interval</i> csec <i>centisecond-interval</i> }
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<i>advertise-interval</i> : Indicates the advertisement interval of a VRRP group (unit: second). csec <i>centisecond-interval</i> : An interval for a master router in a backup group to send VRRP packets. It is an integer from 50 to 99. The unit is centisecond. No default value is provided. The command is only effective for VRRPv3 packets. If it is configured for VRRPv2 packets, the default interval is one second.
Command	Interface configuration mode

Mode	
Usage Guide	<p>If a router is elected as the Master in a VRRP group, it sends VRRP advertisement packets at the set interval to announce its VRRP state, priority and other information.</p> <p>According to the RFC standards, if an IPv4 VRRP group adopts VRRPv3 for sending multicast packets, the maximum advertisement interval is 40 seconds. Therefore, if the interval is set longer than 40 seconds, this maximum interval will be applied, though the configuration is effective.</p>

▾ Configuring the IPv4 VRRP Preemption Mode

Command	vrrp group preempt [delay seconds]
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	delay seconds : Indicates the preemption delay for the Master router to claim its status. The default value is 0 second.
Command Mode	Interface configuration mode
Usage Guide	<p>If a VRRP group runs in Preemption mode, a higher priority router will take the place of the lower priority Master. If a VRRP group runs in Non-preemption mode, a router with the priority higher than that of the Master remains Backup. It makes little sense to configure the Preemption mode when the VRRP group uses the IP address of an Ethernet interface, in which case the group has the highest priority and automatically becomes the Master in the group.</p>

▾ Configuring the IPv4 VRRP Router Priority

Command	vrrp group priority level
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<i>level</i> : Indicates the priority of an interface in a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	This command is used to manually configure the priority of a VRRP group.

▾ Configuring the IPv4 VRRP Tracked Interface

Command	vrrp group track { interface-type interface-number bfd interface-type interface-number ipv4-address } [priority]
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<p><i>interface-type interface-number</i>: Indicates the interface to be tracked.</p> <p>bfd interface-type interface-number ipv4-address: A specified adjacent IP address tracked through BFD.</p> <p><i>priority</i>: Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.</p>
Command Mode	Interface configuration mode
Usage Guide	<p>A tracked interface must be a routable Layer-3 logic interface (for example, a Routed port, an SVI interface, a Loopback interface, or a Tunnel interface).</p> <p>The priority of the router owns the virtual IP address associated with a VRRP group must be 255, and no</p>

	tracked interface can be configured on it.
--	--

▾ Configuring the IPv4 VRRP Tracked IP Address

Command	<code>vrrp group track ipv4-address [interval interval-value] [timeout timeout-value] [retry retry-value] [priority]</code>
Parameter Description	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p><i>ipv4-address</i>: Indicates the IPv4 address to be tracked.</p> <p><i>interval interval-value</i>: Indicates the probe interval. The unit is second. Unless configured manually, the value is 3 seconds by default.</p> <p><i>timeout timeout-value</i>: Indicates the probe timeout of waiting for responses. If no response is received when the timeout is up, it is regarded that the destination is inaccessible. The unit is second. Unless configured manually, the value is 1 second by default.</p> <p><i>retry retry-value</i>: Indicates the probe retries. If the probe packet is sent continually for retry-value times but no response is received, it is regarded that the destination is inaccessible. The unit is times. Unless configured, the value is 3 times by default.</p> <p><i>priority</i>: Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.</p>
Command Mode	Interface configuration mode
Usage Guide	<p>To monitor a host, specify its IPv4 address for an IPv4 VRRP group.</p> <p>If a VRRP group owns the actual IP address of an Ethernet interface, the group priority is 255, and no monitored IP address can be configured.</p>

▾ Configuring the IPv4 VRRP Learning Timer

Command	<code>vrrp group timers learn</code>
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	Once the learning timer is enabled on a VRRP router, a Backup router learns the advertisement interval of the Master during the timer. Based on this, the Backup router calculates the interval for determining the Master router as failed instead of using the locally configured advertisement interval. This command achieves synchronization with the learning timer between the Master and Backup routers.

▾ Configuring the IPv4 VRRP Group Description

Command	<code>vrrp group description text</code>
Parameter Description	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p><i>text</i>: Indicates the description of a VRRP group.</p>
Command Mode	Interface configuration mode
Usage Guide	A VRRP description helps distinguishing VRRP groups. A description has 80 bytes at most, otherwise wrong

	configuration is prompted.
--	----------------------------

↘ **Configuring the IPv4 VRRP Delay**

Command	<code>vrrp delay { minimum <i>min-seconds</i> reload <i>reload-seconds</i> }</code>
Parameter	minimum <i>min-seconds</i> : Indicates the VRRP delay after an interface state changes.
Description	reload <i>reload-seconds</i> : Indicates the VRRP delay after the system starts.
Command Mode	Interface configuration mode
Usage Guide	After the delay is configured for a VRRP group on an interface, the VRRP group starts after the delay instead of immediately upon system startup or the interface's resumption, ensuring non-preemption. If the interface receives a VRRP packet during the delay, the delay will be canceled and the VRRP will be started immediately. The two types of delay share a value range of 0 to 60 seconds. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface.

↘ **Configuring the IPv4 VRRP Version**

Command	<code>vrrp group version { 2 3 }</code>
Parameter	2 : Indicates VRRPv2.
Description	3 : Indicates VRRPv3.
Command Mode	Interface configuration mode
Usage Guide	Considering the compatibility between VRRPv2 and VRRPv3, specify a standard for IPv4 VRRP based on the actual network condition. VRRPv2 is developed in RFC3768, while VRRPv3 is described in RFC5798. This command is only applicable to IPv4 VRRP.

↘ **Specifying a Sub VLAN of a Super VLAN to Receive the IPv4 VRRP Packets**

Command	<code>vrrp detection-vlan {first-subvlan <i>subvlan-id</i>}</code>
Parameter	first-subvlan : Sends IPv4 VRRP packets only to the first UP Sub VLAN interface in a Super VLAN.
Description	<i>subvlan-id</i> : Sends IPv4 VRRP packets to a specified Sub VLAN.
Command Mode	Interface configuration mode
Usage Guide	This command is used to specify a Sub VLAN of a Super VLAN to receive the IPv4 VRRP packets. IPv4 VRRP packets are sent in a Super VLAN using the following three methods. Packets are sent to the first UP Sub VLAN interface in a Super VLAN, or to a specified Sub VLAN interface in a Super VLAN, or to all the Sub VLAN interfaces in a Super VLAN. If both VRRP and VRRP PLUS are enabled on a Super VLAN interface, VRRP packets are sent to all the UP Sub VLAN interfaces of the Super VLAN interface. This command is configured on a VLAN interface and effective only to Super VLAN interfaces.

↘ **Configuring the BFD Support for IPv4 VRRP on an Interface**

Command	<code>vrrp group bfd <i>ip-address</i></code>
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<i>ip-address</i> : Indicates the interface IP address.

Command Mode	Interface configuration mode
Usage Guide	<p>For a Backup router, run this command to correlate an IPv4 VRRP group with BFD without caring the configured IP address. For the Master, as the primary IP address of a Backup router is not known, the router IP address can only be specified by the administrator.</p> <p>If global IPv4 VRRP BFD is configured, this configuration cannot be performed.</p> <p>To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.</p>

↘ **Configuring Global IPv4 VRRP BFD**

Command	<code>vrrp bfd interface-type interface-number ip-address</code>
Parameter	<i>interface-type interface-number</i> : Indicates interface type and ID.
Description	<i>ip-address</i> : Indicates the interface IP address.
Command Mode	Global configuration mode
Usage Guide	<p>If global IPv4 VRRP BFD is configured, the configured BFD support will be deleted.</p> <p>To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.</p> <p>A global IPv4 VRRP BFD session is only applicable to an IPv4 VRRP group consisting of two routers.</p>

Configuration Example

↘ **Configuring VRRP+MSTP**

Scenario Figure 5-8	
Configuration Steps	<ul style="list-style-type: none"> ● Enable MSTP on routers (switches A, B, C, D, E and F in this example). Configure VLAN-Instance mapping (mapping VLAN 10 and VLAN 20 to Instance 1, VLAN 30 and VLAN 40 to Instance 2, and the rest VLANs to Instance 0), and configure gateways (Switch A and Switch B in this example) as the root bridges of corresponding instances.

- Add the SVIs of all VLANs to corresponding VRRP backup groups, and configure gateways as the master and backup routers for corresponding backup groups. See configuration details in the following table.

Gateway	VLAN ID	SVI	Backup Group	Virtual IP Address	State
Switch A	10	192.168.10.2	VRRP 10	192.168.10.1	Master
Switch B		192.168.10.3			Backup
Switch A	20	192.168.20.2	VRRP 20	192.168.20.1	Master
Switch B		192.168.20.3			Backup
Switch A	30	192.168.30.2	VRRP 30	192.168.30.1	Backup
Switch B		192.168.30.3			Master
Switch A	40	192.168.40.2	VRRP 40	192.168.40.1	Backup
Switch B		192.168.40.3			Master

- Configure the uplink port (port Gi 0/1 of Switch A and Switch B) of master routers as a monitored interface of master router.
 - Step 1: Create VLAN. Create VLAN 10, VLAN 20, VLAN 30 and VLAN 40 respectively on Switch A and Switch B.
 - Step 2: Configure MST regions. Map VLAN 10 and VLAN 20 to Instance 1, VLAN 30 and VLAN 40 to Instance 2, and the rest VLANs to Instance 0.
 - Step 3: Configure Switch A as the root bridge for MST 0 and MST 1, and Switch B as the root bridge for MST 2.
 - Step 4: Enable MSTP.
 - Step 5: Configure SVIs of all the VLANs, add the SVIs to corresponding backup groups, and configure virtual IP addresses for the groups. See configuration in the above table.
 - Step 6: Configure master routers and backup routers for all the groups.
 - Step 7: Configure the uplink ports of master routers as monitored ports of VRRP groups. Caution: Monitored ports should be Layer 3 ports.
- Step 8: Configure the Internet interfaces of the core routers as AP interfaces.

5.5 Monitoring

Displaying

Description	Command
Displays the brief or detailed information of IPv4/IPv6 VRRP.	show [ipv6] vrrp [brief group]
Displays the information of an IPv4/IPv6 VRRP group on a specified interface.	show [ipv6] vrrp interface <i>type number</i> [brief]
Displays the statistics of VRRP packets.	show vrrp packet statistics [<i>interface-type interface-number</i>]

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs VRRP errors, events, packets and status.	debug [ipv6] vrrp
Debugs VRRP errors.	debug [ipv6] vrrp errors
Debugs VRRP events.	debug [ipv6] vrrp events
Debugs VRRP packets.	debug vrrp packets [acl <i>acl-id</i> [icmp protocol] interface <i>type number</i> [group]] debug ipv6 vrrp packets [acl <i>acl-name</i> [icmp protocol] interface <i>type number</i> [group]]
Debugs VRRP status.	debug [ipv6] vrrp state

6 Configuring VRRP Plus

6.1 Overview

Virtual Router Redundancy Protocol Plus (VRRP Plus) is an extension of VRRP. It uses VRRP to implement gateway backup and load balancing in the IEEE 802.3 local area network (LAN).

A disadvantage of VRRP is that the router in backup state cannot forward packets. To use VRRP to implement load balancing, you need to manually configure multiple VRRP groups and set the gateway addresses of hosts in the LAN to virtual IP addresses of different VRRP groups. This increases the workload of the network administrator. VRRP Plus is designed to address this issue.

With VRRP Plus, load balancing is automatically implemented. That is, traffic of different hosts is automatically distributed to members of the VRRP Plus group, and it is unnecessary to configure multiple VRRP groups or set the gateway addresses of hosts in the LAN to virtual IP addresses of different VRRP groups. This greatly reduces the workload of the network administrator.

6.2 Applications

Application	Description
Enabling Load Balancing Within a VRRP Group	Implement load balancing within a VRRP group without configuring multiple groups or configuring different default gateways for hosts.

6.2.1 Enabling Load Balancing Within a VRRP Group

Scenario

Enable load balancing within a VRRP group without configuring without configuring multiple VRRP groups or configuring different default gateways for hosts.

As shown in Figure 6-1, configure data as follows:

Figure 6-1 Application Topology of IPv4 VRRP Plus

Remarks	<ol style="list-style-type: none"> Two layer-3 (L3) devices, Router A and Router B, form a VRRP Plus group, and the virtual IP address of the group is 192.168.12.1. Router A is the master device of VRRP and functions as a balancing virtual gateway (BVG). Router B is the backup device of VRRP and functions as a balancing virtual forwarder (BVF). Host 1 to Host 4 are hosts in the LAN with the network segment 192.168.12.0/24. Their default gateway addresses are set to the virtual IP address 192.168.12.1 of the VRRP Plus group. The load balancing policy is configured on the device to respond to the ARP requests sent from different hosts. For example, when Host 1 and Host 2 request the gateway ARP, the MAC address 0000.5e00.0101 is returned to Host 1 and Host 2. When Host 3 and Host 4 request the gateway ARP, the MAC address 001A.A916.0201 is returned to Host 3 and Host 4. In this way, packets exchanged between Host 1/Host 2 and the external network are sent to Router A, and packets exchanged between Host 3/Host 4 and the external network are sent to Router B, thereby implementing load balancing.
----------------	---

Deployment

- Deploy VRRP Plus on Router A and Router B to implement load balancing on the local host.

6.3 Features

Basic Concepts

↘ BVG

The BVG allocates virtual MAC addresses to members of the VRRP Plus group. It responds to the gateway ARP/ND requests in the LAN, and forwards packets of hosts in the LAN.

↘ BVF

The BVF forwards packets of hosts in the LAN. If a virtual MAC address is allocated to a BVF, the BVF participates in packet forwarding; otherwise, the BVF does not participate in packet forwarding.

Overview

Feature	Description
VRRP Plus	Extend VRRP and use VRRP to implement gateway backup and load balancing in the IEEE 802.3 LAN.

6.3.1 VRRP Plus

With VRRP Plus, load balancing is automatically implemented. That is, traffic of different hosts is automatically distributed to members of the VRRP Plus group, and it is unnecessary to configure multiple VRRP groups or set the gateway addresses of hosts in the LAN to the virtual IPv4/IPv6 addresses of different VRRP groups.

Basic Principles

Hosts in a LAN use the unified gateway IPv4/IPv6 address (that is, virtual IP address of the VRRP group). When different hosts request the gateway ARP/ND, the BVG responds with different virtual MAC addresses. In this way, traffic of different hosts are distributed to different members of the VRRP Plus group, thereby implementing load balancing.

Relationship Between VRRP Plus and VRRP

VRRP Plus relies on VRRP, and runs in the following way:

A master device in VRRP corresponds to a BVG in VRRP Plus, and a backup device in VRRP corresponds to a BVF in VRRP Plus. Gateway addresses of hosts in the LAN are set to the virtual IPv4/IPv6 address of VRRP.

MAC Address Allocation Rules of the BVG and BVF

The BVG allocates virtual MAC addresses to BVFs. For an IPv4 VRRP Plus group, the BVG directly uses the virtual MAC address of VRRP to ensure compatibility between IPv4 VRRP Plus and VRRP. That is, the virtual MAC address used by the BVG is 00-00-5E-00-01-{VRID}, where VRID is the VRRP group number. The virtual MAC address used by a BVF is 00-1A-A9-16-{MemberID}-{VRID}, where MemberID is the member ID of the BVF in the VRRP Plus group. Currently, a VRRP Plus group can have up to four members. The BVG uses the member ID 01, and the other BVFs use the member IDs 02 to 04.

Load Balancing Policy of VRRP Plus

The BVG responds to the gateway ARP/NS requests sent from hosts in a LAN. Based on the specific load balancing policy, the BVG responds hosts with different virtual MAC addresses. There are three types of load balancing policies:

- Host-dependent policy: A specified virtual MAC address is used to respond to the requests sent by a specified host.
- Round-robin policy: Virtual MAC addresses in the backup group are used in a cyclic manner to respond to the gateway ARP/NS requests sent by hosts.
- Weighted policy: The ARP/NA requests are responded based on the forwarding capability of each device.

If the load balancing mode is changed, load balancing is always implemented in the new load balancing mode. For example, if the polling response mode is previously used, and later the weighted mode is used, load balancing is implemented in weighted mode regardless of the earlier responses of the device. If the weighted policy is used, and the total weight of virtual routers in a VRRP Plus group is 0, the ARP/NS requests are not responded.

▾ Proxy of the Virtual MAC Address

When a device with a virtual MAC address becomes faulty in the backup group, traffic of hosts that use this virtual MAC address as the gateway MAC address will be interrupted.

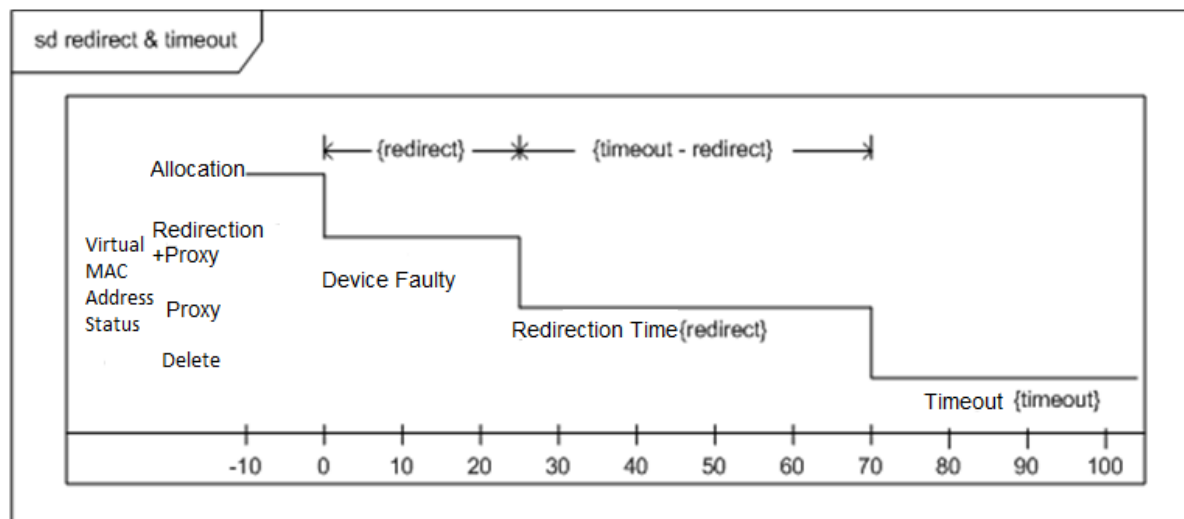

The BVG in the VRRP Plus backup group can quickly detect the fault, and automatically allocates the virtual MAC address of the faulty BVF to another device in the backup group. The new device acts as the proxy of the faulty device to forward packets of the virtual MAC address. In addition, this proxy device takes over traffic of original hosts to prevent traffic interruption. The virtual MAC address allocated to a device in the backup group can be called master virtual MAC address, and the virtual MAC address used by this device on behalf of another device is called proxy virtual MAC address.

▾ Redirection Time and Timeout of the Proxy Virtual MAC Address

VRRP Plus provides the proxy function for the virtual MAC address so that another device can take the place of a faulty device with a virtual MAC address to forward packets. If the BVF is recovered from the fault, its forwarding role is recovered and the BVF continues to forward packets of the virtual MAC address allocated to this BVF. If the faulty BVF is not recovered, the backup group stops redirecting traffic to this virtual MAC address. That is, when ARP requests are received again, this virtual MAC address is no longer responded. After a sufficient long period of time, it is believed that hosts that use the MAC address as the gateway MAC address already update the ARP/ND table entry of the gateway address, and the traffic is already taken over by other devices. At this time, this virtual MAC address can be deleted, and packets sent to this virtual MAC address are dropped.

VRRP Plus supports configuration of the redirection time and timeout of the backup group. When a device is faulty, the backup group allocates the virtual MAC address of the faulty device to another device. Within the redirection time, the backup group continues to use this virtual MAC address to respond the ARP/NS requests. When the redirection time expires, the backup group no longer uses this virtual MAC address to respond the requests. When the timeout elapses, the backup group deletes this virtual MAC address and stops using this virtual MAC address for proxy forwarding. Figure 6-2 shows the changes to the role of the virtual MAC address within the redirection time and timeout.

Figure 6-2 Changes to the Role of the Virtual MAC Address Within the Redirection Time and Timeout

Weight-based Forwarding

VRRP Plus supports the weight configuration of the backup group. Different weights are configured for different devices. In this way, more traffic is distributed to the device with a greater weight and less traffic is distributed to the device with a smaller weight, thereby fully utilizing the forwarding performance of different devices. When the weight of a BVF in the backup group is smaller than the lower threshold, the BVF automatically exits from the forwarding role. When the weight recovers and is greater than the upper threshold, the BVF automatically applies for the forwarding role. The forwarding role can be recovered when one or more remaining virtual MAC addresses or proxy virtual MAC addresses exist.

Association of VRRP Plus with BFD

VRRP Plus supports association with bidirectional forwarding detection (BFD) to adjust the weight based on the link status. Each device in a backup group can associate its weight with the link status. When a link is abnormal or interrupted, the device automatically decreases its weight. When the weight is too low, the device automatically exits from the forwarding role. If the backup group is currently using the weighted load balancing policy, traffic can be distributed based on the new weight. When the associated link recovers, the device can automatically restore its original weight and the forwarding role. If the backup group is currently using the weighted load balancing policy, traffic can be distributed based on the recovered weight.

Weight-based Forwarding Preemption

VRRP Plus supports the function of seizing the forwarding role. In VRRP Plus, at most four devices can participate in load balancing. That is, a VRRP Plus backup group generates at most four virtual MAC addresses. If more than four devices are added to a VRRP Plus group, only four devices participate in packet forwarding. The remaining devices only listen to the status of other devices and do not participate in packet forwarding. Only when a device participating in packet forwarding is faulty, another device that originally does not participate in packet forwarding will take the place of the faulty device to forward packets. Assume that a VRRP Plus backup group already has four devices and all these devices participate in packet forwarding; a fifth device is added to the VRRP Plus group, and the forwarding capability of this device is strong or the original forwarding role encounters a link failure and consequently degradation of forwarding performance. In this case, if the preemption mode is enabled, the fifth device can seize the forwarding role from a device with a smaller weight (that is, with lower forwarding capability). A greater weight is configured for a device with stronger forwarding capability. When the weight

of a device in listening state is found greater than that of a forwarding device, the device in listening state automatically seizes the forwarding role from the forwarding device. That is, the device with stronger forwarding capability forwards packets, whereas the device with lower forwarding capability is in listening state. This can minimize the waste of resources.

The BVG in a backup group is responsible for allocation of virtual MAC addresses. Therefore, the BVG role cannot be seized, and only the forwarding role of a BVF can be seized. If the BVG device is faulty, VRRP re-elects a new master device, which assumes the BVG role.

▾ **Factors Affecting the Forwarding Policy**

1. After VRRP Plus is configured, the ARP/NS requests are received from hosts can be responded based on different load balancing policies to implement load balancing among these hosts. However, load balancing cannot be implemented for hosts that have learned the VRRP virtual gateway addresses before configuration of VRRP Plus. Therefore, if VRRP Plus is configured after the VRRP state is changed to Master, real load balancing cannot be implemented before aging of the ARP/NDs learned by hosts. Load balancing is implemented only after the gateway ARP/NDs recorded by the hosts age and the hosts request for new gateway addresses.
2. Periodical sending of gratuitous ARPs on an interface also affect the load balancing function of VRRP Plus. When VRRP Plus is enabled, the function of sending gratuitous ARPs of VRRP virtual IP addresses will be disabled. When an virtual IP address overlaps with an actual IP address, gratuitous ARPs of this address are no longer sent.
3. When an address conflict occurs between a host and the local device, the ARP/NA module will broadcast gratuitous ARP/NA packets of this address. If a conflict of the VRRP Plus virtual address occurs, sending gratuitous ARP/NA packet will result re-learning of the host's gateway MAC address, which negatively affects the load balancing function of VRRP Plus. Therefore, the load balancing function of VRRP Plus is currently not supported in this scenario.

6.4 Configuration

Configuration Item	Description and Command
Configuring VRRP Plus	 (Mandatory) It is used to enable the VRRP Plus function.
	vrrp balance Enables the VRRP Plus function of a VRRP backup group with the specified group ID in interface configuration mode.
	 (Optional) It is used to configure parameters of a VRRP Plus backup group.
	vrrp load-balancing Configures the load balancing policy of VRRP Plus in interface configuration mode.
	vrrp timers redirect Configures the redirection time and timeout of the proxy virtual MAC address in a VRRP Plus backup group in interface configuration mode.
vrrp weighting Configures the weight and upper and lower thresholds of a VRRP Plus backup group in interface configuration mode.	

Configuration Item	Description and Command
	vrrp forwarder preempt Configures the forwarding preemption function of a VRRP Plus backup group in interface configuration mode.

6.4.1 Configure VRRP Plus

Configuration Effect

- Enable the VRRP Plus function. (By default, this function is disabled.)
- Configure a weight tracking object of a VRRP Plus backup group.

Notes

- To enable the VRRP Plus function, you must configure the VRRP virtual IP address for the corresponding backup group.

Configuration Steps

↘ Enabling VRRP Plus on an Interface

- By default, VRRP Plus is enabled. Perform this configuration if VRRP Plus is required.

↘ Configuring the Load Balancing Policy of VRRP Plus

- After VRRP Plus is enabled, the host-dependent load balancing policy is used by default.

↘ Configuring the Redirection Time and Timeout of the Proxy Virtual MAC Address in a VRRP Plus Backup Group

- After VRRP Plus is enabled, the redirection time is set to 300s and timeout is set to 14,400s by default.

↘ Configuring the Weight and Upper and Lower Thresholds of a VRRP Plus Backup Group

- After VRRP Plus is enabled, the weight of the backup group is set to 100, the lower threshold to 1, and the upper threshold to 100 by default.

↘ Configuring the Forwarding Preemption Function of a VRRP Plus Backup Group

- After VRRP Plus is enabled, the forwarding preemption function is enabled by default.

Verification

- Run the **show group vrrp balance** command to display the VRRP backup group configuration. If the backup group has the packet forwarding tasks, "local" is displayed in the **forwarders** column, and the virtual MAC address allocated to this backup group is also displayed.

Related Commands

↘ Enabling VRRP Plus on an Interface

Command	vrrp group balance
---------	---------------------------

Parameter Description	<i>group</i> : Indicates the ID of the VRRP group. The value range of the group ID varies according to the product model.
Command Mode	Interface configuration mode
Usage Guide	VRRP Plus can be enabled only after a VRRP group is configured.

▾ Configuring the Load Balancing Policy of a VRRP Plus Backup Group

Command	<code>vrrp group load-balancing{host-dependent round-robin weighted }</code>
Parameter Description	<i>group</i> : Indicates the ID of the VRRP group. host-dependent : Indicates the host-dependent load balancing policy. round-robin : Indicates the round-robin load balancing policy. weighted : Indicates the weighted load balancing policy.
Command Mode	Interface configuration mode
Usage Guide	After VRRP Plus is enabled, the host-dependent load balancing policy is used by default. The load balancing policy of the entire backup group is determined by the policy configured on the BVG. If you wish to use the same load balancing policy after the role of the BVG device changes, configure the same policy on all devices in the backup group.

▾ Configuring the Redirection Time and Timeout of the Proxy Virtual MAC Address in a VRRP Plus Backup Group

Command	<code>vrrp group timers redirect redirect timeout</code>
Parameter Description	<i>group</i> : Indicates the ID of the VRRP group. <i>redirect</i> : Indicates the redirection time. The value ranges from 0 to 3,600s. The default value is 300s, that is, 5 minutes. <i>timeout</i> : Indicates the timeout time. The value ranges from (redirect + 600) to 64,800s. The default value is 14400, that is, 4 hours.
Command Mode	Interface configuration mode
Usage Guide	After VRRP Plus is enabled, the redirection time is set to 300s and timeout is set to 14,400s by default. When a device is faulty, the backup group allocates the virtual MAC address of the faulty device to another device. Within the redirection time, the backup group continues to use this virtual MAC address to respond the ARP/NS requests. When the redirection time expires, the backup group no longer uses this virtual MAC address to respond the requests. When the timeout elapses, the backup group deletes this virtual MAC address.

▾ Configuring the Weight and Upper and Lower Thresholds of a VRRP Plus Backup Group

Command	<code>vrrp group weighting maximum [lower lower] [upper upper]</code>
Parameter Description	<i>maximum</i> : Indicates the weight of the backup group. The value ranges from 2 to 254. The default value is 100. lower lower : Indicates the lower threshold of the backup group. The value ranges from 1 to (maximum - 1). The default value is 1.

	upper <i>upper</i> : Indicates the upper threshold of the backup group. The value ranges from lower to maximum . The default value is 100.
Command Mode	Interface configuration mode
Usage Guide	After VRRP Plus is enabled, the weight and upper and lower thresholds of a VRRP Plus backup group are configured by default. You can use this command to configure different weights for different devices so that more traffic is distributed to the device with a greater weight and less traffic is distributed to the device with a smaller weight. When the weight of a BVF in the backup group is lower than the lower threshold, the BVF automatically exits from the forwarding role. When the weight recovers and is higher than the upper threshold, the forwarding role of the BVF is automatically restored.

📌 **Configuring the Forwarding Preemption Function of a VRRP Plus Backup Group**

Command	vrrp group forwarder preempt
Parameter Description	<i>group</i> : Indicates the ID of the VRRP group.
Command Mode	Interface configuration mode
Usage Guide	After VRRP Plus is enabled, the forwarding preemption function is enabled by default. VRRP Plus supports configuration of the forwarding preemption function of a backup group. When the weight of a device in listening state is found greater than that of a forwarding device, the device in listening state automatically seizes the forwarding role from the forwarding device. That is, the device with stronger forwarding capability forwards packets, whereas the device with lower forwarding capability is in listening state.

Configuration Example

📌 **Enabling Load Balancing Within an IPv4 VRRP Group**

<p>Scenario</p> <p>Figure 6-3</p>	
Configuration	<ul style="list-style-type: none"> Configure a tracking object respectively on Router A and Router B to track the status of the local

Steps	<p>GigabitEthernet 0/14 interface.</p> <ul style="list-style-type: none"> ● Configure a VRRP group and enable VRRP Plus respectively on Router A and Router B. Configure the local IP addresses so that Router A becomes a BVG (master) device, and Router B becomes a BVF (backup) device. ● Configure the weighted load balancing policy. Configure the weight tracking object, and set the decrement value to 100. ● Retain default configurations of the weight, upper and lower thresholds, redirection time, timeout, and forwarding preemption of the backup group. ● Set the default gateway addresses of Host 1 to Host 4 in the LAN to the virtual IP address of VRRP, that is, 192.168.12.1.
Router A	<pre>RuijieA#config RuijieA(config)#track 1 interface GigabitEthernet0/14 line-protocol RuijieA(config)#interface GigabitEthernet0/0 // 'no switchport' is used on the switch. 	MAC address: 001a. a916. 0201 Owner ID is 00d0. f822. 33a3 Preemption enabled
--	--

Common Errors

- VRRP Plus does not take effect because the VRRP virtual IP address is not configured for the related group.

6.5 Monitoring

Displaying

Description	Command
Displays the brief or detailed configuration of VRRP Plus.	show vrrp balance
Displays the actions of the VRRP Plus group on a specified interface.	show vrrp balance interface

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the VRRP Plus function.	debug vrrp balance
Debugs errors.	debug vrrp balance error
Debugs events of the VRRP Plus group.	debug vrrp balance event
Debugs the messages between the VRRP module and the track module.	debug vrrp balance messages
Debugs the VRRP Plus packets.	debug vrrp balance packets
Debugs the VRRP Plus group status.	debug vrrp balance state
Debugs the timers of the VRRP Plus group.	debug vrrp balance timer

7 Configuring BFD

7.1 Overview

Communication failures will interrupt networking and thus affect services. Therefore, it is essential to rapidly locate communication failures on links with adjacent devices to ensure a timely action and service availability. Bidirectional Forwarding Detection (BFD) provides a method of rapidly detecting connectivity of the forwarding path between two adjacent routers in an underloaded way. It can quickly spot faults on the bidirectional forwarding path between two routers for upper-layer protocols such as routing protocols and Multi-Protocol Label Switching (MPLS). As a result, a standby forwarding path is adopted to maintain the performance of the existing network.

Protocols and Standards

- draft-ietf-bfd-base-09: Bidirectional Forwarding Detection
- draft-ietf-bfd-generic-05: Generic Application of BFD
- draft-ietf-bfd-mib-06: Bidirectional Forwarding Detection Management Information Base
- draft-ietf-bfd-v4v6-1hop-09: BFD for IPv4 and IPv6 (Single Hop)
- draft-ietf-bfd-multihop-07: BFD for IPv4 and IPv6 (Multi-hop)
- draft-ietf-bfd-mpls-07: BFD For MPLS LSPs

✔ Currently, draft-ietf-bfd-mib-06 and draft-ietf-bfd-multihop-07 are not supported.

7.2 Applications

Application	Description
BFD Support for OSPF	OSPF utilizes BFD to rapidly detect the neighbor status.
BFD Support for Static Routing	Static routing utilizes BFD to rapidly detect the next-hop reachability of a route.

7.2.1 BFD Support for OSPF

Scenario

The Open Shortest Path First (OSPF) protocol dynamically discovers a neighbor by using hello packets. After BFD is enabled, a BFD session is established with the neighbor in the full adjacency to detect the neighbor status. When the neighbor fails, OSPF immediately performs network convergence. The convergence time can be shortened from 120 seconds (by default, on a non-broadcast network, OSPF hello packets are transmitted at an interval of 30 seconds and the neighbor failure time is four times the interval, that is, 120 seconds) to 1 second.

Use the following figure as an example. Router A and Router B are connected through a Layer-2 switch, OSPF is configured on the routers to establish routes, and BFD support for OSPF is enabled on the interfaces of Router A and Router B. When

the link between Router B and the Layer-2 switch malfunctions, BFD can rapidly detect the fault and advertise it to OSPF, so as to trigger fast OSPF convergence.

Figure 7-1

Remarks	A and B are routers. Switch is a Layer-2 switch. A and B are connected through the Layer-2 switch.
----------------	--

Deployment

- Configure IP addresses for interconnected interfaces of Router A and Router B.
- Run OSPF on Router A and Router B.
- Set BFD parameters on interconnected interfaces of Router A and Router B.
- Enable BFD support for OSPF on Router A and Router B.

7.2.2 BFD Support for Static Routing

Scenario

BFD support for static routing prevents routers from selecting a faulty static route as the forwarding path and enables rapid routing failover by using an available backup forwarding path.

Different from dynamic routing protocols, static routing does not have the neighbor discovery (ND) mechanism. When BFD support for static routing is configured, the next-hop reachability of a static route relies on the BFD session status. If a BFD session fails, the next hop of a static route is thought unreachable and will not be added to the routing information base (RIB).

Use the following figure as an example. Router A and Router B are connected through a Layer-2 switch, static routing is configured on the routers to establish forwarding paths, and BFD support for static routing is enabled on the interfaces of Router A and Router B. When the link between Router B and the Layer-2 switch malfunctions, BFD can rapidly detect the fault and advertise it to static routing, so as to trigger the system to delete the static route from the RIB, thereby preventing routing errors.

Figure 7-2

Remarks	A and B are routers. Switch is a Layer-2 switch. A and B are connected through the Layer-2 switch.
----------------	--

Deployment

- Configure IP addresses for interconnected interfaces of Router A and Router B.
- Configure static routing on Router A and Router B.
- Set BFD parameters for interconnected interfaces of Router A and Router B.
- Enable BFD support for static routing on Router A and Router B.

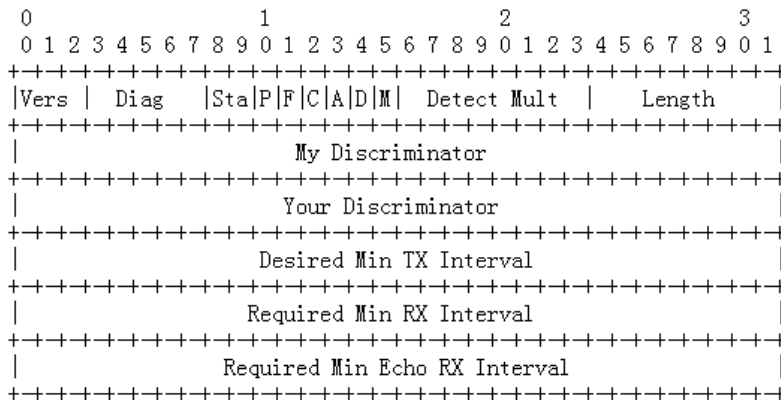

7.3 Features

Basic Concepts

Packet Format

Detection packets transmitted by BFD are User Datagram Protocol (UDP) packets, which are classified into control packets and echo packets. Echo packets concern only the local system of a BFD session. Therefore, their formats are not specified. BFD specifies the format of only control packets. Currently, there are two versions (version 0 and version 1) for the format of control packets. Version 1 is adopted by default for establishing a BFD session. If a device receives packets of version 0 from the peer system, the device automatically switches to version 0.

Figure 7-3

Field	Description
Vers	Indicates the BFD protocol version number, which is 1 currently.
Diag	Indicates the cause for the local system's last change in session state, including: 0 -- No Diagnostic. 1 -- Control Detection Time Expired 2 -- Echo Function Failed 3 -- Neighbor Signaled Session Down

Field	Description
	4 -- Forwarding Plane Reset 5 --Path Down 6 -- Concatenated Path Down 7 --Administratively Down
Sta	Indicates the BFD local session state, including: 0 -- AdminDown. 1 -- Down. 2 -- Init. 3 -- Up.
P	Indicates that the transmitter in a BFD session adds this bit in a verification request upon parameter changes, waiting for the peer response.
F	Indicates the bit that must be set in the response packet for responding to the P bit.
C	Indicates the control plane independent. If set, changes of the control plane do not affect BFD detection. For example, if the control plane is OSPF, when OSPF is restarted or experiences graceful restart (GR), BFD can continue to detect the link status.
A	Indicates the authentication present. If set, a session is to be authenticated.
D	Indicates the demand request. If set, the transmitter desires to detect links in Demand mode.
M	Indicates the multipoint bit to be used in point-to-multipoint extensions. It must be set to 0 currently.
Detect Mult	Indicates the detection timeout multiplier. It is used by the detector to calculate the detection timeout time.
Length	Indicates the packet length.
My Discriminator	Indicates the discriminator of the local end connected by a BFD session.
Your Discriminator	Indicates the discriminator of the remote end connected by a BFD session.
Desired Min Tx Interval	Indicates the minimum interval of transmitting BFD packets supported by the local end.
Required Min RX Interval	Indicates the minimum interval of receiving BFD packets supported by the local end.
Required Min Echo RX Interval	Indicates the minimum interval of receiving echo packets supported by the local end. It is set to 0 if the local end does not support the echo function.
Auth Type	(Optional) Indicates the authentication type, including: Simple Password Keyed MD5 Meticulous Keyed MD5 Keyed SHA1 Meticulous Keyed SHA1
Auth Length	Indicates the authentication data length.
Authentication Data	Indicates the authentication data area.

📌 Session Status

A BFD session can be in any of the four basic states: Down, Init, Up, and AdminDown.

4. Down: Indicates that a session is in the Down state or is established just now.
5. Init: Indicates that the local system has communicated with the peer system and desires to bring the session to the Up state.
6. Up: Indicates that a session has been negotiated successfully.
7. AdminDown: Indicates that a session is in the AdminDown state.

BFD migrates the state machine based on the local session state and received BFD packets from the peer end.

A BFD state machine is established and torn down using a three-way handshake mechanism, to ensure that both ends know the status change.

Transmission Interval and Detection Time

Both ends negotiate BFD parameters during the establishment of a BFD session, to determine the transmission interval and detection time.

After a BFD session is established, both ends can dynamically negotiate BFD parameters (for example, minimum transmission interval and minimum receiving interval). After protocols at both ends transmit relevant negotiation packets, they adopt the new transmission interval and detection time, without affecting the current state of the session.

Overview

Feature	Description
BFD Session Establishment	Establishes a BFD session.
BFD Session Detection	Rapidly detects a bidirectional forwarding path.
BFD Support for Applications	Rapidly advertises the BFD detection result.
BFD Protection	Protects BFD from attacks for stability.
BFD Flapping Dampening	Protects stability of associated applications in the case of line instability.

7.3.1 BFD Session Establishment

BFD detection starts from the establishment of a BFD session.

Working Principle

Session Establishment Process

BFD itself is unable to discover neighbors. It needs an upper-layer protocol to specify a neighbor to establish a session.

As shown in the following figure, two routers running OSPF and BFD are connected through a Layer-2 switch.

Figure 7-4

BFD session establishment process:

8. OSPF discovers a neighbor and establishes a connection with the neighbor.
9. OSPF instructs BFD to establish a session with the neighbor.
10. BFD establishes a session with the neighbor.

↘ BFD Session Establishment Mode

The BFD protocol specifies that a BFD session can be established in two modes:

- Active mode
Before the establishment of a session, BFD actively transmits a control packet for establishing a BFD session regardless of whether it receives a control packet for establishing a BFD session from the peer end.
- Passive mode
BFD does not actively transmit a control packet for establishing a BFD session before a session is established but wait till it receives a control packet for establishing a BFD session from the peer end.

i The passive mode is not supported currently.

↘ Negotiation of BFD Session Parameters

Both ends negotiate BFD session parameters during the establishment of a BFD session, to determine the transmission interval and detection time. Pay attention to the following points:

11. BFD session parameters (including **Desired Min Tx Interval**, **Required Min RX Interval**, and **Detect Mult**) must be set for interfaces at both ends. Otherwise, a BFD session cannot be established.
12. Interfaces at both ends negotiate BFD session parameters and detect the session based on the parameters during the establishment of a BFD session.
13. After a BFD session is established, both ends can dynamically negotiate BFD parameters (for example, minimum transmission interval and minimum receiving interval). After protocols at both ends transmit relevant negotiation packets, they adopt the new transmission interval and detection time, without affecting the current state of the session.

7.3.2 BFD Session Detection

Link detection starts after the establishment of a BFD session. BFD periodically transmits BFD control packets. If it fails to receive BFD packets from the peer end within the detection time, it deems that the session is Down and notifies the associated application to accelerate the convergence.

Working Principle

↘ Detection Process

As shown in the following figure, two routers running OSPF and BFD are connected through a Layer-2 switch.

Figure 7-5

Handling procedure after a BFD session is Down:

14. The link between Router A and Switch fails.
15. The BFD session between Router A and Router B is Down.
16. BFD notifies the local OSPF that the forwarding path to the neighbor is faulty.
17. OSPF processes the neighbor Down situation. If a backup forwarding path is available, it starts protocol convergence to enable the alternative forwarding path.

↘ Detection Mode

BFD supports the following detection modes:

- Asynchronous mode

In asynchronous mode, systems transmit BFD control packets periodically to each other. If a system fails to receive BFD control packets from the peer end within the detection time, it advertises that the session is Down.

- Query mode

In query mode, it is assumed that each system has an independent method for confirming its connection with other systems. After a BFD session is established, the system stops transmitting BFD control packets unless it needs to explicitly verify the connectivity. In such a case, the system transmits a shot-sequence BFD control packet. If a system fails to receive a returned packet within the detection time, it advertises that the session is Down. If it receives a response from the peer end, the forwarding path is reachable.

- Echo mode

In echo mode, the local system periodically transmits BFD echo packets and a remote system receives and loops back the packets through the forwarding path. If the local system fails to receive several consecutive echo packets within the detection time, it advertises that the session is Down. The echo function can be used together the preceding two detection modes. The echo packet detection function does not require the involvement of the control plane of the remote system. Packets are returned by the forwarding plane of the remote system, which reduces the delay and ensures faster fault detection in comparison with transmission of control packets. The enabling of the echo function in asynchronous mode can greatly

reduce transmission of control packets because the detection is accomplished by the echo function. The enabling of the echo function in query mode can thoroughly cancel transmission of control packets after a session is established. The echo function must be enabled at both ends of a BFD session. Otherwise, the echo function does not take effect.

-
-  The query mode is not supported and cannot be configured at present.
 -  Only BFD session version 1 supports the BFD echo mode.
 -  The echo mode is not supported for an IPv6 BFD session with the link-local address as the source or destination address.
-

7.3.3 BFD Support for Applications

By BFD support, the associated applications can utilize the fast fault detection of BFD to improve the protocol convergence performance. In general, the fault detection time can be shortened within 1 second.

Working Principle

After BFD support for a certain application is enabled, a BFD session is established based on the BFD configuration. When a link fault occurs, BFD can rapidly identify the fault and notify the associated application to process, thereby improving its convergence. Currently, BFD supports the following applications:

- BFD support for RIP

After BFD support for the Routing Information Protocol (RIP) is enabled, RIP can utilize the BFD fault detection, which is faster than the ND mechanism of RIP, to improve the protocol convergence. In general, the fault detection time can be shortened within 1 second.

-
-  For more details about BFD support for RIP, see *Configuring RIP*.
-

- BFD support for OSPF

After BFD support for OSPF is enabled, OSPF can utilize the BFD fault detection, which is faster than the ND mechanism of OSPF, to improve the protocol convergence. In general, the fault detection time can be shortened within 1 second.

-
-  For more details about BFD support for OSPF, see *Configuring OSPF*.
-

- BFD support for OSPFv3

After BFD support for OSPFv3 is enabled, OSPFv3 can utilize the BFD fault detection, which is faster than the ND mechanism of OSPFv3, to improve the protocol convergence. In general, the fault detection time can be shortened within 1 second.

-
-  For more details about BFD support for OSPFv3, see *Configuring OSPFv3*.
-

- BFD support for BGP

After BFD support for the Border Gateway Protocol (BGP) is enabled, BGP can utilize the BFD fault detection, which is faster than the ND mechanism of BGP, to improve the protocol convergence. In general, the fault detection time can be shortened within 1 second.

 For more details about BFD support for BGP, see *Configuring BGP*.

- BFD support for IS-IS

The Intermediate System to Intermediate System (IS-IS) protocol dynamically discovers a neighbor by using hello packets. After BFD is enabled, IS-IS uses BFD to establish a BFD session with a neighbor that is in the Up state and detect the neighbor status. When a BFD neighbor fails, IS-IS immediately performs network convergence. The convergence time can be shortened from 30 seconds (by default, on a point-to-point network, IS-IS hello packets are transmitted at an interval of 10 seconds and the neighbor failure time is triple the interval, that is, 30 seconds) to 1 second.

 For more details about BFD support for IS-IS, see *Configuring IS-IS*.

- BFD support for static routing

After BFD support for static routing is enabled, BFD prevents routers from selecting an unavailable static route as the forwarding path during routing and enables routers to rapidly switch to an available backup forwarding path.

Different from dynamic routing protocols, static routing does not have the ND mechanism. Therefore, after BFD support for static routing is configured, the next-hop reachability of a static route relies on the BFD session state. If a BFD session detects a fault, the next hop of a static route is unreachable and the static route is not added to the RIB.

If the remote system deletes a BFD session during the establishment of a BFD session, the BFD session becomes Down. In this case, the system ensures that the forwarding behavior of static routing is not affected.

 For more details about BFD support for static routing, see *Configuring NSM*.

- BFD support for PBR

After BFD support for PBR is configured, BFD prevents routers from selecting an unavailable policy route as the forwarding path during routing and enables routers to rapidly switch to an available backup forwarding path.

BFD support for PBR is equivalent to that for static routing. BFD tracks and detects the forwarding path to a specified neighbor. When a BFD session fails, BFD notifies the PBR that the next hop is unreachable. Then, the policy route to the next hop does not take effect.

If the remote system deletes a BFD session during the establishment of a BFD session, the BFD session becomes Down. In this case, the system ensures that the PBR forwarding behavior is not affected.

 For more details about BFD support for PBR, see *Configuring PBR*.

- BFD support for VRRP

The BFD support for the Virtual Router Redundancy Protocol (VRRP) can replace the ND mechanism of VRRP to rapidly detect the running status of the active and standby routers. When a fault occurs, it accelerates the active/standby router switching and improves network performance. In general, the fault detection time can be shortened within 1 second.

VRRP can also utilize BFD to track a specified neighbor. If the forwarding path to the neighbor fails during a BFD session, it automatically lowers the VRRP priority to a certain extent to trigger active/standby router switching. This configuration takes effect only when the dynamic routing protocol or other applications notify BFD to establish a session with a neighbor.

i For more details about BFD support for VRRP, see *Configuring VRRP*.

- BFD support for VRRP Plus

The BFD support for VRRP Plus can replace the BVF detection conducted by the balancing virtual gateway (BVG) of VRRP Plus to rapidly detect the running status of balancing virtual functions (BVs). When a fault occurs, it accelerates the forwarding entity switching and improves network performance. In general, the fault detection time can be shortened within 1 second.

VRRP Plus is based on the VRRP protocol. Therefore, no additional configuration is required for BFD support and only VRRP needs to be enabled on devices at both ends and a BFD session is correctly associated.

i For more details about BFD support for VRRP Plus, see *Configuring VRRP Plus*.

- BFD support for MPLS

The BFD support for Multiple protocol Label Switching (MPLS) refers that label switched paths (LSPs) use BFD to rapidly detect the neighbor status. The following detection modes are supported:

18. BFD detects static LSPs.
 19. BFD detects LSPs generated by the Label Distribution Protocol (LDP).
 20. BFD can detect reverse links of LSPs by using the IP protocols.
-

i For more details about BFD support for MPLS, see *Configuring MPLS*.

- BFD support for Layer-3 interfaces

BFD supports changing status of Layer-3 interfaces. In interface configuration mode, use the **bfd bind peer-ip** command to detect the direct address of a specified Layer-3 interface. After this CLI command is executed, a BFD session is created and the status of a Layer-3 interface can be changed based on the detection result of the BFD session, for example, BFD Down or BFD Up. This function is often used in various types of fast reroute (FRR), which uses BFD to detect the interface status to implement fast FRR switching.

i Only LDP FRR switching is supported in BFD support for Layer-3 interfaces.

- BFD support for Layer-3 AP member ports

After BFD support for Layer-3 AP member ports is enabled, BFD can rapidly detect a fault occurring on a member port link so that traffic on this link is rapidly distributed to other effective member links. In general, the fault detection time can be shortened within 1 second.

i For more details about BFD support for Layer-3 AP member ports, see *Configuring AP*.

7.3.4 BFD Protection

The BFD protection is used to protect BFD against session flapping caused by attacks (for example, a large number of ping packets attack devices).

Working Principle

The BFD protocol is very sensitive. If a BFD-enabled device is attacked (for example, attacked by a large number of ping packets) and BFD sessions flap, the BFD protection can be configured to provide protection. If both BFD and BFD protection are enabled on a device, the device discards the BFD packet from the previous hop, affecting the establishment of a BFD session between the previous-hop device and other devices.

7.3.5 BFD Flapping Dampening

A BFD session may frequently switch over between Down and Up due to link instability. As a result, an associated application (such as static routing) may frequently switch forwarding paths and the running services are affected. The BFD flapping dampening can solve this problem.

Working Principle

A BFD session may frequently switch over between Down and Up. This function allows users to set the delay for status change advertisement. After a BFD session is Up for a certain period of time, BFD notifies an associated application of BFD Up. Otherwise, BFD notifies an associated application of BFD Down.

7.4 Configuration

Configuration	Description and Command	
Configuring BFD Basic Functions	 (Mandatory) It is used to establish a BFD session.	
	bfd interval	Sets BFD parameters.
	N/A	Configures the BFD support for applications.  The configuration command varies with the associated applications. For details, see their configuration guides.
	 (Optional) It is used to configure the BFD detection mode, slow timer, and BDF support for Layer-3 interfaces.	
	bfd echo	Configures the BFD echo mode.
	bfd slow-timer	Configures the BFD slow timer.
	bfd bind peer-ip	Configures the BFD support for Layer-3 interfaces.
Configuring BFD Protection	 (Optional) It is used to protect BFD against attacks. 	
	bfd cpp	Enables BFD protection.
Configuring BFD Flapping Dampening	 (Optional) It is used to protect associated protocols against BFD flapping.	
	bfd up-dampening	Configures BFD flapping dampening.

7.4.1 Configuring BFD Basic Functions

Configuration Effect

- Configure BFD support for applications.
- Establish a BFD session.
- A BFD session detects link faults.

Notes

- Pay attention to the following points when setting BFD session parameters:
 21. It is recommended that parameter settings be consistent at both ends of a BFD session, to ensure that application protocols associated with BFD take effect simultaneously and prevent occurrence of one-way forwarding due to different dampening time at both ends.
 22. Take into account of transmission bandwidth differences of different interfaces when setting parameters. If the minimum transmission interval and minimum receiving interval are set to very small values, data transmission may be affected due to very large BFD bandwidth occupancy.
- Pay attention to the following points when configuring BFD support for applications:
 23. Ensure that it is enabled on neighbors of a BFD session. Otherwise, a BFD session cannot be established. If a dynamic routing protocol or another application requires BFD to establish a session with a neighbor, the BFD session can also be established.
 24. If the interface specified by a BFD session is different from the actual BFD packet outbound interface because of IP routing, or if the interface specified during BFD session creation is different from the actual BFD packet inbound interface, a BFD session cannot be established.
- Pay attention to the following points when configuring the BFD detection mode:
 25. In the process that the forwarding plane of the peer device returns echo packets transmitted by the local end to the local end, the echo packets may be lost due to congestion of the peer device, causing a session detection failure. In this case, configure Quality of Service (QoS) policies to ensure that echo packets are processed preferentially or disable the echo function.
 26. The echo detection function of BFD does not support multi-hop detection. Ensure that the echo function is disabled when configuring multi-hops.
 27. The echo mode takes effect only after this mode is enabled at both ends of a BFD session.
 28. Before enabling the echo mode of BFD, run the **no ip redirects** command on the neighbors of a BFD session to disable the function of ICMP packet redirection, and run the **no ip deny land** command to disable the Distributed Denial of Service (DDoS) function (prevent the Land-based attack).

Configuration Steps

▾ Setting BFD Parameters

- Mandatory.

- BFD parameters need to be set at BFD session egresses of routers at both ends detected by BFD if no special requirements are raised.
- Take into account of transmission bandwidth differences of different interfaces when setting parameters. If the minimum transmission interval and minimum receiving interval are set to very small values, data transmission may be affected due to very large BFD bandwidth occupancy.

Command	bfd interval <i>milliseconds</i> min_rx <i>milliseconds</i> multiplier <i>interval-multiplier</i>
Parameter	interval <i>milliseconds</i> : Indicates the minimum TX interval, with the unit of milliseconds.
Description	min_rx <i>milliseconds</i> : Indicates the minimum RX interval, with the unit of milliseconds. multiplier <i>interval-multiplier</i> : Indicates the detection timeout multiplier.
Defaults	No BFD session parameter is configured.
Command Mode	Interface configuration mode
Usage Guide	The fast forwarding function must be enabled before the BFD function is enabled on routers.

↘ Enabling the BFD Echo Mode

- (Optional) Ports run in asynchronous mode by default. If a BFD session needs to run in echo mode, the echo mode needs to be configured.
- Complete the configuration on ports of switches or routers.
- A session runs in asynchronous mode as long as either of routers at both ends is configured to run in asynchronous mode. If routers at both ends are configured to run in echo mode by default, a BFD session finally runs in echo mode.

Command	bfd echo
Parameter	N/A
Description	
Defaults	The BFD echo mode is disabled.
Command Mode	Interface configuration mode
Usage Guide	This command cannot be configured on Layer-3 AP ports. By default, when BFD session parameters are set, the system automatically enables the echo mode. The minimum TX interval and minimum RX interval of echo packets adopt the Interval milliseconds and min_rx milliseconds parameters of a session. Before enabling the echo mode of BFD, run the no ip redirects command on the neighbors of a BFD session to disable the function of ICMP packet redirection, and run the no ip deny land command to disable the Distributed Denial of Service (DDoS) function (prevent the Land-based attack).

↘ Configuring the BFD Slow Timer

- (Optional) The default slow timer is 3,000 milliseconds. The value can be changed as required.
- Configure this function in global configuration mode of switches or routers.

- In BFD echo mode or session building, the slow timer is used to control packets. If the value increases, the required time for negotiating and establishing a BFD session becomes longer, and the time required for transmitting slow BFD packets in echo mode is longer.

Command	bfd slow-timer [<i>milliseconds</i>]
Parameter Description	<i>milliseconds</i> : Indicates the BFD slow timer, with the unit of milliseconds. The value ranges from 1,000 to 30,000 and the default value 3,000 is adopted if it is not set.
Defaults	The transmission interval of slow control packets is 3,000 milliseconds.
Command Mode	Global configuration mode
Usage Guide	This command is used to specify the slow timer in echo mode.

↘ Configuring the BFD Support for Layer-3 Interfaces

- (Optional) Currently, this function is used only when MPLS LDP is used for FRR.
- Configure this function on interfaces of switches or routers.

Command	bfd bind peer-ip <i>src-address</i> [source-ip <i>dst-address</i>] process-pst
Parameter Description	<i>src-address</i> : Indicates the peer IP address of an interface. <i>dst-address</i> : Indicates the local IP address of an interface.
Defaults	BFD support for Layer-3 interfaces is not configured by default.
Command Mode	Interface configuration mode
Usage Guide	This command is used to enable BFD support for Layer-3 interfaces so as to rapidly detect connectivity of Layer-3 interfaces.

↘ Configuring the BFD Support for Applications

- Mandatory.
- This function is disabled by default.
- The configuration command varies with the associated applications. For details, see their configuration guides.
- This function must be configured at both ends so that a BFD session can be established.
- In RIP routing configuration mode, run the **bfd all interfaces** command to enable BFD support for RIP on all interfaces. For details, see *Configuring RIP*.
- In OSPF routing configuration mode, run the **bfd all interfaces** command to enable BFD support for OSPF on all interfaces. For details, see *Configuring OSPF*.
- In OSPFv3 routing configuration mode, run the **bfd all interfaces** command to enable BFD support for OSPFv3 on all interfaces. For details, see *Configuring OSPFv3*.
- In BGP routing configuration mode, run the **neighbor address fall-over bfd** command to enable BFD support for BGP. For details, see *Configuring BGP*.

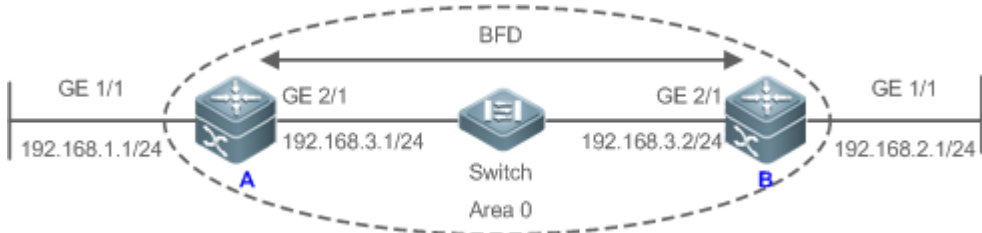

- In IS-IS routing configuration mode, run the **bfd all interfaces** command to enable BFD support for IS-IS on all interfaces. For details, see *Configuring IS-IS*.
- In global configuration mode, run the **ip route static bfd [vrf vrf-name] interface-type interface-number gateway [source ip-address]** command to enable BFD support for static routing. For details, see *Configuring NSM*.
- In global configuration mode, run the **ipv6 route static bfd [vrf vrf-name] interface-type interface-number gateway [source ipv6-address]** command to enable BFD support for IPv6 static routing. For details, see *Configuring NSM*.
- Run the **set ip next-hop verify-availability next-hop-address bfd [vrf vrf-name] interface-type interface-number gateway** command to enable BFD support for PBR. For details, see *Configuring PBR*.
- Run the **set ipv6 next-hop verify-availability next-hop-address bfd [vrf vrf-name] interface-type interface-number gateway** command to enable BFD support for IPv6 PBR. For details, see *Configuring PBR*.
- Run the **vrrp bfd interface-type interface-number ip-address** command to enable BFD support for VRRP. For details, see *Configuring VRRP*.
- VRRP Plus is based on the VRRP protocol. Therefore, no additional configuration is required for BFD support for VRRP Plus. Only VRRP needs to be enabled on devices at both ends and a BFD session is correctly associated.
- Run the **bfd bind static-lsp peer-ip ip-address source-ip ip-address [local-discriminator discr-value remote-discriminator discr-value] [process-state]** command to enable BFD support for static LSP. For details, see *Configuring MPLS*.
- Run the **bfd bind ldp-lsp peer-ip ip-address nexthop ip-address [interface interface-type interface-number] source-ip ip-address [local-discriminator discr-value remote-discriminator discr-value] [process-state]** command to enable BFD for LDP LSP. For details, see *Configuring MPLS*.
- Run the **bfd bind backward-lsp-with-ip peer-ip ip-address [vrf vrf-name] interface interface-type interface-number [source-ip ip-address] { local-discriminator discr-value remote-discriminator discr-value }** command to enable BFD support for dynamic LSP. For details, see *Configuring MPLS*.

Verification

- The verification command varies with the associated applications. For details, see their configuration guides.

Configuration Example

Configuring BFD support for OSPF

<p>Scenario Figure 7-6</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure IP addresses for interconnected interfaces of Router A and Router B. ● Run OSPF on Router A and Router B. ● Set BFD parameters for interconnected interfaces of Router A and Router B.

● Enable BFD support for OSPF on Router A and Router B.	
A	<pre>A#configure terminal A(config)#interface GigabitEthernet2/1 A(config-if-GigabitEthernet2/1)# no switchport //The configuration is not required on routers. Common Errors

- BFD parameters are not set for device interfaces at one end.
- The BFD support for applications is disabled.
- The BFD support for applications is enabled only at one end.

7.4.2 Configuring BFD Protection

Configuration Effect

- If a BFD-enabled device is attacked (for example, attacked by a large number of ping packets) and BFD session flaps accordingly, the BFD protection can be enabled to provide protection.

Notes

- The BFD basic functions must be configured.
- If both BFD and BFD protection are enabled on a device, the device discards the BFD packet from the previous hop, affecting the establishment of a BFD session between the previous-hop device and other devices.
- This function and limitations are applicable only to switches.

Configuration Steps

↳ Enabling BFD Protection

- Optional.
- Configure this function in global configuration mode on switches or routers.
- The BFD protection function raises the processing priority of BFD packets and ensures normal running of BFD services in a scenario in which devices are attacked.

Command	bfd cpp
Parameter	N/A
Description	
Defaults	The BFD protection function is enabled by default.
Command Mode	Global configuration mode
Usage Guide	Enable the BFD protection function to provide protection if a device encounters BFD flapping due to attacks.

Verification

Run the **show running-config** command to verify the configuration on an interface.

Configuration Example

▾ Enabling BFD Protection

Configuration Steps	<ul style="list-style-type: none"> ● Configure this function on a switch on a network where attacks exist. ● Configure the BFD protection function.
	<pre>Ruijie#configure terminal Ruijie(config)# bfd cpp Ruijie(config)# end</pre>
Verification	N/A

7.4.3 Configuring BFD Flapping Dampening

Configuration Effect

- A BFD session may frequently switch over between Down and Up due to link instability. As a result, a relevant application (such as static routing) may frequently switch forwarding paths and the running services are affected.
- Users can set the delay for status change advertisement, after which BFD notifies an associated application of BFD Up. After a BFD session is Up for a certain period of time, BFD notifies an associated application of BFD Up. Otherwise, BFD notifies it of BFD Down. The purpose is to reduce flapping of associated protocols caused by instable links.

Notes

- The BFD basic functions must be configured.
- If a BFD session does not frequently switch over between Down and Up, the enabling of BFD flapping dampening will delay notifying an associated application of BFD Up.

Configuration Steps

▾ Configuring BFD Flapping Dampening

- (Optional) The BFD flapping dampening is disabled on ports by default. If a BFD session frequently switches over between Down and Up, it is advised to enable this function.
- Configure this function on ports of switches or routers.
- With BFD flapping dampening enabled, it is relieved that associated applications, such as route re-calculation, process quantities of advertisements because of frequent status BFD change. The larger the configured time is, the longer the required BFD stability time is. BFD notifies an application module of BFD Up only after the stability time reaches the configured time.

Command	bfd up-dampening [<i>milliseconds</i>]
Parameter Description	<i>milliseconds</i> : Indicates the delay for status change advertisement, after which BFD notifies an associated application of BFD Up, with the unit of milliseconds. The value ranges from 0 to 300,000. The value 0 indicates that BFD notifies the application layer immediately when a session switches over from Down to Up and the default value is 0.
Defaults	The BFD flapping dampening function is disabled by default.
Command Mode	Interface configuration mode
Usage Guide	This function needs to be enabled only when the link is instable. If a BFD session does not frequently switch over between Down and Up, the enabling of BFD flapping dampening will delay notifying an associated application of BFD Up.

Verification

Run the **show running-config** command to verify the configuration on an interface.

Configuration Example

↘ Configuring BFD Flapping Dampening with the Advertisement Delay as 60,000 Milliseconds

Configuration Steps	<ul style="list-style-type: none"> ● Configure this function in an environment where BFD frequent flaps due to link instability. ● Set the delay for status change advertisement to 60,000 milliseconds.
	<pre>Ruijie#configure terminal Ruijie(config)# interface fastEthernet 0/2 Ruijie(config)# bfd up-dampening 60000 Ruijie(config)# end</pre>
Verification	N/A

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs BFD events.	debug bfd event [interface <i>interface-type interface-number</i> ipv4 <i>ip-address</i> ipv6 <i>ipv6-address</i>]
Debugs BFD packets.	debug bfd packet [interface <i>interface-type interface-number</i> ipv4 <i>ip-address</i> ipv6 <i>ipv6-address</i>]

8 Configuring IP Event Dampening

8.1 Overview

When the Layer-3 port on a Layer-3 device frequently goes Up and Down due to manual enabling/disabling or other external causes, the routing table on the device will flap repeatedly. If a routing protocol is configured, the protocol may propagate the flap to the entire network, causing repeated updates and recalculation of neighboring routes, which wastes network bandwidths and destabilizes the network. Repeated route updates and recalculation on devices consume many CPU resources, which affects the normal running of customer networks.

IP Event Dampening detects abnormal Up/Down flapping and automatically suppresses frequent port state changes, which prevents the propagation of single-point link failures by a routing protocol. When the port is restored, it will be automatically unsuppressed, thus reducing network flaps and CPU resource consumption while improving network stability.

Protocols and Standards

- RFC2439: BGP Route Flap Dampening

i At its core, the suppression algorithm used by IP Event Dampening is the same as that used by BGP Route Flap Dampening.

8.2 Applications

Application	Description
Routed Port Flap Dampening	Monitors the state change of the Layer-3 port on a router, and suppresses frequent port flapping.

8.2.1 Routed Port Flap Dampening

Scenario

In a network that runs a routing protocol, when a port on a router connected to another router frequently goes Up and Down, neighboring routes will be repeatedly updated and recalculated. The routing protocol may propagate the flap to the entire network, causing a network flap. IP Event Dampening can be enabled on the connected routers to monitor port state changes and suppress frequent port flapping, thus reducing network flaps and CPU resource consumption while improving network stability.

Figure 8-1

Remarks	A and B are routers.
----------------	----------------------

Deployment

Configure IP Event Dampening on portGE0/1 on Router A and portGE0/1 on Router B respectively.

 The subinterfaces and the virtual templates of interfaces on routers do not support the dampening feature.

8.3 Features

Basic Concepts

↘ Penalty

A port that goes Up or Down gets a penalty for each state change, but the penalty decays exponentially when the port is stable. In this way, port behaviors can be sensed and controlled intelligently.

↘ Suppress Threshold

When the cumulative penalty of a port exceeds a suppress threshold, the port is considered to flap and will be suppressed.

↘ Half-Life Period

The half-life period is the period required for the penalty to decrease to half of the original value when the port is stable. It defines the speed at which the penalty decays exponentially. The shorter the half-life period, the faster the penalty decays, and the faster the port is detected to be stable, but the flap detection sensitivity is reduced.

↘ Reuse Threshold

When the port no long flaps and its penalty decays to a certain degree (below the suppress threshold), the port is considered to be stable and is unsuppressed.

↘ Maximum Suppress Time

When a port keeps flapping and reaches a very large penalty, the port will not be usable for a long time. To avoid this problem, the maximum suppress time is defined to always maintain the port suppression duration below a certain value no matter how long the port has flapped.

Overview

Feature	Description
Port Flap Suppression	Configure the criteria and parameters of flap suppression on ports to enable switches or routers to identify and suppress frequently flapping ports, which ensures route stability and avoids route flap propagation.

8.3.1 Port Flap Suppression

Working Principle

A port configured with IP Event Dampening is assigned a penalty. The port gets a penalty of 1,000 each time when it goes Down, but the penalty decreases with time. If the port goes Down again, the penalty increases accordingly. When the cumulative penalty exceeds the suppress threshold, the port will be suppressed. For the affected upper-layer protocol, the suppressed port is always Down no matter what the actual port state is. When the penalty decreases to the reuse threshold, the port will be unsuppressed, and the upper-layer protocol can sense the actual port state.

If a Layer-3 port is not configured with IP Event Dampening, or is not suppressed by it, the routing protocol or other protocol concerned about the port status still work normally. When the port is suppressed, the upper-layer protocol considers the port to be Down. Any state change of the port before the port is unsuppressed does not affect the routing table and the route calculation and advertisement performed by the upper-layer routing protocol.

Related Configuration

↘ [Configuring IP Event Dampening](#)

- By default, IP Event Dampening is disabled on Layer-3 ports.
- Run the **dampening** [*half-life-period* [*reuse-threshold* *suppress-threshold* *max-suppress* [**restart** [*restart-penalty*]]]] command to enable or disable IP Event Dampening on Layer-3 ports.

8.4 Configuration

Configuration	Description and Command
Enabling IP Event Dampening	 (Mandatory)It is used to suppress Layer-3 port flapping.
	dampening Configures IP Event Dampening.

8.4.1 Enabling IP Event Dampening

Configuration Effect

When a port configured with IP Event Dampening keeps flapping until the predefined threshold is exceeded, the port is set to Down.

Notes

- When a Layer-3 port on a switch is converted to a Layer-2 port (for example, from a routed port to a switch port), the IP Event Dampening configuration on the port will be deleted.
- Only the main interface on a router can be configured with IP Event Dampening. The configuration takes effect for all subinterfaces of the main interface, but you cannot run the **dampening** command directly on subinterfaces and virtual templates.

Configuration Steps

▾ Configuring IP Event Dampening

- Mandatory.
- Perform the configuration in Layer-3 interface configuration mode.
- You can specify the half-life period, reuse threshold, suppress threshold, maximum suppress time, and initial penalty. If you do not set these parameters, their default values will be used.

Verification

Use any one of the following commands to check whether the configuration takes effect:

- **show running-config**
- **show interfaces [interface-id] dampening**, which is used to check the IP Event Dampening configuration on a specified port

Related Commands

Displays the counters on suppressed ports.	show dampening interface
Displays the IP Event Dampening configuration on ports.	show interfaces dampening

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Enables debugging of IP Event Dampening.	debug dampening interface

9 Configuring VSU

9.1 Overview

In order to improve the reliability of networks, the two devices at core layer and convergence layer of traditional networks are configured with two cores to provide redundancy. Access and convergence devices are respectively connected to the cores through two links. The following figure shows typical traditional network architecture. Redundant network architecture increases the complexity of network design and operation. At the same time, a large number of redundant links reduce the utilization of network resources and return on investment.

Figure 9-1 Traditional Network Architecture

Virtual Switching Unit (VSU) is a kind of network system virtualization technology that supports combining multiple devices into a single virtualized device. As shown in Figure 9-2, access, convergence and core layer devices can respectively form VSUs, and then these VSUs connect to one another to form an end-to-end VSU network. Compared with traditional network, this networking can:

- Simplify the network topology.
- Reduce the costs of network management and maintenance.
- Shorten application recovery time and service interruption time.
- Enhance the utilization of network resources.

Figure 9-2 End-to-End VSU Networking

9.2 Applications

Application	Description
Managing Multiple Devices in a Unified Manner	Uses multiple physical devices as a logical device for unified management.
Simplifying Networking Topology	Uses a VSU as a logical device to simplify the networking topology.

9.2.1 Managing Multiple Devices in a Unified Manner

Scenario

When multiple physical devices form a VSU system, the physical devices can be viewed as a logical device. All configurations are managed on the global master device.

As shown in Figure 9-3, four devices (numbered as 1, 2, 3, and 4 from left to right) form a VSU system. Device 1 is the global master device, device 2 is the global slave device, and devices 3 and 4 are the global candidate devices.

- All devices are configured simply on the global master device.

Figure 9-3

Remarks	The devices from left to right in Figure 9-3 are Device 1, Device 2, Device 3 and Device 4. For details on VSL, see the description in section 1.3.1.
----------------	---

<p>Device 1 is the global master device.</p> <p>Device 2 is the global slave device.</p> <p>Devices 3 and 4 are the global candidate devices.</p>

Deployment

- The global master device controls the entire VSU system, runs control-plane protocols and is involved in data forwarding.
- The global slave device is involved in data forwarding, does not run control-plane protocols, and works as the backup and takes over the work of the global master device when faulty.
- The global candidate devices are involved in data forwarding and do not run control-plane protocols. When the global slave device is faulty, a global candidate device can take over the work of the global slave device. In this case, when the global master and slave devices are faulty, the VSU system will restart.

9.2.2 Simplifying Networking Topology

Scenario

In traditional networks as shown in Figure 9-4, redundant devices and lines need to be added to increase the networking reliability; however, many algorithms also need to be introduced to prevent loops, which make the networking more complex. In the VSU system, all devices are viewed as a logical device. Different devices back up each other, and no loop prevention algorithm needs to be introduced, which can simplify the network.

- Two aggregate switches form a VSU system. It is unnecessary to configure a loop prevention algorithm. The two switches are redundant mutually.
- The access switch is connected to the aggregate switches through the uplink AP.
- When a switch in the VSU system is faulty, the other link still works.

Figure 9-4

Deployment

- The global master device controls the entire VSU system, runs control-plane protocols and is involved in data forwarding.

- The global slave device is involved in data forwarding, does not run control-plane protocols, and works as the backup and takes over the work of the global master device when the global master device is faulty.
- The access switch is oriented to users and allows access by users' devices.

9.3 Features

Basic Concepts

VSU System

VSU system is a single logical entity consisting of two or multiple devices in traditional network architecture. For example, the convergence layer VSU system as shown in the following figure can be seen as a single device that interacts with the core layer and access layer.

Figure 9-5 Convergence layer VSU

In the above VSU network structure, the member devices form a logical entity through internal links and the access layer devices are connected to the VSU through aggregated links. In this way, there is no layer 2 loop between the access and convergence layers.

Figure 9-6 Access layer VSU

Except the core and convergence layer devices, the access layer devices can also form a VSU system. A server that requires high availability can adopt multiple network cards to form an Aggregate Port (AP) to connect access layer devices. Since AP can only connect to the same access device, the risk of single device fault increases. In this case, VSU can be used to solve the problem. In the VSU mode, a server adopts multiple network cards and binds them into an AP to connect different member devices in the same VSU group. This way can prevent single point failure and network interruption caused by single link failure.

↘ VSU Domain ID

A VSU domain has only one ID. Only the devices with the same domain IDs can form a VSU system.

↘ Member Device ID

Every member device in a VSU system has a unique ID, namely, Switch ID. Switch IDs can be used in device management or configuring interfaces on member devices. You need to configure an ID for a device when adding the device to a VSU system and ensure that the ID is unique in the same VSU system. If an ID conflict occurs, the VSU system will reserve one device according to priority.

↘ Member Device Role

A VSU system consists of several devices. When establishing a VSU system, you need to select a global master device and a global slave device. All other devices are global candidate devices. A global master device is elected from multiple devices based on an election protocol. All other devices are global slave devices in the 1: N hot standby mode. When the 1:1 hot standby mode is supported, one device is the global master device, one device is the global slave device, and all other devices are global candidate devices.

The global master device is responsible for controlling the entire VSU system, running control plane protocols and participating in data forwarding. Other devices, including the global slave devices and candidate devices, participate in data forwarding but do not run control plane protocols. All received control plane data flows are forwarded to the global master device for processing.

The global slave device also receives the statuses of the global master device in real-time and provide 1:1 or 1:N redundancy with the global master device. If the global master device becomes faulty, the global slave device will take over services from the master device and manage the entire VSU system.

i The following is the method for selecting the master device of a VSU system:

1. Rules for selecting the master device of a VSU system include (Continue with the next rule if the previous rule does not help in selecting the master device): a) Select the currently running host as the master device with the highest priority (All devices are not master devices during startup). b) Select the device with the highest priority as the master device. c) Select the device with the lowest device No. as the host. d) Select the device with the smallest MAC address as the master device.
2. In the 1:N hot standby mode, select the device that has the most familiar configurations with the master device as the slave device to prevent dual active devices. The selection order is: the nearest/the highest priority/the smallest MAC address.
3. VSU system supports hot adding a support device. Even the hot added device has a higher priority than the master device has, the VSU system does not perform active/standby switch.
4. The startup order of member device may affect the election of master device. A member device may not join in the VSU system because it starts up too slowly. In this case, the device will be hot added to the VSU system. Even the device has a higher priority than the master device, the VSU system does not perform active/standby switchover.

Overview

Feature	Description
---------	-------------

Virtual Switching Link (VSL)	In a VSU system, a virtual link is used to connect all devices.
Topology	Describes the internal topology of a VSU system.
Dual-Active Detection (DAD)	Avoids that dual master switches coexist in a VSU domain.
System Management	Describes possible connections between external devices and VSU devices.
Quick Blinking Location	Manages devices in the VSU system.

9.3.1 Virtual Switching Link (VSL)

Working Principle

↘ VSL

The VSU system is a network entity that consists of multiple devices. These devices need to share control information and part of data streams. The VSL is a special link used for transmission of control information and data streams among devices of the VSU system. For example, the VSL can be established between two devices through 10 Gigabit Ethernet interfaces. Figure 9-7 shows the position of the VSL in the VSU system.

Figure 9-7 VSL

The VSL exists in the form of AP groups. The data streams transmitted through the VSL balance load among the aggregation port members according to the traffic balancing algorithm.

↘ VSL Traffic

The control streams transmitted through the VSL between devices include:

1. The protocol packets received by the member devices: These protocol packets need to be forwarded through the VSL to the global master device for processing.
2. The protocol packets processed by the global master device: These protocol packets need to be forwarded through the VSL to the interfaces of other member devices and then sent to the peer devices by these interfaces.

The data streams transmitted through the VSL between devices include:

1. The data stream flooded on the VLAN
2. The data streams that need to be forwarded across devices and transmitted through the VSL

Furthermore, the internal management packets of the VSU system are also transmitted through the VSL. The management packets include the protocol information switched by the hot backup and configuration information delivered by the host to other member devices.

i In terms of the switched port analyzer (SPAN) function, the interface associated with the VSL cannot be regarded as the source port or destination port of the SPAN.

↘ VSL Failure

If a certain member link connected to the VSL AP group fails to work, the VSU will adjust the configurations of the VSL aggregation port automatically to prevent the traffic from being transmitted through the faulty member link.

If all member links are disconnected to the VSL AP group, the VSU topology will change. If the original VSU topology is a ring topology, the ring will convert into a line. For details, see topology ring and line conversion in the section of *Topology Changes*.

↘ Detecting Error Frames on a VSL Interface

When a large number of consecutive error frames are detected on a VSL interface, the interface must be disabled and switched to another VSL interface. The detection method is as follows:

If error frames are found on a VSL interface, perform error frame correction. The system detects the VSL interface every 5 seconds by default. If the number of error frames is greater than the value of *num* as compared with that detected last time, it is assumed that error frames are detected once. If error frames are detected consecutively for the value of *times*, it is assumed that the interface is abnormal. If multiple VSL links are available when error frames are detected, the VSL will be switched. The last VSL will not be switched in order to prevent topology splitting.

Different user scenarios have different requirements for *num* and *times*. The default value of *num* is 3 and that of *times* is 10. If users have strict requirements on the scenarios, select smaller values for *num* and *times*; if reverse, select greater values.

9.3.2 Topology

The VSU system supports line topology and ring topology. Devices are connected through a VSL to form a line that is called the line topology.

Working Principle

↘ Topology

The line topology is simple. It uses a very few ports and cables. Two devices are connected with a communication link only. Therefore, the VSL has low reliability.

Figure 9-8 Line topology

Except for the line topology, devices can also form a ring topology, as shown in Figure 9-9. In the ring topology, the two communication links between devices can back up for each other and perform link redundancy to improve the reliability of the VSU system.

Figure 9-9 Ring Topology

- i** You are advised to select the ring topology for the VSU system, thus the normal operation of the whole VSU system will not be affected by any single faulty device or VSL.
- i** Besides selecting the ring topology networking, you are advised to configure multiple VSLs for every VSL member to improve the reliability of a single VSL. At least two links are recommended and a maximum of four links can be configured. A reasonable configuration comprises more than two VSLs crossing different cards.

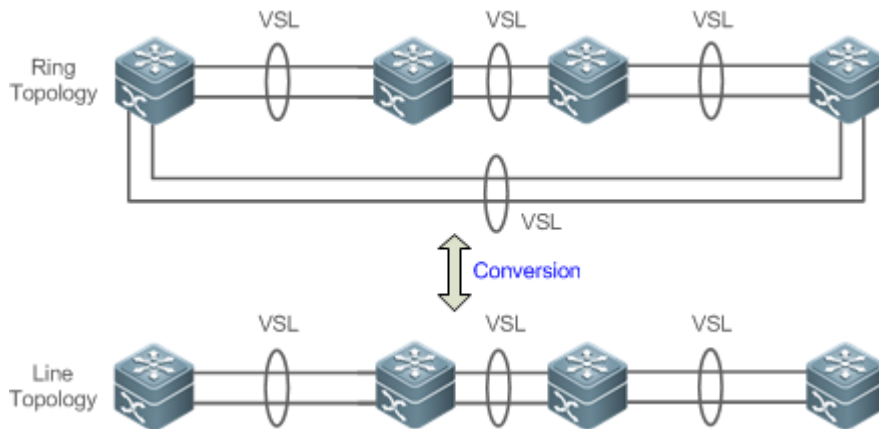

Topology Convergence

Before the establishment of the VSU, the member devices need to discover neighbors through topology discovery protocols and check devices in the VSU system to confirm the range of the management domain. Then a global master device is selected to manage the whole VSU system and a global slave device is selected for backup of the master device. Then the whole VSU topology is converged. As the start up time differs for different devices, the first convergence time of the topology is also different.

Topology ring and Line Conversion

In a ring topology, if a VSL link is disconnected, the ring topology will convert into a line topology. The whole VSU system will still run normally without network disconnection. To prevent other VSL links and nodes from being faulty, you are advised to locate the VSL failures and recover the availability of the VSL. After the VSL link is recovered, the line topology will convert into the ring topology.

Figure 9-10 Ring-to-line and line-to-ring

Topology Splitting

In the line topology, if the VSL link is disconnected, the line topology will be split, as shown in Figure 9-11. A VSU group is split into two groups. In this condition, two devices with the absolutely same configurations may exist on the network, which will cause abnormal operation of the network. Therefore, the multi-active detection (MAD) function (for details, see 1.1.4.6 Multi-Active Detection) needs to be deployed to solve the problem of topology splitting.

Figure 9-11 Topology splitting

Topology Combining

If the two VSU groups are connected through the VSL link, the line topology will be combined. During the topology combining, restart one VSU group and then hot add the other VSU group.

The principle of topology combining: Minimizing influences on the services during topology combining. The rules are as follows (Judge from the first item. If you cannot select the optimal topology, continue to judge the next item):

- Use the device priority as the first criteria for judging topology combining. Reserve the VSU group containing a device with the highest priority.
- If the previous item cannot help make a judgment, select the VSU group with a smaller switch ID (that of the two global master switches).
- If the previous item cannot help make a judgment, reserve the VSU group with a smaller MAC address (that of the global master switches).

Figure 9-12 Topology combining

-
-  During topology combining of two VSU groups, the two VSU groups need to be elected. The VSU group that fails the election will restart automatically and not add to the other VSU group.
-

9.3.3 Dual-Active Detection (DAD)

Working Principle

When the VSL is disconnected, the slave device switches to the master device. If the original master device is still running, a series of problems including IP address conflict on the LAN will be caused due to there are two master devices and their configurations are the same completely. In this condition, the VSU system must detect the two devices and take recovery measures. The VSU system provides two methods to perform MAD as follows:

- Bidirectional forwarding detection (BFD)
- AP-based detection

MAD Rules

1. Select the VSU group with the highest priority.
2. If the previous item cannot help make a judgment, select the VSU group with more physical devices.
3. If the previous item cannot help make a judgment, select the VSU group with a higher health. (Health: total bandwidth of all physical interfaces (except for management and VSL interfaces) in the UP state in the topology.)
4. If the previous item cannot help make a judgment, select the VSU group with a smaller switch ID (that of the two global master switches).
5. If the previous item cannot help make a judgment, reserve the VSU group with a smaller MAC address (that of the two global master switches).
6. If the previous item cannot help make a judgment, reserve the VSU group with a greater startup time (that of the global master switches).

 If DAD is not configured, network interruption may be caused after topology splitting.

BFD

The VSU system supports the BFD to detect multiple master devices. Figure 9-13 shows the topology. A link is added for the two devices on the edges for MAD specially. When the VSL link is disconnected between the global master and slave devices, two master devices exist concurrently. If the BFD function is set, the two master devices will send the BFD packets to each other through the BFD link. Thereby the same devices are detected on the current system. Finally shut down the VSU system of a master device according to some rules (for details, see the topology combining rules in the section 1.1.4.4 *Topology Changes*) and enter the recovery state to avoid network abnormality.

Figure 9-13 BFD

- ⚠ When there is a pair of BFD links, you are advised to deploy the detection links at the two ends of the topology.
- ⚠ You need to adopt the extension BFD and you cannot configure the dual-active detection port by using the existing BFD configurations and commands.

↘ **MAD**

The VSU system also supports the MAD dual-active detection mechanism. Figure 9-14 shows the topology. The VSU system and the upstream device both need to support the MAD function. When the VSL link is disconnected, two master devices exist concurrently. The two master devices respectively send the MAD packets to the member ports of the MAD-APs and then the MAD packets are forwarded to each other through the upstream device. As shown in Figure 9-14, the MAD-AP has four member ports. Each member port is connected to a different device of the VSU system. When the topology splitting occurs, the four member ports all send and receive the MAD packets. Thereby the same devices are detected on the current system. Finally shut down the VSU system of a master device according to some rules (for details, see the topology combining rules in the section *Topology Changes*) and enter the recovery state to avoid network abnormality.

Figure 9-14 MAD based on upstream and downstream devices

- ✔ In the topology above, the upstream device must be Ruijie device and support the MAD packet forwarding function.

9.3.4 VSU Traffic Forwarding

Working Principle

↘ **Cross-device AP Group**

An AP binds multiple physical links together to form a logical link. The VSU system supports the AP across the member devices.

As shown in Figure 9-15, two devices form a VSU group. The external access device Switch A is connected to the VSU in the form of the AP. In terms of Switch A, there is no difference between the AP in Figure 9-15 and the common AP group.

Figure 9-15 Cross-device aggregation port

▾ Troubleshooting

You are advised to configure the cross-device AP with the physical link between the peripheral device and each VSU device. On the one hand, the VSL bandwidth can be reserved (prioritize the AP member of the same chassis as the egress to transmitted the cross-chassis AP traffic and prevent unnecessary traffic from being transmitted through the VSL link). On the other hand, the network reliability can be improved (if a certain chassis is faulty, the member ports of normal devices can work normally).

The follows sections describe the possible faults of the cross-device AP and the consequences.

- Single link failure

If a single link of the cross-device AP is faulty but other links still work normally, the cross-device AP will reallocate the traffic for the remaining normal links.

- Link failure of all cross-device AP member ports on the global master device

If the links of all cross-device AP member ports on the global master device fail to work, only the member ports of other member devices continue working normally. In terms of the data stream transmitted through the AP to the VSU system, if the data stream forwarding egress is on the global master device, the system will forward the data stream to the corresponding egress on the global master device through the VSL link.

The control plane protocols are still running on the global master device. Therefore, the protocol packets that enter the VSU system need to be forwarded to the global master device through the VSL link for protocol computing.

- Failure of all links of other member devices

If all links of the cross-device AP and a single device A fail to work, only the member ports of other member devices continue working normally. In terms of the data stream transmitted through the AP to the VSU system, if the data stream forwarding egress is on the member device A, the system will forward the data stream to the corresponding egress on the member device A through the VSL.

- Global master device fault

If the global master device is faulty, the hot backup switching is performed to switch the original slave device to the master device. Meanwhile, the member ports on other member devices continue working. The link failure is detected on the peer device connected to the VSU through this AP. Therefore, the traffic balancing algorithm needs to be adjusted to allocate the data stream to normal links.

- Member device fault

If a member device is faulty, the AP member link connected to this member device is disconnected. However, other member links still work normally. The link failure is detected on the peer device connected to the VSU through this AP. Therefore, the traffic balancing algorithm needs to be adjusted to allocate the data stream forwarding paths to normal links.

↘ Traffic Balancing

In a VSU system, traffic may have multiple egresses. The AP and ECMP have their own traffic balancing algorithms, for example, using destination or source MAC addresses. For details, see the *Configuring Aggregate Port*. The local forwarding first (LFF) can be configured detailed in this configuration manual. Packets received by a device are forwarded on this device first. In this way, packets can be forwarded to other devices without using a VSL.

9.3.5 System Management

Working Principle

↘ Access to the Console

The master device console of VSU system manages multiple devices on the system simultaneously. The consoles of the slave and candidate devices do not support command line input. However, you can configure the VSU system on the master device for a specified member device and log in to the master device console through the serial port of the slave device. A session can be used to redirect to the master console of a device.

↘ Slot Naming

In terms of the chassis device, in the VSU mode, the slot is named with the device number (Switch ID). Therefore, the slot number turns from one-dimensional into two-dimensional. For example, cable clip 1/1 indicates the slot numbered 1 of the slot 1 on a member device.

↘ Interface Naming

In the VSU working mode, a slot number may occur in multiple devices. Therefore, the interface is named with the device number (Switch ID).

For example, interface gigabitEthernet 1/0/1 indicates the Gigabit port 1 on the slot 0 of the device whose ID is 1; interface gigabitEthernet 2/0/2 indicates the Gigabit port 2 on the slot 0 of the device whose ID is 2.

↘ Access to the File System

In the VSU working mode, you can access to the file system on other member devices from the master device. The detailed access method is the same to that of the local file system. The unique difference is that different URL prefixes are used.

↘ System Upgrade

Generally the VSU system requires version consistency of the main program version numbers of the member devices. However, there are so many member devices that it takes too much time and energy to perform upgrade one by one in the standalone mode and it is also easy to make mistakes. Ruijie switches provide consummate system upgrade solution to help you with system upgrade by adopting the two methods as follows:

- When the VSU system is being established: the system will automatically align the main program version numbers of all member devices. Once the main program versions are discovered inconsistency, the main program of the master device will be selected to be synchronized to all member devices.
- After the VSU system is established: the main program version will be synchronized to all member devices automatically by using the file that is downloaded by the TFTP.

➤ **SYSLOG**

All member devices of the VSU system can display the SYSLOG. The SYSLOG generated by the master device is displayed on the master device console with the same format to that in the standalone mode. The SYSLOG generated by other member devices is also displayed on the master device console, but the message format is different from that in the standalone mode because the device number information is added.

For example, the SYSLOG information generated in the standalone state is "%VSU-5-DTM_TOPO_CVG:Node discovery done. Topology converged." The SYSLOG information generated by the member device numbered 3 is "%VSU-5-DTM_TOPO_CVG:(3) Node discovery done. Topology converged."

9.4 Configuration

Configuration		Configuration and Command		
Configuring VSU in the Standalone Mode	 (Mandatory) It is used to configure VSU in the standalone mode.			
	switch virtual domain	Configures the domain ID.		
	switch	Configures the switch ID.		
	switch priority	Configures the switch priority.		
	vsl-port	Enters the VSL interface configuration mode.		
	port-member interface	Configures the VSL member interface.		
	switch convert mode virtual	Changes the standalone mode to the VSU mode.		
	 (Optional) It is used to configure the device attributes in the VSU mode.			
Configuring VSU in the VSU Mode	Configuring VSU Attributes	 (Optional) It is used to configure the device attributes in the VSU mode.		
		switch domain	Changes the domain ID.	
		switch renumber	Changes the switch ID.	
		switch description	Configures the device description.	
	Configuring the VSL	switch crc	Configures error frame check.	
		 (Optional) It is used to configure a VSL.		

Configuration		Configuration and Command	
		vsl-port	Enters the VSL interface configuration mode.
		port-member interface	Configures a VSL member interface.
	Configuring Dual-Active Detection	 (Mandatory) It is used to configure DAD.	
		dual-active detection	Configures DAD.
		dual-active bfd interface	Configures the BFD DAD interface.
		dual-active interface	Configures an AP as a DAD interface.
		dual-active exclude interface	Configures an excluded interface.
	Configuring Traffic Balancing	 (Optional) It is used to configure traffic balancing in the VSU mode.	
		switch virtual aggregateport-lff enable	Configures the AP LFF mode.
		switch virtual ecmp-lff enable	Configures the ECMP LFF mode.
	Changing the VSU Mode to the Standalone Mode	 (Optional) It is used to change the VSU mode to the standalone mode.	
		switch convert mode standalone	Changes the VSU mode to the standalone mode.

9.4.1 Configuring VSU in the Standalone Mode

Configuration Effect

Start up the switch in the standalone mode to set relevant VSU parameters to establish the VSU system.

Configuration Steps

📌 Configuring VSU Attributes

- A switch starts in the standalone mode by default. You need to set the same domain ID on the two chassis of the established VSU system. The domain ID must be unique within the local area network (LAN). Furthermore, you need to set the ID of each chassis in the VSU.
- Run the **switch virtual domain** *domain_id* command to configure the domain ID. This command is mandatory.
- Run the **switch** *switch_id* command to configure the device ID in the VSU. This command is mandatory. For devices with the same priorities in the VSU system, a device with the smallest device ID is selected as the global master device.
- Run the **switch** *switch_id* **priority** *priority_num* command to configure the device priority. This command is mandatory.
- The value ranges from 1 to 255. A larger value means a higher priority.
- Run the **switch** *switch_id* **description** *switch1* command to configure the device alias. This command is optional. The default name is Ruijie. For easy identification of devices in the network environment, this item can be selected to set the device alias.

- A maximum of 32 characters are allowed.

Command	switch virtual domain <i>number</i>
Parameter Description	<i>Number</i> : Indicates domain ID of the VSU
Defaults	The default domain ID is 100.
Command Mode	Domain configuration mode
Usage Guide	Only two devices with the same domain ID can form a VSU. The domain ID must be unique within the LAN.

Command	switch <i>switch_id</i>
Parameter Description	<i>switch_id</i> : indicates the switch ID in the VSU system. The value varies with products.
Defaults	The default device ID is 1.
Command Mode	Domain configuration mode
Usage Guide	<p>The device ID identifies each virtual device member. In VSU mode, the interface name format changes to "switch/slot/port" from "slot/port", in which "switch" is the device ID.</p> <p>If either chassis are active or if the role of the just started chassis is uncertain and both have the same priority, the chassis with a smaller ID is elected as the active one.</p> <p>This command can be only used to modify the device ID in standalone mode. In VSU mode, run the switch renumber command to modify the device ID. The modified device ID takes effect only after you restart the device, regardless of in standalone mode or in VSU mode.</p>

Command	switch <i>switch_id</i> priority <i>priority_num</i>
Parameter Description	<i>switch_id</i> : Indicates a switch ID for which a priority needs to be configured. <i>priority_num</i> : Indicates the switch priority, ranging from 1 to 255.
Defaults	The default device priority is 100.
Command Mode	Domain configuration mode
Usage Guide	<p>A larger value means a higher priority. A device with the highest priority is chosen as the master device. You can run this command in the standalone or VSU mode. The modified priority takes effect only after you restart the device.</p> <p>This command is not used to modify the value of <i>switch_id</i>. In the standalone mode, if <i>switch_id</i> is set to 1, running the switch 2 priority 200 command does not work. You can first set <i>switch_id</i> to 2 and then run the switch 2 priority 200 command. In the VSU mode, <i>switch_id</i> indicates the ID of the currently running switch. If the ID does not exist, the configuration does not take effect.</p>

Command	switch <i>switch_id</i> description <i>dev-name</i>
----------------	---

Parameter	<i>switch_id</i> : Indicates the device ID.
Description	<i>dev-name</i> : Indicates the device description, no greater than 32 characters.
Defaults	N/A
Command Mode	Domain configuration mode
Usage Guide	This command is configured on a device in whether standalone or VSU mode and takes effect immediately after configuration.

 The command used for configuring a priority can modify the priority only rather than modify a switch ID. Therefore, you must enter the current switch ID correctly for the configuration. For example, you have set the switch ID to 1. If you enter **switch 2 priority 100**, the priority configuration cannot take effect.

↘ Configuring the VSL

- To establish the VSU system, you need to decide which ports are configured as the VSL member ports.
- Run the **vsl-port** command to enter the VSL interface configuration mode. This command is mandatory.
- Run the **port-member interface** *interface-name* [**copper** | **fiber**] command to add a VSL interface. This command is mandatory.
- When the device enters the VSL interface configuration mode, the VSL interface can be configured or deleted.

Command	vsl-port
Parameter	N/A
Description	
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	You can run this command in the standalone or VSU mode.

Command	port-member interface <i>interface-name</i> [copper fiber]
Parameter Description	<i>interface-name</i> : Indicates a two-dimensional interface name, such as Tengigabitethernet 1/1 and Tengigabitethernet 1/3. copper : Indicates the copper interface attribute. fiber : Indicates the optical interface attribute.
Defaults	N/A
Command Mode	VSL interface configuration mode
Usage Guide	Add a member interface of the VSL link. <i>interface-name</i> indicates the two-dimensional interface name in the standalone mode. The two-dimensional interface can be the 10 Gigabit interface or Gigabit interface. (The Gigabit interface can be an opto-copper interface. If the media type is not specified, the Gigabit copper interface is adopted by default.) For an opto-copper interface, you must specify its optical or copper interface

	<p>attribute. A VSL interface for a chassis device must be a 10 Gigabit interface.</p> <p>You can run this command in the VSU mode or standalone mode. The command can take effect after the command configuration is saved and the device where the VSL member interface resides is restarted.</p>
--	---

 In the standalone mode, the VSL configurations cannot take effect immediately unless the device shifts into the VSU mode and restart.

 **Configuring Error Frame Check**

- Run the **switch crc** command to configure error frame check. This command is optional. Run this command to modify the default method for checking error frames.
- If error frames are found on a VSL interface, perform error frame correction. The system detects the VSL interfaces every 5 seconds by default. If the number of error frames is greater than 3 as compared with that detected last time, it is assumed that error frames are detected once. If error frames are detected consecutively for 10 times, it is assumed that the interface is abnormal. If multiple VSL links are available when error frames are detected, the VSL will be switched. The last VSL will not be switched in order to prevent topology splitting.

Command	switch crc errors <i>error_num</i> times <i>time_num</i>
Parameter Description	<p><i>error_num</i>: Configures the increase of error frames between two detections. When the number of error frames is greater than the increase, it is assumed that error frames are detected once.</p> <p><i>time_num</i>: Configures the number of times after which an action needs to be taken (the action can be displaying a prompt or disabling the interface).</p>
Defaults	The default value of errors is 3; the default value of times is 10.
Command Mode	Domain configuration mode
Usage Guide	The system detects the VSL interfaces every 5 seconds by default. If the number of error frames is greater than 3 as compared with that detected last time, it is assumed that error frames are detected once. If error frames are detected consecutively for 10 times, it is assumed that the interface is abnormal. The default action for an abnormal interface is displaying a log prompt. You can set the action to disabling the interface. If the interface is disabled, you must recover it by unplugging and plugging it.

 Different products have different requirements for error frame check and different processing for VSL interfaces. In version 11.0, error frame check is configurable.

 **Changing the Standalone Mode to the VSU Mode**

- Use the **switch convert mode virtual** command to change the standalone mode to the VSU Mode.
- In the standalone mode, the software will take the following actions after you run the **switch convert mode virtual** command.

Back up the global configuration file *config.text* in the standalone mode as *standalone.text* for subsequent use.

Clear the contents of the configuration file *config.text*.

Write the relevant VSU configurations to the special configuration file *config_vsu.dat*.

- If there is a *virtual_switch.text* file on the switch, the system will prompt you whether to overwrite the contents of the file *virtual_switch.text* to the file *config.text* (the file *virtual_switch.text* is a backup file for the file *config.text* when the switch shifts from the VSU mode to the standalone mode). Then you can click **Yes** or **No**. Finally the switch restarts in the VSU mode and reads VSU parameters in the file *config_vsu.dat*.

Command	switch convert mode virtual
Parameter Description	N/A
Defaults	The switch is in the standalone mode by default.
Command Mode	Privileged EXEC mode
Usage Guide	Change the standalone mode to the VSU mode.

Verification

Run the **show switch virtual config [switch_id]** command to check the VSU configuration of the current switch in the standalone mode.

Command	show switch virtual config [switch_id]
Parameter Description	<i>switch_id</i> : Indicates the switch ID. After this parameter is specified, only the VSU configuration of the specified device is displayed.
Command Mode	Privileged EXEC mode
Usage Guide	Use this command to display the VSU configuration in the standalone or VSU mode.

! The relevant VSU configurations are set for a single physical switch and the configurations are stored in the special configuration file *config_vsu.dat*. Therefore, you can view the current VSU configurations by running the **show switch virtual config** command rather than the **show running config** command.

In the standalone mode, the VSU running information is null. When you enter commands such as **show switch virtual**, the system will prompt you that the switch is in the standalone mode and there is no VSU running information.

Configuration Example

Configuring VSU in the Standalone Mode

<p>Scenario Figure 9-16</p>	<div style="text-align: center;"> <p>The diagram shows two network switches connected by a horizontal line representing a VSU system. The left switch is labeled 'Switch-1 Chassis 1 Priority 200' and has two VSL interfaces labeled '1/1' and '1/2'. The right switch is labeled 'Switch-2 Chassis 2 Priority 100' and also has two VSL interfaces labeled '1/1' and '1/2'. The connections between the switches are labeled '1/1' and '1/2'.</p> </div> <p>Switch 1 and Switch 2 form a VSU system. The domain ID is 100. The chassis on the left side is configured as Chassis 1, with the priority of 200, alias of Switch 1, and the VSL interfaces of 1/1 and 1/2. The chassis on the right side is configured as Chassis 2, with the priority of 100, alias of Switch 2, and the VSL interfaces of 1/1 and 1/2.</p>
---	---

Configuration Steps	<ol style="list-style-type: none"> 5. Perform the following configuration on the Switch 1: <ul style="list-style-type: none"> ● Configure VSU attributes and VSL interfaces. ● Change the standalone mode to the VSU mode. 6. Perform the following configuration on the Switch 2: <ul style="list-style-type: none"> ● Configure VSU attributes and VSL interfaces. ● Change the standalone mode to the VSU mode.
Switch-1	<pre>Ruijie# configure terminal Ruijie(config)# switch virtual domain 100 Ruijie(config-vs-domain)#switch 1 Ruijie(config-vs-domain)#switch 1 priority 200 Ruijie(config-vs-domain)#witch 1 description switch-1 Ruijie(config-vs-domain)# switch crc errors 10 times 20 Ruijie(config-vs-domain)#exit Ruijie(config)#vsl-port Ruijie(config-vsl-port)#port-member interface Tengigabitethernet 1/1 Ruijie(config-vsl-port)#port-member interface Tengigabitethernet 1/2 Ruijie(config)#exit Ruijie#switch convert mode virtual</pre>
Switch-2	<pre>Ruijie# configure terminal Ruijie(config)# switch virtual domain 100 Ruijie(config-vs-domain)# switch 2 Ruijie(config-vs-domain)# switch 2 priority 200 Ruijie(config-vs-domain)# switch 2 description switch-2 Ruijie(config-vs-domain)# switch crc errors 10 times 20 Ruijie(config-vs-domain)#exit Ruijie(config)#vsl-port Ruijie(config-vsl-port)#port-member interface Tengigabitethernet 1/1 Ruijie(config-vsl-port)#port-member interface Tengigabitethernet 1/2 Ruijie(config-vsl-port)#exit Ruijie#switch convert mode virtual</pre>
Verification	<ul style="list-style-type: none"> ● Run the show switch virtual config command to view the VSU attributes of Switch 1 and Switch 2.
Switch-1	<pre>Ruijie#show switch virtual config</pre>

```
switch_id: 1 (mac: 0x1201aeda0M)
!
switch virtual domain 100
!
switch 1
switch 1 priority 100
!
switch convert mode virtual
!
port-member interface Tengigabitethernet 1/1
!
port-member interface Tengigabitethernet 1/2
!
switch crc errors 10 times 20
!
```

Switch-2

```
Ruijie#show switch virtual config
switch_id: 2 (mac: 0x1201aeda0E)
!
switch virtual domain 100
!
switch 2
switch 2 priority 100
!
switch convert mode virtual
!
port-member interface Tengigabitethernet 1/1
!
port-member interface Tengigabitethernet 1/2
!
switch crc errors 10 times 20
```

Common Errors

- ✔ A VSL interface of a chassis device must be 10 Gigabit or higher.

9.4.2 Configuring VSU in the VSU Mode

9.4.2.1 Configuring VSU Attributes

Configuration Effect

During the VSU system running, you can modify the parameters, such as domain ID, switch ID, and priority of the master device or the slave device. However, you can only log in to the VSU master device console to modify these parameters, but cannot enter the global configuration mode from the slave device console.

Notes

- Among the commands above, the all configuration commands take effect only after the switch restarts except the **switch sw_id description switch1** command that can take effect immediately.

Configuration Steps

↘ Entering the Domain Configuration Mode

- Optional.
- Run this command in the VSU mode to enter the domain configuration mode. Switches with the same domain ID form a VSU system. You can modify or configure the domain ID, switch priority, and switch ID only after entering the domain configuration mode in the VSU mode.

Command	switch virtual domain <i>domain_id</i>
Parameter Description	<i>domain_id</i> : Indicates the virtual domain ID of the VSU system.
Defaults	The default domain ID is 100.
Command Mode	Domain configuration mode
Usage Guide	Only two devices with the same domain ID can form a VSU system. The domain ID must be unique on a LAN.

↘ Changing the Domain ID

- Optional.
- To modify the value of *domain_id* for a device, you can configure this item on the master device console of the VSU system.

Command	switch <i>switch_id</i> domain <i>new_domain_id</i>
Parameter	<i>switch_id</i> : Indicates the ID of the currently running switch in the VSU mode, ranging from 1 to 8.
Description	<i>new_domain_id</i> : Indicates the modified domain ID, ranging from 1 to 255.
Defaults	The default domain ID is 100.
Command Mode	Domain configuration mode
Usage Guide	Run this command only in the VSU mode. In addition, the setting can take effect only after the device is restarted.

↘ Changing the Switch ID

- Optional.
- To modify the value of *switch_id* for a device, you can configure this item on the master device console of the VSU system.

Command	switch <i>switch_id</i> renumber <i>new_switch_id</i>
Parameter	<i>switch_id</i> : Indicates the ID of a switch. In a VSU system, the switch ID ranges from 1 to 16 for cassette switches, and from 1 to 4 for chassis switches.
Description	<i>new_switch_id</i> : Indicates the modified switch ID.
Defaults	N/A
Command Mode	Domain configuration mode
Usage Guide	Run this command only in the VSU mode. In addition, the setting can take effect only after the device is restarted.

↘ Changing the Switch Priority

- Optional.
- To modify the priority of a device, you can configure this item on the master device console of the VSU system.
- A larger value means a higher priority. Select the device with the highest priority as the master device.

Command	switch <i>switch_id</i> priority <i>priority_num</i>
Parameter	<i>switch_id</i> : Indicates a switch ID for which a priority needs to be configured.
Description	<i>priority_num</i> : Indicates the switch priority, ranging from 1 to -255 for cassette switches.
Defaults	The default priority is 100.
Command Mode	Domain configuration mode
Usage Guide	<p>A larger value means a higher priority. Select the device with the highest priority as the master device. You can run this command in the standalone or VSU mode. The modified priority takes effect only after you restart the device.</p> <p>This command is not used to modify the value of switch_id. In the standalone mode, if switch_id is set to 1, running the switch 2 priority 200 command does not work. You can first set switch_id to 2 and then run the switch 2 priority 200 command. In the VSU mode, switch_id indicates the ID of the currently running</p>

	switch. If the ID does not exist, the configuration does not take effect.
--	---

↘ **Configuring the Device Description**

- Optional.
- To configure the description for a device, you can configure this item on the master device console of the VSU system.
- Run the **switch** *switch_id* **description** *switch1* command to configure the device description. A maximum of 32 characters are allowed.

Command	switch <i>switch_id</i> description <i>dev-name</i>
Parameter	<i>switch_id</i> : Indicates a switch ID for which a priority needs to be configured.
Description	<i>dev_name</i> : Indicates the device name.
Defaults	N/A
Command Mode	Domain configuration mode
Usage Guide	You can run this command in the standalone or VSU mode. The configuration takes effect immediately in the VSU mode.

↘ **Configuring Error Frame Check**

- Optional.
- Run the **switch crc errors** *error_num* **times** *time_num* command to configure the conditions for triggering error frame check.

Command	switch crc errors <i>error_num</i> times <i>time_num</i>
Parameter Description	<i>error_num</i> : Configures the increase of error frames between two detections. When the number of error frames is greater than the increase, it is assumed that error frames are detected once. <i>time_num</i> : Configures the number of times after which an action needs to be taken (the action can be displaying a prompt or disabling the interface).
Defaults	The default value of errors is 3 ; the default value of times is 10 .
Command Mode	Domain configuration mode
Default Level	14
Usage Guide	N/A

↘ **Saving the Configuration File**

Run the **exit** command to exit from the virtual device configuration mode and run the **write** command to save the configurations to the *config_vsu.dat* file.

Verification

Use the **show switch virtual [topology | config]** command to display the current VSU running information, topology or configuration parameters.

Command	show switch virtual [topology config]
----------------	--

Parameter Description	Topology: Indicates topology information. Config: Indicates the VSU configurations.
Command Mode	Privileged EXEC mode
Usage Guide	View the domain ID, and the device ID, status and role of each device.

Configuration Example

Configuring VSU Attributes

<p>Scenario Figure 9-17</p>	 <p>Switch 1 and Switch 2 form a VSU system. Modify the chassis ID of Switch 2 to 3 and its priority to 150. Assume that Switch 1 is the global master switch and perform the configuration on the global master switch.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> Modify the configurations of Switch 2.
<p>Switch-1</p>	<pre>Ruijie#config Ruijie(config)# switch virtual domain 100 Ruijie(config-vs-domain)# switch 2 renumber 3 Ruijie(config-vs-domain)# switch 2 priority 150 Ruijie(config-vs-domain)# switch 2 description switch-3</pre>
<p>Verification</p>	<ul style="list-style-type: none"> Run the show switch virtual config command for verification.
<p>Switch-1</p>	<pre>Ruijie#show switch virtual config switch_id: 1 (mac: 0x1201aeda0M) ! switch virtual domain 100 ! switch 1 switch 1 priority 100 ! switch convert mode virtual ! port-member interface Tengigabitethernet 1/1</pre>

```
!  
port-member interface Tengigabitethernet 1/2  
!  
  
switch_id: 3 (mac: 0x1201aeda0E)  
!  
switch virtual domain 100  
!  
switch 3  
switch 3 priority 150  
!  
switch convert mode virtual  
!  
port-member interface Tengigabitethernet 1/1  
!  
port-member interface Tengigabitethernet 1/2  
!  
switch 3 description switch-3  
!
```

9.4.2.2 Configuring the VSL

Configuration Effect

When switches form a VSU system or when the VSU system is running, you can shift between common interfaces and VSL interfaces. However, you can only log in to the master device console of the VSU system for modification, but cannot enter the global configuration mode from the slave device console.

Notes

- You can log in to the console of the VSU system by using a serial port or telnet, in order to add or delete the configurations of VSL member interfaces.
- To prevent incorrect connections in actual scenarios, the VSL AP uses dynamic negotiation. You need to configure the VSL interface pool first, and then add the VSL interface pool to the same AP after successful negotiation. Interfaces connecting to the same device are within the same AP.

Configuration Steps

➤ Entering the VSL Interface Configuration Mode

- Run the **vsl-port** command to enter the VSL-PORT configuration mode. This command is optional.
- When the device enters the VSL-PORT configuration mode, the VSL interface can be configured or deleted.

Command	vsl-port
Parameter	N/A
Description	
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	You can run this command in the standalone or VSU mode.

↘ Configuring a VSL Member Interface

- Run the **port-member interface** *interface-name* [**copper** | **fiber**] command to add a VSL interface. This command is optional.
- Run the **port-member interface** command to configure a VSL member interface.

Command	port-member interface <i>interface-name</i> [copper fiber]
Parameter	<i>interface-name</i> : Indicates a two-dimensional interface name, such as GigabitEthernet 0/1 and GigabitEthernet 0/3.
Description	copper : Indicates the copper interface attribute. fiber : Indicates the optical interface attribute.
Defaults	N/A
Command Mode	VSL interface configuration mode
Usage Guide	You can run this command in the VSU mode or standalone mode. The command can take effect after the command configuration is saved and the device where the VSL member interface resides is restarted.

During the VSU system running, the configured VSL member links take effect immediately. VSL interfaces need to be configured for all devices.

For chassis devices, VSL interfaces must be optical interfaces of 10 Gigabit or higher; for cassette devices, VSL interfaces can be optical and copper interfaces of Gigabit or higher.

Modules on chassis devices must be modules of 10 Gigabit or higher.

40G one-to-four interfaces cannot be configured as VSL interfaces.

- ⚠ For a 40G port (no matter whether splitting is performed for the interface), its member interfaces (namely, four 10G interfaces) cannot be shifted to VSL member interfaces.
- ❗ If an interface has been configured as an NLB reflex interface, this interface can be shifted to a VSL member interface only after the NLB reflex interface configuration is deleted.
- ⚠ To prevent a loop that may occur when a VSL member interface exits from the VSL AP, the system automatically sets the member interface to the shutdown state when the command is executed to make the VSL member interface exit from the VSL AP. After the VSL member interface exits from the VSL AP, you can reconnect the link and run the **no shutdown** command to enable this interface again. When you configure a VSL interface, the system will shut it down

first. If the configuration fails and you want to use it as a common interface, you can run the **no shutdown** command to enable this interface again. Add a member interface number that must be a three-dimensional interface number. For example, in the VSL-PORT configuration mode, if you run the **port-member interface** `Tengigabitethernet 1/1/1` command, it indicates that you configure the global three-dimensional interface 1/1/1 as a VSL interface.

- ! If VSU topology splitting occurs when you change a VSL interface to a common interface, the VSL interface cannot be deleted. You can disconnect the physical interface first and then delete the VSL interface.

Verification

- Use the `show switch virtual link [port]` to display the current VSL link running information in the VSU mode.

Command	<code>show switch virtual link [port]</code>
Parameter Description	port: Displays the status information of the VSL member interfaces.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Configuration Example

Configuring the VSL

Scenario Figure 9-18	
Configuration Steps	<ul style="list-style-type: none"> Add interface 1/1/3 as the VSL interface for Switch 1 and delete interface 1/1/2 from the VSL interface.
Switch-1	<pre>Ruijie#config Ruijie(config)# vsl-port Ruijie(config-vsl-port)# port-member interface Tengigabitethernet 1/1/3 Ruijie(config-vsl-port)# no port-member interface Tengigabitethernet 1/1/2</pre>
Verification	<ul style="list-style-type: none"> Run the show switch virtual config command to view the VSL. Assume that Switch 1 is the global master switch and run the command on the global master switch.
Switch-1	<pre>Ruijie#show switch virtual config switch_id: 1 (mac: 0x1201aeda0M) !</pre>

	<pre>switch virtual domain 100 ! switch 1 switch 1 priority 100 ! switch convert mode virtual ! port-member interface Tengigabitethernet 1/1 ! port-member interface Tengigabitethernet 1/3 !</pre>
	<pre>switch_id: 3 (mac: 0x1201aeda0E) ! switch virtual domain 100 ! switch 3 switch 3 priority 150 ! switch convert mode virtual ! port-member interface Tengigabitethernet 1/1 ! port-member interface Tengigabitethernet 1/2 ! switch 3 description switch-3 !</pre>

9.4.2.3 Configuring Dual-Active Detection

Configuration Effect

Configure the relevant detection mechanism to prevent the dual-active is being generated.

Notes

- The DAD can be configured only in the VSU mode. You are not allowed to configure the DAD mechanism in the standalone mode.
- All DAD configurations will take effect immediately after being configured on the master or slave devices in global configuration mode by running the **show running-config** command.
- The BFD-detected configuration information can be displayed only by running the dual-active detection display command rather than the BFD display command.

Configuration Steps

↳ Configuring the BFD DAD

- The BFD DAD requires establishing a directly connected link between two switches. The interfaces on the two ends must be physical routing interfaces. The following configuration must be performed on both chassis.
- Enter the interface configuration mode of the DAD interface and configure the DAD interface as a routing interface.
- After exiting from the interface configuration mode, run the **switch virtual domain *domain_id*** command to enter the domain configuration mode.
- In the domain mode, run the **dual-active detection bfd** command to enable BFD. This command is optional and can be used when BFD DAD needs to be configured.
- In the domain configuration mode, run the **dual-active bfd interface *interface-name*** command to configure the BFD DAD interface. This command is optional and can be used to configure the BFD DAD interface when BFD DAD is configured.
- Delete the BFD DAD interface. If no BFD DAD interface is available, BFD detection cannot be used.

Command	switch virtual domain <i>domain_id</i>
Parameter Description	<i>domain_id</i> : Indicates the domain ID.
Defaults	The default domain ID is 100.
Command Mode	Domain configuration mode
Usage Guide	Only two devices with the same domain ID can form a VSU system. The domain ID must be unique on a LAN.

Command	dual-active detection { aggregateport bfd }
Parameter Description	Aggregateport : Specifies the AP detection mode. bfd : Specifies the BFD detection mode.
Defaults	The DAD is disabled.
Command Mode	Domain configuration mode
Usage Guide	Configure this command only in the VSU mode.

Command	dual-active bfd interface <i>interface-name</i>
Parameter	<i>interface-name</i> : Indicates the interface type and ID.
Description	
Defaults	N/A
Command Mode	Domain configuration mode
Usage Guide	A BFD DAD interface must be a routing interface and on different switches.

The BFD detection interfaces must be directly connected physical routing ports. The two ports must be on different devices.

The interface type is not limited. The dual-active detection link is only used to transmit BFD packets with a small amount of traffic. Therefore, you are advised to adopt the Gigabit interface or 100 M interface as the dual-active detection interface.

After the layer 3 routing interface that is configured with two master devices is converted into a layer 2 switch interface (run the switchport command under this interface), the BFD dual-active detection will be cleared automatically.

You are advised to directly connect BFD detection interfaces only to the master and slave devices.

-  When the VSU system detects dual-active conflict and brings another VSU group to the recovery state, you can resolve the problem only by rectifying the VSL fault, but not directly restoring the VSU group in the recovery state; otherwise, dual-active conflict may be caused on the network.

↘ Configuring the AP-based DAD

- To configure the AP-based DAD, you must configure an aggregate port (AP) first and then specify the AP port as the DAD interface.
- Run the **port-group** *ap-num* command to add a physical member interface to the AP.
- After entering the domain configuration mode, run the **dual-active detection aggregateport** command to enable AP detection mode. This command is optional. You can run this command when AP detection needs to be configured.
- Run the **dual-active interface** *interface-name* command to configure the AP as the DAD interface. This command is optional. You can run this command to configure the AP as the DAD interface when AP detection needs to be configured.
- Run the **dad relay enable** command to enable dual-active detection packet relay for upstream and downstream interfaces. This command is optional. You can run this command to relay DAD packets (dual-active detection packets) when AP-based DAD is configured.
- Disabling AP-based DAD will inactivate DAD.
- Delete the detected interface. If no AP-based DAD interface is available, AP-based DAD cannot be used.
- The AP-based DAD packet relay is disabled by default.

Command	dual-active detection { aggregateport bfd }
Parameter	aggregateport : Specifies the AP detection mode.
Description	bfd : Specifies the BFD detection mode.
Defaults	The DAD is disabled.
Command Mode	Domain configuration mode

Usage Guide	Configure this command only in the VSU mode.
--------------------	--

Command	dual-active interface <i>interface-name</i>
Parameter Description	<i>interface-name</i> : Indicates the interface type and interface ID. An AP-based DAD interface must be specified.
Defaults	N/A
Command Mode	Domain configuration mode
Usage Guide	Only one AP-based DAD interface can be configured. This interface must be created before you configure an AP as a DAD interface. Subsequently configured DAD interfaces will overwrite the previous ones.

Command	dad relay enable
Parameter Description	N/A
Defaults	The AP-based DAD packet relay is disabled by default.
Command Mode	Interface configuration mode
Usage Guide	This command can only be executed on the AP.

 You are advised to distribute the physical interfaces that are added to the AP-based detection interface to different devices.

 **Configuring the excluded interface in the recovery mode**

- When two master devices are detected, one of them must enter the recovery mode. In the recovery mode, you need to disable all service interfaces. For some special usages (for example, configuring a management switch from which you can log in to a remote interface), you can set some ports to excluded interfaces that are not disabled in the recovery mode.
- In the domain configuration mode, run the **dual-active exclude interface** *interface-name* command to specify an excluded interface that will not be disabled in the recovery mode. This command is optional.

Command	dual-active exclude interface <i>interface-name</i>
Parameter Description	<i>interface-name</i> : Indicates the interface type and interface ID.
Defaults	N/A
Command Mode	Domain configuration mode
Usage Guide	Configure this command only in the VSU mode. An excluded interface must be a routing interface instead of a VSL interface. You can configure multiple excluded interfaces.

 The excluded interface must be routing rather than VSL.

! After the excluded interface is converted from a routing one into a switch interface (run the **switchport** command under this interface), the configurations of the excluded interface that is associated with this interface will be cleared automatically.

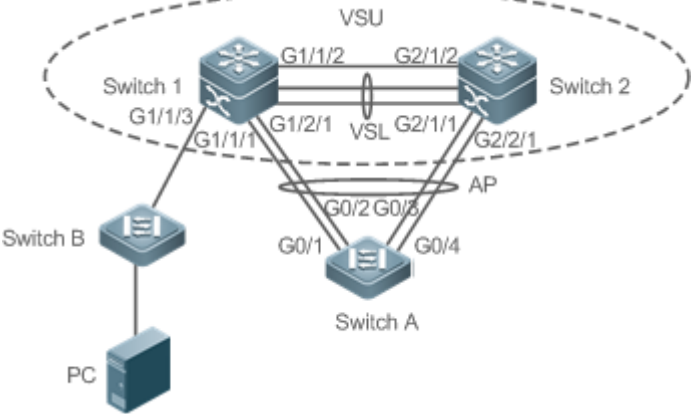

Verification

Use the **show switch virtual dual-active { aggregateport | bfd | summary }** to display the current DAD configuration.

Command	show switch virtual dual-active { aggregateport bfd summary }
Parameter Description	aggregateport: Displays DAD information on the AP. bfd: Displays BFD-based DAD information. summary: Displays DAD summary.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Configuration Example

Configuring the BFD DAD

<p>Scenario Figure 9-19</p>	 <ul style="list-style-type: none"> ● Switch 1 and Switch 2 form a VSU (The domain ID is 1) system. The priorities of Switch 1 and Switch 2 are 200 and 150 respectively. The links between Te1/3/1 and Te1/3/2 of Switch 1 and Te2/3/1 and Te2/3/2 of Switch 2 are established respectively to form a VSL between Switch 1 and Switch 2. The G0/1, G0/2, G0/3 and G0/4 interfaces of Switch A are connected to G1/1/1 and G1/2/1 of Switch 1 and G2/1/1 and G2/2/1 of Switch 2 to form an AP group including four member links. The ID of the AP group is 1. All members of AP group 1 are Gigabit optical interfaces. G1/1/2 and G2/1/2 are routing interfaces. ● G1/1/2 and G2/1/2 are a pair of BFD DAD interfaces.
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure G1/1/2 and G2/1/2 as routing interfaces. ● Enable the BFD DAD. ● Configure G1/1/2 and G2/1/2 as BFD DAD interfaces.

	<p>Since Switch 1 and Switch 2 are in a VSU system, the preceding configuration can be performed on either Switch 1 or Switch 2. on the following example configures the functions on Switch 1.</p>
Switch 1	<pre>Ruijie(config)# interface GigabitEthernet 1/1/2 Ruijie(config-if-GigabitEthernet 1/1/2)# no switchport Ruijie(config)# interface GigabitEthernet 2/1/2 Ruijie(config-if-GigabitEthernet 2/1/2)# no switchport Ruijie(config-if)# switch virtual domain 1 Ruijie(c config-vs-domain)# dual-active detection bfd Ruijie(config-vs-domain)# dual-active bfd interface GigabitEthernet 1/1/2 Ruijie(config-vs-domain)# dual-active bfd interface GigabitEthernet 2/1/2</pre>
Switch A	<pre>Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# interface aggregateport 1 Ruijie(config-if-aggregateport 1)# interface range GigabitEthernet 0/1-4 Ruijie(config-if-aggregateport 1)# port-group 1 Ruijie(config)# interface vlan 1 Ruijie(config-if-vlan 1)#ip address 1.1.1.2 255.255.255.0 Ruijie(config-if-vlan 1)#exit Ruijie(config)#interface aggregateport 1 Ruijie(config-if-AggregatePort 1)# dad relay enable Ruijie(config-if-AggregatePort 1)# exit</pre>
Verification	<ul style="list-style-type: none"> ● View the DAD configuration. ● View the BFD DAD configuration.
Switch 1	<pre>Ruijie# show switch virtual dual-active summary BFD dual-active detection enabled: No Aggregateport dual-active detection enabled: Yes Interfaces excluded from shutdown in recovery mode: In dual-active recovery mode: NO Ruijie# show switch virtual dual-active bfd BFD dual-active detection enabled: Yes</pre>

```
BFD dual-active interface configured:

GigabitEthernet 1/1/2: UP

GigabitEthernet 2/1/2: UP
```

Common Errors

- A BFD DAD interface is not a routing interface.
- Neither BFD DAD nor AP-based DAD are enabled and activated.

9.4.2.4 Configuring Traffic Balancing

Configuration Effect

In the VSU system, if egresses are distributed on multiple devices, the Local Forward First (LFF) can be configured.

Notes

The default configuration is LFF.

Configuration Steps

▾ Configuring the AP LFF mode

- In the domain configuration mode, run the **switch virtual aggregateport-lff enable** command to enable the AP LFF mode. This command is optional.
- The member ports of AP can be distributed on two chassis of the VSU system. You can configure whether the AP egress traffic is forwarded through local member ports first based on actual traffic conditions.
- If this function is disabled, traffic is forwarded based on the AP configuration rules. For details, see the *Configuring Aggregate Port*.

Command	switch virtual aggregateport-lff enable
Parameter	N/A
Description	
Defaults	This function is enabled by default.
Command Mode	Domain configuration mode
Usage Guide	Enable the AP LFF in the VSU mode.

▾ Configuring the ECMP LFF mode

- In the domain configuration mode, run the **switch virtual ecmp-lff enable** command to enable the ECMP LFF mode. This command is optional.
- The Equal-Cost MultiPath (ECMP) routing egress can be distributed on two chassis of the VSU system. You can configure whether the ECMP egress traffic is forwarded through local member ports first based on actual traffic conditions.

- If this function is disabled, traffic is forwarded based on the ECMP configuration rules. For details, see the *Configuring Aggregate Port*.

Command	switch virtual ecmp-lff enable
Parameter	N/A
Description	
Defaults	This function is enabled by default.
Command Mode	Domain configuration mode
Usage Guide	Enable the ECMP LFF in the VSU mode.

- ⚠ In the VSU mode, the across-chassis AP LFF mode and the ECMP LFF mode are disabled by default.
- ⚠ To deploy a VSU system for layer-3 switches, you are advised to configure the IP-based AP load balancing (src-ip, dst-ip abd src-dst-ip).

Verification

Use the **show switch virtual balance** command to display the current traffic balancing mode of the VSU system.

Command	show switch virtual balance
Parameter	N/A
Description	
Command Mode	Privileged EXEC mode
Usage Guide	Use this command to display the configuration of the traffic balancing mode in the VSU mode.

Configuration Example

Configuring the LFF

Scenario Figure 9-20	<p>The diagram shows two switches, Switch-1 and Switch-2, connected in a VSU system. Switch-1 is labeled 'Switch-1 Chassis 1 Priority 100' and Switch-2 is labeled 'Switch-2 Chassis 2 Priority 100'. They are connected via two links: the top link is labeled '1/1/1' on Switch-1 and '2/1/1' on Switch-2; the bottom link is labeled '1/1/2' on Switch-1 and '2/1/2' on Switch-2.</p>
	In Figure 9-20, Switch 1 and Switch 2 form a VSU system. It is assumed that Switch 1 is the global master switch and configuration is performed on Switch 1.
Configuration Steps	<ul style="list-style-type: none"> ● Configure the AP LFF.
Switch-1	<pre>Ruijie#config Ruijie(config)# switch virtual domain 100 Ruijie(config-vs-domain)# switch virtual aggregateport-lff enable</pre>

Verification	<ul style="list-style-type: none"> Run the show switch virtual balance command for verification.
Switch-1	<pre>Ruijie#show switch virtual balance Aggregate port LFF: enable Ecmp lff enable</pre>

9.4.2.5 Changing the VSU Mode to the Standalone Mode

Configuration Effect

Dismiss the VSU system into individual devices that can operate in the standalone mode.

Configuration Steps

- Run the **switch convert mode standalone** [*switch_id*] command to change the VSU mode to the standalone mode. This command is optional.
- After you run this command, the system will prompt you as follows: Whether to restore the configuration file to standalone text? If **yes**, the configuration file will be restored; if **no**, the configuration of virtual device mode will be cleared.

Command	switch convert mode standalone [<i>switch_id</i>]
Parameter	<i>switch_id</i> : Indicates the switch ID.
Description	
Defaults	The switch is in the standalone mode by default.
Command Mode	Privileged EXEC mode
Usage Guide	<p>After you run the switch convert mode standalone command, the master switch backs up the global configuration files of all VSDs in the VSU mode as <i>vsd.virtual_switch.text.vsd ID</i>. Then, the master switch clears the global configuration files <i>config.text</i> of all VSDs in the VSU mode, and asks you whether to overwrite the global configuration files <i>config.text</i> with <i>vsd.standalone.text.vsd ID</i>. If you select yes, the content of <i>vsd.standalone.text.vsd ID</i> will overwrite the global configuration file <i>config.text</i> of all VSDs; otherwise, the master switch does not recover <i>config.text</i>. Finally, restart the switch.</p> <p>This command can be used in the standalone mode or VSU mode. If the command is executed in the standalone mode, the mode switching is performed on the current switch. If the command contains the <i>sw_id</i> parameter and is executed in the VSU mode, the mode switching is performed on the switch with the ID specified by <i>sw_id</i>. If the command does not contain the <i>sw_id</i> parameter, the mode switching is performed on the master switch. You are advised to switch the mode of the slave switch and then that of the master switch.</p>

Configuration Example

↘ Changing the VSU Mode to the Standalone Mode

<p>Scenario Figure 9-21</p>	<div style="text-align: center;">  </div> <p>In Figure 9-21, it is assumed that Switch 1 and Switch 2 form a VSU system and Switch 1 is the global master switch.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Change the mode of Switch 1 to the standalone mode. ● Change the mode of Switch 2 to the standalone mode.
<p>Switch-1</p>	<pre>Ruijie# switch convert mode standalone 1 Ruijie# switch convert mode standalone 2</pre>
<p>Verification</p>	<p>Run the show switch virtual config command to display the switch status.</p>
<p>Switch-1</p>	<pre>Ruijie#show switch virtual config switch_id: 1 (mac: 0x1201aeda0M) ! switch virtual domain 100 ! switch 1 switch 1 priority 100 ! switch convert mode standalone ! port-member interface Tengigabitethernet 1/1 ! port-member interface Tengigabitethernet 1/3 !</pre>
	<pre>switch_id: 2 (mac: 0x1201aeda0E) ! switch virtual domain 100 ! switch 2</pre>

```

switch 2 priority 150
!
switch convert mode standalone
!
port-member interface Tengigabitethernet 1/1
!
port-member interface Tengigabitethernet 1/2
!
switch 2 description switch-2
!

```

9.5 Monitoring

Displaying

Description	Command
Displays the current VSU operation, topology or configuration.	show switch virtual [topology config role]
Displays the current dual-active configuration.	show switch virtual dual-active { bfd aggregateport summary }
Displays the current VSL running information in the VSU mode.	show switch virtual link [port]
Redirects to the console of the master switch or any switch.	session { device <i>switch_id</i> master }
Displays the current switch ID.	show switch id

10 Configuring RNS

10.1 Overview

The reliable network service (RNS) tests specific services provided by a peer device to monitor the service availability, integrity of the end-to-end connection, and service quality. Using the RNS test results, you can:

- Learn the network performance in time and take measures accordingly to handle related network performance problems.
- Diagnose and locate network faults.

10.2 Applications

10.2.1 Testing and Evaluating Service Performance

Scenario

As shown in the following figure, a company is going to deploy a video conference system between the headquarters and branches, and has completed the related quality of service (QoS) configurations. Before formal deployment, it must be checked whether the services can be provisioned normally under the existing service pressure of the company. The video conference system is sensitive to the User Datagram Protocol (UDP) delay and UDP transmission jitter of the network. The traditional ping tool can test the Internet Control Message Protocol (ICMP) performance, but cannot effectively evaluate the UDP transmission performance and cannot meet the requirement for jitter measurement.

Remarks	A, B, and C are switches.
----------------	---------------------------

Deployment

- Configure RNS on the egress switching device or switch of each branch to test the UDP jitter and delay.

- On Switch A, specify the IP address and UDP port of the egress switching device or switch in the headquarters, and then UDP packets can be automatically sent. Based on the configurations, the egress switching device or switch in the headquarters can automatically respond to the UDP packets. The egress switching device or switch of the branch processes the sent and received packets, and calculates the UDP jitter. To learn the performance in different periods of time, you also need to configure scheduling functions, such as periodically start/stop and repeated running, for the RNS.

10.2.2 Locating Network Faults

Scenario

On the campus network as shown in Figure 10-1, Student 1 reports a Web server access failure, Student 3 reports an Internet access failure, and Student 6 reports an email sending/receiving failure.

Figure 10-1

Deployment

- The administrator directly enables the DNS function on the access switch of the dormitories to test whether the domain name service (DNS) server is faulty. If DNS fails, an ICMP echo packet is automatically triggered to test whether the Web server is reachable.
- When a fault occurs, the administrator only needs to start a test, and the subsequent tests can be automatically triggered. Then, the administrator can check the test results to locate the fault, which greatly reduces the workload for the administrator.

10.3 Features

Basic Concepts

↘ RNS Instance

An RNS instance can be treated as an RNS process. Before performing the RNS, you must create an RNS instance. In the RNS instance, you need to configure the RNS parameters, such as the test type, test destination address, and test frequency. The instance ID is globally unique.

Feature	Description
RNS Instance	Monitor the network connectivity, service availability, integrity of end-to-end connection, and service quality.
Track Support for the RNS	Track the test results and notify the related module of the results.

10.3.1 RNS Test

Monitor the network connectivity, service availability, integrity of end-to-end connection, and service quality. For example, test whether the DNS function of the device is normal. Currently, the RNS supports the following types of tests: ICMP echo, DNS, and TCP.

Working Principle

↘ ICMP Echo Test

ICMP echo is a basic function of the RNS, and is implemented in compliance with the RFC 2925. An ICMP packet is sent to check whether the destination is reachable and to calculate the network response time and packet loss rate.

An ICMP echo request packet is sent to the destination IP address based on the preset test time and frequency. Upon receipt of the ICMP echo request packet, an ICMP echo reply packet is returned from the destination IP address. Through the ICMP echo test, the response time and packet loss rate is calculated based on the information relating to the received ICMP echo reply packet, for example, the receipt time and number of packets. In this way, the current network performance and status are reflected. The ICMP echo test results and historical records will be recorded, and you can use the command line to display them.

 The prerequisite for a successful ICMP echo test is that destination devices can correctly respond to ICMP echo request packets.

↘ DNS Test

In a DNS test, a DNS client is simulated to send a domain name resolution request to a specified DNS server. You can determine whether the DNS server is available and the domain name resolution speed by checking the domain name resolution result and the time required for domain name resolution. In the DNS test, the domain name resolution process is simulated, and the mapping between the resolved domain name and the IP address is not saved. The DNS test results and historical records will be recorded in the test group. You can use the command line to check the test results and historical records.

↘ Procedure for Configuring an RNS Instance Test

1. Create an instance and configure the test based on the test type.
2. Start the instance.
3. Use the RNS instance to construct a packet of the specific test type and send the packet to the peer end.
4. Upon receipt of the test packet, the peer end returns a reply packet of a corresponding type.
5. The RNS instance calculates the packet loss rate and round trip time based on whether a reply packet is received and the time of reply packet receipt.
6. Use the show or debug command to check the test result.

 The preceding describes general procedures for RNS instance tests. For details about configuration, see the following sections.

Related Configuration

↘ **Configuring the Test Repeat Interval**

By default, the test repeat interval is 60s.

In RNS configuration mode, run the **frequency** *millisecond* command to configure the test repeat interval.

Configure the frequency based on the following formula to ensure correct test calculation.

(frequency milliseconds) > (timeout milliseconds) >= (threshold milliseconds)

↘ **Configuring the Test Timeout**

The default timeout varies according to the test type. You can run the **show ip rns configuration** command to display the timeout of a specific test type.

In RNS configuration mode, run the **timeout** *milliseconds* command to configure the timeout of an instance.

Configure the timeout based on a formula. For details, see the "Usage Guide" of the **frequency** command.

Configure the test time threshold.

↘ **Configuring the Test Threshold**

By default, the test threshold is 5,000 ms.

In RNS configuration mode, run the **threshold** *milliseconds* command to configure the instance test threshold.

Configure the threshold based on a formula. For details, see the "Usage Guide" of the **frequency** command.

↘ **Configuring a Tag for the Test**

No default configuration is available.

In RNS configuration mode, run the **tag** *text* command to configure a test tag.

You can run the **tag** command to specify a tag to identify the test.

↘ **Configuring the Protocol Payload Size**

The default protocol payload size varies with the test type. By default, the protocol payload size is the minimum or appropriate size for protocol packets of the corresponding test type.

In RNS configuration mode, run the **request-data-size** *bytes* command to configure the protocol payload size.

Perform this configuration in IP RNS configuration mode.

📄 **Configuring the TOS Field of the Test Packet**

By default, the TOS is 0.

In RNS configuration mode, run the **tos** *number* command to configure the TOS field in the IPv4 header of RNS test packets.

📄 **Configuring the VRF**

No default configuration is available.

In RNS configuration mode, run the **vrf** *vrf-name* command to virtual routing and forwarding (VRF) for the RNS instance.

10.3.2 Track Support for the RNS

Objects that can be tracked include: test result of an RNS instance, RNS list status, link status on an interface, and track list status. When the track status changes, an action of other modules is triggered.

Working Principle

The test result of an RNS instance is tracked as follows:

- Configure a track object for tracking the test result of an RNS instance.
- When the test result of the RNS instance changes, the RNS module sends a status change message to the track module.
- The track module receives the test result. After the preset delay, if the test result remains unchanged, the status of the track object is modified, and the module of the track object is notified of the modification. If the test result recovers within the period, the status of the track object is not modified and the corresponding module is not notified.

Related Configuration

📄 **Configuring a Track Object for Tracking the Link Status of An Interface**

By default, the function of tracking the link status of an interface is disabled.

Run the **track interface line-protocol** command to configure a track object, which is used to track the link status of an interface.

If the link status of the interface is UP, the status of the track object is UP. If the link status of the interface is DOWN, the status of the track object is also DOWN.

📄 **Configuring a Track Object for Tracking the Test Result of an RNS Instance**

By default, the function of tracking the test result of an RNS instance is disabled.

Run the **track rns** command to configure a track object, which is used to track the test result of an RNS instance. The RNS instance ID ranges from 1 to 500.

If the RNS test succeeded, the track object is in Up state. If the RNS test failed, the track object is in Down state.

↘ **Configuring a Track Object for Tracking the Status of a Track List**

By default, the function of tracking the status of a track list is disabled.

Run the **track list** command to configure a track object, which is used to track the status of a track list. The result can be the AND or OR operation result of all member status.

If the result of this track object is set to the AND operation result of all member status, when all RNS tests succeeded, the track object is in Up state. If one RNS test failed, the track object is in Down state. If the result of this track object is set to the OR operation result of all member status, when all RNS tests failed, the track object is in Down state. If one RNS test succeeded, the track object is in Up state.

↘ **Configuring a Track List Member**

By default, no member is configured for the track list.

Run the **object** command to configure a track list member. The status of the member can be the same as or contrary to that of the corresponding track object.

↘ **Adjusting the Delay for Notifying the Status Change of a Track Object**

By default, the delay for notifying the status change of a track object is 0.

Run the **delay** command to adjust the delay for track notification, including the delay for notifying the status change of a track object from UP to DOWN and the delay for notifying the status change of a track object from DOWN to UP. The delay ranges from 0 to 180. The unit is second.

A longer delay indicates that it takes more time before the module that is concerned with the track object is notified of the status. A shorter delay indicates that it takes less time before the module that is concerned with the track object is notified of the status.

10.4 Configuration

Configuration Item	Description and Command
Configuring RNS Basic	 (Mandatory) It is used to configure basic function parameters of the RNS.

Configuration Item	Description and Command	
Functions	ip rns	Supports detailed configuration and brief configuration. <ul style="list-style-type: none"> Detailed configuration: An RNS operation object is defined, and used as the configuration ID for subsequent tests and parameters. Brief configuration: Subsequent configuration is not required, and tests can be started in one step. Currently, ICMP echo, DNS, and TCP tests can be started in one step.
	ip rns reaction-configuration	Configures the proactive threshold monitoring and triggering mechanism of the RNS test.
	ip rns reaction-trigger	Triggers another type of the RNS test in pending state when the monitoring threshold exceeds the expectation during an RNS test.
	ip rns schedule	Configures the scheduling method, start time, and life time of an RNS test.
	ip rns restart	Restarts an RNS test.
	ip rns reset	Clears all the IP RNS configurations.
Configuring the ICMP Echo Test	 (Optional) It is used to implement the ICMP echo test.	
	icmp-echo	Creates an ICMP echo test instance.
	request-data-size	Configures the protocol payload size.
	frequency	Configures the test repeat interval.
	tag	Configures a tag.
	threshold	Configures the test time threshold.
	timeout	Configures the test timeout.
	tos	Configures the TOS field in the IPv4 header of test packets.
vrf	Configure the VRF of a test.	
Configuring the DNS Test	 (Optional) It is used to implement the DNS test.	
	dns	Creates a DNS test instance.
	frequency	Configures the test repeat interval.
	tag	Configures a tag.
	threshold	Configures the test time threshold.
	timeout	Configures the test timeout.
	tos	Configures the TOS field in the IPv4 header of test packets.
vrf	Configures the VRF of a test.	
Configuring the Track	 (Optional) It is used to configure the track support for other test modules.	

Configuration Item	Description and Command	
Support for the RNS	track rns	Configures a track object for tracking the test result of an RNS instance.
	track rns-list	Configures a track object for tracking the status of an RNS list.
	track interface line-protocol	Configures a track object for tracking the link status of an interface.
	track list	Configures a track object for tracking the status of a track list.
	object	Configures a member object for a track list object.
	delay	Configures the delay for notifying the status change of a track object.

10.4.1 Configuring RNS Basic Functions

Configuration Effect

- Detailed configuration: Configures an RNS instance to complete basic configuration of the RNS instance.
- Brief configuration: Configure and start an RNS instance at a time. (Optional)

Notes

- In detailed configuration mode, if you do not configure the test type after entering the IP RNS mode by running the command, the RNS instance will not be created.
- In detailed configuration mode, after configuring an RNS instance, you need to run the **ip rns schedule** command to configure the startup policy; otherwise, the test will not be implemented.

Configuration Steps

▾ Defining an RNS Operation Object

- Mandatory.
- Unless otherwise required, define an RNS operation object on each switch.
- Brief configuration is optional.

▾ Configuring the Proactive Threshold Monitoring and Triggering Mechanism for an RNSTest

- Perform this configuration if it is required to configure the proactive threshold monitoring and triggering mechanism for the test.
- Perform this configuration on every switching device unless otherwise required.

▾ Enabling an RNS Instance to Trigger Another RNS Instance

- Perform this configuration if it is required to trigger another RNS test in pending state when the monitoring threshold exceeds the expectation during an RNS test.

- If schedule parameters are not configured for the triggered RNS instance, the default schedule parameters are applied.
- Unless otherwise required, apply this configuration to each switch.

↘ **Configuring Schedule Parameters of an RNS Instance**

- Perform this configuration on every switching device unless otherwise required.
- In the case of brief configuration, this command is already configured using the default values, and manual configuration is not required.

↘ **Restarting an RNS Instance**

- Perform this configuration, or directly run the **ip rns schedule X start-time now** command if it is required to restart an IP RNS instance in pending state.

↘ **Clearing Configurations of All RNS Instances**

- Perform this configuration if it is required to clear configurations of all the IP RNS instances, for example, when a lot of instances are configured but configurations are found incorrect.

Verification

- Run the **show ip rns configuration** command to display configurations of RNS instances.

Related Commands

↘ **Defining an IP RNS Operation Object**

Command	ip rns <i>operation-number</i> [{ dns <i>destination-hostname</i> name-server <i>ip-address</i> icmp-echo <i>destination-ip-address</i> } [frequency <i>seconds</i>] [timeout <i>milliseconds</i>] [threshold <i>milliseconds</i>]]]
Parameter Description	<i>operation-number</i> : Indicates the RNS instance ID. The value ranges from 1 to 500. For details about configuration of the optional items, including dns , icmp-echo , and tcp-connect , see the configuration of the specific test type. For details about configuration of frequency , timeout , and threshold , see the configuration of the specific test type.
Command Mode	Global configuration mode
Usage Guide	Currently, the RNS supports only IPv4-related tests, but not IPv6-related tests. At most 500 tests can be configured, depending on the performance of devices. The test function is only a value-added function. When a large number of tests are configured and consume a lot of system resources, the test function may be temporary disabled to ensure normal operation of core services, such as route forwarding. Detailed configuration (executing mandatory items of ip rns operation-number): Run this command and enter the IP-RNS configuration mode. In this mode, you can define various test types. If the test type is not configured, the RNS test is not created. After configuring an RNS test, you must run the ip rns schedule

command to configure its schedule parameters; otherwise, the test cannot be conducted.

After configuring the type of an RNS test, you can run the **ip rns** command to enter the mode of the test type. To modify the type of an RNS instance, you need to first delete the RNS instance by running the **no ip rns** command in global configuration mode.

Brief configuration (executing the optional test items that proceeds **ip rns**):After optional items are executed, it is equivalent that **ip rns operation-number**, **ip rns schedule**, detailed test configuration (such as the ICMP echo test), **frequency**, **timeout**, and **threshold** are executed according to the logical sequence.

Among these commands, the **ip rns schedule** command is executed to start a test by using the **start-time now life forever** parameter. For details about restrictions of other configuration items, see the related description in the detailed configuration.

Similarly, to modify a briefly configured test, you need to first delete this RNS instance by running the **no ip rns** command in global configuration mode.

📌 **Configuring the Proactive Threshold Monitoring and Triggering Mechanism for the Test**

Command	ip rns reaction-configuration <i>operation-number</i> react <i>monitored-element</i> [action-type <i>option</i>] [threshold-type (average [<i>number-of-measurements</i>] consecutive [<i>occurrences</i>] immediate never xofy [<i>x-value y-value</i>])] [threshold-value <i>upper-threshold lower-threshold</i>]
Parameter Description	<p><i>operation-number</i>: Indicates the RNS instance ID. The value ranges from 1 to 500.</p> <p><i>monitored-element</i>: Specifies the monitored element.</p> <p>action-type <i>option</i>: Indicates the action taken after the test is triggered.</p> <p>average [<i>number-of-measurements</i>]: Indicates that the subsequent associated actions are triggered if the average of <i>number-of-measurements</i> of the monitored element exceeds the threshold.</p> <p>consecutive [<i>occurrences</i>]: Indicates that the test is triggered if the consecutive number of <i>occurrences</i> of the monitored element exceeds the threshold. The default value of <i>occurrences</i> is 5. The value ranges from 1 to 16.</p> <p>immediate: Indicates that the test is triggered immediately after the monitored element exceeds the threshold.</p> <p>never: Indicates that the test is never triggered.</p> <p>xofy [<i>x-value y-value</i>]: Indicates that results of X tests exceed the threshold in the last Y tests. The default values of X and Y are 5. The value of X or Y ranges from 1 to 16.</p> <p>threshold-value <i>upper-threshold lower-threshold</i>: Indicate the upper and lower thresholds.</p> <ul style="list-style-type: none"> ● When monitored-element is rtt, the thresholds are the time. For default values, see "Usage Guide". The value ranges from 0 to 60,000 ms. ● Note that you do not need to configure threshold-value when react is set to timeout.
Command Mode	Global configuration mode

Usage Guide	You can configure multiple thresholds for one RNS test to monitor different elements. The following table provides the mapping between test types and monitored elements.		
	monitored-element	icmp-echo	dns
	timeout	✓	✓
	rtt	✓	✓
	The following table lists the default thresholds of each monitored element.		
	Monitored Element	Upper Threshold	Lower Threshold
	timeout	-	-
	rtt	5000ms	0ms

📌 **Enabling an RNS Instance to Trigger Another RNS Instance**

Command	<code>ip rns reaction-trigger operation-number target-operation</code>
Parameter Description	<i>operation-number</i> : Indicates the number of the source RNS instance that triggers the action. The value ranges from 1 to 500. <i>target-operation</i> : Indicates the number of the target RNS instance that is triggered. The value ranges from 1 to 500.
Command Mode	Global configuration mode
Usage Guide	The trigger function is generally used in network fault diagnosis scenario. In a common scenario, you do not need to configure the trigger function.

📌 **Configuring Schedule Parameters of an RNS Instance**

Command	<code>ip rns schedule operation-number[life{ forever seconds}] [start-time{ hh:mm[:ss] [month day daymonth] pending now after hh:mm:ss}] [recurring]</code>
Parameter Description	<i>operation-number</i> : Indicates the number of the RNS operation. The value ranges from 1 to 500. lifeforever : Indicates that the RNS operation life time is valid forever. life seconds : Indicates the running time of the RNS instance in seconds. <i>hh:mm[:ss]</i> : Indicates the start time of the RNS instance, in 24-hour format. <i>month</i> : Indicates the start month of the RNS instance. The default value is the current month. <i>day</i> : Indicates the start date of the RNS instance. The default value is the current date. pending : Indicates that the start time of the RNS instance is not defined, which is the default. now : Indicates that the operation start time is now, that is, the operation starts now. after hh:mm:ss : Indicates that the RNS instance starts after a delay of hh:mm:ss. recurring : Indicates whether the RNS instance starts at the same time every day.

Command Mode	Global configuration mode
Usage Guide	<p>If the schedule parameters of an RNS instance have been configured by running the ip rns schedule command, parameters cannot be modified during running. To modify the configuration, you need to run the no ip rns schedule command to delete the schedule parameters.</p> <p>life { <i>seconds</i> } indicates the running time of the RNS instance. That is, the test stops after a period of time in seconds.</p>

↘ **Restarting an RNS Test by Running the ip rns restart Command**

Command	ip rns restart <i>operation-number</i>
Parameter Description	<i>operation-number</i> : Indicates the number of the RNS instance. The value ranges from 1 to 500.
Command Mode	Global configuration mode
Usage Guide	<p>This command restarts an RNS test for which the scheduling policy is configured and is in pending state. This command is invalid for an RNS test for which the scheduling policy is not configured.</p>

↘ **Clearing Configurations of All the IP RNS Instances by Running the ip rns reset Command**

Command	ip rns reset
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	<p>This command clears configurations of all the IP RNS instances. It is used only in extreme cases, for example, when a lot of RNS tests are configured but the configurations are found incorrect.</p>

Configuration Example

↘ **Configuring RNS Basic Functions**

Scenario Figure 10-2	<p>The diagram illustrates a network topology for RNS configuration. On the left, a switch labeled 'Switch A' is identified as the 'RNS Client' with the IP address 10.1.1.1/16. This switch is connected to a central cloud representing an 'ISP'. The ISP is then connected to another switch labeled 'Switch B', which is identified as the 'RNS Server' with the IP address 10.2.2.2/16.</p>
Configuration Steps	<ul style="list-style-type: none"> ● Configure instance 1 on Switch A. ● Configure the scheduling method, start time, and life time of instance 1. ● Configure the proactive threshold monitoring and triggering mechanism of instance 1.

	<ul style="list-style-type: none"> ● Trigger instance 2 in pending state when the monitoring threshold of instance 1 exceeds the expectation.
Switch A	<pre>A# configure terminal A(config)# ip rns 1 A(config-ip-rns)#icmp-echo 10.1.1.1 A(config-ip-rns-icmp-echo)#exit A(config)ip rns schedule 1 start-time now life forever A(config)ip rns reaction-configuration 1 react timeout threshold-type immediate action-type trigger A(config)ip rns reaction-trigger 1 2</pre>
Verification	<p>Run the show ip rns configuration command to display the instance configurations.</p> <pre>Router#show ip rns configuration 1 Entry number: 1 Tag: ruijie555 Type of operation to perform: icmp-echo Operation timeout (milliseconds): 5000 Operation frequency (milliseconds): 60000 Threshold (milliseconds): 5000 Recurring (Starting Everyday): FALSE Life (seconds): 3500 Next Scheduled Start Time:Start Time already passed Target address/Source address: 2.2.2.3/0.0.0.0 Request size (ARR data portion): 36</pre>

10.4.2 Configuring the ICMP Echo Test

Configuration Effect

Create an ICMP echo test instance.

Notes

- The RNS basic functions must be configured.

Configuration Steps

📌 Creating an ICMP Echo Test Instance

- Mandatory.
- Unless otherwise required, create ICMP echo test instances on each switch.

▾ **Configuring Common Optional Parameters of the Test**

- Mandatory if common optional parameters of the test, for example, the repeat interval, tag, time threshold, timeout, and TOS, are required to be changed..
- Perform this configuration on every switching device unless otherwise required.

▾ **Configuring the Protocol Payload Size**

- Perform this configuration if it is required to change the protocol payload size of the test.
- Perform this configuration on every switching device unless otherwise required.

Verification

- Run the **show ip rns configuration** command to display the instance configurations.

Related Commands

▾ **Creating an ICMP Echo Test Instance**

<p>Command</p>	<p>icmp-echo { <i>destination-ip-address</i> <i>destination-hostname</i> [name-server <i>ip-address</i>] } [source-ipaddr <i>ip-address</i>] [out-interface <i>type num</i> [next-hop <i>A.B.C.D</i>]]</p> <p>Or</p> <p>icmp-echo oob { <i>destination-ip-address</i> <i>destination-hostname</i> [name-server <i>ip-address</i>] } [source-ipaddr <i>ip-address</i>] via <i>type num</i> next-hop <i>A.B.C.D</i></p>
<p>Parameter Description</p>	<p>oob: Indicates the test on the MGMT interface.</p> <p><i>destination-ip-address</i>: Indicates the destination IP address.</p> <p><i>destination-hostname</i>: Indicates the destination host name.</p> <p>name-server <i>ip-address</i>: Specifies the DNS server when the destination host name is configured. By default, the DNS server configured by using the ipname-server command is used for address resolution.</p> <p>source-ipaddr <i>ip-address</i>: Indicates the source IP address.</p> <p>out-interface <i>type num</i>: Specifies the outgoing interface (non-MGMT interface) of the test packet.</p> <p>via <i>type num</i>: Specifies the MGMT interface as the outgoing interface of the test packet.</p> <p>next-hop <i>A.B.C.D</i>: Indicates the IP address of the next hop.</p>
<p>Command Mode</p>	<p>IP RNS configuration mode (config-ip-rns)</p>
<p>Usage Guide</p>	<p>After an ICMP echo test is started, the system sends an ICMP echo request packet to test whether the device is connected to the target host. After an ICMP-Echo test instance is created, the system enters the IP RNS ICMP echo mode. By default, the protocol payload size of an ICMP echo request packet is 36 bytes. You can run the request-data-size command to change the packet size. You need to configure the RNS test type (for example, ICMP echo and DNS) before configuring parameters. To modify the type of an RNS</p>

	instance, you need to delete the RNS instance by running the no ip rns command in global configuration mode.
--	---

↘ Configuring the Protocol Payload Size of an RNS Instance

Command	request-data-size <i>bytes</i>
Parameter Description	<i>bytes</i> : Indicates the bytes of a test packet. The minimum and maximum bytes vary with the test type. You need to configure this parameter based on the command prompt in corresponding test mode.
Command Mode	IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	This command is used to stuff some bytes in the test packet so that large packets can be used for the test.

↘ Configuring the Test Repeat Interval

Command	frequency <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : Indicates the packet sending interval in ms. The default value is 60,000 ms. The value ranges from 10 to 604,800,000. The maximum value is one week.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	After an RNS instance is started, tests are conducted periodically. You can run the frequency command to specify the repeat interval. You need to configure the frequency based on the following formula to ensure correct test calculation. $(\text{frequency milliseconds}) > (\text{timeout milliseconds}) \geq (\text{threshold milliseconds})$

↘ Configuring a Tag for an RNS Instance

Command	tag <i>text</i>
Parameter Description	<i>text</i> : Sets the test tag. The value is a string of up to 79 characters.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	This command specifies a tag for a test, which is often used to indicate the function of the test.

↘ Configuring the Time Threshold for an RNS Instance

Command	threshold <i>milliseconds</i>
Parameter	<i>milliseconds</i> : Indicates the time threshold for the test. The value ranges from 0 to 60,000, in the unit of milliseconds. The default value is 5,000.

Description	
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	Configure the threshold based on the following formula to ensure correct test calculation. (frequency milliseconds) > (timeout milliseconds) >= (threshold milliseconds)

↘ Configuring the Timeout for an RNS Instance

Command	timeout <i>millisecond</i>
Parameter Description	<i>millisecond</i> : Indicates the test timeout. The value ranges from 10 to 604,800,000. The unit is ms. The default timeout varies according to the test type.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	Configure the timeout based on the following formula to ensure correct test calculation. (frequency milliseconds) > (timeout milliseconds) >= (threshold milliseconds)

↘ Configuring the TOS Field in the IPv4 Packet Header of an IP RNS Test

Command	tos <i>number</i>
Parameter Description	<i>number</i> : Sets the TOS field in the IPv4 header of test packets. The value ranges from 0 to 255. The default value is 0.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	TOS is an 8-bit field in the IPv4 packet header. By setting the TOS, you can control the priority of the test packet. For different TOS fields, the processing priorities are different on the intermediate routers.

↘ Configuring the VRF of an RNS Test

Command	vrf <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Specifies the VRF name.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	This command specifies the VRF of the test packet.

Configuration Example

Figure 10-3	 <p>Switch A Switch B</p>
	Configure RNS instance 1 and related parameters on Switch A.
Switch A	<pre>A# configure terminal A(config)# ip rns 1 A(config-ip-rns)#icmp-echo 10.2.2.2 A(config-ip-rns-icmp-echo)#exit A(config)#ip rns schedule 1 start-time now life forever</pre>
	Run the show ip rns configuration command to display the instance configurations.
Switch A	<pre>A#show ip rns configuration 1 Entry number: 1 Tag: Type of operation to perform: icmp-echo Operation timeout (milliseconds): 5000 Operation frequency (milliseconds): 60000 Threshold (milliseconds): 5000 Recurring (Starting Everyday): FALSE Life (seconds): foerver Next Scheduled Start Time:Start Time already passed Target address/Source address: 10.2.2.2/0.0.0.0 Request size (ARR data portion): 36</pre>

10.4.3 Configuring the DNS Test

Configuration Effect

Create a DNS test instance.

Notes

- The RNS basic functions must be configured.

Configuration Steps

📄 Creating a DNS Test Instance

- Mandatory.
- Unless otherwise required, create DNS test instances on each switch.

📄 Configuring Common Optional Parameters of the Test

- Mandatory if common optional parameters of the test, for example, the repeat interval, tag, time threshold, timeout, and TOS, are required to be changed.
- Perform this configuration on every switching device unless otherwise required.

Verification

- Run the **show ip rns configuration** command to display the instance configurations.

Related Commands

↳ Creating a DNS Test Instance

Command	dns <i>destination-hostname</i> name-server <i>a.b.c.d</i> [source-ipaddr <i>ip-address</i>] [out-interface <i>type num</i>] [next-hop <i>A.B.C.D</i>] Or dns oob <i>destination-hostname</i> name-server <i>a.b.c.d</i> [source-ipaddr <i>ip-address</i>] via <i>type num</i> next-hop <i>A.B.C.D</i>
Parameter Description	oob : Indicates the test on the MGMT interface. <i>destination-hostname</i> : Indicates the destination host name. name-server : Indicates the DNS IP address. source-ipaddr <i>ip-address</i> : Indicates the source IP address. out-interface type num : Specifies the outgoing interface (non-MGMT interface) of the test packet. via type num : Specifies the MGMT interface as the outgoing interface of the test packet. next-hop : Indicates the IP address of the next hop when the outgoing interface is specified.
Command Mode	IP RNS configuration mode (config-ip-rns)
Usage Guide	After a DNS test is started, the system sends a DNS parsing request packet to test whether the device is connected to the target host. After a DNS test instance is created, the system enters the IP RNS DNS mode. You need to configure the RNS test type before configuring parameters. To modify the type of an RNS instance, you need to delete the RNS instance by running the no ip rns command in global configuration mode.

↳ Configuring the Test Repeat Interval

Command	frequency <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : Indicates the packet sending interval in ms. The default value is 60,000 ms. The value ranges from 10 to 604,800,000. The maximum value is one week.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	After an RNS instance is started, tests are conducted periodically. You can run the frequency command to specify the repeat interval. You need to configure the frequency based on the following formula to ensure correct test calculation.

	$(\text{frequency milliseconds}) > (\text{timeout milliseconds}) \geq (\text{threshold milliseconds})$
--	--

↘ Configuring a Tag for an RNS Instance

Command	<code>tag text</code>
Parameter Description	<i>text</i> : Sets the test tag. The value is a string of up to 79 characters.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	This command specifies a tag for a test, which is often used to indicate the function of the test.

↘ Configuring the Time Threshold for an RNS Instance

Command	<code>threshold milliseconds</code>
Parameter Description	<i>milliseconds</i> : Indicates the time threshold for the test. The value ranges from 0 to 60,000, in the unit of milliseconds. The default value is 5,000.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	Configure the threshold based on the following formula to ensure correct test calculation. $(\text{frequency milliseconds}) > (\text{timeout milliseconds}) \geq (\text{threshold milliseconds})$

↘ Configuring the Time Threshold for an RNS Instance

Command	<code>timeout millisecond</code>
Parameter Description	<i>millisecond</i> : Indicates the test timeout. The value ranges from 10 to 604,800,000. The unit is ms. The default timeout varies according to the test type.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	Configure the timeout based on the following formula to ensure correct test calculation. $(\text{frequency milliseconds}) > (\text{timeout milliseconds}) \geq (\text{threshold milliseconds})$

↘ Configures the TOS Field in the IPv4 Header of Test Packets

Command	<code>tos number</code>
Parameter Description	<i>number</i> : Sets the TOS field in the IPv4 header of test packets. The value ranges from 0 to 255. The default value is 0.
Command	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)

Mode	
Usage Guide	TOS is an 8-bit field in the IPv4 packet header. By setting the TOS, you can control the priority of the test packet. For different TOS fields, the processing priorities are different on the intermediate routers.

▾ Configuring the VRF of an RNS Test

Command	<code>vrf vrf-name</code>
Parameter Description	<i>vrf-name</i> : Specifies the VRF name.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	This command specifies the VRF of the test packet.

Configuration Example

Scenario Figure 10-4	<p>The diagram illustrates a network topology for RNS testing. On the left, a switch labeled 'Switch A' is connected to a central cloud labeled 'ISP'. Above the connection to the ISP, the IP address '10.1.1.1/16' is indicated. On the right, the 'ISP' cloud is connected to a server labeled 'Dns server'. Above this connection, the IP address '10.2.2.2/16' is indicated.</p>
Configuration Steps	Configure RNS instance 1 and related parameters on Switch A.
Switch A	<pre>A# configure terminal A(config)# ip rns 1 A(config-ip-rns)# dns www.ruijie.com.cn name-server 10.2.2.2 A(config-ip-rns-dns)#exit A(config)ip rns schedule 1 start-time now life forever</pre>
Verification	Run the show ip rns configuration command to display the instance configurations.

Switch A	<pre>A#show ip rns configuration 1 Entry number: 1 Tag: Type of operation to perform: dns Operation timeout (milliseconds): 5000 Operation frequency (milliseconds): 60000 Threshold (milliseconds): 5000 Recurring (Starting Everyday): FALSE Life (seconds): forever Next Scheduled Start Time:Start Time already passed Target host name: www.ruijie.com.cn Name Server: 10.2.2.2</pre>
-----------------	---

Common Errors

- The DNS IP address is incorrect.

10.4.4 Configuring the Track Support for the RNS

Configuration Effect

- Configure the track function to track the test result of an RNS instance.
- Configure the track function to track the link status of an interface.
- Configure the track function to track the status of a track list.
- Configure the track function to track the status of an RNS list.

Notes

- To configure the track function to track the test result of an RNS instance, you need to configure the related RNS instance.
- To configure the track function to track the link status of an interface, you need to configure the related interface.
- To configure the track function to track the status of a track list, you need to configure the members for the related track list.
- To configure the track function to track the status of an RNS list, you need to configure the members for the related RNS list.

Configuration Steps

📌 Configuring a Track Object

- Perform this operation if it is required to create a track object.
- The following four methods are available to create a track object:
 - Create a track object for tracking the test result of an RNS instance: Perform this configuration on every switching device unless otherwise required.
 - Create a track object for tracking the link status of an interface: Perform this configuration on every switching device unless otherwise required.
 - Create a track object for tracking the status of a track list: Perform this configuration on every switching device unless otherwise required.
 - Create a track object for tracking the status of an RNS list: Perform this configuration on every switching device unless otherwise required.

▾ Configuring the Notification Delay of a Track Object

- Perform this configuration if it is required to delay notification of the status change of a track object.
- Delay for notifying the status change of a track object includes the delay for notifying the status change of a track object from UP to DOWN and the delay for notifying the status change of a track object from DOWN to UP. You can configure either delay or both of delays.
- Perform this configuration on every switching device unless otherwise required.

▾ Configuring a Track Member

- Perform this configuration if it is required to configure a track object for tracking the status of a track list.
- When configuring a track member, you can set the status of a member meeting conditions to UP or DOWN.
- Perform this configuration on every switching device unless otherwise required.

Verification

Observe the status of a track object when the status of the track object (such as test results of an RNS instance, link status of an interface, or status of a track list) changes.

- After the preset delay, run the **show track** command to check whether the current track status changes.

Related Commands

▾ Configuring a Track Object for Tracking the Link Status of An Interface

Command	track <i>object-number</i> interface <i>interface-type interface-number</i> line-protocol
Parameter	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700.
Description	<i>Interface-type interface-number</i> : Indicates the interface type and interface number.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure a track object for tracking the link status of an interface. When the link status of the interface is UP, the status of the corresponding track object is UP.

↘ Configuring a Track Object for Tracking the Test Result of an RNS Test

Command	<code>track object-number rns entry-number</code>
Parameter Description	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700. <i>entry-number</i> : Indicates the number of an RNS instance. The value ranges from 1 to 500.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure a track object for tracking the result of an RNS test. If the test succeeded, the track object is in Up state.

↘ Configuring a Track Object for Tracking the Status of a Track List

Command	<code>track object-number list boolean { and or }</code>
Parameter Description	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure a track object for tracking the status of a track list. The result can be the AND or OR operation result of all member status.

↘ Configuring a Track Member

Command	<code>object object-number[not]</code>
Parameter Description	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700.
Command Mode	Track configuration mode
Usage Guide	Run this command to configure a member for a track list. The number of track list members that can be configured is restricted only by the capacity of track objects.

Configuring the Notification Delay of a Track Object

Command	<code>delay { up seconds [down seconds] [up seconds] down seconds }</code>
Parameter Description	up seconds : Specifies the delay for notifying the status change of a track object from DOWN to UP. The value ranges from 0 to 180. The unit is second. The default value is 0. down seconds : Specifies the delay for notifying the status change of a track object from UP to DOWN. The value ranges from 0 to 180. The unit is second. The default value is 0.
Command Mode	Track configuration mode
Usage Guide	When the status of a track object frequently changes, the status of the client that use this track object will frequently change as well. Using this command can delay notification of the status change of a track object. For example, if the status of a track object changes from UP to DOWN, and delay down 10 is configured, the DOWN status of the track object is notified 10s later. If the status of the track objects changes to UP again within this period of

	time, no notification is sent. For the client that uses this track object, the status of the track object is always UP.
--	---

↘ **Displaying the Track Object Statistics**

Command	show track [<i>object-number</i>]
Parameter Description	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700. The default is all track objects.
Command Mode	Privileged EXEC mode
Usage Guide	Run this command to display statistics of track objects.

Configuration Example

↘ **Configuring Track Object3 for Tracking the Link Status of the Interface FastEthernet 1/0**

Configuration Steps	<ul style="list-style-type: none"> ● Configure a track object for tracking the link status of an interface. ● Configure the delay for notifying the status change from UP to DOWN.
	<pre>Ruijie# configure terminal Ruijie(config)# track 3 interface FastEthernet 1/0 line-protocol Ruijie(config-track)# delay down 10 Ruijie(config-track)# exit</pre>
Verification	<p>Change the link status of the interface FastEthernet 1/0 to DOWN.</p> <ul style="list-style-type: none"> ● Immediately check the status of the track object, and verify that the status is still UP. ● Check the status of the track object 10s later, and verify that the status changes to DOWN.
	<pre>Ruijie# show track 3 Track 3 Interface FastEthernet 1/0 The state is Up, delayed Down (5 secs remaining) 1 change, current state last: 300 secs Delay up 0 secs, down 10 secs</pre>

↘ **Configuring Track Object 3 (When the status of track object 1 is UP, and the status of track object 2 is DOWN, the status of track object 3 is UP.)**

Configuration Steps	<ul style="list-style-type: none"> ● Configuring track object 1 and track object 2. ● Configure track object 3, and its members include track object 1 and track object 2.
----------------------------	--

	<pre>Ruijie # config Ruijie(config)#track 1 interface gigabitEthernet 0/0 line-protocol Ruijie(config-track)#delay up 20 down 40 Ruijie(config-track)#exit Ruijie(config)# Ruijie(config)#track 2 interface gigabitEthernet 0/1 line-protocol Ruijie(config-track)#delay down 30 Ruijie(config-track)#exit Ruijie(config)# track 3 list Boolean and Ruijie(config-track)#object 1 Ruijie(config-track)#object 2 not Ruijie(config-track)# exit</pre>
Verification	<p>When the status of track objects 1 and 2 change, check the status of track object 3.</p> <ul style="list-style-type: none"> ● When the status of track object 1 changes from DOWN to UP, and the status of track object 2 remains DOWN, verify that the status of track object 3 changes from DOWN to UP. ● When the status of track object 1 remains UP, and the status of track object 2 changes from DOWN to UP, verify that the status of track object 3 changes from UP to DOWN.
	<pre>Ruijie# show track 3 Track 3 List boolean and Object 1 Object 2 not The state is Down 1 change, current state last:10 secs Delay up 0 secs, down 0 secs</pre>

📌 Configuring Track Object 5 for Tracking the Test Result of RNS Instance 7

Configuration Steps	<ul style="list-style-type: none"> ● Configure an RNS test. ● Configure a track object to track the result of the RNS test. ● Configure the delay for notifying the test result change from successful to unsuccessful, and the delay for notifying the test result change from unsuccessful to successful.
	<pre>Ruijie# configure terminal</pre>

	<pre>Ruijie (config)#ip rns 7 Ruijie (config-ip-rns)#icmp-echo 2.2.2.2 Ruijie (config-ip-rns-icmp-echo)#exit Ruijie (config)#ip rns schedule 7 start-time now life forever Ruijie(config)# track 5 rns 7 Ruijie (config-track)# delay up 20 down 30 Ruijie (config-track)# exit</pre>
<p>Verification</p>	<p>Let the test result of RNS instance 7 change from successful to unsuccessful.</p> <ul style="list-style-type: none"> ● When the test result changes to unsuccessful, immediately check the status of track object 7, and verify that the status is still UP. ● Check the status of the track object 30s later, and verify that the status changes to DOWN.
	<pre>Ruijie# show track 5 Track 5 Reliable Network Service 7 The state is Down 2 change, current state last: 10 secs Delay up 20 secs, down 30 secs</pre>

📌 **Configuring Track Object 5 for Tracking the Test Results of an RNS List (consisting of RNS Instances 1, 2–5, and 8)**

<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure and start an RNS test (see "RNS Configuration"). ● Configure a track object for tracking the test result of an RNS list. ● Configure the delay for notifying the test result change from UP to DOWN, and the delay for notifying the test result change from DOWN to UP.
	<pre>Ruijie(config)# track 5 rns-list 1,2-5,8 and Ruijie (config-track)# delay up 20 down 30 Ruijie (config-track)# exit</pre>
<p>Verification</p>	<p>Let the test result of one of the RNS instances 1, 2-5, and 8 changes from successful to unsuccessful.</p> <ul style="list-style-type: none"> ● When the test result changes to unsuccessful, immediately check the status of track object 7, and verify that the status is still UP. ● Check the status of the track object 30s later, and verify that the status changes to DOWN.

```
Ruijie# show track 5

Track 5

  rns-list 1,2-5,8 and

The state is Down

  2 change, current state last: 10 secs

  Delay up 20 secs, down 30 secs
```

Common Errors

- The track object for tracking an RNS test is configured, but the RNS test is not configured.
- The track object for tracking the link status of an interface is configured, but the corresponding interface is not configured.
- The track object for tracking the status of a track list, but no member of the RNS list is configured.
- The track object configured for tracking an RNS list, but the RNS test is not configured.

10.5 Monitoring

Displaying

Description	Command
Displays configurations of one or more RNS instances.	show ip rns configuration [<i>operation-number</i>]
Displays detailed statistics of one or more RNS instances.	show ip rns collection-statistics [<i>operation-number</i>]
Displays the current RNS status.	show ip rns operational-state [<i>operation-number</i>]
Displays the proactive threshold monitoring information of one or more RNS instances.	show ip rns reaction-configuration [<i>operation-number</i>]
Displays information about the test triggered by one or more RNS instances.	show ip rns reaction-trigger [<i>operation-number</i>]
Displays the brief statistics of one or more RNS instances.	show ip rns statistics [<i>operation-number</i>]
Displays the brief statistics of one or more track objects.	show track [<i>object-number</i>]
Displays the brief statistics of a track client.	show track client

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the track module.	debug track { all proc-event rdnd-event client }
Debugs the RNS module.	debug rns { all interface lib rdnd-event restart rns_id [0, 500] }

11 Configuring VSD

11.1 Overview

As Information Communication Technology (ICT) networks especially data center networks keep growing, service types emerge one after another. On one hand, network management becomes increasingly complicated. On the other hand, increasingly-higher requirements are posed on network properties such as service isolation, security and reliability. In addition, with the rapid improvement of hardware capacity and the maturity of multi-shelf, cluster, distributed routing & switching systems, the service processing capacity of a single physical network device has been raised to a new level. It becomes imperative to make full use of the powerful service processing capacity to resiliently meet present service demands while promoting expansibility smoothly in the future.

A Virtual Switch Device (VSD) is a network virtualization technology that divides one physical device into several logical devices. Each logical device is called a VSD, which has independent hardware and software resources, including interfaces, a routing table and a forwarding table to be separately maintained, and configuration files managed by specific administrators. From users' perspective, each VSD is an independent device.

A physical device can be virtualized into several logical devices using the VSD technology, as shown in Figure 11-1. A physical device bears several network nodes on the logical topology to maximize the utilization of existing resources and reduce operation costs. Meanwhile, different VSDs are deployed with different services to shield services from faults, thereby improving network security and reliability.

Figure 11-1 VSD

As shown in Figure 11-1, VSD0 is the system default VSD while VSD1 and VSD2 are non-default VSDs created by users.

- VSD1: client domain, also called the non-default VSD (the same as VSD2). It is created and deleted by VSD0, with its physical resources assigned by VSD0. The client domain can use only the resources assigned by VSD0. It cannot use or obtain other resources.
- Physical port resources: physical Ethernet ports on line cards only, excluding any other types of ports such as console and management ports.

Advantages

- The VSD technology divides physical ports based on service chips to ensure superposition of service capacity, which means service specifications are exclusively shared among VSDs. For example, if the VLAN service specifications are 4063 VLANs, the VLAN service specifications are 4063 VLANs for both VSD 1 and VSD2.
- Each VSD works independently. If isolated, VSDs cannot communicate with each other, thereby achieving relatively high security.
- VSD supports flexible resource scheduling. For example, if there are new branches, the administrator can divide VSDs on demand to reduce costs in the purchase and hardware upgrade of network devices, so as to enhance utilization of present network resources.

Management

- Out-of-band management: VSDs are managed via a management (MGMT) port. All VSDs share a MGMT port on the supervisor module, and have different MGMT ports of their own with IP addresses configured. Users can log in to the VSD CLI corresponding to the specified IP address of a MGMT port.

Figure 11-2 Out-of-band Management

- In-band management: VSDs are managed via a physical Ethernet port. Users can log in to the VSD console corresponding to the specified VSD port. For example, Eth 2/1 port can only place you in the VSD1 CLI, as shown in Figure 11-3.

Figure 11-3 In-band Management

- CLI management: VSDs are managed via a serial port on the supervisor module. By default, you log in to the VSD0 CLI via the serial port.

Protocols and Standards

- VSD is a Ruijie-proprietary protocol.

11.2 Applications

Application	Description
Providing isolated services within a physical device	Virtualize a physical device into several logical devices that provide isolated services.

11.2.1 Providing Isolated Services within a Physical Service

Scenario

The VSD technology can be used to virtualize one physical device into several logical devices that provide independent services.

As shown in Figure 11-4, a convergence device is virtualized into three logical devices that provide isolated services to areas A, B, and C.

- VSD1 is the uplink device of area A, VSD2 is the uplink device of area B, and VSD3 is the uplink device of area C.
- VSD1, VSD2, and VSD3 respectively connect to devices in the corresponding areas via their own links.

Figure 11-4

Deployment

- VSD1, VSD2, and VSD3 are independent logical devices, deployed with services based on requirements of areas A, B, and C.

11.3 Features

Basic Concepts

↘ Default VSD

The VSD-capable physical device is the default VSD. Therefore, login to such a device is actually login to the default VSD. Any configuration on the physical device is applied to the default VSD. The default VSD exists originally and cannot be deleted. It has all permissions of the physical device, and uses and manages all hardware resources of the device. The default VSD not only creates and deletes non-default VSDs, but also assigns hardware resources to the non-default VSDs. By default, hardware resources that are not assigned to the non-default VSDs are used by the default VSD. The default VSD is numbered 0.

↘ Non-Default VSD

In comparison, a non-default VSD has to be created by the default VSD before use. It is created without physical port resources (other resources of the physical device such as CPU and memory shared with the default VSD), and has no available physical port resources until assigned by the default VSD. Non-default VSDs cannot be created or deleted by another non-default VSD.

↘ Physical Device Resources

Physical device resources include:

- **Physical ports:** physical port resources that exclude virtual ports and serial ports.
- **SD cards:** storage resources of external storage SD cards.
- **Multi-service cards:** firewall cards. When assigned a firewall card, a non-default VSD is equipped with the firewall function.

i By default, physical port resources and multi-card resources belong to the default VSD while other physical resources are shared between the default VSD and non-default VSDs.

↘ MAC Address

A physical switch normally has a system MAC address. When a physical device is virtualized into several logical devices, each logical device requires a system MAC address. Therefore, each VSD will be automatically assigned a MAC address (while the system MAC of the default VSD is that of the physical device).

📌 **VSD's Master/Slave Role**

A classis-type device is normally equipped with two supervisor modules to ensure high availability. When working properly, one of the supervisor modules plays the master role while the other serves as the salve. Service data of the master supervisor module will be backed up to the slave supervisor module. Once divided, each VSD is distributed on both the master supervisor module and the slave supervisor module to play roles. To prevent other VSD users from being affected by the master/slave switching executed by non-default VSD users, only the VSDO administrator can execute the master/slave switching command.

Features

Feature	Function
VSD	Virtualize a physical device into several logical devices.

11.3.1 VSD

Working Principle

VSD can be regarded as a kind of virtualization technology that virtualizes a physical device into several logical devices. VSD virtualization is constructed based on the virtualization technology for operating systems. Different from the virtual machine technology, it utilizes system services provided by the operating system kernel to ensure mutually isolated user space services. Operating systems that adopt this virtualization include Linux Containers (Linux LXC), OpenVZ, Linux-VServer, and FreeBSD jails.

Figure 11-5 Structure of VSD 1:N Virtualization

As shown in Figure 11-5, the default VSD is VSD0 while the non-default ones created by users are VSD1 to VSDn.

- **System MGR:** When a VSD is created, the System MGR will initiate all processes required to start the VSD. When a VSD needs to enable a new service, the System MGR will initiate the corresponding service process (for example, when VSD2 starts the OSPF service, the System MGR will initiate a corresponding OSPF process). When a VSD is deleted, the System MGR will delete all service processes belonging to the VSD.
- **VSD MGR:** The VSD MGR is used to support non-default VSD management to create and delete non-default VSDs. More importantly, the VSD MGR provides the System MGR or Resource MGR with related APIs to achieve system management or resource management of non-default VSDs.
- **Resource MGR:** It allocates resources such as VLANs and VRFs to various VSDs during resource management.
- **INFRASTRUCTURE layer:** It provides interfaces between upper-layer applications and hardware resources.
- **KERNEL:** There is only one kernel as VSD is light-weight virtualization.

11.4 Configuration

Configuration	Suggestions and Related Commands	
Configuring a VSD	 Mandatory configuration, which is used to create a VSD.	
	vsd <i>vsd_name</i> [id <i>vsd_number</i>]	Creates a VSD.
	allocate interface <i>int_index</i>	Allocates physical ports to the VSD.
	allocate slot <i>slot_id</i>	Allocates multi-service cards to the VSD.
	cpu weight <i>weight_value</i>	Allocates the CPU weight to a VSD.
	memory ratio <i>limit_ratio</i>	Allocates the maximum memory ratio to a VSD.
Restarting a VSD	 Optional configuration, which is used to restart a VSD as necessary.	
	reset vsd [<i>vsd_name</i>]	Restarts a non-default VSD.
Switching Between VSDs	 Optional configuration, which is used to switch between the default VSD and a non-default VSD.	
	switchto vsd <i>vsd_name</i>	Switches from the default VSD to a non-default VSD.
	switchback	Switches back from the non-default VSD to the default VSD.

11.4.1 Configuring a VSD

Configuration Effect

- Create a non-default VSD.
- Allocate physical port resources to the newly created non-default VSD.

- Allocate multi-service cards to the newly created non-default VSD.

Precautions

- Users can use the VSD function in a VSU environment. When allocating ports to the VSD, the line card where the ports are located will be reset, thereby disconnecting the VSL link on the line card. As there is only one VSL link in the system, the VSU will also be topologically split. It is recommended that you use the VSD function in the VSU environment and configure VSL ports on several line cards to ensure the stability of the VSU and prevent the VSU from being affected by allocating VSD ports or restarting the VSD.
- The VSD0 administrator can set any eligible port of any VSD as a VSL port to be centrally managed by VSD0. The VSD0 administrator can switch any VSL port back to a normal port that will return to the VSD of the chip where the port is located. For example, all ports on a line card are under VSD2, and only one port is set as a VSL port. When the administrator switches the VSL port to a normal port, it will return to VSD2.
- The dual-host detection port in the VSD environment must be set in VSD0. When VSD0 detects the dual host status, all VSDs enter the recovery status.

Configuration Steps

↳ Creating a VSD

- To use the VSD function, you must configure it first.

Command	vsd <i>vsd_name</i> [id <i>vsd_number</i>]
Parameter	<i>vsd_name</i> : VSD name
Description	<i>vsd_number</i> : VSD ID. If not specified, the minimum available ID will be used.
Defaults	No VSD is created by default.
Command Mode	Global configuration mode
Usage Guide	<p>This command is used to create a VSD and enter the VSD configuration mode. If a VSD has been created, use this command to enter the VSD configuration mode.</p> <p>When entering the specified VSD configuration mode, you do not need to enter the <i>vsd_number</i>. If you enter the <i>vsd_number</i>, make sure that it is consistent with the current VSD number; otherwise, an error message appears.</p> <hr/> <p> Get a corresponding license before you create a non-default VSD, with the total number of non-default VSDs created not greater than the total authorized number. The name of a VSD is independent from and irrelevant to the hostname of the device.</p>

↳ Allocating Physical Port Resources

- The configuration is mandatory.

Command	allocate interface <i>int_index</i>
Parameter	<i>int_index</i> : Interface index
Description	

Defaults	All physical ports belong to VSD 0.
Command Mode	VSD configuration mode
Usage Guide	<p>This command is used to allocate or reclaim physical ports to or from a non-default VSD.</p> <hr/> <p> If no physical port is available for a non-default VSD, the VSD can only be managed but not used. If all physical ports are allocated to a non-default VSD, the default VSD will have no physical port available. The VSL interface cannot be allocated.</p>

➤ **Allocating Multi-Service Card Resources**

- The configuration is optional.
- To use a multi-service card such as a firewall card in a certain non-default VSD environment, users have to perform this configuration in VSD mode. If a multi-service card is used by a non-default VSD, other non-default VSDs cannot use this multi-service card. For example, a firewall card is used in a non-default VSD2, and then other VSDs cannot use it.

Command	allocate slot <i>slot_id</i>
Parameter Description	<i>slot_id</i> : Multi-service slot ID
Defaults	The multi-service card belongs to VSD 0.
Command Mode	VSD configuration mode
Usage Guide	This command is used to allocate multi-service card resources to a non-default VSD or to reclaim multi-service card resources from the non-default VSD.

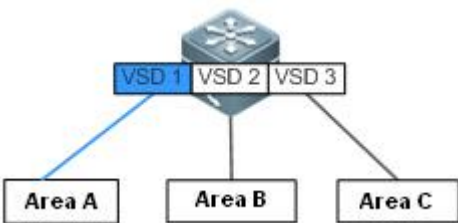

Verification

A newly created VSD is an independent logical device, and its configuration can be verified after you log in to the VSD.

- Check whether you can log in to the newly created VSD.
- Check whether you can configure ports after logging in to the VSD.

Configuration Example

➤ **Creating Three Logical Devices on a Physical Device**

Scenario Figure 11-6	
Configuration Steps	<ul style="list-style-type: none"> ● Create VSD A; ● Allocate physical port 1/1-24 to VSD A;

	<ul style="list-style-type: none"> ● Allocate multi-service card 3 to VSD A. ● Create VSD B; ● Allocate physical port 1/25-48 to VSD B; ● Allocate multi-service card 4 to VSD B. ● Create VSD C; ● Allocate physical port 2/1-12 to VSD C; ● Allocate multi-service card 5 to VSD C.
VSD A	<pre>Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# vsd VSDA Ruijie(config-bsd)# allocate int gi 1/1 Interface-group[1/1 ~ 1/24] and their config will be removed from vsd[0]. Are you sure to continue(y/n)? [no]y Ruijie(config-bsd)# allocate slot 3 Allocating slot 3 may cause some service in source vsd to stop. Are you sure to continue (y/n)? [no]y Ruijie(config-bsd)#</pre>
VSD B	<pre>Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# vsd VSDB Ruijie(config-bsd)# allocate int gi 1/25 Interface-group[1/25 ~ 1/48] and their config will be removed from vsd[0]. Are you sure to continue(y/n)? [no]y Ruijie(config-bsd)# allocate slot 4 Allocating slot 4 may cause some service in source vsd to stop. Are you sure to continue (y/n)? [no]y Ruijie(config-bsd)#</pre>
VSD C	<pre>Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# vsd VSDC Ruijie(config-bsd)# allocate int gi 2/1 Interface-group[2/1 ~ 2/12] and their config will be removed from vsd[0]. Are you sure to continue(y/n)? [no]y Ruijie(config-bsd)# allocate slot 5 Allocating slot 5 may cause some service in source vsd to stop. Are you sure to continue (y/n)? [no]y Ruijie(config-bsd)#</pre>
Verification	Log in to the corresponding VSD to perform relevant port configuration.
VSD A	<pre>Ruijie# switchto vsd VSDA</pre>

	<pre>***** Ruijie General Operating System Software Copyright (c) 1998-2013s by Ruijie Networks. All Rights Reserved. Neither Decompiling Nor Reverse Engineering Shall Be Allowed. ***** Ruijie-VSDA> enable Ruijie-VSDA# show int</pre>
VSD B	<pre>Ruijie# switchto vsd VSDB ***** Ruijie General Operating System Software Copyright (c) 1998-2013s by Ruijie Networks. All Rights Reserved. Neither Decompiling Nor Reverse Engineering Shall Be Allowed. ***** Ruijie-VSDA> enable Ruijie-VSDA# show int</pre>
VSD C	<pre>Ruijie# switchto vsd VSDC ***** Ruijie General Operating System Software Copyright (c) 1998-2013s by Ruijie Networks. All Rights Reserved. Neither Decompiling Nor Reverse Engineering Shall Be Allowed. ***** Ruijie-VSDA> enable Ruijie-VSDA# show int</pre>

Common Errors

- You create a VSD without any valid license.
- The total number of non-default VSDs created exceeds the maximum number authorized.
- You reclaim a port that does not belong to a non-default VSD.
- You allocate a physical port belonging to a non-default VSD to another non-default VSD.
- No new physical port resources are available for allocation.

11.4.2 Restarting a VSD

Configuration Effect

- Restarting a single non-default VSD will only affect services in the non-default VSD.

Notes

- The interface card of the non-default VSD will be reset. If a VSL port is involved on the line card where the VSD port is located, the VSU might be topologically split. Therefore, it is recommended that the restart operation be performed only when services are not busy.
- The default VSD cannot be restarted.

Configuration Steps

- To restart a VSD, perform this configuration.

Command	Use this command to log in from the default VSD to a non-default VSD. switchto vsd <i>vsd_name</i>	
Parameter Description	Parameter	Description
	vsd <i>vsd_name</i>	Name of a non-default VSD
Command Mode	Privileged EXEC mode	
Usage Guide	This command is used to log in from the default VSD to a non-default VSD.	

Command	Use this command to switch back from the non-default VSD to the default VSD. switchback	
Parameter Description	Parameter	Description
	N/A	N/A
Command Mode	Privileged EXEC mode	
Usage Guide	This command is used to switch back from a non-default VSD to the default VSD. This command does not support login to the non-default VSD via Telnet, which means that this command is effective only when switching from the default VSD to the non-default VSD (that is to say, switchto shall go before switchback).	

Verification

When a VSD is restarted, only its services will be interrupted. Other VSDs will not be affected unless the port on the interface card is shared by two VSDs.

11.4.3 Switching Between VSDs

Configuration Effect

- Switch from VSD0 to a non-default VSD or vice versa.

Notes

- Users cannot switch between VSDs if directly logging in via the out-of-band or in-band port.

Configuration Steps

- To switch between VSDs, perform this configuration. The switching between non-default VSDs has to be performed via the default VSD. For example, to switch from non-default VSD1 to VSD2, you have to switch first from VSD1 to the default VSD0 and then from VSD0 to VSD2.

Verification

Check the current VSD ID after logging in.

Configuration Example

- **Switching to a Non-default VSD**

Configuration Steps	<ul style="list-style-type: none"> ● Switch from VSD0 to a non-default VSD; ● Switch from the non-default VSD back to VSD0.
	<pre>Ruijie# switchto vsd admin ***** Ruijie General Operating System Software Copyright (c) 1998-2013s by Ruijie Networks. All Rights Reserved. Neither Decompiling Nor Reverse Engineering Shall Be Allowed. ***** admin#</pre>
	<pre>Ruijie# switchto vsd admin ***** Ruijie General Operating System Software Copyright (c) 1998-2013s by Ruijie Networks. All Rights Reserved. Neither Decompiling Nor Reverse Engineering Shall Be Allowed. ***** admin# switchback Ruijie#</pre>
Verification	Check the VSD where the current user resides.
	<pre>Ruijie# sho vsd current-vsds Current vsd is 0 - Ruijie Ruijie #</pre>

Common Errors

N/A

11.5 Monitoring

Displaying

Command	Function
<code>show vsd { current-vsds membership detail all } [vsd_name]</code>	Displays VSD information.

12 Configuring NLB Group

12.1 Overview

NLB Group, also called the cluster service, is a cluster technology developed to support Network Load Balance (NLB) of Microsoft®.

NLB Group allows all member servers in a cluster to receive IP packets sent to the cluster. As compared with common cluster technologies, switches enabled with NLB Group can directly connect to servers without using layer-2 switches. In addition, data packets can be sent to the server only from specified ports to prevent flooding in the broadcast domains.

When setting up a cluster to provide external services, you can enable NLB Group on the switch to improve service reliability.

12.2 Applications

Application	Description
Supporting Web Server NLB Group	Uses NLB to set up a web server cluster with the support of NLB Group on layer-3 switches.

12.2.1 Supporting Web Server NLB Group

Scenario

As shown in Figure 12-1, a web server is set up using NLB Group to provide website services externally. By default, NLB Group is disabled on layer-3 switches, that is, IP packets sent to the cluster cannot be sent to the active and standby servers at the same time. Normally, a layer-2 switch is needed between the cluster server and layer-3 switch. In this way, IP packets can be sent to the active and standby servers at the same time but a unicast data packet has only one next-hop address. To allow the active and standby servers to receive IP data packets sent to the cluster, you need to configure the cluster service on the layer-3 switch. After this, packets sent to the NLB Group with IP address 192.168.1.10 are sent to the active and standby servers through ports Gi 1/1 and Gi 1/2 at the same time.

Figure 12-1 NLB Group Application Diagram

Deployment

- Enable NLB Group on layer-3 switches.

12.3 Features

Basic Concepts

➤ NLB

NLB is a cluster technology built in Windows Server by Microsoft®. It provides network load balance for TCP/IP-based services and applications to improve availability and extensibility.

i For details about the NLB service, visit Microsoft® website <http://technet.microsoft.com>.

➤ VRF

NLB Group supports VPN Routing and Forwarding (VRF). VPN refers to the VPN to which the NLB Group belongs on the layer-3 switch.

➤ NLB-Address

NLB Group IP address. NLB allows all PCs in an NLB Group to share the same IP address to provide external services.

➤ Reflector-Port

Reflector port. To implement the NLB Group service, the layer-3 switch sends IP packets sent to the NLB Group to all member hosts of the NLB Group server through a reflector port.

 A reflector port must be configured. It can only be a layer-2 switching port (layer-2 AP port) and no configuration is allowed on the reflector port. To ensure normal NLB Group service, the reflector port must be idle, that is, no network cable or optical fiber cable can be inserted into the port.

↘ Destination-Port

Destination port to which packets are sent, that is, the port that connects the member host in the NLB Group and layer-3 switch, for example, Gi 1/1 and Gi 1/2 in Figure 12-1.

 The NLB Group server communicates with the layer-3 switch using SVI, but not the routed port.

Overview

Feature	Description
NLB Group	Supports NLB Group of Microsoft.

12.3.1 NLB Group

Working Principle

Using Figure 12-1 for example, the following describes the working principle of NLB Group:

1. A user sends an IP packet whose destination IP address is the NLB Group IP address, 192.168.1.10.
2. The IP packet reaches the layer-3 switch through routing.
3. After reaching the layer-3 switch through Gi 2/1, the IP packet is sent to the reflector port and then forwarded to the destination ports Gi 1/1 and Gi 1/2 by the reflector port.
4. The active and standby servers in the NLB Group receive the IP packet.

Related Configuration

↘ Enabling NLB Group

- By default, NLB Group is disabled.
- After NLB Group attributes are configured, the NLB Group service is automatically enabled.

↘ Configuring NLB Group Attributes

- By default, no NLB Group attribute is configured.
- Run the **nlb-group** *group-number* [**vrf** *vrf-name*] **ip** *nlb-address* **reflector-port** *interface-name* command to configure NLB Group attributes. The value of **group-number** ranges from 1 to 100. If **vrf** is not specified, a global VRF is used.

↘ Configuring the NLB Group Destination Port

- By default, no NLB Group destination port is configured.

- Run the **nlb-group** *group-number* **destination-port** *interface-name* command to configure the NLB Group destination port. A maximum of 32 destination ports can be configured.

12.4 Configuration

Configuration	Description and Command
Configuring NLB Group Attributes	 (Mandatory) It is used to enable NLB Group.
	nlb-group <i>group-number</i> [vrf <i>vrf-name</i>] ip <i>nlb-address</i> reflector-port <i>interface-name</i> Configures NLB Group attributes.
Configuring the NLB Group Destination Port	 (Optional) By default, all ports in the VLAN where the NLB Group resides are used as the NLB Group destination ports.
	nlb-group <i>group-number</i> destination-port <i>interface-name</i> Configures the NLB Group destination port.

12.4.1 Configuring NLB Group Attributes

Configuration Effect

- Enable NLB Group to send IP packets sent to the NLB Group to all member hosts in the NLB Group.

Notes

- NLB Group does not support dynamic switching of the operation mode in the NLB Group.
- When the NLB cluster server works in IGMP multicast mode, layer-3 multicast cannot be enabled on the layer-3 switch; otherwise, NLB Group may be abnormal. If layer-3 multicast must be enabled, configure the NLB Group server to work in non-IGMP multicast mode, that is, unicast mode or multicast mode.

Configuration Steps

▾ Configuring NLB Group Attributes

- Mandatory.
- Configure the attributes on the switch.

Verification

Use a client to access the NLB Group and send a service request.

- Check whether a response is received to the request.
- Check whether all member hosts receive the request.

Related Commands

↘ Configuring NLB Group Attributes

Command	<code>nlb-group group-number [vrf vrf-name] ip nlb-address reflector-port interface-name</code>
Parameter	<i>group-number</i> : Specifies the NLB Group number.
Description	<i>vrf-name</i> : Specifies the VRF. <i>nlb-address</i> : Specifies the NLB Group IP address. <i>interface-name</i> : Specifies the interface name.
Command Mode	Global configuration mode
Usage Guide	To remove NLB group attributes, run the <code>no nlb-group group-number [vrf vrf-name] ip nlb-address reflector-port interface-name</code> or <code>no nlb-group group-number</code> command. To delete all NLB groups, run <code>no nlb-group all</code> .

Common Errors

- A layer-3 port is configured as the reflector port.

12.4.2 Configuring the NLB Group Destination Port

Configuration Effect

- Configure NLB Group so that IP packets sent to the NLB Group are sent to the NLB Group server through specified ports.

Notes

- When the NLB Group server works in NLB IGMP multicast mode, you can configure NLB Group attributes as well as selecting whether to enable IGMP Snooping. If IGMP Snooping is enabled, the switch automatically learns the NLB Group destination port through IGMP Snooping and users do not need to manually configure the port. If the NLB Group destination port is configured and IGMP Snooping is enabled, only the destination ports receiving IGMP Report messages can receive the packet to access NLB Group, that is, the ports not only configured by users but also learned through IGMP Snooping. If IGMP Snooping is disabled, the switch cannot automatically learn the NLB Group destination port, which is the same as that when NLB Group works in unicast mode.

Configuration Steps

↘ Configuring the NLB Group Destination Port

- Optional.
- When the NLB Group server works in unicast or multicast mode, it is advised to configure the ports directly connected to member hosts as NLB Group destination ports.
- Destination ports are configured on the switch.

Verification

- Check whether the configurations are successful.

Related Commands

▾ **Configuring the NLB Group Destination Port**

Command	<code>nlb-group group-number destination-port interface-name</code>
Parameter	<i>group-number</i> : Specifies the NLB Group number.
Description	<i>interface-name</i> : Specifies the interface name.
Command Mode	Global configuration mode
Usage Guide	To delete NLB Group destination ports, run the no nlb-group group-number destination-port interface-name or no nlb-group group-number command.

Configuration Example

Data Center Configuration

1. Configuring L2GRE

1 Configuring L2GRE

1.1 Overview

Generic Routing Encapsulation (GRE) encapsulates the data packets of some network layer protocols (for example, IP and IPX) for enabling these encapsulated data packets to be transmitted through another network layer protocol (for example, IP). Layer 2 GRE (L2GRE) provides layer 2 VPN (L2VPN) services through GRE tunnels in the IP core network.

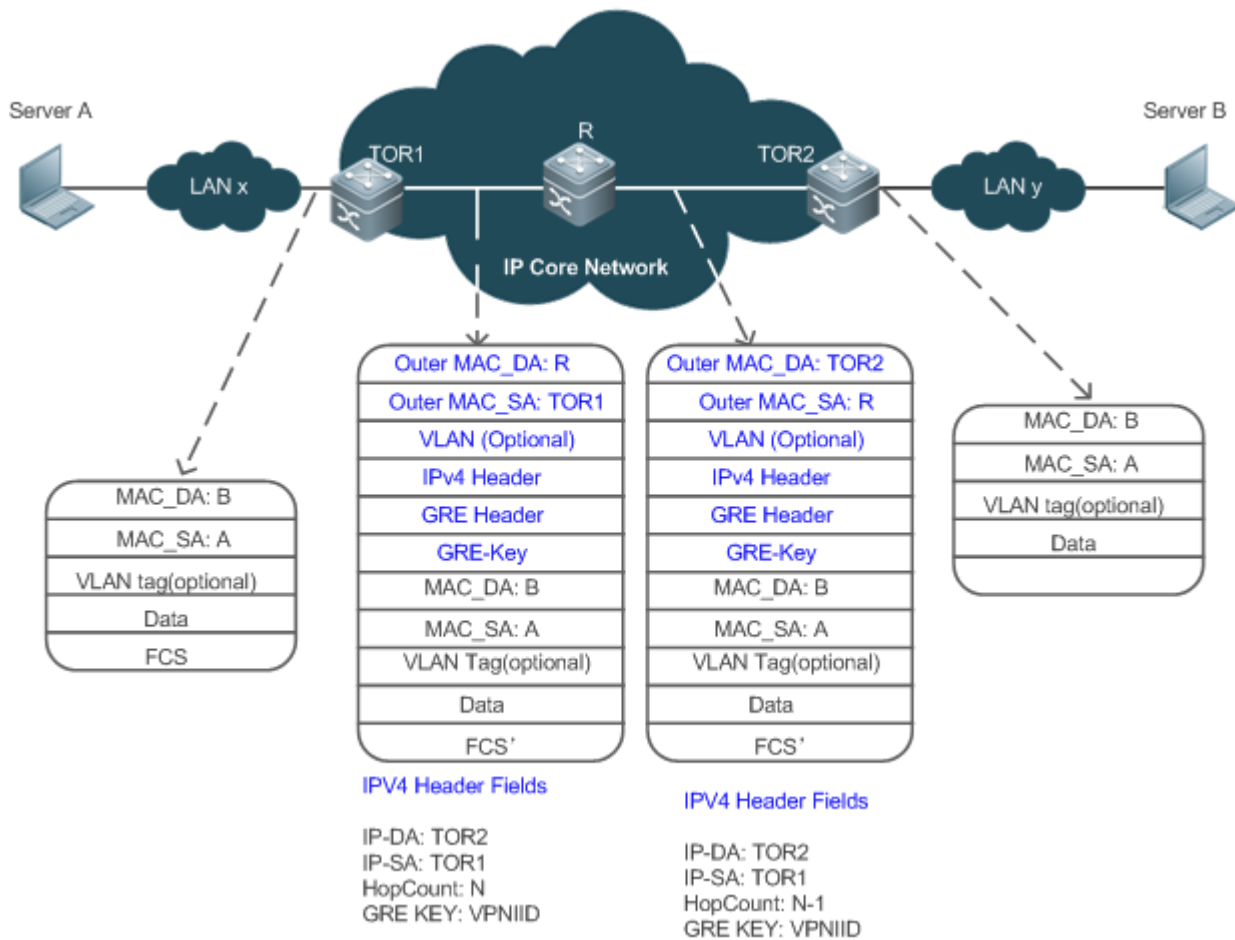

L2GRE provides two types of L2VPN services, that is, L2GRE LINE and L2GRE LAN.

L2GRE LINE is an end-to-end layer 2 service bearing technology, it belongs to point-to-point L2VPN, and it provides IP network-based layer 2 VPN services.

L2GRE LAN is a technology that provides a virtual private Ethernet in the IP network.

L2GRE encapsulates the Ethernet packets into GRE packets for transmission over the IP network. At the receiving end, L2GRE decapsulates the GRE packets into Ethernet packets for forwarding. See Figure 1-1.

Figure 1-1

After receiving the Ethernet packets from the LAN x, switch TOR1 encapsulates the Ethernet packets into L2GRE packets.

- L2GRE packets are forwarded in the IP core network, which is the same as the forwarding of GRE packets by router R shown in Figure 1-1.
- After receiving the GRE packets, switch ToR2 decapsulates, and then forwards the packets in the LAN.

1.2 Applications

Application	Description
L2GRE LINE	Scenario where two data centers are interconnected at layer 2 by L2GRE LINE over the IP core network
L2GRE LAN	Scenario where three data centers are interconnected at layer 2 by L2GRE LAN over the IP core network

1.2.1 L2GRE LINE

Scenario

Two data centers are interconnected at layer 2 by L2GRE LINE over the IP core network, as shown in Figure 1-2.

Figure 1-2

- Data center 1 and data center 3 are interconnected at layer 2 by L2GRE LINE over the IP core network.
- Data centers 1 and 3 use L2GRE LINE for layer 2 forwarding.

Deployment

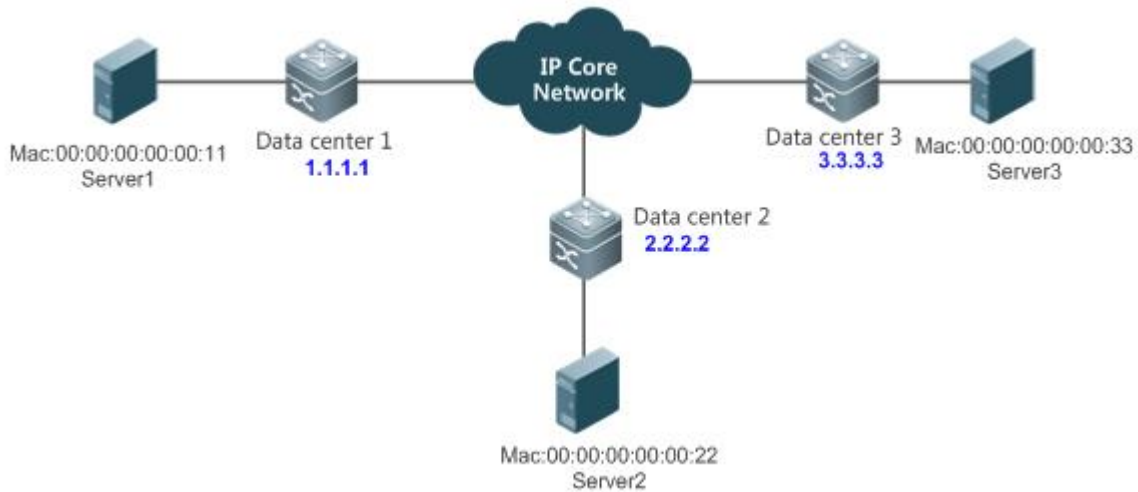

- Configure an IPv4 unicast routing protocol (for example, OSPF) on the switch to ensure that the unicast route is reachable.
- Configure L2GRE LINE on the data center switches to implement point-to-point layer 2 interconnection.

1.2.2 L2GRE LAN

Scenario

Three data centers are interconnected at layer 2 by L2GRE LAN over the IP core network, as shown in Figure 1-3.

Figure 1-3

- Data center 1, data center 2, and data center 3 are interconnected at layer 2 by L2GRE LAN over the IP core network.
- Data centers 1, 2, and 3 use L2GRE LAN for forwarding packets to each other.

Deployment

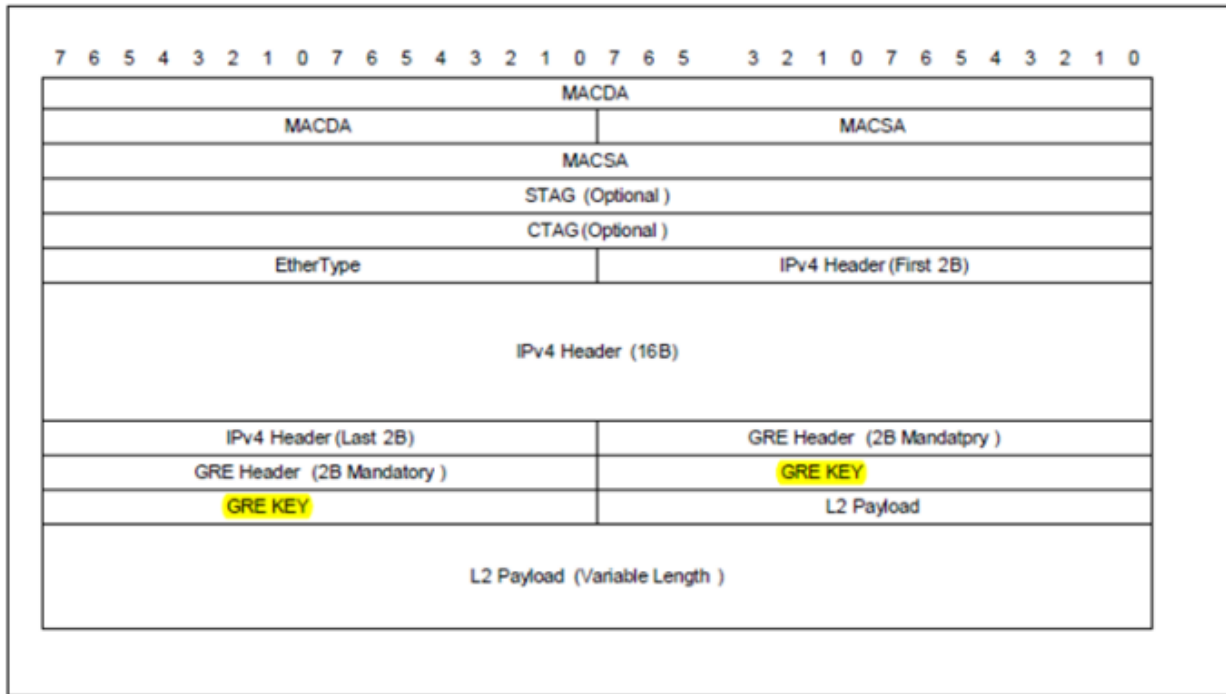

- Configure an IPv4 unicast routing protocol (for example, OSPF) on the switch to ensure that the unicast route is reachable.
- Configure L2GRE LAN on the switches of data centers to implement layer 2 interconnection in LAN mode.

1.3 Features

Basic Concept

↳ L2GRE Packet Format

L2GRE encapsulates Ethernet packets into GRE packets for transmission over the IP core network. The following figure shows the format of the packet encapsulated by L2GRE.

In this figure:

- MACDA: indicates the destination address of the route egress.
- MACSA: indicates the address of the present switch.
- STAG: indicates carrier's VLAN TAG, which is optional.
- CTAG: indicates user's VLAN TAG, which is optional.
- EtherType: indicates the Ethernet type, which is 0x0800 herein.
- IPv4 HEADER: indicates the information of outer IP header.
- GRE HEADER, GRE KEY: indicate the header information of encapsulated GRE packets.
- L2 Payload: indicates the original Ethernet packet.

The default MTU value of an interface is 1,500 bytes. Generally, when a packet is encapsulated into an L2GRE packet, the length of the packet increases by 46 bytes (external Ethernet header: 14 bytes, IP header: 20 bytes, GRE header: 8 bytes, and inner tag: 4 bytes). Sometimes, the length may increase by 52 bytes (external Ethernet header: 14 bytes, two outer tags: 8 bytes, IP header: 20 bytes, GRE header: 8 bytes, and inner tag: 4 bytes) at most. Therefore, users need to increase the MTU of each interface to 1546 bytes at least. You can use the `mtu 1546` command to complete this configuration in interface configuration mode.

➤ GRE Header

- C: GRE checksum. L2GRE does not support GRE checksum. Its value is 0.
- R: It is not used currently. Its value is 0.
- K: A flag indicating whether GRE KEY exists. L2GRE uses GRE KEY to carry L2GRE VPN information. Set K to 1.
- S: indicates whether GRE serial number exists. L2GRE does not support serial number. S = 0.
- S: Strict source route check. L2GRE does not support it. Set it to 0.
- R: It is not used. Set it to 0.
- Flags: It is not used. Set it to 0.
- Version: Indicates the version. Set it to 0.
- Protocol Type: This protocol transmits Ethernet packets over the GRE. The corresponding protocol number is 0x6558.
- GRE KEY: KEY of the GRE.

▾ **GRE KEY Header**

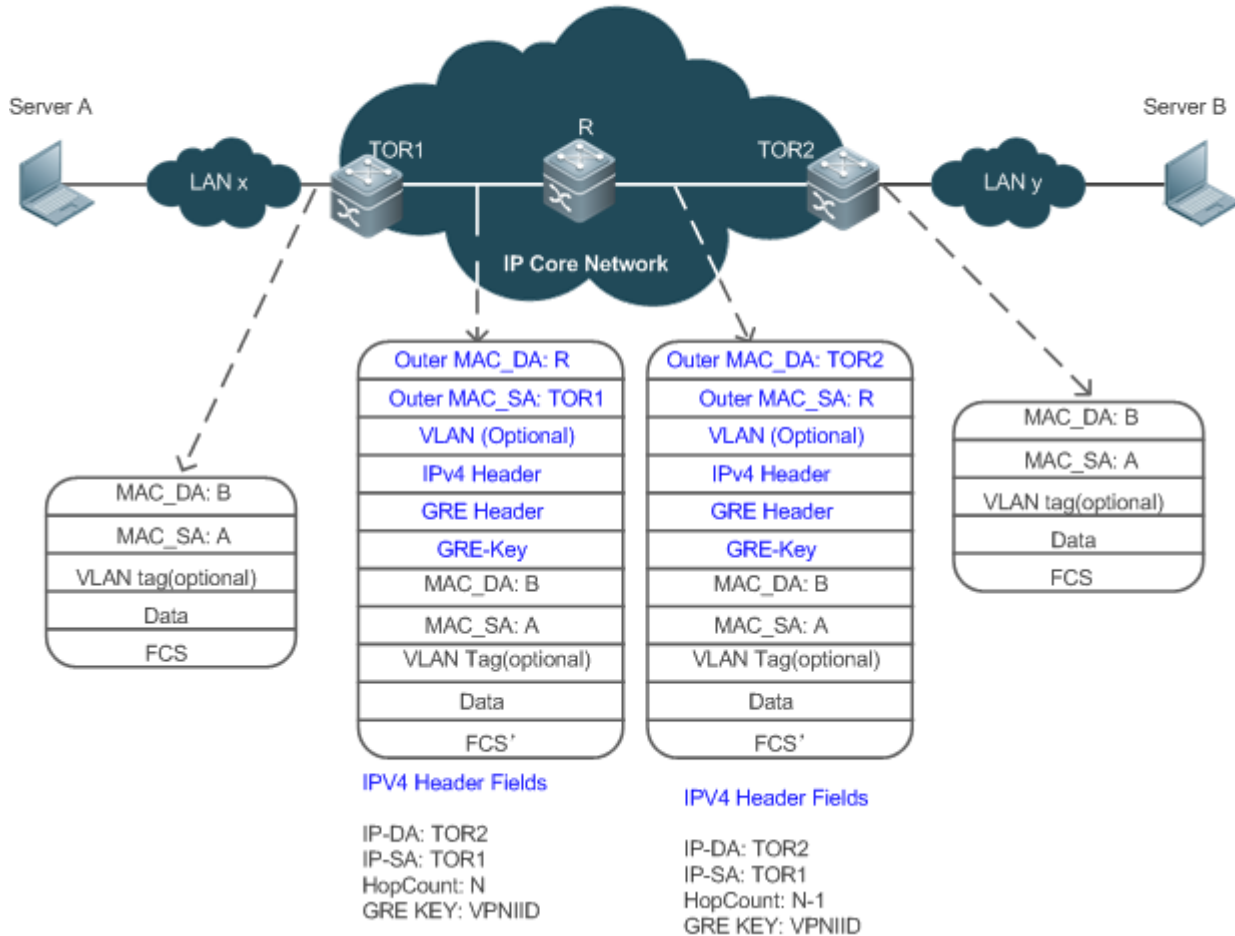

GRE Key (4 bytes)

- VPNID: 24 bits. It is used to mark the L2VPN instance information.
- Entropy: Stream ID. It is mainly used to implement load balancing of L2GRE packets. Currently, it is not supported.

▾ **L2GRE Forwarding Principles**

L2GRE encapsulates the Ethernet packets into GRE packets for transmission over the IP network. At the receiving end, L2GRE decapsulates the GRE packets into Ethernet packets for forwarding. See the following figure.

- After receiving Ethernet packets from the LAN x, switch TOR 1 encapsulates the Ethernet packets into L2GRE packets.
- L2GRE packets are forwarded in the IP core network, which is the same as the forwarding of GRE packets by router R shown in the preceding figure.
- After receiving the GRE packets, switch TOR2 decapsulates the packets and forwards them in the LAN.

Overview

Feature	Description
L2GRE LAN	A technology that enables layer 2 interconnection in virtual private Ethernet mode over the IP network
L2GRE LINE	A technology that enables layer 2 interconnection in point-to-point mode over the IP network

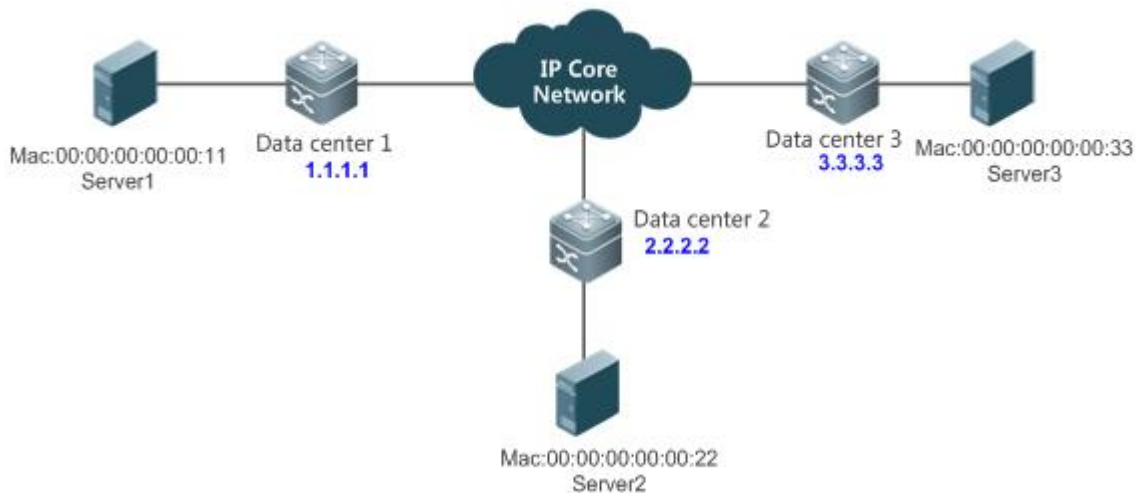

1.3.1 L2GRE LAN

L2GRE LAN is a technology that provides a virtual private Ethernet in the IP network.

Working Principle

As shown in Figure 1-4, three data centers are interconnected at layer 2 by L2GRE LAN over the IP core network. The L2GRE instance ID is 100.

Figure 1-4

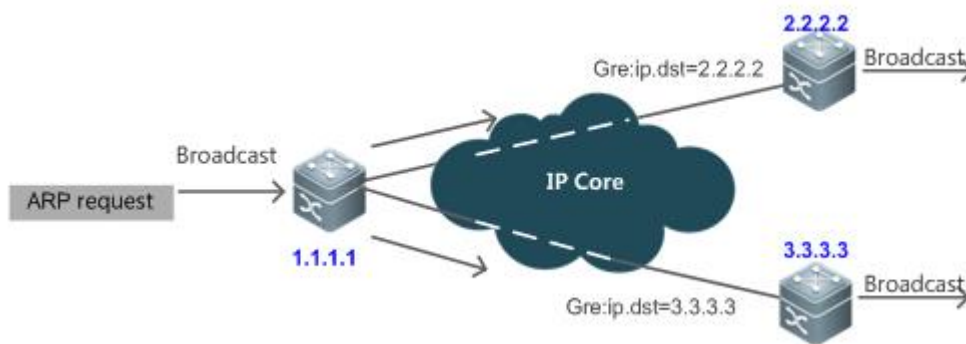

The following takes the process that Server 1 sends an ARP request to Server 2 and Server 2 replies to the request as an example to describe the L2GRE packet forwarding process.

1. Server 1 sends an ARP request. Switch 1 receives the ARP request broadcast packet, and then floods the packet to data centers 2 and 3. L2GRE supports two flooding modes, that is, unicast L2GRE packet flooding and multicast L2GRE packet flooding.
2. The L2GRE packet is forwarded through the IP core network.
3. After receiving the L2GRE packet encapsulated by switch 1, data center 3 decapsulates the packet into an Ethernet packet, learns an address (L2GRE ID: 100 MAC: 00:00:00:00:00:11 IP: 1.1.1.1) from the Ethernet packet, and forwards the packet.
4. After receiving the L2GRE packet encapsulated by switch 1, data center 2 decapsulates the packet into an Ethernet packet, learns an address (L2GRE ID: 100 MAC: 00:00:00:00:00:11 IP: 1.1.1.1) from the Ethernet packet, and forwards the packet. Server 2 receives the ARP request and replies to the request.
5. After receiving the ARP reply packet from server 2, data center 2 searches the address table and obtains the destination IP address of the egress interface 1.1.1.1. Then data center 2 encapsulates the packet into a unicast L2GRE packet destined for the switch with IP address 1.1.1.1. The packet is forwarded in L2GRE known unicast forwarding mode.
6. The L2GRE packet is forwarded through the IP core network.
7. After receiving the L2GRE packets with the ARP reply from server 2, data center 1 decapsulates the packets into Ethernet packets, learns an address (L2GRE ID: 100 MAC: 00:00:00:00:00:22 IP: 2.2.2.2) from the packets, and forwards the Ethernet packets. Finally, server 1 receives the ARP reply.

↳ Unicast L2GRE Packet Flooding

This mode floods the unicast L2GRE packet. After receiving the ARP request, data center 1 encapsulates the ARP request packet into the unicast L2GRE packets destined for data center 2 and data center 3 respectively. See Figure 1-5.

Figure 1-5

➤ Multicast L2GRE Packet Flooding

This mode floods multicast L2GRE packet. After receiving the ARP request, data center 1 encapsulates the ARP request packet into a multicast GRE packet and forwards the packet to data center 2 and data center 3 respectively. See Figure 1-6.

Figure 1-6

Related Configuration

➤ Configuring an L2GRE LAN Instance

By default, no L2GRE instance is configured in a switch.

Use the **l2gre instance name vpnid id type lan** command to create an L2GRE LAN instance.

➤ Configuring the Local Address of the L2GRE Instance

Use the **source** command in L2GRE instance configuration mode to configure the local address.

➤ Configuring the Peer Address of the L2GRE Instance

Use the **destination** command in L2GRE instance configuration mode to configure the peer address.

➤ Configuring an Allowed VLAN for the L2GRE Instance

Use the **extend-vlan** command in L2GRE instance configuration mode to configure the allowed VLAN for packet forwarding.

✚ [Configuring the Keepalive Function for the L2GRE Instance](#)

Use the **keepalive** command in L2GRE instance configuration mode to configure the keepalive function.

✚ [Enabling Multicast L2GRE Packet Flooding for the L2GRE LAN Instance](#)

Use the **multicast** command in L2GRE instance configuration mode to enable multicast L2GRE packet flooding.

Configure the TTL value used for L2GRE encapsulation in global configuration mode.

✚ [Configuring TTL of the L2GRE Packet](#)

Use the **l2gre ttl** command in global configuration mode to configure the TTL of the L2GRE packet.

✚ [Configuring L2GRE Broadcast Isolation](#)

Use the **broadcast disable** command in L2GRE instance configuration mode to isolate L2GRE broadcast.

1.3.2 L2GRE LINE

L2GRE LINE is an end-to-end layer 2 service bearing technology, it belongs to point-to-point L2VPN, and it provides IP network-based layer 2 VPN services.

Working Principle

As shown in Figure 1-7, two data centers are interconnected at layer 2 by L2GRE LINE over the IP core network. The L2GRE instance ID is 100.

Figure 1-7

The following takes the process that Server 1 sends an ARP request to Server 3 and Server 3 replies to the request as an example to describe the L2GRE packet forwarding process.

1. Server 1 sends an ARP request. Data center 1 receives the ARP request broadcast packet, encapsulates the packet into an L2GRE packet, and forwards the L2GRE packet to data center 3.
2. The L2GRE packet is forwarded through the IP core network.
3. After receiving the L2GRE packet encapsulated by data center 1, data center 3 decapsulates the packet into an Ethernet packet. Server 3 receives the ARP request and replies to the request.
4. After receiving the ARP reply packet from server 3, data center 3 encapsulates the packet into an L2GRE packet and forwards the packet to data center 1.
5. The L2GRE packet is forwarded through the IP core network.

6. After receiving the L2GRE packets with the ARP reply from server 2, data center 1 decapsulates the packets into Ethernet packets. Finally, server 1 receives the ARP reply.

Related Configuration

↘ Configuring an L2GRE LINE Instance

By default, no L2GRE instance is configured in a switch.

Use the **l2gre instance** *name* **vpnid** *id* **type** **line** to create an L2GRE LINE instance.

↘ Configuring the Local Address of the L2GRE Instance

Use the **source** command in L2GRE instance configuration mode to configure the local address.

↘ Configuring the Peer Address of the L2GRE Instance

Use the **destination** command in L2GRE instance configuration mode to configure the peer address.

↘ Configuring an Allowed VLAN for the L2GRE Instance

Use the **extend-vlan** command in L2GRE instance configuration mode to configure the allowed VLAN for packet forwarding.

↘ Configuring the Keepalive Function for the L2GRE Instance

Use the **keepalive** command in L2GRE instance configuration mode to configure the keepalive function.

↘ Configuring TTL of the L2GRE Packet

Use the **l2gre ttl** command in global configuration mode to configure the TTL of the L2GRE packet.

1.4 Configuration

Configuration	Description and Command
	 Mandatory configuration. Establish L2GRE service.
Configuring L2GRE Instance	l2gre instance <i>name</i> vpnid <i>id</i> type {lan line} Creates an L2GRE instance, or enter L2GRE LINE or L2GRE LAN configuration mode.
	source { <i>ip-address</i> interface <i>interface-number</i> } Configures the local address of the L2GRE instance.
	destination <i>ip-address</i> Configures the peer address of the L2GRE instance.
	extend-vlan <i>vlan-id</i> Configures an allowed VLAN for the L2GRE instance.
	 Optional configuration.
	multicast <i>ip-address</i> Enables the multicast L2GRE packet flooding function.

	keepalive [<i>seconds</i> [<i>retries</i>]]	Configures the keepalive function for the L2GRE tunnel.
	path-mtu-discovery	Enables path MTU discovery.
	broadcast disable	Enables broadcast isolation.
	arp-inhibition enable	Enables ARP flooding inhibition.

1.4.1 Configuring L2GRE Instance

Configuration Effect

- An L2GRE instance is created to provide IP core network-based layer 2 VPN services.
- Two types of L2GRE instance are available, that is, L2GRE LINE and L2GRE LAN. One instance belongs to only one type.

Notes

- L2GRE instances need the assistance of existing unicast routes in the network. Therefore, IPv4 unicast routes must be configured in the network.
- If the multicast GRE flooding mode of the L2GRE LAN is used, IGMPv3 needs to be configured as well.

Configuration Steps

↘ Creating an L2GRE Instance

- Mandatory configuration.

↘ Configuring the Local Address of the L2GRE Instance

- Mandatory configuration.
- Unless otherwise specified, the local address uses svi interface or router interface.

↘ Configuring the Peer Address of the L2GRE Instance

- Mandatory configuration.
- Only one peer address can be configured for the L2GRE LINE instance.
- At least one peer address needs to be configured for the L2GRE LAN instance.

↘ Configuring an Allowed VLAN for the L2GRE Instance

- Mandatory configuration.
- Only the VLAN included in the forwarding VLAN list of the L2GRE instance allows forwarding by the L2GRE instance.

Verification

Use the allowed VLAN in the L2GRE instance to send a packet through a port.

- Check whether other ports of this VLAN at the local end of the L2GRE instance can receive this packet.

- Check whether other ports of this VLAN at the peer end of the L2GRE instance can receive this packet.

Related Commands

↳ Creating or Accessing an L2GRE Instance

Command	l2gre instance <i>name</i> vpnid <i>id</i> type { lan line }
Parameter	<i>name</i> : L2GRE instance name
Description	vpnid <i>id</i> : VPN ID corresponding to the L2GRE instance type {lan line}: L2GRE instance type
Command Mode	Global configuration mode
Configuration Usage	-

↳ Configuring the Local Address of the L2GRE Instance

Command	source { <i>ip-address</i> interface <i>interface-number</i> }
Parameter	<i>ip address</i> : IP address
Description	interface <i>interface-number</i> : Interface name
Command Mode	L2GRE LINE configuration mode L2GRE LAN configuration mode
Configuration Usage	When you use the interface <i>interface-number</i> command, the interface can only be an SVI interface, routed port, or loopback interface.

↳ Configuring the Peer Address of the L2GRE Instance

Command	destination <i>ip-address</i>
Parameter	<i>ip-address</i> : IP address
Description	
Command Mode	L2GRE LINE configuration mode L2GRE LAN configuration mode
Configuration Usage	Up to one peer destination address can be configured for the L2GRE LINE instance. One or multiple peer destination addresses can be configured for the L2GRE LAN instance.

↳ Configuring an Allowed VLAN for the L2GRE Instance

Command	extend-vlan <i>vlan-id</i>
Parameter	<i>vlan-id</i> : The VLAN in the L2GRE instance for packet forwarding
Description	
Command Mode	L2GRE LINE configuration mode L2GRE LAN configuration mode
Configuration Usage	extend-vlan of different instances shall not conflict with each other, that is, different instances shall use different VLANs.

↳ Enabling the Multicast L2GRE Packet Flooding Function

Command	multicast <i>ip-address</i>
Parameter	<i>ip address</i> : multicast IP address
Description	
Command Mode	L2GRE LAN configuration mode
Configuration Usage	The multicast L2GRE packet flooding function can be used only after both the multicast IP and multicast GRE are enabled. This command is specific to the L2GRE LAN instance.

▾ Setting the TTL Used for L2GRE Encapsulation

Command	l2gre ttl <i>tll-value</i>
Parameter	<i>tll-value</i> : TTL value
Description	
Command Mode	Global configuration mode
Configuration Usage	-

▾ Configuring the Keepalive Function for the L2GRE Tunnel

Command	keepalive [<i>seconds</i> [<i>retries</i>]]
Parameter	<i>seconds</i> : Discovery interval. The default value is 30 seconds.
Description	<i>retries</i> : Retry times. If the peer end does not reply when the retry times are reached, timeout occurs. The default value is 3.
Command Mode	L2GRE LINE configuration mode L2GRE LAN configuration mode
Configuration Usage	-

▾ Enabling L2GRE Path MTU Discovery

Command	path-mtu-discovery [<i>age-timer seconds</i>]
Parameter	<i>seconds</i> : Discovery interval. The default value is 10 minutes.
Description	
Command Mode	L2GRE LINE configuration mode L2GRE LAN configuration mode
Configuration Usage	L2GRE encapsulates an L2GRE header for a packet. As a result, the length of the packet increases by about 46 bytes. You can enable path MTU discovery to implement quick discovery of L2GRE network exceptions caused by MTU problems of the carrier's IP core network.

▾ Enabling L2GRE Broadcast Isolation

Command	broadcast disable
Parameter	-

Description	
Command Mode	L2GRE LAN configuration mode
Configuration Usage	After broadcast isolation is enabled, unknown unicast packets will not be flooded to other sites. Quick aging of address table entries may make data stream become unknown unicast packets that cannot be flooded to other sites, resulting in network congestion. Therefore, after broadcast isolation is enabled, you need to adjust the aging time of the address table to be longer than that of the host ARP to prevent aging of the address table entries within a short time.

▾ Enabling L2GRE ARP Flooding Inhibition

Command	arp-inhibition enable
Parameter Description	-
Command Mode	L2GRE LAN configuration mode
Configuration Usage	When ARP flooding inhibition is enabled, after a packet is received from the L2GRE tunnel on the edge device and decapsulated, if this packet is an ARP reply packet, L2GRE ARP flooding inhibition entries are created locally based on this packet. Afterwards, when receiving an ARP request from the host at the local site, which requests for the hosts at other sites, the edge device preferentially conducts pickup based on the L2GRE ARP flooding inhibition entries. If no entry is available, the edge device floods the ARP request to the core network, reducing the number of ARP flooding times.

Configuration Examples

i The following describes only L2GRE-related configuration.

▾ L2GRE LINE Configuration Example

Scenario Figure 1-8	<p>The diagram illustrates a network topology for L2GRE configuration. At the top center is a cloud labeled 'IP CORE'. Two switches are connected to this core. The switch on the left is labeled 'Data center A' and has an interface 'Gi 1/1' with IP address '1.1.1.1' and another interface 'Gi 1/2' connected to a server labeled 'HOST-A'. The switch on the right is labeled 'Data center B' and has an interface 'Gi 1/1' with IP address '2.2.2.2' and another interface 'Gi 1/2' connected to a server labeled 'HOST-B'. The interface 'Gi 1/2' in Data center B is also labeled 'VLAN100'.</p>
Configuration Steps	<ul style="list-style-type: none"> Configure an IPv4 unicast routing protocol (for example, OSPF) on the switch to ensure that the unicast route is reachable. Omitted.

- Configure the VLAN on the switch.
- Create an L2GRE instance.
- Configure the local address of the L2GRE instance.
- Configure the peer address of the L2GRE instance.
- Configure an allowed VLAN for the L2GRE instance.
- Enable the keepalive function (optional).
- Configure the initial TTL of the L2GRE packet.

A

```
A# configure terminal

📌 L2GRE LAN Configuration Example

Scenario Figure 1-9	
-------------------------------	--

Configuration Steps

- Configure an IPv4 unicast routing protocol (for example, OSPF) on the switch to ensure that the unicast route is reachable. Omitted.
- Configure the VLAN on the switch.
- Create an L2GRE instance.
- Configure the local address of the L2GRE instance.
- Configure the peer address of the L2GRE instance.
- Configure an allowed VLAN for the L2GRE instance.
- Configure the keepalive function (optional).

A

```
A# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
A(config)# vlan 100
A(config-vlan)# exit
A(config)# interface GigabitEthernet 1/2

Network Management & Monitoring Configuration

1. Configuring SNMP
2. Configuring RMON
3. Configuring NTP
4. Configuring SNTP
5. Configuring SPAN-RSPAN
6. Configuring sFlow

1 Configuring SNMP

1.1 Overview

Simple Network Management Protocol (SNMP) became a network management standard RFC1157 in August 1988. At present, because many vendors support SNMP, SNMP has in fact become a network management standard and is applicable to the environment where systems of multiple vendors are interconnected. By using SNMP, the network administrator can implement basic functions such as information query for network nodes, network configuration, fault locating, capacity planning, and network monitoring and management.

📄 [SNMP Versions](#)

Currently, the following SNMP versions are supported:

- SNMPv1: The first official version of SNMP, which is defined in RFC1157.
- SNMPv2C: Community-based SNMPv2 management architecture, which is defined in RFC1901.
- SNMPv3: SNMPv3 provides the following security features by identifying and encrypting data.
 1. Ensuring that data is not tampered during transmission.
 2. Ensuring that data is transmitted from legal data sources.
 3. Encrypting packets and ensuring data confidentiality.

[Protocols and Standards](#)

- RFC 1157, Simple Network Management Protocol (SNMP)
- RFC 1901, Introduction to Community-based SNMPv2
- RFC 2578, Structure of Management Information Version 2 (SMIv2)
- RFC 2579, Textual Conventions for SMIv2
- RFC 3411, An Architecture for Describing Simple Network Management Protocol (SNMP) Management Frameworks
- RFC 3412, Message Processing and Dispatching for the Simple Network Management Protocol (SNMP)
- RFC 3413, Simple Network Management Protocol (SNMP) Applications
- RFC 3414, User-based Security Model (USM) for version 3 of the Simple Network Management Protocol (SNMPv3)
- RFC 3415, View-based Access Control Model (VACM) for the Simple Network Management Protocol (SNMP)
- RFC 3416, Version 2 of the Protocol Operations for the Simple Network Management Protocol (SNMP)
- RFC 3417, Transport Mappings for the Simple Network Management Protocol (SNMP)
- RFC 3418, Management Information Base (MIB) for the Simple Network Management Protocol (SNMP)
- RFC 3419, Textual Conventions for Transport Addresses

1.2 Applications

Application	Description
Managing Network Devices Based on SNMP	Network devices are managed and monitored based on SNMP.

1.2.1 Managing Network Devices Based on SNMP

Scenario

Take the following figure as an example. Network device A is managed and monitored based on SNMP network manager.

Figure 1-1

Remarks	A is a network device that needs to be managed. PC is a network management station.
----------------	--

Deployment

The network management station is connected to the managed network devices. On the network management station, users access the Management Information Base (MIB) on the network devices through the SNMP network manager and receive messages actively sent by the network devices to manage and monitor the network devices.

1.3 Features

Basic Concepts

SNMP is an application layer protocol that works in C/S mode. It consists of three parts:

- SNMP network manager
- SNMP agent
- MIB

Figure 1-2 shows the relationship between the network management system (NMS) and the network management agent.

SNMP Network Manager

The SNMP network manager is a system that controls and monitors the network based on SNMP and is also called the NMS.

SNMP Agent

The SNMP agent (hereinafter referred to as the agent) is software running on the managed devices. It is responsible for receiving, processing, and responding to monitoring and control packets from the NMS. The agent may also actively send messages to the NMS.

MIB

The MIB is a virtual network management information base. The managed network devices contain lots of information. To uniquely identify a specific management unit among SNMP packets, the MIB adopts the tree hierarchical structure. Nodes in the tree indicate specific management units. A string of digits may be used to uniquely identify a management unit system among network devices. The MIB is a collection of unit identifiers of network devices.

Figure 1-3 Tree Hierarchical Structure

↳ **Operation Types**

Six operation types are defined for information exchange between the NMS and the agent based on SNMP:

- Get-request: The NMS extracts one or more parameter values from the agent.
- Get-next-request: The NMS extracts the parameter value next to one or more parameters from the agent.
- Get-bulk: The NMS extracts a batch of parameter values from the agent.
- Set-request: The NMS sets one or more parameter values of the agent.
- Get-response: The agent returns one or more parameter values, which are the operations in response to the three operations performed by the agent on the NMS.
- Trap: The agent actively sends a message to notify the NMS of something that happens.

The first four packets are sent by the NMS to the agent and the last two packets are sent by the agent to the NMS. (Note: SNMPv1 does not support the Get-bulk operation.) Figure 1-4 describes the operations.

Figure 1-4 SNMP Packet Types

The three operations performed by the NMS on the agent and the response operations of the agent are based on UDP port 161. The trap operation performed by the agent is based on UDP port 162.

Overview

Feature	Description
Basic SNMP Functions	The SNMP agent is configured on network devices to implement basic functions such as information query for network nodes, network configuration, fault locating, and capacity planning.
SNMPv1 and SNMPv2C	SNMPv1 and SNMPv2C adopt the community-based security architecture, including authentication name and access permission.
SNMPv3	SNMPv3 redefines the SNMP architecture, namely, it enhances security functions, including the security model based on users and access control model based on views. The SNMPv3 architecture already includes all functions of SNMPv1 and SNMPv2C.

1.3.1 Basic SNMP Functions

Working Principle

Working Process

SNMP protocol interaction is response interaction (for exchange of packets, see Figure 1-4). The NMS actively sends requests to the agent, including Get-request, Get-next-request, Get-bulk, and Set-request. The agent receives the requests, completes operations, and returns a Get-response. Sometimes, the agent actively sends a trap message and an Inform message to the NMS. The NMS does not need to respond to the trap message but needs to return an Inform-response to the agent. Otherwise, the agent re-sends the Inform message.

Related Configuration

Shielding or Disabling the SNMP Agent

By default, the SNMP function is enabled.

The **no snmp-server** command is used to disable the SNMP agent.

The **no enable service snmp-agent** command is used to directly disable all SNMP services.

Setting Basic SNMP Parameters

By default, the system contact mode, system location, and device Network Element (NE) information are empty. The default serial number is 60FF60, the default maximum packet length is 1,572 bytes, and the default UDP port ID of the SNMP service is 161.

The **snmp-server contact** command is used to configure or delete the system contact mode.

The **snmp-server location** command is used to configure or delete the system location.

The **snmp-server chassis-id** command is used to configure the system serial number or restore the default value.

The **snmp-server packetsize** command is used to configure the maximum packet length of the agent or restore the default value.

The **snmp-server net-id** command is used to configure or delete the device NE information.

The **snmp-server udp-port** command is used to set the UDP port ID of the SNMP service or restore the default value.

Configuring the SNMP Host Address

By default, no SNMP host is configured.

The **snmp-server host** command is used to configure the NMS host address to which the agent actively sends messages or to delete the specified SNMP host address. In the messages sent to the host, the SNMP version, receiving port, authentication name, or user can be bound. This command is used with the **snmp-server enable traps** command to actively send trap messages to the NMS.

Setting Trap Message Parameters

By default, SNMP is not allowed to actively send a trap message to the NMS, the function of sending a Link Trap message on an interface is enabled, the function of sending a system reboot trap message is disabled, and a trap message does not carry any private field.

By default, the IP address of the interface where SNMP packets are sent is used as the source address.

By default, the length of a trap message queue is 10 and the interval for sending a trap message is 30s.

The **snmp-server enable traps** command is used to enable or disable the agent to actively send a trap message to the NMS.

The **snmp trap link-status** command is used to enable or disable the function of sending a Link Trap message on an interface.

The **snmp-server trap-source** command is used to specify the source address for sending messages or to restore the default value.

The **snmp-server queue-length** command is used to set the length of a trap message queue or to restore the default value.

The **snmp-server trap-timeout** command is used to set the interval for sending a trap message or to restore the default value.

The **snmp-server trap-format private** command is used to set or disable the function of carrying private fields in a trap message when the message is sent.

The **snmp-server system-shutdown** command is used to enable or disable the function of sending a system reboot trap message.

📌 Setting the SNMP Attack Protection and Detection Function

By default, the SNMP attack protection and detection function is disabled.

The **snmp-server authentication attempt *times* exceed { lock | lock-time *minutes* | unlock }** command is used to set and enable the attack protection and detection function.

📌 Setting Password Dictionary Check for Communities and Users

By default, password dictionary check for communities and users is disabled.

The **snmp-server enable secret-dictionary-check** command is used to enable password dictionary check for SNMP communities and users. This command is used with the **password policy** command.

📌 Setting the SNMP Logging Function to Record the Get, Get-Next, and Set Operations Performed by the NMS on the SNMP Agent

By default, SNMP logging is disabled.

The **snmp-server logging { get-operation | set-operation }** command is used to enable the function of recording the Get and Set operations. **get-operation** controls the Get and Get-Next operations records, and **set-operation** controls the Set operation records.

📌 Configuring the Heartbeat Trap Function and Interval

By default, the heartbeat trap function is enabled and heartbeat trap messages are sent at the interval of 5 minutes.

Run the **no snmp-server heartbeat on** command to disable the heartbeat trap function.

Run the **snmp-server heartbeat period** to configure the interval for sending heartbeat trap messages.

1.3.2 SNMPv1 and SNMPv2C

SNMPv1 and SNMPv2C adopt the community-based security architecture. The administrator who can perform operations on the MIB of the agent is limited by defining the host address and authentication name (community string).

Working Principle

SNMPv1 and SNMPv2 determine whether the administrator has the right to use MIB objects by using the authentication name. The authentication name of the NMS must be the same as an authentication name defined in devices.

SNMPv2C adds the Get-bulk operation mechanism and can return more detailed error message types to the management workstation. The Get-bulk operation is performed to obtain all information from a table or obtain lots of data at a time, so as to reduce the number of request responses. The enhanced error handling capabilities of SNMPv2C include extension of error codes to differentiate error types. In SNMPv1, however, only one error code is provided for errors. Now, errors can be differentiated based on error codes. Because management workstations supporting SNMPv1 and SNMPv2C may exist on the network, the SNMP agent must be able to identify SNMPv1 and SNMPv2C packets and return packets of the corresponding versions.

↳ Security

One authentication name has the following attributes:

- Read-only: Provides the read permission of all MIB variables for authorized management workstations.
- Read-write: Provide the read/write permission of all MIB variables for authorized management workstations.

Related Configuration

↳ Setting Authentication Names and Access Permissions

The default access permission of all authentication names is read-only.

The **snmp-server community** command is used to configure or delete an authentication name and access permission.

This command is the first important command for enabling the SNMP agent function. It specifies community attributes and NMS scope where access to the MIB is allowed.

1.3.3 SNMPv3

SNMPv3 redefines the SNMP architecture and includes functions of SNMPv1 and SNMPv2 into the SNMPv3 system.

Working Principle

The NMS and SNMP agent are SNMP entities. In the SNMPv3 architecture, SNMP entities consist of the SNMP engine and SNMP applications. The SNMP engine is used to send and receive messages, identify and encrypt information, and control

access to managed objects. SNMP applications refer to internal applications of SNMP, which work by using the services provided by the SNMP engine.

SNMPv3v determines whether a user has the right to use MIB objects by using the User-based Security Model (USM). The security level of the NMS user must be the same as that of an SNMP user defined in devices so as to manage devices.

SNMPv3 requires the NMS to obtain the SNMP agent engine IDs on devices when the NMS manages devices. SNMPv3 defines the discover and report operation mechanisms. When the NMS does not know agent engine IDs, the NMS may first send a discover message to the agent and the agent returns a report message carrying an engine ID. Later, management operations between the NMS and the agent must carry the engine ID.

↳ Security

- SNMPv3 determines the data security mechanism based on the security model and security level. At present, security models include: SNMPv1, SNMPv2C, and SNMPv3. SNMPv3 includes SNMPv1 and SNMPv2C into the security model.

SNMPv1 and SNMPv2C Security Models and Security Levels

Security Model	Security Level	Authentication	Encryption	Description
SNMPv1	noAuthNoPriv	Authentication name	N/A	Data validity is confirmed through authentication name.
SNMPv2c	noAuthNoPriv	Authentication name	N/A	Data validity is confirmed through authentication name.

SNMPv3 Security Model and Security Level

Security Model	Security Level	Authentication	Encryption	Description
SNMPv3	noAuthNoPriv	User name.	N/A	Data validity is confirmed through user name.
SNMPv3	authNoPriv	MD5 or SHA	N/A	The data authentication mechanism based on HMAC-MD5 or HMAC-SHA is provided.
SNMPv3	authPriv	MD5 or SHA	DES	The data authentication mechanism based on HMAC-MD5 or HMAC-SHA and data encryption mechanism based on CBC-DES are provided.

↳ Engine ID

An engine ID is used to uniquely identify an SNMP engine. Because each SNMP entity includes only one SNMP engine, one SNMP engine uniquely identifies an SNMP entity in a management domain. Therefore, the SNMPv3 agent as an entity must has a unique engine ID, that is, SnpEngineID.

An engine ID is an octet string that consists of 5 to 32 bytes. RFC3411 defines the format of an engine ID:

- The first four bytes indicate the private enterprise ID (allocated by IANA) of a vendor, which is expressed in hexadecimal.
- The fifth byte indicates remaining bytes:
- 0: Reserved.

- 1: The later four bytes indicate an IPv4 address.
- 2: The later 16 bytes indicate an IPv6 address.
- 3: The later six bytes indicate a MAC address.
- 4: Text consisting of 27 bytes, which is defined by the vendor.
- 5: Hexadecimal value consisting of 27 bytes, which is defined by the vendor.
- 6-127: Reserved.
- 128-255: Formats specified by the vendor.

Related Configuration

▾ [Configuring an MIB View and a Group](#)

By default, one view is configured and all MIB objects can be accessed.

By default, no user group is configured.

The **snmp-server view** command is used to configure or delete a view and the **snmp-server group** command is used to configure or delete a user group.

One or more instructions can be configured to specify different community names so that network devices can be managed by NMSs of different permissions.

▾ [Configuring an SNMP User](#)

By default, no user is configured.

The **snmp-server user** command is used to configure or delete a user.

The NMS can communicate with the agent by using only legal users.

An SNMPv3 user can specify the security level (whether authentication and encryption are required), authentication algorithm (MD5 or SHA), authentication password, encryption password (only DES is available currently), and encryption password.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic SNMP Functions	 (Mandatory) It is used to enable users to access the agent through the NMS.	
	enable service snmp-agent	Enables the agent function.
	snmp-server community	Sets an authentication name and access permission.
	snmp-server user	Configures an SNMP user.
	snmp-server view	Configures an SNMP view.
	snmp-server group	Configures an SNMP user group.

Configuration	Description and Command	
	snmp-server authentication	Configures the SNMP attack protection and detection function.
	snmp-server enable secret-dictionary-check	Configures password dictionary check for communities and users.
Enabling the Trap Function	 (Optional) It is used to enable the agent to actively send a trap message to the NMS.	
	snmp-server host	Configures the NMS host address.
	snmp-server enable traps	Enables the agent to actively send a trap message to the NMS.
	snmp trap link-status	Enables the function of sending a Link Trap message on an interface.
	snmp-server system-shutdown	Enables the function of sending a system reboot trap message.
	snmp-server trap-source	Specifies the source address for sending a trap message.
	snmp-server trap-format private	Enables a trap message to carry private fields when the message is sent.
	snmp-server heartbeat	Configures the heartbeat trap function and interval.
Shielding the Agent Function	 (Optional) It is used to shield the agent function when the agent service is not required.	
	no snmp-server	Shields the agent function.
Setting SNMP Control Parameters	 (Optional) It is used to set or modify SNMP control parameters.	
	snmp-server contact	Sets the device contact mode.
	snmp-server location	Sets the device location.
	snmp-server logging	Sets the logging function.
	snmp-server chassis-id	Sets the serial number of the device.
	snmp-server net-id	Sets NE information about the device.
	snmp-server packet-size	Modifies the maximum packet length.
	snmp-server udp-port	Modifies the UDP port ID of the SNMP service.
	snmp-server queue-length	Modifies the length of a trap message queue.
snmp-server trap-timeout	Modifies the interval for sending a trap message.	

1.4.1 Configuring Basic SNMP Functions

Configuration Effect

Enable users to access the agent through the NMS.

Notes

- By default, no authentication name is set on network devices and SNMPv1 or SNMPv2C cannot be used to access the MIB of network devices. When an authentication name is set, if no access permission is specified, the default access permission is read-only.

Configuration Steps

↳ Configuring an SNMP View

- Optional
- An SNMP view needs to be configured when the View-based Access Control Model (VACM) is used.

↳ Configuring an SNMP User Group

- Optional
- An SNMP user group needs to be configured when the VACM is used.

↳ Configuring an Authentication Name and Access Permission

- Mandatory
- An authentication name must be set on the agent when SNMPv1 and SNMPv2C are used to manage network devices.

↳ Configuring an SNMP User

- Mandatory
- A user must be set when SNMPv3 is used to manage network devices.

↳ Enabling the Agent Function

- Optional
- By default, the agent function is enabled. When the agent function needs to be enabled again after it is disabled, this command must be used.

↳ Enabling the SNMP Attack Protection and Detection Function

- Optional
- By default, the SNMP attack protection and detection function is disabled. When malicious attacks need to be prevented, the configuration item must be used on the agent.

↳ Setting Password Dictionary Check for Communities and Users

- Optional
- By default, password dictionary check is not performed for communities and users. If community names and user names are too simple and are easily cracked, enable password dictionary check for communities and users. The configuration must be used with the **password policy** command.

➤ Setting the SNMP Logging Function to Record the Get, Get-Next, and Set Operations Performed by the NMS on the SNMP Agent

- Optional
- The SNMP logging function is used to record the Get, Get-Next, and Set Operations performed by the NMS on the SNMP agent. When the Get and Get-Next operations are performed, the agent records the IP address of the NMS user, operation type, and OID of the operation node. When the Set operation is performed, the agent records the IP address of the NMS user, operation type, OID of the operation node, and set value. These logs are sent to the information center of devices. The level of these logs is informational, that is, the logs are used as prompt information of devices.

Verification

Run the **show snmp** command to check the SNMP function on devices.

Related Commands

➤ Configuring an SNMP View

Command	snmp-server view <i>view-name</i> <i>oid-tree</i> { include exclude }
Parameter	<i>view-name</i> : View name
Description	<i>oid-tree</i> : MIB objects associated with a view, which are displayed as an MIB subtree. include : Indicates that the MIB object subtree is included in the view. exclude : Indicates that the MIB object subtree is not included in the view.
Command Mode	Global configuration mode
Usage Guide	Specify a view name and use it for view-based management.

➤ Configuring an SNMP User Group

Command	snmp-server group <i>groupname</i> { v1 v2c v3 { auth noauth priv } } [read <i>readview</i>] [write <i>writeview</i>] [access { ipv6 <i>ipv6-aclname</i> <i>aclnum</i> <i>aclname</i> }]
Parameter	v1 v2c v3 : Specifies the SNMP version.
Description	auth : Messages sent by users in the group need to be verified but data confidentiality is not required. This configuration is valid for SNMPv3 only. noauth : Messages sent by users in the group do not need to be verified and data confidentiality is not required. This configuration is valid for SNMPv3 only. priv : Messages sent by users in the group need to be verified and confidentiality of transmitted data is required. This configuration is valid for SNMPv3 only. <i>readview</i> : Associates one read-only view. <i>writeview</i> : Associates one read/write view. <i>aclnum</i> : ACL number. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified. <i>aclname</i> : ACL name. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified.

	<i>ipv6-aclname</i> : IPv6 ACL name. The specified ACL is associated and the range of IPv6 NMS addresses from which access to the MIB is allowed is specified.
Command Mode	Global configuration mode
Usage Guide	Associate certain users with a group and associate the group with a view. Users in a group have the same access permission. In this way, you can determine whether managed objects associated with an operation are in the allowable range of a view. Only managed objects in the range of a view can be accessed.

📌 Configuring an Authentication Name and Access Permission

Command	snmp-server community [0 7] <i>string</i> [view <i>view-name</i>] [[ro rw] [host <i>ipaddr</i>]] [ipv6 <i>ipv6-aclname</i>] [<i>aclnum</i> <i>aclname</i>]
Parameter Description	<p>0: Indicates that the input community string is a plaintext string.</p> <p>7: Indicates that the input community string is a ciphertext string.</p> <p><i>string</i>: Community string, which is equivalent to the communication password between the NMS and the SNMP agent.</p> <p><i>view-name</i>: Specifies a view name for view-based management.</p> <p>ro: Indicates that the NMS can only read variables of the MIB.</p> <p>rw: The NMS can read and write variables of the MIB.</p> <p><i>aclnum</i>: ACL number. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified.</p> <p><i>aclname</i>: ACL name. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified.</p> <p><i>ipv6-aclname</i>: ACL name. The specified ACL is associated and the range of IPv6 NMS addresses from which access to the MIB is allowed is specified.</p> <p><i>ipaddr</i>: Associates NMS addresses and specifies NMS addresses for accessing the MIB.</p>
Command Mode	Global configuration mode
Usage Guide	<p>This command is the first important command for enabling the SNMP agent function. It specifies community attributes and NMS scope where access to the MIB is allowed.</p> <p>To disable the SNMP agent function, run the no snmp-server command.</p>

📌 Configuring an SNMP User

Command	snmp-server user <i>username</i> <i>groupname</i> { v1 v2c v3 [encrypted] [auth { md5 sha } <i>auth-password</i>] [priv des56 <i>priv-password</i>] } [access { ipv6 <i>ipv6-aclname</i> <i>aclnum</i> <i>aclname</i> }]
Parameter Description	<p><i>username</i>: User name.</p> <p><i>groupname</i>: Specifies the group name for a user.</p> <p>v1 v2c v3: Specifies the SNMP version. Only SNMPv3 supports later security parameters.</p> <p>encrypted: The specified password input mode is ciphertext input. Otherwise, plaintext is used for input. If ciphertext input is selected, enter a key consisting of continuous hexadecimal digits. An MD5 protocol authentication key consists of 16 bytes and an SHA authentication protocol key consists of 20 bytes. Two characters stand for one byte. Encrypted keys are valid for this engine only.</p>

	<p>auth: Specifies whether authentication is used.</p> <p>md5: Specifies the MD5 authentication protocol. sha specifies the SHA authentication protocol.</p> <p><i>auth-password:</i> Configures a password string (not more than 32 characters) used by the authentication protocol. The system converts the passwords into the corresponding authentication keys.</p> <p>priv: Specifies whether confidentiality is used. des56 specifies the use of the 56-bit DES encryption protocol.</p> <p><i>priv-password:</i> Configures a password string (not more than 32 characters) used for encryption. The system converts the password into the corresponding encryption key.</p> <p><i>aclnum:</i> ACL number. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified.</p> <p><i>aclname:</i> ACL name. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified.</p> <p><i>ipv6-aclname:</i> IPv6 ACL name. The specified ACL is associated and the range of IPv6 NMS addresses from which access to the MIB is allowed is specified.</p>
Command Mode	Global configuration mode
Usage Guide	Configure user information so that the NMS can communicate with the agent by using a valid user. For an SNMPv3 user, you can specify the security level, authentication algorithm (MD5 or SHA), authentication password, encryption algorithm (at present, only DES is available), and encryption password.

▾ **Enabling the Agent Function**

Command	enable service snmp-agent
Parameter Description	
Configuration mode	Privileged mode.
Usage Guide	This command is used to enable the SNMP agent function of a device.

▾ **Enabling the SNMP Attack Protection and Detection Function**

Command	snmp-server authentication attempt <i>times</i> exceed { lock lock-time <i>minutes</i> unlock }
Parameter Description	<p><i>times:</i> Number of continuous failed attempts.</p> <p>lock: After continuous authentication fails, the source IP address is permanently forbidden to initiate authentication for access. The administrator needs to manually unlock the IP address.</p> <p>lock-time <i>minutes</i>: After continuous authentication fails, the source IP address is forbidden to initiate authentication for access in a period of time. Beyond the period, the source IP address can be authenticated for access again.</p> <p>unlock: After continuous authentication fails, the source IP address is allowed to access the MIB continuously, which is equivalent to the fact that the SNMP attack protection and detection function is not configured.</p>
Command Mode	Global configuration mode

Usage Guide	<p>Configure the SNMP attack protection and detection function so that the corresponding measure can be taken after continuous authentication fails.</p> <p>The permanently forbidden source IP addresses can be authenticated for access again only after the administrator manually unlocks the IP addresses.</p> <p>The source IP address that are forbidden to access the MIB in a period of time can be authenticated for access again after the period expires or after the administrator manually unlocks the IP addresses.</p>
--------------------	--

📌 Setting Password Dictionary Check for Communities and Users

Command	snmp-server enable secret-dictionary-check
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	<p>This command must be used with the password policy command to set check rules, for example, the password must consist of not less than six characters.</p> <p>To disable password dictionary check, run the no snmp-server enable secret-dictionary-check command.</p>

📌 Setting the SNMP Logging Function to Record the Get, Get-Next, and Set Operations Performed by the NMS on the SNMP Agent

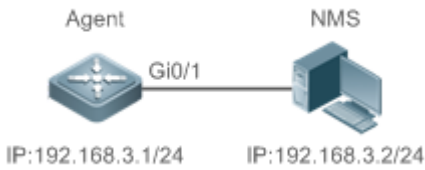

Command	snmp-server logging { get-operation set-operation }
Parameter Description	<p>get-operation: Enables the logging of Get and Get-Next operations.</p> <p>set-operation: Enables the logging of the Set operation.</p>
Command Mode	Global configuration mode
Usage Guide	<p>This command is used to record the Get, Get-Next, and Set operations performed by the NMS on the SNMP agent. When the Get and Get-Next operations are performed, the agent records the IP address of the NMS user, operation type, and OID of the operation node. When the Set operation is performed, the agent records the IP address of the NMS user, operation type, OID of the operation node, and set value.</p> <p> A large number of logs will affect device performance. In normal conditions, you are advised to disable the SNMP logging function. Exercise caution when using the GET operation logging function; otherwise, spamming may occur due to a large number of requests.</p>

📌 Displaying the SNMP Status Information

Command	show snmp [mib user view group host locked-ip process-mib-time]
Parameter Description	<p>mib: Displays information about the SNMP MIB supported in the system.</p> <p>user: Displays information about an SNMP user.</p> <p>view: Displays information about an SNMP view.</p> <p>group: Displays information about an SNMP user group.</p> <p>host: Displays information about user configuration.</p>

	<p>locked-ip: Source IP address that is locked after continuous authentication fails.</p> <p>process-mib-time: Displays the MIB node with the longest processing time.</p>
Configuration mode	Privileged mode.
Usage Guide	N/A

📄 Configuration Example Configuring SNMP v1/2c

<p>Scenario Figure 1-5</p>	<div style="text-align: center;">  </div> <ul style="list-style-type: none"> ● The NMS is connected to an agent through the Ethernet. The IP address of the agent is 192.168.3.1/24, and the IP address of the NMS is 192.168.3.2/24. ● The NMS monitors and manages the agent through SNMP v1 or SNMP v2c.
	<ul style="list-style-type: none"> ● When the agent is faulty or an error occurs, the agent can actively report the related information to the NMS.
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure the SNMP basic information, including the version and community name. ● Allow the NMS (192.168.3.2/24) to send Trap messages. ● Configure the IP address of the agent, and set the IP address of the Gi0/1 interface to 192.168.3.1/24.
<p>Agent</p>	<pre>Ruijie(config)#snmp-server community public rw Ruijie(config)#snmp-server host 192.168.3.2 traps version 2c public Ruijie(config)#snmp-server enable traps Ruijie(config)#interface gigabitEthernet 0/1 Ruijie(config-if-gigabitEthernet 0/1)#ip address 192.168.3.1 255.255.255.0 Ruijie(config-if-gigabitEthernet 0/1)#exit</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● Run the show running-config command to display configuration information of the device. ● Run the show snmp host command to display the host information configured by the user.
<p>NMS</p>	<p>On the NMS that uses the SNMP v1/v2c, configure the read/write community name, timeout time, and retry times. You can use the NMS to query and configure the device.</p> <hr/> <p>⚠️ Configurations on the NMS must be consistent with those on the device; otherwise, related operations cannot be performed.</p>

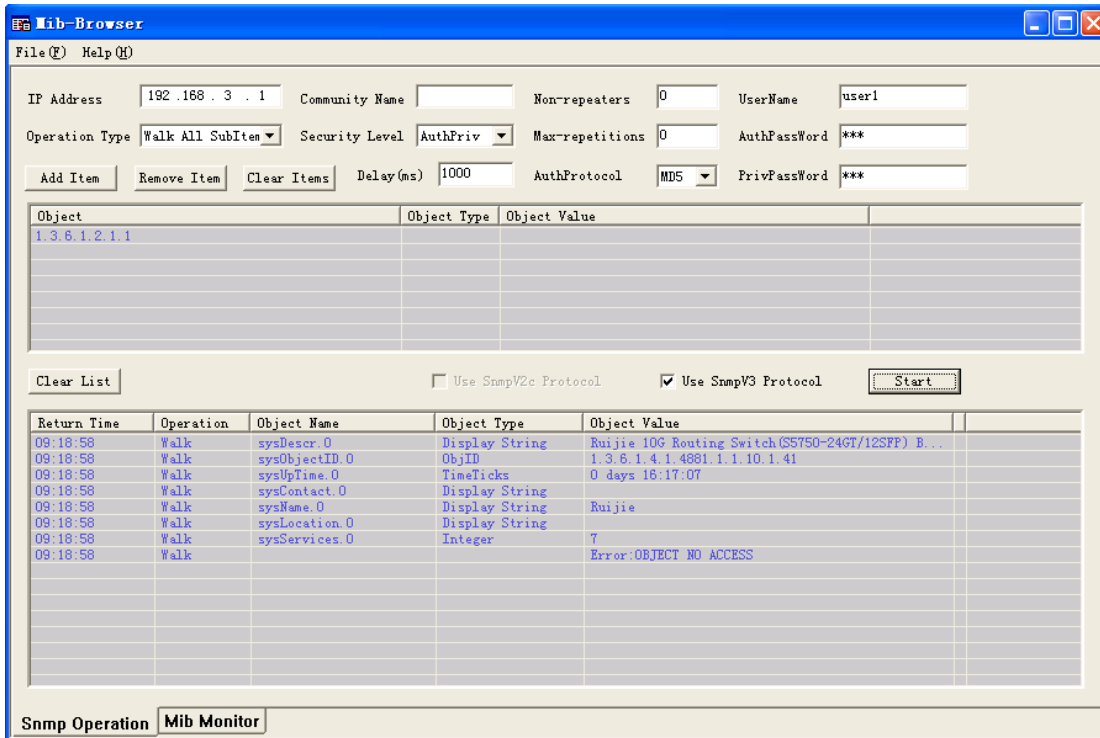

📄 Configuring SNMP v3 (Default View)

<p>Scenario Figure 1-6</p>	<div data-bbox="342 233 764 401" data-label="Diagram"> </div> <ul style="list-style-type: none"> ● The NMS manages network devices (agents) based on the user authentication and encryption mode, for example, the NMS uses user1 as the user name, MD5 as the authentication mode, 123 as the authentication password, DES56 as the encryption algorithm, and 321 as the encryption password. ● You can access all MIB nodes. ("read default write default" indicates that all MIB nodes can be accessed.) ● Network devices can actively send authentication and encryption messages to the NMS.
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure an MIB group. Create a group "g1", select the version "v3", set the security level to the authentication and encryption mode "priv", and configure permissions to read and write the view "default". "Default" indicates that all MIB nodes can be accessed. ● Configure an SNMP user. Create a user named "user1" under group "g1", select "v3" as the version, and set the authentication mode to "md5", authentication password to "123", encryption mode to "DES56", and encryption password to "321". ● Configure the SNMP host address. Set the host address to 192.168.3.2, select "3" as the version, set the security level to the authentication and encryption mode "priv", and associate the user name "user1". Enable the agent to actively send a trap message to the NMS. ● Configure the IP address of the agent. Set the address of the Gi0/1 interface to 192.168.3.1/24.
<p>Agent</p>	<pre style="background-color: #f0f0f0; padding: 10px;"> Ruijie(config)#snmp-server group g1 v3 priv read default write default Ruijie(config)#snmp-server user user1 g1 v3 auth md5 123 priv des56 321 Ruijie(config)#snmp-server host 192.168.3.2 traps version 3 priv user1 Ruijie(config)#snmp-server enable traps Ruijie(config)#interface gigabitEthernet 0/1 Ruijie(config-if-gigabitEthernet 0/1)#ip address 192.168.3.1 255.255.255.0 Ruijie(config-if-gigabitEthernet 0/1)#exit </pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● Run the show running-config command to display configuration information of the device. ● Run the show snmp user command to display the SNMP user. ● Run the show snmp view command to display the SNMP view. ● Run the show snmp group command to display the SNMP group. ● Run the show snmp host command to display the host information configured by the user. ● Install MIB-Browser.

NMS

SNMP v3 adopts the authentication and encryption security mechanisms. On the NMS, configure the user name, and select a security level. Based on the selected security level, configure the authentication mode, authentication password, encryption mode, and encryption password. In addition, configure the timeout time and retry times. You can use the NMS to query and configure the device. For details about the configuration, see the following figure.

 Configurations on the NMS must be consistent with those on the device; otherwise, related operations cannot be performed.

Configuring SNMPv3 Configuration (Specified View)

Scenario
Figure 1-7

- The NMS manages network devices (agents) based on the user authentication and encryption mode, for example, the NMS uses user1 as the user name, MD5 as the authentication mode, 123 as the authentication password, DES56 as the encryption algorithm, and 321 as the encryption password.
- Network devices can control the operation permission of users to access MIB objects. For example, the user named user1 can read MIB objects under the system node (1.3.6.1.2.1.1) and can only write

	<p>MIB objects under the SysContact node (1.3.6.1.2.1.1.4.0).</p> <ul style="list-style-type: none"> ● Network devices can actively send authentication and encryption messages to the NMS.
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure a MIB view and a MIB group. Create a MIB view “view1”, which includes the associated MIB object (1.3.6.1.2.1.1); then create a MIB view “view2”, which includes the associated MIB object (1.3.6.1.2.1.1.4.0). Create a group “g1”, select the version “v3”, set the security level to the authentication and encryption mode “priv”, and configure permissions to read the view “view1” and write the view “view2”. ● Configure an SNMP user. Create a user named “user1” under group “g1”, select “v3” as the version, and set the authentication mode to “md5”, authentication password to “123”, encryption mode to “DES56”, and encryption password to “321”. ● Configure the SNMP host address. Set the host address to 192.168.3.2, select “3” as the version, set the security level to the authentication and encryption mode “priv”, and associate the user name “user1”. Enable the agent to actively send a trap message to the NMS. ● Set the IP address of the agent. Set the address of the Gi0/1 interface to 192.168.3.1/24.
<p>Agent</p>	<pre>Ruijie(config)#snmp-server view view1 1.3.6.1.2.1.1 include Ruijie(config)#snmp-server view view2 1.3.6.1.2.1.1.4.0 include Ruijie(config)#snmp-server group g1 v3 priv read view1 write view2 Ruijie(config)#snmp-server user user1 g1 v3 auth md5 123 priv des56 321 Ruijie(config)#snmp-server host 192.168.3.2 traps version 3 priv user1 Ruijie(config)#snmp-server enable traps Ruijie(config)#interface gigabitEthernet 0/1 Ruijie(config-if-gigabitEthernet 0/1)#ip address 192.168.3.1 255.255.255.0 Ruijie(config-if-gigabitEthernet 0/1)#exit</pre>
<p>Verification</p>	<ol style="list-style-type: none"> 1. Run the show running-config command to display configuration information of the device. 2. Run the show snmp user command to display the SNMP user. 3. Run the show snmp view command to display the SNMP view. 4. Run the show snmp group command to display the SNMP group. 5. Run the show snmp host command to display the host information configured by the user. 6. Install MIB-Browser.
<p>Agent</p>	<pre>Ruijie# show running-config ! interface gigabitEthernet 0/1 no ip proxy-arp ip address 192.168.3.1 255.255.255.0</pre>

security model: v3 authPriv

Install MIB-Browser, enter IP address 192.168.3.1 in IP Address and user1 in UserName, select AuthPriv for Security Level, enter 123 in AuthPassWord, select MD5 for AuthProtocol, and enter 321 in PrivPassWord. Click Add Item and select a management unit for which the MIB needs to be queried, for example, System in the following figure. Click Start. The MIB is queried for network devices. The lowest pane in the following figure shows query results.

Common Errors

1.4.2 Enabling the Trap Function

Configuration Effect

Enable the agent to actively send a trap message to the NMS.

Notes

N/A

Configuration Steps

- [Configuring the SNMP Host Address](#)

- Optional
- Configure the host address of the NMS when the agent is required to actively send messages.

▾ Enabling the Agent to Actively Send a Trap Message to the NMS

- Optional
- Configure this item on the agent when the agent is required to actively send a trap message to the NMS.

▾ Enabling the Function of Sending a Link Trap Message on an Interface

- Optional
- Configure this item on the agent when a link trap message needs to be sent on an interface.

▾ Enabling the Function of Sending a System Reboot Trap Message

- Optional
- Configure this item on the agent when the RGOS system is required to send a trap message to the NMS to notify system reboot before reloading or reboot of the device.

▾ Specifying the Source Address for Sending a Trap Message

- Optional
- Configure this item on the agent when it is required to permanently use a local IP address as the source SNMP address to facilitate management.

▾ Enabling a Trap Message to Carry Private Fields when the Message Is Sent

- Optional
- Configure this item on the agent when private fields need to be carried in a trap message.

▾ Configuring the Heartbeat Trap Function and Interval

- Optional.
- By default, the heartbeat trap function is enabled, and the heartbeat trap messages are sent at an interval of 5 minutes.
- Configure this item if the heartbeat trap function needs to be disabled or the interval for sending heartbeat trap messages needs to be modified.

Verification

Run the **show snmp** command to display the SNMP status.

Run the **show running-config** command to display configuration information of the device.

Related Commands

▾ Setting the NMS Host Address

Command	<code>snmp-server host [oob] { host-addr ipv6 ipv6-addr } [vrf vrfname] [traps inorms] [version { 1 2c </code>
---------	--

	3 { auth noauth priv }] community-string [udp-port port-num] [via mgmt-name] [notification-type]
Parameter Description	<p>oob: Configures Out-Of-Band (OOB) communication for the alarm server (that is, information is sent to the alarm server through the MGMT interface).</p> <p><i>host-addr:</i> Address of the SNMP host.</p> <p><i>ipv6-addr:</i> (IPv6) address of the SNMP host.</p> <p><i>Vrfname:</i> Configures a VRF forwarding table name.</p> <p>traps informs: Configures the host to send a trap message or an inform message.</p> <p>version: SNMP version, which can be set to V1, V2C, or V3.</p> <p>auth noauth priv: Sets the security level of V3 users.</p> <p><i>community-string:</i> Community string or user name (V3).</p> <p><i>port-num:</i> Configures the port ID of the SNMP host.</p> <p>via mgmt-name: Specifies a management port when OOB is configured.</p> <p><i>notification-type:</i> Type of trap messages that are actively sent, for example, snmp.</p> <hr/> <p> If no trap type is specified, all trap messages are sent.</p>
Command Mode	Global configuration mode
Usage Guide	<p>This command is used with the snmp-server enable traps command to actively send trap messages to the NMS.</p> <p>You can configure different SNMP hosts to receive trap messages. A host can support different traps, ports, and VRF forwarding tables. If the same host is configured (the port and VRF configuration are the same), the last configuration is combined with the previous configurations, that is, to send different trap messages to the same host, configure one type of trap messages each time. These configurations are finally combined.</p> <hr/> <p> In this command, the via parameter can be specified only when the oob parameter is enabled. In addition, the vrf parameter cannot be used.</p>

↳ Enabling the Agent to Actively Send a Trap Message to the NMS

Command	snmp-server enable traps [notification-type]
Parameter Description	<p><i>notification-type:</i> Enables trap notification for the corresponding events, including the following types:</p> <p>snmp: Enables trap notification for SNMP events.</p> <p>bgp: Enables trap notification for BGP events.</p> <p>bridge: Enables trap notification for bridge events.</p> <p>isis: Enables trap notification for ISIS events.</p> <p>mac-notification: Enables trap notification for MAC events.</p> <p>ospf: Enables trap notification for OSPF events.</p> <p>urpf: Enables trap notification for URPF events.</p> <p>vrrp: Enables trap notification for VRRP events.</p> <p>web-auth: Enables trap notification for Web authentication events.</p>
Command	Global configuration mode

Mode	
Usage Guide	This command must be used with the snmp-server host command to so that trap messages can be actively sent.

▾ Enabling the Function of Sending a Link Trap Message on an Interface

Command	snmp trap link-status
Parameter Description	-
Configuration mode	Interface configuration mode
Usage Guide	For interfaces (Ethernet interface, AP interface, and SVI interface), when this function is enabled, the SNMP sends a Link Trap message if the link status on the interfaces changes. Otherwise, the SNMP does not send the message.

▾ Enabling the Function of Sending a System Reboot Trap Message

Command	snmp-server system-shutdown
Parameter Description	-
Configuration mode	Global configuration mode
Usage Guide	When the function of notification upon SNMP system reboot is enabled, a trap message is sent to the NMS to notify system reboot before reloading or reboot of the device.

▾ Specifying the Source Address for Sending a Trap Message

Command	snmp-server trap-source <i>interface</i>
Parameter Description	<i>interface</i> : Used as the interface for the SNMP source address.
Configuration mode	Global configuration mode
Usage Guide	By default, the IP address of the interface where SNMP packets are sent is used as the source address. To facilitate management and identification, this command can be run to permanently use one local IP address as the source SNMP address.

▾ Enabling a Trap message to Carry Private Fields when the Message Is Sent

Command	snmp-server trap-format private
Parameter Description	N/A
Configuration mode	Global configuration mode
Usage Guide	This command can be used to enable a trap message to carry private fields when the message is sent. At

	present, supported private fields include the alarm generation time. For the specific data types and data ranges of the fields, see RUIJIE-TRAP-FORMAT-MIB.mib.
--	---

↘ **Configuring the Heartbeat Trap Function**

Command	snmp-server heartbeat on
Parameter Description	N/A
Configuration Mode	Global configuration mode
Usage Guide	By default, the heartbeat trap function is enabled. You can run the no snmp-server heartbeat command to disable this function.

↘ **Configuring the Interval for Sending Heartbeat Trap Messages**

Command	snmp-server heartbeat period <i>time</i>
Parameter Description	<i>time</i> : Indicates the interval (unit: second).
Configuration Mode	Global configuration mode
Usage Guide	This command configures the interval for sending heartbeat trap messages.

Configuration Example

↘ **Enabling the Trap Function**

<p>Scenario Figure 1-8</p>	<p>Agent (IP:192.168.3.1/24) --- Gi0/1 --- NMS (IP:192.168.3.2/24)</p>

1.4.3 Shielding the Agent Function

Configuration Effect

Shield the agent function when the agent service is not required.

Notes

- Run the **no snmp-server** command to shield the SNMP agent function when the agent service is not required.
- Different from the shielding command, after the **no enable service snmp-agent** command is run, all SNMP services are directly disabled (that is, the SNMP agent function is disabled, no packet is received, and no response packet or trap packet is sent), but configuration information of the agent is not shielded.

Configuration Steps

▾ Shielding the SNMP Agent Function for the Device

- Optional
- To shield the configuration of all SNMP agent services, use this configuration.

▾ Disabling the SNMP Agent Function for the Device

- Optional
- To directly disable all services, use this configuration.

Verification

Run the **show services** command to check whether SNMP services are enabled or disabled.

Run the **show snmp** command to display the SNMP status.

Run the **show running-config** command to display configuration information of the device.

Related Commands

Shielding the SNMP Agent Function for the Device

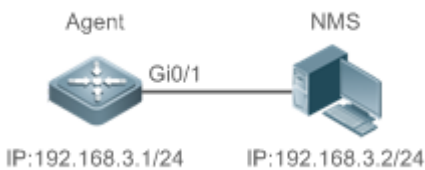

Command	no snmp-server
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	<p>By default, the SNMP agent function is disabled. When SNMP agent parameters (for example, NMS host address, authentication name, and access permission) are set, the SNMP agent service is automatically enabled. The enable service snmp-agent command must also be run at the same time so that the SNMP agent service can take effect. If the SNMP agent service is disabled or the enable service snmp-agent command is not run, the SNMP agent service does not take effect. Run the no snmp-server command to disable SNMP agent services of all versions supported by the device.</p> <p>After this command is run, all SNMP agent service configurations are shielded (that is, after the show running-config command is run, no configuration is displayed. Configurations are restored after the SNMP agent service is enabled again). After the enable service snmp-agent command is run, the SNMP agent configurations are not shielded.</p>

Disabling the SNMP Agent Function for the Device

Command	no enable service snmp-agent
Parameter Description	N/A
Configuration mode	Global configuration mode
Usage Guide	This command can be used to disable the SNMP service, but it will not shield SNMP agent parameters.

Configuration Example

Enabling the SNMP Service

Scenario Figure 1-9	 <p>After the SNMP service is enabled and the SNMP agent server is set, the NMS can access devices based on SNMP.</p>
Configuration Steps	<ol style="list-style-type: none"> 1. Enable the SNMP service. 2. Set parameters for the SNMP agent server to make the SNMP service take effect.

A gent	<pre>Ruijie(config)#enable service snmp-agent</pre>
Verification	1. Run the show services command to check whether the SNMP service is enabled or disabled.
Agent	<pre>Ruijie#show service web-server : disabled web-server(https): disabled snmp-agent : enabled ssh-server : disabled telnet-server : enabled</pre>

Common Errors

N/A

1.4.4 Setting SNMP Control Parameters

Configuration Effect

Set basic parameters of the SNMP agent, including the device contact mode, device location, serial number, and parameters for sending a trap message. By accessing the parameters, the NMS can obtain the contact person of the device and physical location of the device.

Notes

N/A

Configuration Steps

▾ Setting the System Contact Mode

- Optional
- When the contact mode of the system needs to be modified, configure this item on the agent.

▾ Setting the System Location

- Optional
- When the system location needs to be modified, configure this item on the agent.

▾ Setting the System Serial Number

- Optional
- When the system serial number needs to be modified, configure this item on the agent.

▾ Setting NE Information about the Device

- Optional
- When the NE code needs to be modified, configure this item on the agent.

▾ Setting the Maximum Packet Length of the SNMP Agent

- Optional
- When the maximum packet length of the SNMP agent needs to be modified, configure this item on the agent.

▾ Setting the UDP Port ID of the SNMP Service

- Optional
- When the UDP port ID of the SNMP service needs to be modified, configure this item on the agent.

▾ Setting the Queue Length of Trap Messages

- Optional
- When the size of the message queue needs to be adjusted to control the message sending speed, configure this item on the agent.

▾ Setting the Interval for Sending a Trap Message

- Optional
- When the interval for sending a trap message needs to be modified, configure this item on the agent.

▾ Configuring SNMP Flow Control

- Optional
- If a large number of SNMP request packets result in high CPU usage for SNMP tasks, configure SNMP flow control to limit the number of request packets processed per second in each SNMP task, so as to control the CPU usage for SNMP tasks.

Verification

Run the **show snmp** command to display the SNMP status.

Run the **show running-config** command to display configuration information of the device.

Related Commands

▾ Setting the System Contact Mode

Command	snmp-server contact <i>text</i>
Parameter Description	<i>text</i> : String that describes the system contact mode.
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Setting the System Location

Command	snmp-server location <i>text</i>
Parameter Description	<i>text</i> : String that describes system information.
Configuration mode	Global configuration mode
Usage Guide	N/A

▾ Setting the System Serial Number

Command	snmp-server chassis-id <i>text</i>
Parameter Description	<i>text</i> : Text of the system serial number, which may be digits or characters.
Configuration mode	Global configuration mode
Usage Guide	In general, the device serial number is used as the SNMP serial number to facilitate identification of the device.

▾ Setting NE Information about the Device

Command	snmp-server net-id <i>text</i>
Parameter Description	<i>text</i> : Text that is used to set the device NE code. The text is a string that consists of 1 to 255 characters that are case-sensitive and may include spaces.
Configuration mode	Global mode.
Usage Guide	Set the NE code of the device.

▾ Setting the Maximum Packet Length of the SNMP Agent

Command	snmp-server packetsize <i>byte-count</i>
Parameter Description	<i>byte-count</i> : Packet size, ranging from 484 bytes to 17,876 bytes.
Configuration mode	Global mode.
Usage Guide	N/A

▾ Setting the UDP Port ID of the SNMP Service

Command	snmp-server udp-port <i>port-num</i>
Parameter Description	<i>port-num</i> : Specifies the UDP port ID of the SNMP service, that is, the ID of the protocol port that receives SNMP packets.
Configuration mode	Global mode.
Usage Guide	Specify the protocol port ID for receiving SNMP packets.

➤ **Setting the Length of a Trap Message Queue**

Command	snmp-server queue-length <i>length</i>
Parameter Description	<i>length</i> : Queue length, ranging from 1 to 1,000.
Configuration mode	Global configuration mode
Usage Guide	Adjust the size of the message queue to control the message sending speed.

➤ **Setting the Interval for Sending a Trap Message**

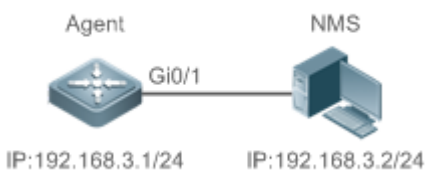

Command	snmp-server trap-timeout <i>seconds</i>
Parameter Description	<i>seconds</i> : Interval (unit: second). The value range is 1 to 1,000.
Configuration mode	Global configuration mode
Usage Guide	Adjust the interval for sending a message to control the message sending speed.

➤ **Configuring SNMP Flow Control**

Command	snmp-server flow-control pps [<i>count</i>]
Parameter Description	<i>count</i> : Number of SNMP request packets processed per second. The value range is 50 to 65,535.
Command Mode	Global configuration mode
Usage Guide	If a large number of SNMP request packets result in high CPU usage for SNMP tasks, configure SNMP flow control to limit the number of request packets processed per second in each SNMP task, so as to control the CPU usage for SNMP tasks.

Configuration Example

➤ **Setting SNMP Control Parameters**

Scenario Figure 1-10	 <p>The diagram illustrates a network connection between an Agent and an NMS. The Agent is represented by a blue square icon with a crosshair, and the NMS is represented by a blue laptop icon. They are connected by a horizontal line labeled 'Gi0/1'. Below the Agent icon is the IP address 'IP:192.168.3.1/24', and below the NMS icon is the IP address 'IP:192.168.3.2/24'.</p> <ul style="list-style-type: none"> The NMS manages network devices (agents) based on the community authentication mode and can obtain basic system information about the devices, for example, system contact mode, location, and serial number.
Configuration	1. Set SNMP agent parameters. Set the system location, contact mode, and serial number.

Steps	2. Set the IP address of the agent. Set the address of the Gi0/1 interface to 192.168.3.1/24.

2 Configuring RMON

2.1 Overview

The Remote Network Monitoring (RMON) aims at resolving problems of managing local area networks (LANs) and remote sites by using one central point. In RMON, network monitoring data consists of a group of statistics and performance indicators, which can be used for monitoring the network utilization, so as to facilitate network planning, performance optimization, and network error diagnosis.

RMON is mainly used by a managing device to remotely monitor and manage managed devices.

Protocols and Standards

STD 0059 / RFC 2819: Remote Network Monitoring Management Information Base

RFC4502: Remote Network Monitoring Management Information Base Version 2

RFC 3919: Remote Network Monitoring (RMON) Protocol Identifiers for IPv6 and Multi Protocol Label Switching (MPLS)

RFC 3737: IANA Guidelines for the Registry of Remote Monitoring (RMON) MIB Modules

RFC 3434: Remote Monitoring MIB Extensions for High Capacity Alarms

RFC 3395: Remote Network Monitoring MIB Protocol Identifier Reference Extensions

RFC 3287: Remote Monitoring MIB Extensions for Differentiated Services

RFC 3273: Remote Network Monitoring Management Information Base for High Capacity Networks

RFC 2896: Remote Network Monitoring MIB Protocol Identifier Macros

RFC 2895: Remote Network Monitoring MIB Protocol Identifier Reference

2.2 Applications

Application	Description
Collecting Statistics on Information of a Monitored Interface	Applies four functions of RMON to an interface to monitor the network communication of the interface.

2.2.1 Collecting Statistics on Information of a Monitored Interface

Scenario

The RMON Ethernet statistics function is used to monitor accumulated information of an interface, the history statistics function is used to monitor the packet count of an interface within each monitoring interval, and the alarm function is used to immediately acquire packet count exceptions of an interface. The following figure shows the networking topology.

Figure 2-1

Deployment

Interface x is monitored to accumulatively collect statistics on the packet count of the interface and collect statistics on the packet count and bandwidth utilization of the interface within the monitoring interval. If a packet count exception occurs on the interface, an alarm is reported to the network management system (NMS). The configuration key points are as follows:

- Configure the RMON Ethernet statistics function on interface x.
- Configure the RMON history statistics function on interface x.
- Configure the RMON alarm table and define RMON event processing actions in configuration mode. Monitored objects of alarms are the object identifier (OID) values of specific fields in the RMON Ethernet statistical table configured for interface x.

2.3 Features

Basic Concepts

RMON defines multiple RMON groups. Ruijie products support the statistics group, history group, alarm group, and event group, which are described as follows:

Statistics Group

The statistics group is used to monitor and collect statistics on Ethernet interface traffic information, which is accumulated from the entry creation time to the current time. The statistical items include discarded data packets, broadcast data packets, cyclic redundancy check (CRC) errors, large and small blocks, and collisions. Statistical results are stored in the Ethernet statistical table.

History Group

The history group is used to periodically collect network traffic information. It records accumulated values of network traffic information and the bandwidth utilization within each interval, and saves them in the history control table. It includes two small groups:

- The HistoryControl group is used to set the sampling interval, sampling data source, and other control information.

- The EthernetHistory group provides administrators with historical data, including statistics on network segment traffic, error packets, broadcast packets, utilization, and number of collisions.

Alarm Group

The alarm group is used to monitor a specified Management Information Base (MIB) object. When the value of a MIB object exceeds the preset upper limit or is lower than the preset lower limit, an alarm is triggered and the alarm is processed as an event.

Event Group

The event group is used to define the event processing mode. When a monitored MIB object meets alarm conditions, an event is triggered. An event can be processed in any of the following modes:

- none: No action is taken.
- log: Event-relevant information is recorded in the log record table so that administrators can view it at any time.
- snmp-trap: A trap message is transmitted to the NMS to notify the NMS of the event occurrence.
- log-and-trap: Event-relevant information is recorded in the log record table and a trap message is transmitted to the NMS.

Working Principle

RMON supports multiple monitors and two data collection methods. Method 1: A dedicated RMON probe is used to collect data and the NMS can directly acquire all information about the RMON MIB from the RMON probe. Method 2: RMON agents are built into network devices (such as switches and routers) so that the devices have the RMON probe function. The NMS uses basic commands of the Simple Network Management Protocol (SNMP) to exchange data with the RMON agents and collect network management information. This method, however, is limited by device resources and information of only four groups rather than all data of the RMON MIB is acquired.

The following figure shows an example of communication between the NMS and RMON agents. The NMS, through the RMON agents running on devices, can acquire information about overall traffic, error statistics, and performance statistics of the network segment where a managed network device interface is, thereby implementing remote management of network devices.

Figure 2-2

Overview

Feature	Description
RMON Ethernet Statistics	Collects statistics on the packet count, byte count, and other data of a monitored Ethernet interface accumulatively.
RMON History Statistics	Records the counts of packets, bytes, and other data communicated by an Ethernet interface within the configured interval and calculates the bandwidth utilization within the interval.
RMON Alarm	Samples values of monitored variables at intervals. The alarm table is used in combination with the event table. When the upper or lower limit is reached, a relevant event table is triggered to perform event processing or no processing is performed.

2.3.1 RMON Ethernet Statistics

Working Principle

The RMON Ethernet statistics function accumulatively collects statistics on network traffic information of an Ethernet interface from the entry creation time to the current time.

Related Configuration

▾ [Configuring RMON Statistical Entries](#)

- The RMON Ethernet statistics function is disabled by default.
- Run the **rmon collection stats** command to create Ethernet statistical entries on a specified Ethernet interface.
- After statistical entries are successfully created on a specified interface, the statistics group collects statistics on the traffic information of the current interface. The statistical items are variables defined in the RMON Ethernet statistical table, and recorded information is the accumulated values of variables from the creation time of the RMON statistical table to the current time.

2.3.2 RMON History Statistics

Working Principle

The RMON history statistics function records accumulated statistics on traffic information of an Ethernet interface within each interval.

Related Configuration

▾ [Configuring RMON Historical Control Entries](#)

- The RMON history statistics function is disabled by default.
- Run the **rmon collection history** command to create historical control entries on an Ethernet interface.
- The RMON history group collects statistics on variables defined in the RMON history table and records accumulated values of variables within each interval.

2.3.3 RMON Alarm

Working Principle

The RMON alarm function periodically monitors value changes of alarm variables. If the value of an alarm variable reaches the specified upper threshold or lower threshold, a corresponding event is triggered for processing, for example, a trap message is transmitted or one logTable entry record is generated. If a lower threshold or upper threshold is reached multiple times consecutively, only one corresponding event is triggered and another event is triggered till a reverse threshold is reached.

Related Configuration

Configuring the Event Table

- The RMON event group function is disabled by default.
- Run the **rmon event** command to configure the event table.

Configuring Alarm Entries

- The RMON alarm group function is disabled by default.
- Run the **rmon event** command to configure the event table and run the **rmon alarm** command to configure the RMON alarm table.
- The RMON alarm function is implemented by the alarm table and event table jointly. If a trap message needs to be transmitted to a managing device in the case of an alarm event, the SNMP agent must be correctly configured first. For the configuration of the SNMP agent, see the *Configuring SNMP*.
- If a configured alarm object is a field node in the RMON statistics group or history group, the RMON Ethernet statistics function or RMON history statistics function need to be configured on a monitored Ethernet interface first.

2.4 Configuration

Configuration	Description and Command		
Configuring RMON Ethernet Statistics	 (Mandatory) It is used to accumulatively collect statistics on traffic information of an Ethernet interface.		
	<table border="1"> <tr> <td>rmon collection stats</td> <td>Configures Ethernet statistical entries.</td> </tr> </table>	rmon collection stats	Configures Ethernet statistical entries.
rmon collection stats	Configures Ethernet statistical entries.		
Configuring RMON History Statistics	 (Mandatory) It is used to collect, at intervals, statistics on traffic information of an Ethernet interface and the bandwidth utilization within the interval.		
	<table border="1"> <tr> <td>rmon collection history</td> <td>Configures historical control entries.</td> </tr> </table>	rmon collection history	Configures historical control entries.
rmon collection history	Configures historical control entries.		
Configuring RMON Alarm	 (Mandatory) It is used to monitor whether data changes of a variable is within the valid range.		
	<table border="1"> <tr> <td>rmon event</td> <td>Configures event entries.</td> </tr> </table>	rmon event	Configures event entries.
	rmon event	Configures event entries.	
<table border="1"> <tr> <td>rmon alarm</td> <td>Configures alarm entries.</td> </tr> </table>	rmon alarm	Configures alarm entries.	
rmon alarm	Configures alarm entries.		

2.4.1 Configuring RMON Ethernet Statistics

Configuration Effect

Acquire accumulated statistics on traffic information of a monitored Ethernet interface from the entry creation time to the current time.

Notes

This function cannot be configured in batch interface configuration mode.

Configuration Steps

Configuring RMON Statistical Entries

- Mandatory.
- If statistics and monitoring are required for a specified interface, Ethernet statistical entries must be configured on this interface.

Verification

Run the **show rmon stats** command to display Ethernet statistics.

Related Commands

Configuring RMON Statistical Entries

Command	rmon collection stats <i>index</i> [owner <i>ownername</i>]
Parameter	<i>index</i> : Indicates the index number of a statistical entry, with the value ranging from 1 to 65,535.
Description	owner <i>ownername</i> : Indicates the entry creator, that is, <i>ownername</i> , which is a case-sensitive string of 1-63 characters.
Command Mode	Interface configuration mode
Usage Guide	The values of statistical entry parameters cannot be changed.

Configuration Example

Configuring RMON Ethernet Statistics

<p>Scenario</p> <p>Figure 2-3</p>	<pre> graph LR Server[Server] --- Gi0/1[Gi0/1] --- Agent[Agent] Agent --- Network((Network)) Agent --- Console[Console] --- Terminal[Terminal] </pre>
	<p>As shown in the preceding figure, the RMON agent is connected to the server, and the NMS requires the</p>

	<p>RMON statistics group to conduct performance statistics on received packets of interface Gi0/1. Administrators can view the statistics at any time to understand data about received packets of an interface and take measures in a timely manner to handle network exceptions.</p>
Configuration Steps	<ul style="list-style-type: none"> Configure a statistical table instance on interface GigabitEthernet 0/1 to collect statistics on the traffic of this interface.
Agent	<pre>Ruijie# configure terminal Ruijie (config)# interface gigabitEthernet 0/1 Ruijie (config-if-GigabitEthernet 0/1)# rmon collection stats 1 owner admin</pre>
Verification	<p>Run the show rmon stats command to display Ethernet statistics.</p>
Agent	<pre>Ruijie# show rmon stats ether statistic table: index = 1 interface = GigabitEthernet 0/1 owner = admin status = 1 dropEvents = 0 octets = 25696 pkts = 293 broadcastPkts = 3 multiPkts = 0 crcAlignErrors = 0 underSizePkts = 0 overSizePkts = 0 fragments = 0 jabbers = 0 collisions = 0 packets640ctets = 3815 packets65To1270ctets = 1695 packets128To2550ctets = 365 packets256To5110ctets = 2542 packets512To10230ctets = 152</pre>

```
packets1024To15180ctets = 685
```

Common Errors

Statistical table entries are re-configured or configured statistical table entries are modified.

2.4.2 Configuring RMON History Statistics

Configuration Effect

Acquire accumulated statistics on the traffic of a monitored Ethernet interface and the bandwidth utilization within each interval.

Notes

This function cannot be configured in batch interface configuration mode.

Configuration Steps

- Mandatory.
- If network statistics on a specified interface need to be collected, RMON historical control entries must be configured on the interface.

Verification

Run the **show rmon history** command to display history group statistics.

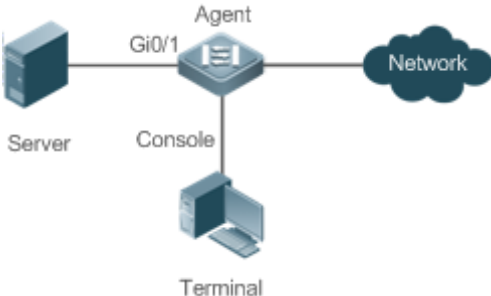

Related Commands

↘ Configuring RMON Historical Control Entries

Command	rmon collection history <i>index</i> [owner <i>ownername</i>] [buckets <i>bucket-number</i>] [interval <i>seconds</i>]
Parameter Description	<p><i>index</i>: Indicates the index number of a history statistical entry, with the value ranging from 1 to 65,535.</p> <p>owner <i>ownername</i>: Indicates the entry creator, that is, <i>ownername</i>, which is a case-sensitive string of 1-63 characters.</p> <p>buckets <i>bucket-number</i>: Sets the capacity of the history table in which a history statistical entry exists, that is, sets the maximum number of records (<i>bucket-number</i>) that can be accommodated in the history table. The value of <i>bucket-number</i> ranges from 1 to 65,535 and the default value is 10.</p> <p>interval <i>seconds</i>: Sets the statistical interval, with the unit of seconds. The value ranges from 1 second to 3,600 seconds and the default value is 1,800 seconds.</p>
Command Mode	Interface configuration mode
Usage Guide	The values of history statistical entry parameters cannot be changed.

Configuration Example

↘ Configuring RMON History Statistics

<p>Scenario Figure 2-4</p>	
	<p>As shown in the preceding figure, the RMON agent is connected to the server, and the NMS needs to collect statistics on received packets of interface Gi0/1 through the RMON history group at an interval of 60 seconds, in an effort to monitor the network and understand emergency data.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> Configure the history control table on interface GigabitEthernet 0/1 to periodically collect statistics on the traffic of this interface.

Common Errors

History control table entries are re-configured or configured history control table entries are modified.

2.4.3 Configuring RMON Alarm

Configuration Effect

Periodically monitor whether value changes of alarm variables are within the specified valid range.

Notes

If a trap message needs to be transmitted to a managing device when an alarm event is triggered, the SNMP agent must be correctly configured. For the configuration of the SNMP agent, see the *Configuring SNMP*.

If an alarm variable is a MIB variable defined in the RMON statistics group or history group, the RMON Ethernet statistics function or RMON history statistics function must be configured on the monitored Ethernet interface. Otherwise, an alarm table fails to be created.

Configuration Steps

↘ **Configuring Event Entries**

- Mandatory.
- Complete the configuration in global configuration mode.

↘ **Configuring Alarm Entries**

- Mandatory.
- Complete the configuration in global configuration mode.

Verification

- Run the **show rmon event** command to display the event table.
- Run the **show rmon alarm** command to display the alarm table.

Related Commands

▾ Configuring the Event Table

Command	rmon event <i>number</i> [log] [trap <i>community</i>] [description <i>description-string</i>] [owner <i>ownername</i>]
Parameter	<i>number</i> : Indicates the index number of an event table, with the value ranging from 1 to 65,535.
Description	<p>log: Indicates a log event. The system logs a triggered event.</p> <p>trap <i>community</i>: Indicates a trap event. When an event is triggered, the system transmits a trap message with the community name of <i>community</i>.</p> <p>description <i>description-string</i>: Sets the description information about an event, that is, <i>description-string</i>. The value is a string of 1-127 characters.</p> <p>owner <i>ownername</i>: Indicates the entry creator, that is, <i>ownername</i>, which is a case-sensitive string of 1-63 characters.</p>
Command Mode	Global configuration mode
Usage Guide	The values of configured event entry parameters can be changed, including the event type, trap community name, event description, and event creator.

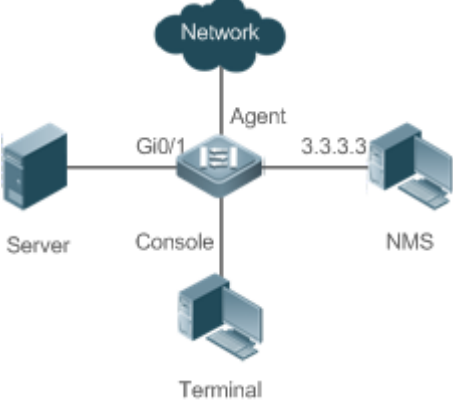

▾ Configuring the RMON Alarm Group

Command	rmon alarm <i>number</i> <i>variable</i> <i>interval</i> { absolute delta } rising-threshold <i>value</i> [<i>event-number</i>] falling-threshold <i>value</i> [<i>event-number</i>] [owner <i>ownername</i>]
Parameter	<i>number</i> : Indicates the index number of an alarm entry, with the value ranging from 1 to 65,535.
Description	<p><i>variable</i>: Indicates an alarm variable, which is a string of 1-255 characters and is represented in dotted format using the node OID (format: entry.integer.instance; example: 1.3.6.1.2.1.2.1.10.1).</p> <p><i>interval</i>: Indicates the sampling interval, with the unit of seconds and the value ranging from 1 to 2,147,483,647.</p> <p>absolute: Indicates that the sampling type is absolute value sampling, that is, variable values are directly extracted when the sampling time is up.</p> <p>delta: Indicates that the sampling type is changing value sampling, that is, changes in the variable values within the sampling interval are extracted when the sampling time is up.</p> <p>rising-threshold <i>value</i>: Sets the upper limit of the sampling quantity (<i>value</i>), with the value ranging from -2,147,483,648 to +2,147,483,647.</p> <p><i>event-number</i>: Indicates that an event with the event number of <i>event-number</i> is triggered when the upper limit or lower limit is reached.</p> <p>falling-threshold <i>value</i>: Sets the lower limit of the sampling quantity (<i>value</i>), with the value ranging from -2,147,483,648 to +2,147,483,647.</p> <p>owner <i>ownername</i>: Indicates the entry creator, that is, <i>ownername</i>, which is a case-sensitive string of 1-63 characters.</p>

Command Mode	Global configuration mode
Usage Guide	Values of configured alarm entry parameters can be changed, including alarm variables, sampling type, entry creator, sampling interval, upper/lower limit of the sampling quantity, and relevant trigger events.

Configuration Example

Configuring RMON Alarm

<p>Scenario Figure 2-5</p>	
	<p>Assume that SNMPv1 runs on the NMS, the community name used for accessing the settings is public, with the attribute of read-write, and the IP address used by the NMS to receive trap messages is 3.3.3.3.</p> <p>Assume that the OID value of unknown protocol packets received by monitored interface GigabitEthernet0/3 is 1.3.6.1.2.1.2.2.1.15.3, the sampling mode is relative sampling, and the sampling interval is 60 seconds.</p> <p>When the relative sampling value is larger than 100 or lower than 10, event 1 and event 2 are triggered respectively. In event 1, a trap message is transmitted and the event is logged. In event 2, the event is only logged.</p> <p>The configuration of the RMON agent is completed on the terminal. The RMON agent is connected to the NMS and is connected to the server through interface Gi0/1. The RMON agent needs to monitor the count of unknown protocol packets received by interface Gi0/1. The sampling interval is 60 seconds. When the absolute sampling value is smaller than 10, the event is only logged. When the absolute sampling value is larger than 100, the event is logged and a trap message is transmitted to the NMS.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure the host address for receiving trap messages. ● Configure an event group to process alarm trigger. ● Configure the alarm function.
<p>Agent</p>	<pre>Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# snmp-server community public rw Ruijie(config)# snmp-server host 3.3.3.3 trap public Ruijie(config)# rmon event 1 description rising-threshold-event log trap public owner admin</pre>

	<pre>Ruijie(config)# rmon event 2 description falling-threshold-event log owner admin Ruijie(config)# rmon alarm 1 1.3.6.1.2.1.2.1.15.3 60 delta rising-threshold 100 1 falling-threshold 10 2 owner admin</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● Run the show rmon event command to display the event table. ● Run the show rmon alarm command to display the alarm table.

stauts: 1
```

Common Errors

- The entered OID of a monitored object is incorrect, the variable corresponding to the OID does not exist, or the type is not an integer or unsigned integer.
- The upper threshold is smaller than or equal to the lower threshold.

2.5 Monitoring

Displaying

Description	Command
Displays all RMON configuration information.	show rmon
Displays the Ethernet statistical table.	show rmon stats
Displays the history control table.	show rmon history
Displays the alarm table.	show rmon alarm
Displays the event table.	show rmon event

3 Configuring NTP

3.1 Overview

The Network Time Protocol (NTP) is an application-layer protocol that enables network devices to synchronize time. NTP enables network devices to synchronize time with their servers or clock sources and provides high-precision time correction (the difference from the standard time is smaller than one millisecond in a LAN and smaller than decades of milliseconds in a WAN). In addition, NTP can prevent attacks by using encrypted acknowledgment.

Currently, Ruijie devices can be used both as NTP clients and NTP servers. In other words, a Ruijie device can synchronize time with a time server, and be used as a time server to provide time synchronization for other devices. When a Ruijie device is used as a server, it supports only the unicast server mode.

Protocols and Standards

- RFC 1305 : Network Time Protocol (Version 3)

3.2 Applications

Application	Description
Synchronizing Time Based on an External Reference Clock Source	A device is used as a client that synchronizes time with an external clock source. After successful synchronization, it is used as a server to provide time synchronization for other devices.
Synchronizing Time Based on a Local Reference Clock Source	A device uses a local clock as a reliable NTP reference clock source and is also used as a server to provide time synchronization for other devices.

3.2.1 Synchronizing Time Based on an External Reference Clock Source

Scenario

As shown in Figure 3-1:

- DEVICE-A is used as a reliable reference clock source to provide time synchronization for external devices.
- DEVICE-B specifies DEVICE-A as the NTP server and synchronizes time with DEVICE-A.
- After successful synchronization, DEVICE-B provides time synchronization for DEVICE-C.

Figure 3-1

Deployment

Configure DEVICE-B to the NTP external reference clock mode.

3.2.2 Synchronizing Time Based on a Local Reference Clock Source

Scenario

As shown in Figure 3-2, DEVICE-B uses a local clock as the NTP reference clock source and provides time synchronization for DEVICE-C.

Figure 3-2

Deployment

Configure DEVICE-B to the NTP local reference clock mode.

3.3 Features

Basic Concepts

↳ NTP Packet

As defined in RFC1305, NTP uses User Datagram Protocol (UDP) packets for transmission and the used UDP port ID is 123.

Figure 3-3 shows the format of an NTP time synchronization packet.

Figure 3-3 Format of an NTP Time Synchronization Packet

0		7		15		23		31	
LI	VN	Mode	Stratum	Poll Interval	Precision				
Root Delay (32-bit)									
Root Dispersion (32-bit)									
Reference Clock Identifier (32-bit)									
Reference Timestamp (64-bit)									
Originate Timestamp (64-bit)									
Receive Timestamp (64-bit)									
Transmit Timestamp (64-bit)									
Authenticator (optional 96-bit)									

- Leap Indicator(LI): indicates a 2-bit leap second indicator.

- **i** 00: indicates no warning information; 01: indicates that there are 61 seconds in the previous minute; 10: indicates that there are 59 seconds in the previous minute; 11: indicates that the clock is not synchronized.

- Version Number(VN): indicates a 3-bit NTP version number. The current version number is 3.
- Mode: indicates a 3-bit NTP working mode.

- **i** 0: indicates no definition; 1: indicates symmetric active; 2: indicates symmetric passive; 3: indicates a client; 4: indicates a server; 5: indicates broadcasting; 6: indicates control information; 7: reserved.

- Stratum: indicates the 8-bit stratum of a local clock. 0: indicates no definition; 1: indicates the master reference clock source; other values: indicate slave reference clock sources.
- Poll Interval: indicates the poll interval (seconds), which is a 8-bit integer.
- Precision: indicates the time precision (seconds) of a local clock, which is a 8-bit integer.
- Root Delay: indicates the round-trip time to the master reference clock source, which is a 32-bit integer.
- Root Dispersion: indicates the largest difference from the master reference clock source, which is a 32-bit integer.
- Reference Clock Identifier: indicates the 32-bit identifier of a reference clock source.
- Reference Timestamp: indicates a 64-bit timestamp, namely, the time that is set or corrected at the last time.
- Originate Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization request leaves from a client.
- Receive Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization request packet arrives at a server.
- Transmit Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization response packet leaves from a server.
- Authenticator (optional): indicates authentication information.

↘ NTP Server

A device uses a local clock as the reference clock source to provide time synchronization for other devices in the network.

↘ NTP Client

A device is used as an NTP client that synchronizes time with an NTP server in the network.

↘ Stratum

In NTP, "stratum" is used to describe the hops from a device to an authority clock source. An NTP server whose stratum is 1 has a directly connected atomic clock or radio controlled clock; an NTP server whose stratum is 2 obtains time from the server whose stratum is 1; an NTP server whose stratum is 3 obtains time from the server whose stratum is 2; and so on. Therefore, clock sources with lower stratums have higher clock precisions.

↘ Hardware Clock

A hardware clock operates based on the frequency of the quartz crystal resonator on a device and is powered by the device battery. After the device is shut down, the hardware clock continues running. After the device is started, the device obtains time information from the hardware clock as the software time of the device.

Overview

Feature	Description
NTP Time Synchronization	Network devices synchronize time with their servers or reliable clock sources to implement high-precision time correction.
NTP Security Authentication	The NTP packet encryption authentication is used to prevent unreliable clock sources from time synchronization interference on a device.
NTP Access Control	An Access Control List (ACL) is used to filter sources of received NTP packets.

3.3.1 NTP Time Synchronization

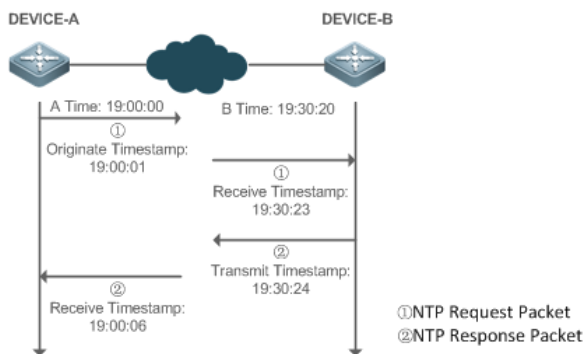

Working Principle

NTP time synchronization is implemented by interaction of NTP packets between a client and a server:

- The client sends a time synchronization packet to all servers every 64 seconds. After receiving response packets from the servers, the client filters and selects the response packets from all servers, and synchronizes time with an optimum server.
- After receiving the time synchronization request packet, a server uses the local clock as the reference source, and fills the local time information into the response packet to be sent to the client based on the protocol requirement.

Figure 3-4 shows the format of an NTP time synchronization packet.

Figure 3-4 Working Principle of NTP

DEVICE-B (B for short) is used as an NTP reference clock source, DEVICE-A (A for short) is used as an NTP client that synchronizes time with DEVICE-B. At a time point, the local clock of A is 19:00:00 and the local clock of B is 19:30:20.

1. A sends an NTP request packet. The local time (T0) when the packet leaves from A is 19:00:00 and is filled in Originate Timestamp.
2. After a 2-second network delay, the local time (T1) when B receives the request packet is 19:30:23 and is filled in Receive Timestamp.

3. B processes the NTP request and sends an NTP response packet one second later. The local time (T2) when the response packet leaves from B is 19:30:24 and is filled in Transmit Timestamp.
4. After a 2-second network delay, A receives the response packet. The local time (T3) when the response packet arrives at A is 19:00:06.

The specific calculations for time synchronization are as follows:

- A obtains the time difference of 30 minutes and 20 seconds between B and A by using the formula $((T1-T0)+(T2-T3))/2$.
- A obtains the packet round-trip delay of four seconds between A and B by using the formula $(T3-T0)-(T2-T1)$.

▾ NTP Working Mode

- External clock reference mode

In this mode, a device is used as both a server and a client. If receiving time synchronization requests from other clients, the device must synchronize time with the specified server first and provide time synchronization for the clients after successful synchronization.

- Local clock reference mode

In this mode, a device uses the default local clock as the reliable clock source and provides time synchronization directly for other clients.

Related Configuration

▾ Configuring an NTP Server

- The NTP function is disabled by default.
- Run the **ntp server** command to specify an NTP server (external clock reference source), which can enable NTP.
- After the configuration, the device works in the external clock reference mode.

▾ Real-time Synchronization

- A device performs time synchronization every 64 seconds by default.

▾ Updating a Hardware Clock

- By default, a device does not update synchronized time to the hardware clock.
- Run the **ntp update-calendar** command to enable a device to automatically update the hardware clock after successfully synchronizing time each time.

▾ Configuring the NTP Master Clock

- By default, a device works in the external clock reference mode.
- Run the **ntp master** command to configure a device to the local clock reference mode.

3.3.2 NTP Security Authentication

To prevent malicious damage on an NTP server, NTP uses the authentication mechanism to check whether the time synchronization information is really from the announced server and check the information return path to provide an anti-interference protection mechanism.

Working Principle

An NTP client and an NTP server are configured with the same key. When sending request and response packets, a device calculates the hash values of the packets by using the MD5 algorithm based on the specified key and NTP packet content, and fills the hash values into the packet authentication information. The receiving device checks whether the packets are sent by a trusted device or modified based on the authentication information.

Related Configuration

↘ **Configuring a Global Security Authentication Mechanism for NTP**

- By default, no NTP security authentication mechanism is enabled.
- Run the **ntp authenticate** command to enable the NTP security authentication mechanism.

↘ **Configuring a Global Authentication Key for NTP**

- By default, no global authentication key is configured.
- Run the **ntp authentication-key** command to enable an NTP global authentication key.

↘ **Configuring a Globally Trusted Key ID for NTP**

- By default, no globally trusted key is configured.
- Run the **ntp trusted-key** command to configure a device as the reference clock source to provide a trusted key for time synchronization externally.

↘ **Configuring a Trusted Key ID for an External Reference Clock Source**

- Run the **ntp server** command to specify an external reference source and the trusted key of this clock source as well.

3.3.3 NTP Access Control

Working Principle

Provide a minimum security measure by using an ACL.

Related Configuration

↘ **Configuring the Access Control Rights for NTP Services**

- By default, there is no access control right for NTP.
- Run the **ntp access-group** command to configure the access control rights for NTP.

3.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of NTP	 (Mandatory) It is used to enable NTP. After NTP is enabled, a device works in the external clock reference mode.	
	ntp server	Configures an NTP server.
	ntp update-calendar	Automatically updates a hardware clock.
	 (Optional) It is used to configure a device to the local clock reference mode.	
	ntp master	Configures the NTP master clock.
	 (Optional) It is used to disable NTP.	
	no ntp	Disables all functions of NTP and clears all NTP configurations.
Configuring NTP Security Authentication	 (Optional) It is used to prevent unreliable clock sources from performing time synchronization interference on a device.	
	ntp authenticate	Enables a security authentication mechanism.
	ntp authentication-key	Configures a global authentication key.
	ntp trusted-key	Configures a trusted key for time synchronization.
	ntp server	Configures a trusted key for an external reference clock source.
Configuring NTP Access Control	 (Optional) It is used to filter the sources of received NTP packets.	
	ntp access-group	Configures the access control rights for NTP.

3.4.1 Configuring Basic Functions of NTP

Configuration Effect

External Clock Reference Mode

- Use a device as a client to synchronize time from an external reference clock source to the local clock.
- After the time synchronization is successful, use the device as a time synchronization server to provide time synchronization.

Local Clock Reference Mode

- Use the local clock of a device as the NTP reference clock source to provide time synchronization.

Notes

- In the client/server mode, a device can be used as a time synchronization server to provide time synchronization only after successfully synchronizing time with a reliable external clock source.
- Once the local clock reference mode is configured, the system will not synchronize time with a clock source with a higher stratum.
- Configuring a local clock as the master clock (especially when specifying a lower stratum) may overwrite an effective clock source. If this command is used for multiple devices in a network, the clock difference between the devices may cause unstable time synchronization of the network.
- Before a local clock is configured as the master clock, if the system never synchronizes time with an external clock source, you may need to manually calibrate the system clock to ensure that there is no excessive difference. For details about how to manually calibrate the system clock, refer to the system time configuration section in the configuration guide.

Configuration Steps

▾ Configuring an NTP Server

- (Mandatory) At least one external reference clock source must be specified (A maximum of 20 different external reference clock sources can be configured).
- If it is necessary to configure an NTP key, you must configure NTP security authentication before configuring the NTP server.

▾ Automatically Updating a Hardware Clock

- Optional.
- By default, the system updates only the system clock, but not the hardware clock after successful time synchronization.
- After this command is configured, the system automatically updates the hardware clock after successful time synchronization.

▾ Configuring the NTP Master Clock

- To switch a device to the local clock reference mode, run this command.

▾ Disabling NTP

- To disable NTP and clear NTP configurations, run the **no ntp** command.
- By default, all interfaces can receive NTP packets after NTP is enabled. To disable NTP for a specified interface, run the **ntp disable** command.

Verification

- Run the **show ntp status** command to display the NTP configuration.

- Run the **show clock** command to check whether time synchronization is completed.

Related Commands

▾ Configuring an NTP Server

Command	ntp server [oob]{ <i>ip-addr</i> <i>domain</i> ip <i>domain</i> ipv6 <i>domain</i> }[version <i>version</i>][source <i>if-name</i>][key <i>keyid</i>][prefer] [via <i>mgmt-name</i>]
Parameter Description	<p>oob: Indicates whether a reference clock source is bound to the MGMT interface.</p> <p><i>vrf-name</i>: Indicates the name of the VRF that is bound to the reference clock source.</p> <p><i>ip-addr</i>: Indicates the IPv4/IPv6 address of the reference clock source.</p> <p><i>domain</i>: Indicates the IPv4/IPv6 domain name of the reference clock source.</p> <p><i>version</i>: Indicates the NTP version number, ranging from 1 to 3.</p> <p><i>if-name</i>: Indicates the interface type, including AggregatePort, Dialer GigabitEthernet, Loopback, Multilink, Null, Tunnel, Virtual-ppp, Virtual-template and Vlan.</p> <p><i>keyid</i>: Indicates the key used for communicating with the reference clock source, ranging from 1 to 4294967295.</p> <p>prefer: Indicates whether the reference clock source has a high priority.</p> <p><i>mgmt-name</i>: Specifies the egress management interface for packets in the oob mode.</p>
Command Mode	Global configuration mode
Usage Guide	<p>By default, no NTP server is configured. Ruijie client system supports interaction with up to 20 NTP servers. You can configure an authentication key for each server (after configuring global authentication and the related key) to initiate encrypted communication with the servers.</p> <hr/> <p> If it is necessary to configure an authentication key, you must configure NTP security authentication before configuring an NTP server.</p> <hr/> <p>The default version of NTP for communicating with a server is NTP version 3. In addition, you can configure the source interface for transmitting NTP packets and specify that the NTP packets from a corresponding server can be received only on the transmitting interface.</p>

▾ Updating a Hardware Clock

Command	ntp update-calendar
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Configuring a Local Reference Clock Source

Command	ntp master [<i>stratum</i>]
Parameter	<i>stratum</i> : specifies the stratum of a local clock, ranging from 1 to 15. The default value is 8.

Description

Configuration Example

↘ **External Clock Reference Mode of NTP**

Scenario Figure 3-5	
	<ul style="list-style-type: none"> ● DEVICE-B is configured to the NTP external clock reference mode. ● DEVICE-A is used as the reference clock source of DEVICE-B. ● DEVICE-C synchronizes time with DEVICE-B.
Configuration Steps	<ul style="list-style-type: none"> ● DEVICE-A configures the local clock as the NTP reference clock source. ● DEVICE-B configures DEVICE-A as the reference clock source. ● DEVICE-C configures DEVICE-B as the reference clock source.
DEVICE-A	<pre>A#configure terminal A(config)# ntp master A(config)#exit</pre>
DEVICE-B	<pre>B#configure terminal</pre>

	<pre>B(config)# ntp server 192.168.1.1 B(config)# exit</pre>
DEVICE-C	<pre>C#configure terminal C(config)# ntp server 192.168.2.1 C(config)# exit</pre>
Verification	<ul style="list-style-type: none"> ● Run the show ntp status command on DEVICE-B to display the NTP configuration. ● DEVICE-B sends a time synchronization packet to 192.168.1.1 in order to synchronize time with DEVICE-A. ● After successfully synchronizing time with DEVICE-A, DEVICE-B can respond to the time synchronization request from DEVICE-C. ● Run the show clock command on DEVICE-B and DEVICE-C to check whether the time synchronization is successful.

Local Clock Reference Mode of NTP

Scenario Figure 3-6	
	<ul style="list-style-type: none"> ● DEVICE-B configures the local clock as the NTP reference clock source. ● DEVICE-C synchronizes time with DEVICE-B.
Configuration Steps	<ul style="list-style-type: none"> ● DEVICE-B configures the local clock as the NTP reference clock source. ● DEVICE-C configures DEVICE-B as the reference clock source.
DEVICE-B	<pre>B#configure terminal B(config)# ntp master B(config)# exit</pre>
DEVICE-C	<pre>C#configure terminal C(config)# ntp server 192.168.2.1 C(config)# exit</pre>
Verification	<ul style="list-style-type: none"> ● Run the show clock command on DEVICE-C to check whether the time synchronization is successful.

3.4.2 Configuring NTP Security Authentication

Configuration Effect

Synchronizing Time from a Trusted Reference Clock Source

Use a device as a client to synchronize time only from a trusted external reference clock source to the local clock.

▾ Providing Time Synchronization for a Trusted Device

Use the local clock of a device as the NTP reference clock source to provide time synchronization for only a trusted device.

Notes

The authentication keys of the client and server must be the same.

Configuration Steps

▾ Configuring a Global Security Authentication Mechanism for NTP

- Mandatory.
- By default, a device disables the security authentication mechanism.

▾ Configuring a Global Authentication Key for NTP

- Mandatory.
- By default, a device is not configured with an authentication key.

▾ Configuring a Globally Trusted Key ID for NTP

- Optional.
- To provide time synchronization for a trusted device, you must specify a trusted authentication key by using the key ID.
- Only one trusted key can be configured. The specified authentication key must be consistent with that of the trusted device.

▾ Configuring an Authentication Key ID for an External Reference Clock Source

- Optional.
- To synchronize time with a trusted reference clock source, you must specify a trusted authentication key by using the key ID.
- Each trusted reference clock source is mapped to an authentication key. The authentication keys must be consistent with the keys of trusted reference clock sources.

Verification

- Run the **show run** command to verify the NTP configuration.
- Run the **show clock** command to check whether time is synchronized only with a trusted device.

Description	

Command Mode	Global configuration mode
Usage Guide	By default, a client does not use a global security authentication mechanism. If no security authentication mechanism is used, communication will not be encrypted. A global security indicator is not enough to imply that the communication between the client and server is implemented in an encrypted manner. Other global keys and an encryption key for the server must also be configured for initiating encrypted communication between the client and server.

▾ **Configuring a Global Authentication Key**

Command	ntp authentication-key <i>key-id</i> md5 <i>key-string</i> [<i>enc-type</i>]
Parameter Description	<i>key-id</i> : indicates the ID of a global authentication key, ranging from 1 to 4294967295. <i>key-string</i> : indicates a key string. <i>enc-type</i> : (optional) indicates whether an entered key is encrypted. 0 indicates no encryption, and 7 indicates simple encryption. The default setting is no encryption.
Command Mode	Global configuration mode
Usage Guide	N/A

▾ **Configuring a Trusted Key for NTP**

Command	ntp trusted-key <i>key-id</i>
Parameter Description	<i>key-id</i> : Indicates the ID of a trusted key, ranging from 1 to 4294967295.
Command Mode	Global configuration mode
Usage Guide	N/A

▾ **Configuring a Trusted Key for an External Reference Clock Source**

Refer to the section *Related Commands*.

Configuration Example

▾ **Security Authentication**

Scenario Figure 3-7	<pre> graph LR C[DEVICE-C] --- Gi 0/1 192.168.2.1 B[DEVICE-B] B --- Gi 0/0 192.168.1.2 A[DEVICE-A] A --- 192.168.1.1 </pre>
	<ul style="list-style-type: none"> ● DEVICE-B is configured to the NTP client/server mode and provides NTP services requiring security authentication for DEVICE-C. The authentication key is "abcd". ● DEVICE-A is used as the reference clock source of DEVICE-B. ● DEVICE-C synchronizes time with DEVICE-B.

Configuration Steps	<ul style="list-style-type: none"> ● DEVICE-B configures DEVICE-A as the reference clock source. ● DEVICE-C configures DEVICE-B as the reference clock source.
DEVICE-B	<pre>B#configure terminal B(config)# ntp authentication-key 1 md5 abcd B(config)# ntp trusted-key 1 B(config)# ntp server 192.168.1.1 B(config)# exit</pre>
DEVICE-C	<pre>C#configure terminal C(config)# ntp authentication-key 1 md5 abcd C(config)# ntp server 192.168.2.1 key 1 C(config)# exit</pre>
Verification	<ul style="list-style-type: none"> ● DEVICE-B sends a time synchronization packet that carries authentication information to 192.168.1.1 in order to synchronize time with DEVICE-A. ● Run the show clock command on DEVICE-B to check whether the time synchronization is successful.

3.4.3 Configuring NTP Access Control

Configuration Effect

Access control for NTP services provides a minimum security measure. A more secure method is to use an NTP authentication mechanism.

Notes

- Currently, the system does not support control query (used to control NTP servers by using network management devices, such as setting the leap second indicator or monitoring its working status). Though rule matching is implemented in the preceding sequence, no request related to control query is supported.
- If no access control rule is configured, all accesses are allowed. If any access control rule is configured, only accesses allowed by the rule can be implemented.

Related Configuration

↘ [Configuring the Access Control Rights for NTP](#)

- Optional.
- Run the **ntp access-group** command to configure the access control rights and a corresponding ACL for NTP.

Verification

Run the **show run** command to verify the NTP configuration.

Related Commands

↘ Configuring the Access Control Rights for NTP Services

Command	<code>ntp access-group { peer serve serve-only query-only } access-list-number access-list-name</code>
Parameter Description	<p>peer: allows time request and control query for local NTP services, and allows a local device to synchronize time with a remote system (full access rights).</p> <p>serve: allows time request and control query for local NTP services, but does not allow a local device to synchronize time with a remote system.</p> <p>serve-only: allows only time request for local NTP services.</p> <p>query-only: allows only control query for local NTP services.</p> <p><i>access-list-number:</i> indicates the number of an IP ACL, ranging from 1 to 99 and from 1300 to 1999. For details about how to create an IP ACL, refer to the <i>Configuring ACL</i>.</p> <p><i>access-list-name:</i> indicates the name of an IP ACL. For details about how to create an IP ACL, refer to the <i>Configuring ACL</i>.</p>
Command Mode	Global configuration mode
Usage Guide	<p>Configure NTP access control rights.</p> <p>When an access request arrives, the NTP service matches rules in the sequence from the minimum access restriction to the maximum access restriction and uses the first matched rule. The matching sequence is peer, serve, serve-only, and query-only.</p>

Configuration Example

↘ Configuring NTP Access Control Rights

Configuration Steps	Allow only the device with the IP address of 192.168.1.1 to send a time synchronization request to a local device.
	<pre>Ruijie(config)# access-list 1 permit 192.168.1.1 Ruijie(config)# ntp access-group serve-only 1</pre>

3.5 Monitoring

Displaying

Description	Command
<code>show ntp status</code>	Displays the current NTP information.

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
debug ntp	Enables debugging.
no debug ntp	Disables debugging.

4 Configuring SNTP

4.1 Overview

The Simple Network Time Protocol (SNTP) is a simplified version of Network Time Protocol (NTP), which is used to synchronize the clocks of computers on the Internet. SNTP is applied in scenarios where it is unnecessary to use all NTP functions.

NTP uses a complex algorithm and has higher requirements for the system whereas SNTP uses a simpler algorithm and provides higher performance. Generally, SNTP precision can reach about 1s, which meets the basic requirements of most scenarios. Since SNTP packets are the same as NTP packets, the SNTP client implemented on a device is fully compatible with an NTP server.

Protocols and Standards

- RFC 2030: Simple Network Time Protocol (SNTP) Version 4 for IPv4, IPv6 and OSI

4.2 Applications

Application	Description
Synchronizing Time with an NTP Server	A device is used as a client to synchronize time with an NTP server.

4.2.1 Synchronizing Time with an NTP Server

Scenario

As shown in Figure 4-1, DEVICE-B uses a local clock as the NTP clock reference source and provides time synchronization for DEVICE-C.

DEVICE-C is used as an SNTP client to synchronize time with DEVICE-B.

Figure 4-1

Deployment

- Specify DEVICE-B as the SNTP server of DEVICE-C.
- Enable SNTP for DEVICE-C.

4.3 Features

Basic Concepts

SNTP Packet

SNTPV4 is developed from NTP, which is intended to simplify the functions of NTP. It does not change the NTP specifications and the original implementation of NTP. The message format of SNTPV4 is the same as that of NTP defined in RFC1305, with only some data fields initialized into preset values.

As defined in RFC1305, SNTP uses User Datagram Protocol (UDP) packets for transmission and the used UDP port ID is 123.

Figure 4-2 shows the format of an SNTP time synchronization packet.

Figure 4-2 Format of an SNTP Time Synchronization Packet

- Leap Indicator(LI): indicates a 2-bit leap second indicator.
-
- **i** 00: indicates no warning information; 01: indicates that there are 61 seconds in the previous minute; 10: indicates that there are 59 seconds in the previous minute; 11: indicates that the clock is not synchronized.
-
- Version Number(VN): indicates a 3-bit NTP/SNTP version number. The current version number is 3.
 - Mode: indicates a 3-bit SNTP/NTP working mode.
-
- **i** 0: indicates no definition; 1: indicates symmetric active; 2: indicates symmetric passive; 3: indicates a client; 4: indicates a server; 5: indicates broadcasting; 6: indicates control information; 7: reserved.
-
- Stratum: indicates the 8-bit stratum of a local clock. 0: indicates no definition; 1: indicates the master clock reference source; other values: indicate slave clock reference sources.
 - Poll Interval: indicates the poll interval (seconds), which is a 8-bit integer.
 - Precision: indicates the time precision (seconds) of a local clock, which is a 8-bit integer.

- Root Delay: indicates the round-trip time to the master clock reference source, which is a 32-bit integer.
- Root Dispersion: indicates the largest difference from the master reference clock source, which is a 32-bit integer.
- Reference Clock Identifier: indicates the 32-bit identifier of a reference clock source.
- Reference Timestamp: indicates a 64-bit timestamp, namely, the time that is set or corrected at the last time.
- Originate Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization request leaves from a client.
- Receive Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization request packet arrives at a server.
- Transmit Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization response packet leaves from a server.
- Authenticator (optional): indicates authentication information.

Overview

Feature	Description
SNTP Time Synchronization	Synchronizes time from an SNTP/NTP server to a local device.

4.3.1 SNTP Time Synchronization

Working Principle

SNTP time synchronization is implemented by interaction of SNTP/NTP packets between a client and a server. The client sends a time synchronization packet to the server at intervals (half an hour by default). After receiving a response packet from the server, the client synchronizes time.

Figure 4-3 shows the format of an SNTP time synchronization packet.

Figure 4-3 Working Principle of SNTP

DEVICE-B (B for short) is used as an NTP reference clock source, DEVICE-A (A for short) is used as an SNTP client that synchronizes time with DEVICE-B. At a time point, the local clock of A is 19:00:00 and the local clock of B is 19:30:20.

1. A sends an SNTP/NTP request packet. The local time (T0) when the packet leaves from A is 19:00:00 and is filled in Originate Timestamp.
2. After a 2-second network delay, the local time (T1) when B receives the request packet is 19:30:23 and is filled in Receive Timestamp.
3. B processes the NTP request and sends an NTP response packet one second later. The local time (T2) when the response packet leaves from B is 19:30:24 and is filled in Transmit Timestamp.
4. After a 2-second network delay, A receives the response packet. The local time (T3) when the response packet arrives at A is 19:00:06.

The specific calculations for time synchronization are as follows:

- A obtains the time difference of 30 minutes and 20 seconds between B and A by using the formula $((T1-T0)+(T2-T3))/2$.
- A obtains the packet round-trip delay of four seconds between A and B by using the formula $(T3-T0)-(T2-T1)$.

Related Configuration

▾ Enabling SNTP

- SNTP is disabled by default.
- Run the **sntp enable** command to enable SNTP.

▾ Configuring an SNTP Server

- By default, no SNTP server is configured.
- Run the **sntp server** command to specify an SNTP server.

▾ Configuring the SNTP Time Synchronization Interval

- By default, the SNTP time synchronization interval is 1,800s.
- Run the **sntp interval** command to specify the time synchronization interval.

4.4 Configuration

Configuration	Description and Command
Configuring SNTP	 (Mandatory) It is used to enable SNTP.
	sntp enable Enables SNTP.
	sntp server Configures the IP address of an SNTP server.
	 (Optional) It is used to configure the SNTP time synchronization interval.

Configuration	Description and Command	
	sntp interval	Configures the SNTP time synchronization interval.

4.4.1 Configuring SNTP

Configuration Effect

An SNTP client accesses an NTP server at fixed intervals to correct the clock regularly.

Notes

All time obtained through SNTP communication is Greenwich Mean Time (GMT). To obtain precise local time, you need to set the local time zone for alignment with GMT.

Configuration Steps

▾ Enabling SNTP

- (Mandatory) SNTP is disabled by default.

▾ Configuring the IP address of an SNTP Server

- (Mandatory) No SNTP/NTP server is configured by default.

▾ Configuring the SNTP Time Synchronization Interval

- Optional.
- By default, a device synchronizes time every half an hour.

Verification

Run the **show sntp** command to display SNTP-related parameters.

Related Commands

▾ Enabling SNTP

Command	sntp enable
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	SNTP is disabled by default. Run the no sntp enable global configuration command to disable SNTP.

▾ Configuring the IP address of an SNTP/NTP Server

Command	sntp server [oob] { ip- address domain } [via mgmt-name] [source source-ip-address]
----------------	--

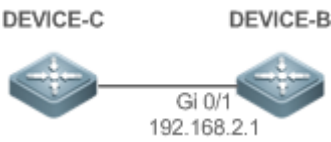

Parameter Description	<p><i>ip-address</i>: indicates the IP address of an SNTP server. No SNTP server is configured by default.</p> <p><i>domain</i>: domain name of the SNTP server. No SNTP server is configured by default.</p> <p>oob: Indicates that the SNTP server supports an out-band management interface.</p> <p><i>mgmt-name</i>: Specifies the egress management interface for packets in the oob mode.</p> <p><i>source-ip-address</i>: Indicates the source IP address.</p>
Command Mode	Global configuration mode
Usage Guide	<p>Since SNTP is fully compatible with NTP, the server can be configured as a public NTP server on the Internet.</p> <p>Since SNTP packets are the same as NTP packets, the SNTP client is fully compatible with the NTP server. There are many NTP servers on the Internet. You can select an NTP server with a shorter delay as the SNTP server on your device.</p>

↘ **Configuring the SNTP Time Synchronization Interval**

Command	sntp interval <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the time synchronization interval, ranging from 60s to 65,535s. The default value is 1,800s.
Command Mode	Global configuration mode
Usage Guide	<p>Run this command to set the interval for an SNTP client to synchronize time with an NTP/SNTP server.</p> <p> The interval configured here does not take effect immediately. To make it take effect immediately, run the sntp enable command.</p>

Configuration Example

↘ **SNTP Time Synchronization**

Scenario Figure 4-4	
	<ul style="list-style-type: none"> ● DEVICE-B indicates an NTP server on the Internet. ● DEVICE-C synchronizes time with DEVICE-B.
Configuration Steps	Enable SNTP for DEVICE-C and configure DEVICE-B as an NTP server.
DEVICE-C	<pre>C#configure terminal C(config)# sntp server 192.168.2.1 C(config)# sntp enable C(config)# exit</pre>
Verification	<ul style="list-style-type: none"> ● Run the show clock command on DEVICE-C to check whether the time synchronization is successful.

- Run the **show sntp** command on DEVICE-C to display the SNTP status and check whether the server is successfully configured.

4.5 Monitoring

Displaying

Description	Command
show sntp	Displays SNTP-related parameters.

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
debug sntp	Enables debugging.

5 Configuring SPAN-RSPAN

5.1 Overview

The Switched Port Analyzer (SPAN) is to copy packets of a specified port to another switch port that is connected to a network monitoring device, so as to achieve network monitoring and troubleshooting.

All input and output packets of a source port can be monitored through SPAN. For example, as shown in the following figure, all packets on Port 5 are mapped to Port 10, and the network analyzer connected to Port 10 receives all packets that pass through Port 5.

Figure 5-1 SPAN Configuration Instance

The SPAN function is mainly applied in network monitoring and troubleshooting scenarios, to monitor network information and rectify network faults.

The Remote SPAN (RSPAN), an extension to SPAN, is capable of remotely monitoring multiple devices. Each RSPAN session is established in a specified remote VLAN. RSPAN breaks through the limitation that a mirrored port and a mirroring port must reside on the same device, and allows a mirrored port to be several network devices away from a mirroring port. Users can observe data packets of the remote mirrored port by using an analyzer in the central equipment room.

The application scenarios of RSPAN are similar to those of SPAN. RSPAN allows users to conduct real-time data monitoring without staying in the equipment room, providing great convenience for users.

VLAN SPAN (VSPAN) considers data streams of some VLANs as data sources and mirrors them to a destination port. The configuration is similar to that of the port-based SPAN. VSPAN has the following features:

- A VLAN that is not a remote VLAN can be specified as the data source of VSPAN.
- Some VLANs that are not remote VLANs can be specified as the data sources of VSPAN.
- When a VLAN is configured as a data source, packets only in the Rx direction can be mirrored.

5.2 Applications

Application	Description
Stream-based SPAN	Data streams with certain characteristics need to be monitored, for example, data streams using a specified access control list (ACL) policy need to be monitored.
One-to-Many RSPAN	Multiple users need to monitor data of the same port.
RSPAN Basic Applications	Packets on the mirroring source device need to be mirrored to the destination device for monitoring.

5.2.1 Stream-based SPAN

Scenario

As shown in the following figure, the network analyzer can be configured to can monitor all data streams forwarded by Switch A to Switch B and specific data streams of Switch B (for example, data streams from PC1 and PC2).

Figure 5-2 SPAN Simple Application Topology

Remarks	0000.0000.0001 is the MAC address of PC1. 0000.0000.0002 is the MAC address of PC2.
----------------	--

Deployment

- In the preceding figure, configure the SPAN function on Switch A connected to the network analyzer, set port Gi 0/1 connected to Switch B as the SPAN source port, and set port Gi 0/2 that is directly connected to the network analyzer as the SPAN destination port.
- Configure stream-based SPAN (only data streams of PC1 and PC2 are allowed) for the source port Gi 0/1 of SPAN.

5.2.2 One-to-Many RSPAN

Scenario

As shown in the following figure, one-to-many RSPAN can be implemented on a single device, that is, both PC 1 and PC 2 can be configured to monitor the transmitted and received traffic of the port connected to the server. Users can make proper configuration (for example, remote VLAN and port MAC loopback) to monitor data streams that pass through port Gi 4/1 on PC 1 and PC 2, thereby monitoring data streams of the server.

Figure 5-3 Application Topology of One-to-Many RSPAN

Deployment

- Create a remote VLAN on Switch A.
- Configure Switch A as the source device of RSPAN and configure the port Gi 4/1 that is directly connected to the server as the RSPAN source port. Select a port that is in the Down state, Gi 4/2 in this example, as the RSPAN output port, add this port to the remote VLAN, and configure MAC loopback (run the **mac-loopback** command in interface configuration mode).
- Add ports that are directly connected to PC 1 and PC 2 to the remote VLAN.

5.2.3 RSPAN Basic Applications

Scenario

As shown in the following figure, the RSPAN function enables the network analyzer to monitor the STA connected to the source device Switch A from the destination device Switch C through the intermediate device Switch B. The devices can normally exchange data with each other.

Figure 5-4 Basic Application Topology of RSPAN

Deployment

- Configure a remote VLAN on Switch A, Switch B, and Switch C.
- On Switch A, configure port Gi 0/1 directly connected to the STA as the source port, configure port Gi 0/2 connected to Switch B as the output port, and configure the switching function for the output port.
- On Switch B, configure port Gi 0/1 connected to Switch A and port Gi 0/2 connected to Switch C as common ports.
- On Switch C, configure port Gi0/1 connected to Switch B as a common source port, configure port Gi 0/2 connected to the network analyzer as the RSPAN destination port, and configure the switching function for the RSPAN destination port.

5.3 Features

Basic Concepts

▾ SPAN Session

A SPAN session is data streams between the SPAN source port and the destination port, which can be used to monitor the packets of one or more ports in the input, output, or both directions. Switched ports, routed ports, and aggregate ports (APs) can be configured as source ports or destination ports of SPAN sessions. Normal operations on a switch are not affected after ports of the switch are added to a SPAN session.

Users can configure a SPAN session on a disabled port but the SPAN session is inactive. A SPAN session is in the active state only after the port on which the SPAN session is configured is enabled. In addition, a SPAN session does not take effect after a switch is powered on. It is active only after the destination port is in the operational state. Users can run the **show monitor [session session-num]** command to display the operation status of a SPAN session.

▾ SPAN Data Streams

A SPAN session covers data streams in three directions:

- Input data streams: All packets received by a source port are copied to the destination port. Users can monitor input packets of one or more source ports in a SPAN session. Some input packets of a source port may be discarded for some reasons (for example, for the sake of port security). It does not affect the SPAN function and such packets are still mirrored to the destination port.

- **Output data streams:** All packets transmitted by a source port are copied to the destination port. Users can monitor output packets of one or more source ports in a SPAN session. Packets transmitted from other ports to a source port may be discarded for some reasons and such packets will not be transmitted to the destination port. The format of output packets of a source port may be changed for some reasons. For example, after routing, packets transmitted from the source port are changed in source MAC addresses, destination MAC addresses, VLAN IDs, and TTLs, and their formats are also changed after copied to the destination port.
- **Bidirectional data streams:** Bidirectional data streams include input data streams and output data streams. In a SPAN session, users can monitor data streams of one or more source ports in the input and output directions.

↳ Source Port

A source port is called a monitored port. In a SPAN session, data streams of the source port are monitored for network analysis and troubleshooting. In a single SPAN session, users can monitor the input, output, and bidirectional data streams, and the number of source ports is not restricted.

A source port has the following features:

- A source port can be a switched port, routed port, or AP.
- A source port cannot be used as a destination port simultaneously.
- A source port and a destination port can belong to the same VLAN or different VLANs.

↳ Destination Port

A SPAN session has one destination port (called a monitoring port) for receiving packets copied from a source port.

A destination port has the following features:

- A destination port can be a switched port, routed port, or AP.
- A destination port cannot be used as a source port simultaneously.

↳ CPU SPAN

CPU SPAN is to monitor packets transmitted from the CPU. Common SPAN monitors forwarded packets of a source port, excluding packets that are actively transmitted by the CPU to the source port. For example, for packets generated when a device actively pings another device, common SPAN cannot monitor the ping packets on the transmit device, unless the port of the receive device is configured as a source port for monitoring. CPU SPAN can directly monitor such packets generated when a device actively pings another device.

CPU SPAN has the following features:

- CPU SPAN can be configured separately, that is, only packets transmitted by the CPU are monitored.
- CPU SPAN can be configured together with common SPAN, that is, common mirrored packets and CPU packets are monitored.

Overview

Feature	Description
---------	-------------

SPAN	Configures mirroring of ports on the same device.
RSPAN	Configures mirroring of ports on different devices.

5.3.1 SPAN

SPAN is used to monitor data streams on switches. It copies frames on one port to another switch port that is connected to a network analyzer or RMON analyzer so as to analyze the communication of the port.

Working Principle

When a port transmits or receive packets, SPAN, after checking that the port is configured as a SPAN source port, copies the packets transmitted and received by the port to the destination port.

↘ [Configuring a SPAN Source Port](#)

Users need to specify a SPAN session ID and source port ID to configure a SPAN source port, and set the optional SPAN direction item to determine the direction of SPAN data streams or specify an ACL policy to mirror specific data streams.

↘ [Configuring a SPAN Destination Port](#)

Users need to specify a SPAN session ID and destination port ID to configure a SPAN destination port, and set the optional switching function item to determine whether to enable the switching function and tag removal function on the SPAN destination port.

Related Configuration

The SPAN function is disabled by default. It is enabled only after a session is created, and the SPAN source and destination ports are configured. A SPAN session can be created when a SPAN source port or destination port is configured.

↘ [Configuring a SPAN Source Port](#)

A SPAN session does not have a SPAN source port by default. Users can run the following command to configure a SPAN source port:

```
monitor session session-num source interface interface-id [ both | rx | tx ] [ acl name ]
```

In the preceding command:

session-num: Indicates the SPAN session ID. The number of supported SPAN sessions varies with products.

interface-id: Indicates the SPAN source port to be configured.

rx: Indicates that only packets received by the source port are monitored after **rx** is configured.

tx: Indicates that only packets transmitted by the source port are monitored after **tx** is configured.

both: Indicates that packets transmitted and received by the source port are copied to the destination port for monitoring after **both** is configured, that is, **both** includes **rx** and **tx**. If none of **rx**, **tx**, and **both** is selected, **both** is enabled by default.

acl: Specifies an ACL policy. After this option is configured, packets allowed by the ACL policy on the source port are monitored. This function is disabled by default.

↘ [Configuring a SPAN Destination Port](#)

A SPAN session does not have a SPAN destination port by default. Users can run the following command to configure a SPAN destination port:

```
monitor session session-num destination interface interface-id [switch ]
```

In the preceding command:

switch: Indicates that the SPAN destination port only receives packets mirrored from the SPAN source port and discards other packets if this option is disabled, and receives both packets mirrored from the SPAN source port and packets from non-source ports if this option is enabled, that is, the communication between this destination port and other devices is not affected.

When the SPAN destination port is configured, the relevant function is disabled by default if **switch** is not configured.

📌 Configuring Stream-based SPAN

This function is disabled by default. Users can run the **monitor session** *session-num* **source interface** *interface-id* **rx acl** *acl-name* command to configure stream-based SPAN.

📌 Configuring CPU SPAN

This function is disabled by default. Users can run the **monitor session** *session-num* **source interface** *interface-id* **tx cpu** command to configure CPU SPAN.

-
- ⚠ Pay attention to the following points when using SPAN:
 - ⚠ The SPAN destination port is used for the Spanning Tree Protocol (STP) calculation.
 - ⚠ SPAN is unavailable if a source port or destination port is disabled.
 - ⚠ If a source port or destination port is added to an AP, the source port or destination port exits from a SPAN session.
 - ⚠ If a VLAN (or VLAN list) is used as a SPAN source, ensure that the destination port has sufficient bandwidth for receiving mirrored data of the VLAN (or VLAN list).
 - ⚠ Not all products support all options of the preceding commands because of product differences.
-

5.3.2 RSPAN

RSPAN is capable of monitoring multiple devices. Each RSPAN session is established in a specified remote VLAN. RSPAN breaks through the limitation that a mirrored port and a mirroring port must reside on the same device, and allows a mirrored port to be several network devices away from a mirroring port.

Working Principle

A remote VLAN is created for the source device, intermediate device, and destination device, all ports involved in an RSPAN session need to be added to the remote VLAN. Mirrored packets are broadcasted in the remote VLAN so that they are transmitted from the source port of the source switch to the destination port of the destination switch.

📌 Configuring a Remote VLAN

Packets from an RSPAN source port are broadcasted in a remote VLAN so as to be copied from the local switch to the remote switch. The RSPAN source port, output port, reflection port, transparent transmission ports of the intermediate device (packet

input port and output port of the intermediate device), destination port and input port of the destination port must be added to the remote VLAN. The RSPAN function requires configuring a VLAN as a remote VLAN in VLAN mode.

↘ **Configuring an RSPAN Session**

The configuration of the RSPAN source port and destination port are similar to that of the SPAN source port and destination port, but the mirroring session ID specified during configuration must be the ID of an RSPAN session.

↘ **Configuring an RSPAN Source Port**

The configuration of an RSPAN source port is the same as that of a SPAN source port, but the specified mirroring session ID must be the ID of an RSPAN session.

↘ **Configuring an RSPAN Output Port**

The output port is located on the source device and must be added to a remote VLAN. Mirrored packets of a source port are broadcasted in this remote VLAN. The source device transmits packets to the intermediate switch or destination switch through the output port.

↘ **Configuring an RSPAN Destination Port**

When an RSPAN destination port is configured, an RSPAN session ID, remote VLAN, and port name must be specified so that packets from the source port are copied to the destination port through the remote VLAN.

↘ **Configuring Stream-based RSPAN**

RSPAN is an extension to SPAN and also supports stream-based mirroring. The configuration is the same as that of stream-based SPAN. Stream-based RSPAN does not affect normal communication.

Users can configure an ACL in the input direction of a source port on an RSPAN source device. Standard ACLs, extended ACLs, MAC ACLs, and user-defined ACLs are supported.

Users can configure a port ACL in the input direction of a source port on an RSPAN source device, and configure a port ACL in the output direction of the destination port on the RSPAN destination device. Users can also configure an ACL in the output direction of a remote VLAN on an RSPAN source switch and configure an ACL in the input direction of the remote VLAN on the RSPAN destination switch.

↘ **Configuring One-to-Many RSPAN**

If data streams of one source port need to be mirrored to multiple destination ports, users can configure an RSPAN session, configure the source port of the RSPAN session as a one-to-many mirroring source port and select another Ethernet port as the forwarding port (output port on the source device). In addition, the MAC loopback function needs to be configured on the RSPAN forwarding port in interface configuration mode, the expected RSPAN output port and RSPAN forwarding port need to be added to the remote VLAN. Then, mirrored packets are looped back on the RSPAN forwarding port and then broadcasted in the remote VLAN, thereby implementing one-to-many RSPAN.

Related Configuration

The RSPAN function is disabled by default. It is enabled only after an RSPAN session is created, and a remote VLAN, RSPAN source port, and RSPAN destination port are configured.

↘ Configuring a Remote VLAN

No remote VLAN is specified for RSPAN by default. Users can run the **remote-span** command in VLAN mode to configure a VLAN as a remote VLAN. One remote VLAN corresponds to one RSPAN session.

↘ Configuring an RSPAN Source Device

This function is disabled by default. Users can run the **monitor session session-num remote-source** command in global configuration mode to configure a device as the remote source device of a specified RSPAN session.

↘ Configuring an RSPAN Destination Device

This function is disabled by default. Users can run the **monitor session session-num remote-destination** command in global configuration mode to configure a device as the remote destination device of a specified RSPAN session.

↘ Configuring an RSPAN Source Port

A source port of an RSPAN session is configured on the source device. The configuration is the same as that of a SPAN source port but an RSPAN session ID needs to be specified. This function is disabled by default.

↘ Configuring an Output Port on the RSPAN Source Device

This function is disabled by default. Users can run the **monitor session session-num destination remote vlan remote-vlan interface interface-name [switch]** command in global configuration mode to configure an output port on the RSPAN source device. If the option **switch** is configured, the output port can participate in normal data packet switching. It is not configured by default. The output port must be added to a remote VLAN.

↘ Configuring a Destination Port on the RSPAN Destination Device

This function is disabled by default. Users can run the **monitor session session-num destination remote vlan remote-vlan interface interface-name [switch]** command in global configuration mode to configure a destination port on the RSPAN destination device. If the option **switch** is configured, the destination port can participate in normal data packet switching. It is not configured by default. The destination port must be added to a remote VLAN.

-
-  Pay attention to the following points when using RSPAN:
 -  A remote VLAN must be configured on each device, their VLAN IDs must be consistent, and all ports that participate in a session must be added to the VLAN.
 -  It is not recommended that common ports be added to a remote VLAN.
 -  Do not configure a port that is connected to an intermediate switch or destination switch as an RSPAN source port. Otherwise, traffic on the network may be in chaos.
-

5.4 Configuration

Configuration	Description and Command
Configuring	 (Mandatory) It is used to create SPAN.

SPAN Basic Functions	monitor session <i>session-num</i> source interface <i>interface-id</i> [both rx tx]	Configures a SPAN source port.
	monitor session <i>session-num</i> destination interface <i>interface-id</i> [switch]	Configures a SPAN destination port.
	monitor session <i>session-num</i> source interface <i>interface-id</i> rx acl <i>acl-name</i>	Configures stream-based SPAN.
	monitor session <i>session-num</i> source vlan <i>vlan-id</i> [rx]	Specifies a VLAN as the data source of SPAN.
	monitor session <i>session-num</i> source filter vlan <i>vlan-id-list</i>	Specifies some VLANs as the data sources of SPAN.
Configuring RSPAN Basic Functions	 (Mandatory) It is used to create RSPAN.	
	monitor session <i>session-num</i> remote-source	Configures an RSPAN session ID and specifies a source device.
	monitor session <i>session-num</i> remote-destination	Configures an RSPAN session ID and specifies a destination device.
	remote-span	Configures a remote VLAN.
	monitor session <i>session-num</i> source interface <i>interface-id</i> [both rx tx]	Configures an RSPAN source port.
	monitor session <i>session-num</i> destination remote vlan <i>remote-vlan-id</i> interface <i>interface-id</i> [switch]	Configures an output port on the RSPAN source device or a destination port on the RSPAN destination device.

5.4.1 Configuring SPAN Basic Functions

Configuration Effect

- Configure a source and destination ports for a SPAN session.
- Configure a destination port to monitor any packets transmitted and received by a source port.

Notes

- If a source port or destination port is added to an AP, the source port or destination port exits from a SPAN session.
- If the switch function is disabled on a SPAN destination port, the destination port receives only mirrored packets and discards other packets that pass through the port. After the switch function is enabled, the destination port can receive non-mirrored packets.

Configuration Steps

↘ Configuring a SPAN Session

- Global configuration mode. Mandatory.
- You can configure a SPAN session when configuring a SPAN source port or destination port, or when configuring a specified VLAN or some VLANs as a data source or data sources of SPAN.

↘ Configuring a SPAN Source Port

- Global configuration mode. Mandatory.
- You can select the SPAN direction when configuring a SPAN source port. The **both** direction is configured by default, that is, both transmitted and received packets are monitored.

↘ Configuring a SPAN Destination Port

Global configuration mode. Mandatory.

A SPAN session is active only when a SPAN source port is configured (or a VLAN is specified as the data source of SPAN) and a SPAN destination port is configured.

Verification

- Run the **show monitor** command or the **show running** command to verify the SPAN configuration. Alternatively, conduct packet capture analysis on the SPAN destination port and check whether the SPAN function takes effect according to the captured packets.

Related Commands

↘ Configuring a SPAN Source Port

Command	monitor session <i>session-num</i> source interface <i>interface-id</i> [both rx tx]
Parameter Description	<i>session-num</i> : Indicates the ID of a SPAN session. <i>interface-id</i> : Indicates the interface ID. both : Indicates that packets in the input and output directions are monitored. It is the default value. rx : Indicates that packets in the input direction are monitored. tx : Indicates that packets in the output direction are monitored.
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Configuring a SPAN Destination Port

Command	monitor session <i>session-num</i> destination interface <i>interface-id</i> [switch]
Parameter Description	<i>session-num</i> : Indicates the ID of a SPAN session. <i>interface-id</i> : Indicates the interface ID. switch : Indicates that the switching function is enabled on the SPAN destination port. It is disabled by

	default.
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Configuring Stream-based SPAN

Command	monitor session <i>session-num</i> source interface <i>interface-id</i> rx acl <i>acl-name</i>
Parameter Description	<i>session-num</i> : Indicates the ID of a SPAN session. <i>interface-id</i> : Indicates the interface ID. <i>acl-name</i> : Indicates an ACL name.
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Specifying a VLAN as the Data Source of SPAN

Command	monitor session <i>session-num</i> source vlan <i>vlan-id</i> [both rx tx]
Parameter Description	<i>session-num</i> : Indicates the ID of a SPAN session. <i>vlan-id</i> : Indicates a specified VLAN ID. both : Indicates that packets in the input and output directions are monitored. It is the default value. rx : Indicates that packets in the input direction are monitored. tx : Indicates that packets in the output direction are monitored.
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Specifying Some VLANs as the Data Sources of SPAN

Command	monitor session <i>session-num</i> source filter vlan <i>vlan-id-list</i>
Parameter Description	<i>session-num</i> : Indicates the ID of a SPAN session. <i>vlan-id-list</i> : Indicates some specified VLAN IDs.
Command Mode	Global configuration mode
Usage Guide	N/A

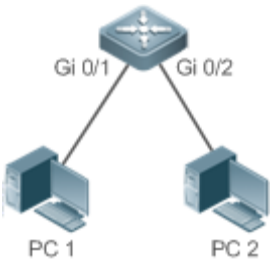

↘ Configuring CPU Packet SPAN

Command	monitor session <i>session-num</i> source interface <i>interface-id</i> txcpu
Parameter Description	<i>session-num</i> : Indicates the ID of a SPAN session. <i>interface-id</i> : Indicates the interface ID. tx : Indicates that packets in the CPU outbound direction are monitored. cpu : Indicates that CPU packets are monitored. It is disabled by default.
Command	Global configuration mode

Mode	
Usage Guide	If CPU packet SPAN is configured, only CPU packets are monitored. If both common mirrored packets and CPU packets need to be monitored, common SPAN and CPU SPAN need to be configured simultaneously.

Configuration Example

↘ The following uses SPAN as an example.

<p>Scenario Figure 5-5</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> As shown in Figure 5-5, add ports Gi 0/1 and Gi 0/2 of Device A to VLAN 1. Create SVI 1 and set the address of SVI 1 to 10.10.10.10/24. Set IP addresses of PC 1 and PC 2 to 10.10.10.1/24 and 10.10.10.2/24 respectively. Configure SPAN for Device A and configure ports Gi 0/1 and Gi 0/2 as the source port and destination port of SPAN respectively.
<p>A</p>	<pre>Ruijie# configure Ruijie(config)# vlan 1 Ruijie(config-vlan)# exit Ruijie(config)# interface vlan 1 Ruijie(config-if-VLAN 1)# ip address 10.10.10.10 255.255.255.0 Ruijie(config-if-VLAN 1)# exit Ruijie(config)# monitor session 1 source interface gigabitEthernet 0/1 Ruijie(config)# monitor session 1 destination interface gigabitEthernet 0/2</pre>
<p>Verification</p>	<p>Run the show monitor command to check whether SPAN is configured correctly. After successful configuration, PC 1 sends ping packets to SVI 1 and PC 2 conducts monitoring by using the packet capture tool.</p>
<p>A</p>	<pre>Ruijie# show monitor sess-num: 1 span-type: LOCAL_SPAN src-intf:</pre>

	<pre>GigabitEthernet 0/1 frame-type Both dest-intf: GigabitEthernet 0/2</pre>
--	--

Common Errors

- The session ID specified during configuration of the SPAN source port is inconsistent with that specified during configuration of the SPAN destination port.
- Packet loss may occur if packets of a port with large bandwidth are mirrored to a port with small bandwidth.

5.4.2 Configuring RSPAN Basic Functions

Configuration Effect

- Configure a source port and destination port on the source device of an RSPAN session and configure the destination port on the destination device.
- Configure the destination port on the RSPAN destination device to monitor any packets that are transmitted or received by the source port.

Notes

- If a source port or destination port is added to an AP, the source port or destination port exits from a SPAN session.
- If the switch function is disabled on an RSPAN destination port, the destination port receives only mirrored packets and discards other packets that pass through the port. After the switch function is enabled, the destination port can receive non-mirrored packets.
- All ports involved in RSPAN must be added to a remote VLAN.
- A remote VLAN must be created on an intermediate device and transparent transmission ports must be added to the remote VLAN.

Configuration Steps

📄 Configuring an RSPAN Session

- Global configuration mode. Mandatory.
- The same session ID needs to be configured on the RSPAN source device and RSPAN destination device.

📄 Configuring an RSPAN Source Device

- Global configuration mode. Mandatory.
- It is used to specify a device to be monitored by RSPAN.

📄 Configuring an RSPAN Destination Device

- Global configuration mode. Mandatory.

- It is used to specify the destination device for outputting RSPAN packets.

▾ Configuring an RSPAN Source Port

- Global configuration mode. Mandatory.
- Complete the configuration on an RSPAN source device. After configuration, RSPAN monitoring can be conducted on packets of the RSPAN source port. You can specify RSPAN to monitor remote VLAN packets in the input direction, output direction, or both directions of the RSPAN source port.

▾ Configuring an RSPAN Output Port

- Global configuration mode. Mandatory.
- Complete the configuration on an RSPAN source device. After configuration, mirrored packets received by the ports added to the remote VLAN can be transmitted to the RSPAN destination device through the output port.

▾ Configuring an RSPAN Destination Port

- Global configuration mode. Mandatory.
- Complete the configuration on the RSPAN destination device. After configuration, the RSPAN destination device forwards mirrored packets received by the ports added to the remote VLAN to the monitoring device through the destination port.

▾ Configuring Port MAC Loopback

- Interface configuration mode. Optional.
- Complete the configuration on an RSPAN device. After this function is configured on the RSPAN destination port and other ports are added to the remote VLAN, RSPAN packets loop back on the destination port, and then broadcasted in the remote VLAN on the source device, implementing one-to-many RSPAN.

Verification

- Run the **show monitor** command or the **show running** command to check whether RSPAN is successfully configured on each device, or conduct packet capture on the destination mirroring port on the RSPAN destination device to check whether packets mirrored from the source port of the RSPAN source device are captured.

Related Commands

▾ Configuring an RSPAN Source Device

Command	monitor session <i>session-num</i> remote-source
Parameter	<i>session-num</i> : Indicates the ID of an RSPAN session.
Description

Usage Guide	N/A

▾ Configuring an RSPAN Source Port

Command	monitor session <i>session-num</i> source interface <i>interface-id</i> [both rx tx][acl <i>acl-name</i>]
Parameter	<i>session-num</i> : Indicates the ID of an RSPAN session.
Description	<i>interface-id</i> : Indicates the interface ID. both : Indicates that packets in the input and output directions are monitored. It is the default value. rx : Indicates that packets in the input direction are monitored. tx : Indicates that packets in the output direction are monitored. <i>acl-name</i> : Indicates an ACL name.
Command Mode	Global configuration mode
Usage Guide	The configuration is the same as that of a SPAN source port but an RSPAN session ID needs to be specified.

▾ Configuring an Output Port on the RSPAN Source Device

Command	monitor session <i>session-num</i> destination remote vlan <i>remote-vlan</i> interface <i>interface-id</i> [switch]
Parameter	<i>session-num</i> : Indicates the ID of an RSPAN session.
Description	<i>remote-vlan</i> : Indicates a remote VLAN. <i>interface-id</i> : Indicates the interface ID. switch : Indicates whether the port participates in packet switching.
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Configuring a Destination Port on the RSPAN Destination Device

Command	monitor session <i>session-num</i> destination remote vlan <i>remote-vlan</i> interface <i>interface-id</i> [switch]
----------------	--

Parameter Description	<i>session-num</i> : Indicates the ID of an RSPAN session. <i>remote-vlan</i> : Indicates a remote VLAN. <i>interface-id</i> : Indicates the interface ID. switch : Indicates whether the port participates in packet switching.
Command Mode	Global configuration mode
Usage Guide	N/A

➤ **Configuring Port MAC Loopback**

Command	mac-loopback
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	To implement one-to-many RSPAN, enable the MAC loopback function on a port (select a port that is in the Down state as the MAC loopback port and do not add any configuration to this port).

Configuration Example

➤ **Configuring RSPAN**

<p>Scenario Figure 5-6</p>	<p>The diagram illustrates a three-switch RSPAN setup. Source Device Switch A (left) has a Source Port Gi0/1 connected to a Monitored User and an Output Port Gi0/2 connected to Intermediate Device Switch B. Intermediate Device Switch B (top) has Common Ports Gi0/1 and Gi0/2. Destination Device Switch C (right) has a Source Port Gi0/1 connected to Intermediate Device Switch B and an RSPAN Destination Port Gi0/2 connected to a Network Analyzer. Dashed blue arrows indicate the mirrored traffic path from the user through Switch A and B to Switch C and the Network Analyzer.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> As shown in the preceding figure, configure a remote VLAN on the source device Switch A, intermediate device Switch B, and destination device Switch C. Configure the RSPAN source device, specify the source port and output port on Switch A. Add ports Gi0/1 and Gi0/2 to the remote VLAN on Switch B. Configure the RSPAN destination device and specify the destination port on Switch C.
<p>A</p>	<pre>Ruijie# configure Ruijie(config)# vlan 7 Ruijie(config-vlan)# remote-span</pre>

	<pre>Ruijie(config-vlan)# exit Ruijie(config)# monitor session 1 remote-source Ruijie(config)# monitor session 1 source interface Gi 0/1 both Ruijie(config)# monitor session 1 destination remote vlan 7 interfaceGi 0/2 switch</pre>
B	<pre>Ruijie(config)# vlan 7 Ruijie(config-vlan)# remote-span Ruijie(config-vlan)# exit Ruijie(config)# interface range Gi0/1-2 Ruijie(config-if-range)#switchport mode trunk</pre>
C	<pre>Ruijie(config)# vlan 7 Ruijie(config-vlan)# remote-span Ruijie(config-vlan)# exit Ruijie(config)# monitor session 1 remote-destination Ruijie(config)# monitor session 1 destination remote vlan 7 interface Gi 0/2</pre>
Verification	<p>Run the show monitor command or the show running command on Switch A, Switch B, and Switch C to check whether RSPAN is configured successfully.</p>
A	<pre>Ruijie# show monitor sess-num: 1 span-type: SOURCE_SPAN src-intf: GigabitEthernet 0/1 frame-type Both dest-intf: GigabitEthernet 0/2 Remote vlan 7 mtp_switch on</pre>
B	<pre>! vlan 1 remote-span !</pre>

	<pre>interface GigabitEthernet 0/1 switchport mode trunk ! Interface GigabitEthernet 0/2 switchport mode trunk !</pre>
<p>C</p>	<pre>Ruijie# show monitor sess-num: 1 span-type: DEST_SPAN dest-intf: GigabitEthernet 0/2 Remote vlan 7 mtp_switch on</pre>

Common Errors

- A remote VLAN must be configured on the source device, intermediate device, and destination device, and their VLAN IDs must be consistent.
- Packet loss may occur if packets of a port with large bandwidth are mirrored to a port with small bandwidth.

📌 **Configuring One-to-Many RSPAN**

<p>Scenario Figure 5-7</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● As shown in the preceding figure, configure a remote VLAN on Switch A, Switch B, and Switch C. ● Configure the source port, output port, and MAC loopback port on Switch A. ● Configure the destination port on Switch B and Switch C.

A	<pre> Ruijie# configure Ruijie(config)# vlan 7 Ruijie(config-vlan)# remote-span Ruijie(config-vlan)# exit Ruijie(config)# monitor session 1 remote-source Ruijie(config)# monitor session 1 source interface fa 0/1 both Ruijie(config)# monitor session 1 destination remote vlan 7 interface fa 0/2 switch Ruijie(config)# interface fa0/2 Ruijie(config-if-FastEthernet 0/2)# mac-loopback Ruijie(config-if-range)# exit Ruijie(config)# interface range fa0/3-4 Ruijie(config-if-range)# switchport mode trunk </pre>
B, C	<pre> Ruijie(config)# vlan 7 Ruijie(config-vlan)# remote-span Ruijie(config-vlan)# exit Ruijie(config)# monitor session 1 remote-destination Ruijie(config)# monitor session 1 destination remote vlan 7 interface fa 0/2 Ruijie(config)# interface fa0/1 Ruijie(config-if)#switchport mode trunk </pre>
Verification	Run the show monitor command or the show running command on Switch A, Switch B, and Switch C to check whether RSPAN is configured successfully.
A	<pre> Ruijie# show monitor sess-num: 1 span-type: SOURCE_SPAN src-intf: FastEthernet 0/1 frame-type Both dest-intf: FastEthernet 0/2 Remote vlan 7 mtp_switch on </pre>

B	<pre>Ruijie# show monitor sess-num: 1 span-type: DEST_SPAN dest-intf: FastEthernet 0/2 Remote vlan 7 mtp_switch on</pre>
C	<pre>Ruijie# show monitor sess-num: 1 span-type: DEST_SPAN dest-intf: FastEthernet 0/2 Remote vlan 7 mtp_switch on</pre>

Common Errors

- A remote VLAN must be configured on the source device, intermediate device, and destination device, and their VLAN IDs must be consistent.
- Packet loss may occur if packets of a port with large bandwidth are mirrored to a port with small bandwidth.
- One MAC loopback port and multiple output ports need to be configured to implement one-to-many RSPAN.

5.5 Monitoring

Displaying

Description	Command
Displays all mirroring sessions existing in the system.	show monitor
Displays a specified mirroring session.	show monitor session <i>session-id</i>

Debugging

-  System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command

Debugs SPAN.	debug span
--------------	-------------------

6 Configuring sFlow

6.1 Overview

sFlow is a network monitoring technology jointly developed by InMon, HP, and FoundryNetworks in 2001. This technology has been standardized. It can provide complete traffic flows of Layer 2 to Layer 4, and it is applicable to traffic analysis in the extra-large network. This technology helps users analyze the performance, trend, and existence of network traffic flows in a detailed manner in real time.

sFlow has the following advantages:

- Accurate: sFlow supports accurate monitoring of traffic on a Gigabit network or a network with higher bandwidth.
- Scalable: One sFlow Collector can monitor thousands of sFlow Agents, and it has high scalability.
- Low cost: sFlow Agent is embedded in a network device, and its cost is low.

Protocol Specification

- sFlow Version 5
- RFC 1014

6.2 Applications

Typical Application	Scenario
Monitoring the LAN Traffic	Regard the device as an sFlow Agent, perform sampling of interface traffic in the LAN, and send the sFlow datagrams to an sFlow Collector for traffic analysis, thereby achieving the purpose of network monitoring.

6.2.1 Monitoring the LAN Traffic

Application Scenario

As shown in Figure 6-1, start switch A that serves as an sFlow Agent, enable flow sampling and counter sampling on port Te 0/1, monitor the traffic in the 192.168.1.0 network segment, encapsulate the sampling data into sFlow datagrams at regular intervals or when the buffer is full, and sent the sFlow data to the sFlow Collector for traffic analysis.

Figure 6-1

Function Deployment

- Configure the addresses of sFlow Agent and sFlow Collector on switch A.
- Enable flow sampling and counter sampling on port Te 0/1 of switch A.

i Lots of server software supports sFlow. You can obtain software supporting sFlow at <http://www.sflow.org/products/collectors.php>. The software sflowtrend is free of charge.

6.3 Features

Basic Concepts

↳ sFlow Agent

sFlow Agent is embedded in a network device. Generally, one network device can serve as an sFlow Agent. sFlow Agent can perform flow sampling and counter sampling, encapsulate sampled data into sFlow datagrams, and send the sFlow datagrams to the sFlow Collector.

sFlow datagrams are encapsulated in UDP. Figure 6-2 shows the sFlow datagram format.

Figure 6-2 sFlow Datagram Format

One sFlow datagram may contain one or multiple flow samples and counter samples.

Figure 6-3 sFlow Header

sFlow Geader Description:

Field	Description
sFlow version	sFlow version. V2, V4, and V5 are available. Currently, Ruijie supports V5 only.
IP version of the agent/switch	IP address version of the sFlow Agent
Agent IP address	IP address of the sFlow Agent
Sub agent id	Sub-agent ID
Datagram sequence number	Serial number of the sFlow datagram
Switch uptime	Duration from the startup time of the switch to the current time
n samples in datagram	The number of samples in the an sFlow datagram. One sFlow datagram may contain one or multiple flow samples and counter samples.

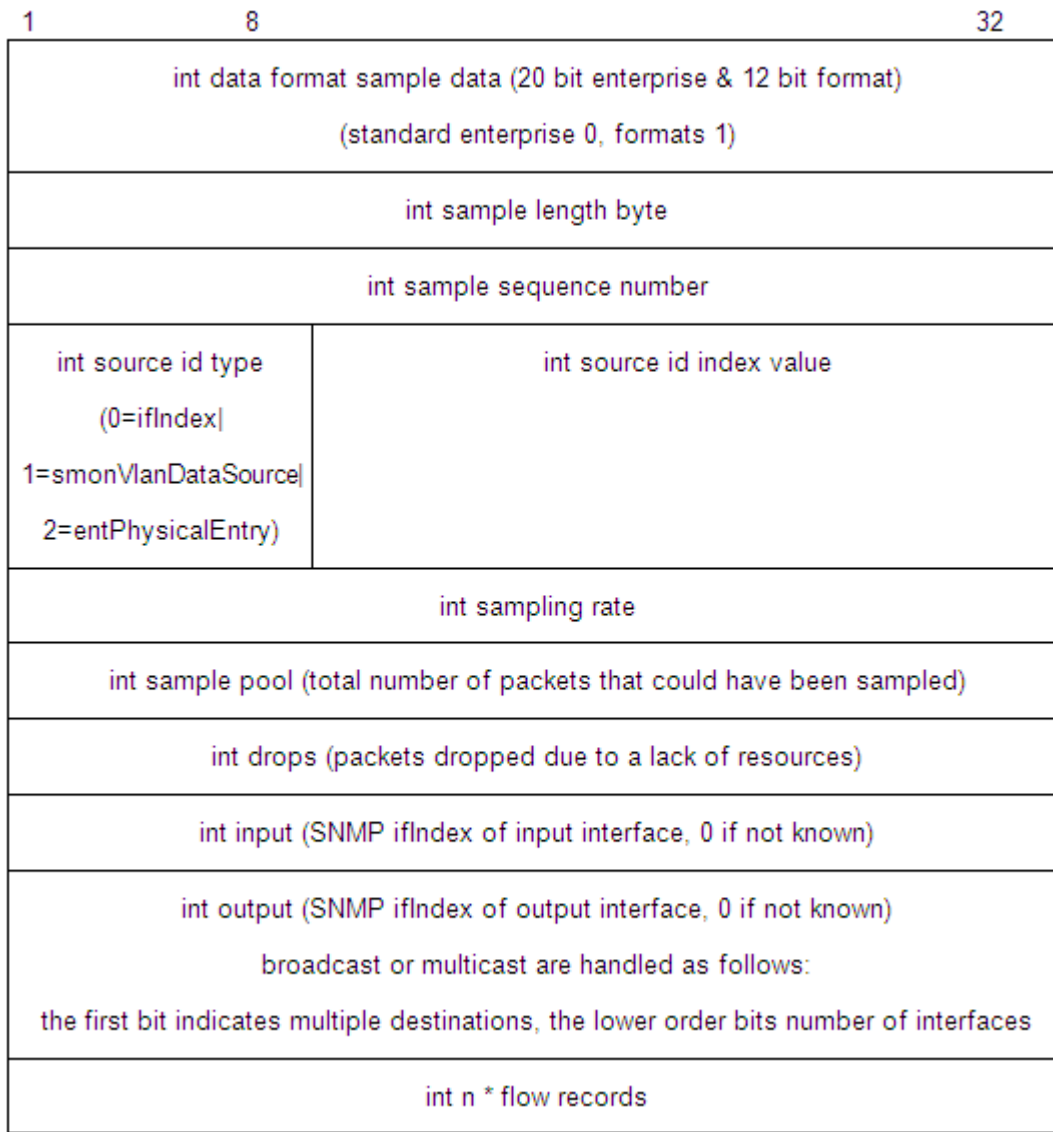

➤ **sFlow Collector**

sFlow Collector receives and analyzes the sFlow datagram sent from the sFlow Agent. sFlow Collector may be a PC or server. A PC or server installed with the application software for sFlow datagram analysis can be regarded as an sFlow Collector.

➤ **Flow Sampling**

Based on the specified sampling rate, the sFlow Agent device performs flow sampling on the traffic flowing through an interface, including copying the header of the packet, extracting the Ethernet header and IP header of the packet, and obtaining the route information of the packet.

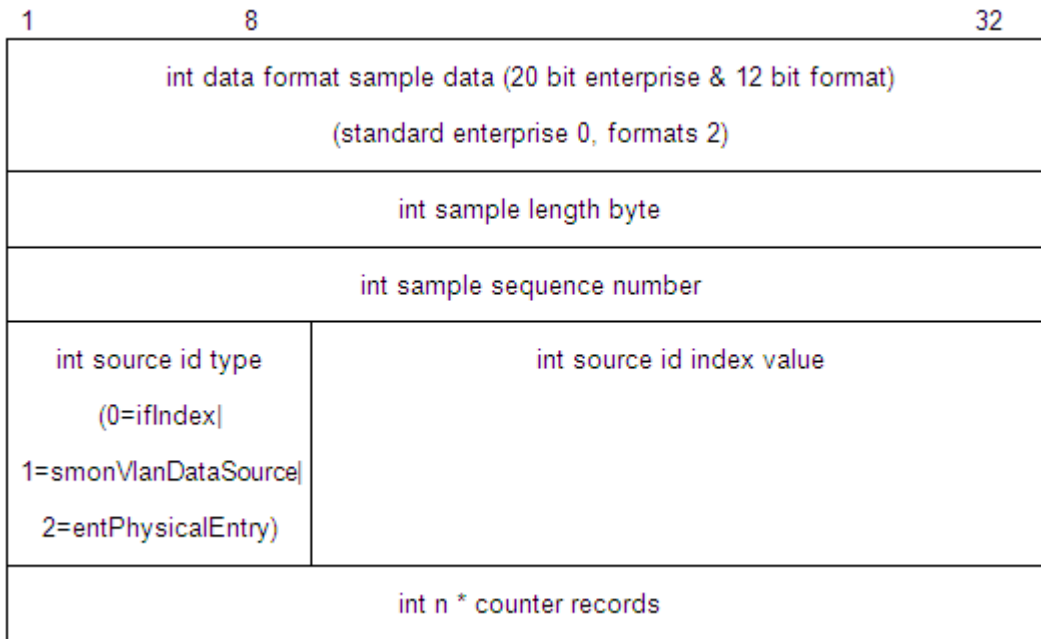

Figure 6-4 Flow Sample Header

↘ Counter Sampling

In counter sampling, an sFlow Agent periodically obtains the statistics and CPU usage on a specified interface. The statistics on the interface include the number of packets input through the interface and the number of packets output through the interface.

Figure 6-5 Counter Sample Header

Functions and Features

Feature	Description
Flow Sampling	Sample the traffic flowing through the interface, and send the encapsulated sFlow datagram to the sFlow Collector for analysis.
Counter Sampling	Periodically send the statistics on the interface to the sFlow Collector for analysis.

6.3.1 Flow Sampling

Sample the traffic flowing through the interface, and send the encapsulated sFlow datagram to the sFlow Collector for analysis.

Working Principle

Based on the specified sampling rate, the sFlow Agent device performs flow sampling on the traffic flowing through an interface, including copying the header of the packet, extracting the Ethernet header and IP header of the packet, and obtaining the route information of the packet. Then, the sFlow Agent encapsulates the flow sampling data into an sFlow datagram and sends the datagram to the sFlow Collector for analysis.

6.3.2 Counter Sampling

Periodically send the statistics on the interface to the sFlow Collector for analysis.

Working Principle

The sFlow Agent performs interface polling on a regular basis. For an interface whose counter sampling interval expires, the sFlow Agent obtains the statistics on this interface, encapsulates the statistics into an sFlow datagram, and sends the datagram to the sFlow Collector for analysis.

6.4 Configuration

Configuration Item	Suggestion & Related Command	
Configuring Basic Functions of sFlow	 Mandatory configuration. Establish communication connections between sFlow Agent and sFlow Collector.	
	sflow agent {address interface}	Configures the sFlow Agent address.
	sflow collector collector-id destination	Configures the sFlow Collector address.
	 Mandatory configuration. Enable flow sampling and counter sampling.	
	sflow counter collector	Enables the sFlow Agent to send counter samples to the sFlow Collector.
	sflow flow collector	Enables the sFlow Agent to send flow samples to the sFlow Collector .
	sflow enable	Enables sFlow sampling for the configuration interface, that is, enables counter sampling and flow sampling.
Configuring Optional Parameters of sFlow	 Optional configuration. Sets the optional parameter attributes of sFlow.	
	sflow collector collector-id max-datagram-size	Configures the maximum length of the sFlow datagram.
	sflow counter interval	Configures the counter sampling interval.
	sflow flow max-header	Configures the maximum length of the packet header copied during flow sampling.
	sflow sampling-rate	Configures the sampling rate of flow sampling.

6.4.1 Configuring Basic Functions of sFlow

Configuration Effect

- sFlow Agent and sFlow Collector can communicate with each other.
- Traffic flowing through the interface are sampled based on the default sampling rate and sent to the sFlow Collector for analysis.
- Statistics of the interface are periodically sent to the sFlow Collector based on the default sampling interval for analysis.

Notes

- Flow sampling can be configured on only physical interfaces.
- To enable the sFlow Collector to analyze the flow sampling results, the IP address of the sFlow Collector on the sFlow Agent device is required.

Configuration Steps

▾ Configuring sFlow Agent Address

- Mandatory configuration.
- Use the **sflow agent address** command to configure the address of the sFlow Agent.
- The sFlow Agent address must be a valid address. That is, the sFlow Agent address must not be a multicast or broadcast address. It is recommended that the IP address of the sFlow Agent device be used.

Command	sflow agent { address { <i>ip-address</i> ipv6 <i>ipv6-address</i> } } { interface { <i>interface-name</i> ipv6 <i>interface-name</i> } }
Parameter Description	address: Configures the IP address of the sFlow agent. <i>ip-address</i> : sFlow Agent IPv4 address ipv6 <i>ipv6-address</i>: sFlow Agent IPv6 address interface: Configures the interface of the sFlow agent. <i>interface-name</i> : Interface of IPv4 address. ipv6 <i>interface-name</i>: Interface of IPv6 address.
Defaults	No sFlow Agent address is configured by default
Command Mode	Global configuration mode
Configuration Usage	This command is used to configure the Agent IP address field in the output sFlow datagram. The datagram not configured with this field cannot be output. The sFlow Agent address shall be a host address. When a non-host address (for example, a multicast or broadcast address) is configured as the sFlow Agent address, a message indicating configuration failure is displayed. It is recommended that the IP address of the sFlow Agent device be configured as the sFlow Agent address.

▾ Configuring sFlow Collector Address

- Mandatory configuration.
- Use the **sflow collector** command to configure the address of the sFlow Collector.
- The sFlow Collector address must be a valid address. That is, the sFlow Collector address must not be a multicast or broadcast address. sFlow Collector must exist, and the route to it must be reachable.

Command	sflow collector <i>collector-id</i> destination { <i>ip-address</i> ipv6 <i>ipv6_address</i> } udp-port [[vrf <i>vrf-name</i>] [oob]] [via mgmt <i>mgmt-name</i>]]
Parameter	<i>collector-id</i> : sFlow Collector ID. The range is from 1 to 2.

Description	<p><i>ip-address</i>: sFlow Agent IPv4 address. It is not configured by default</p> <p>ipv6 <i>ipv6-address</i>: sFlow Agent IPv6 address. It is not configured by default</p> <p><i>udp-port</i>: sFlow Collector listening port number</p> <p>vrf <i>vrf-name</i>: VRF instance name. It is not configured by default</p> <p>oob: The sampled traffics are output through the management interface. By default, this parameter is not configured.</p> <p>via mgmt <i>mgmt-name</i>: Management port. It is not configured by default.</p>
Command Mode	Global configuration mode
Configuration Usage	This command is used to configure the sFlow Collector address. The sFlow Collector address shall be a host address. When a non-host address (for example, a multicast or broadcast address) is configured as the sFlow Collector address, a message indicating configuration failure is displayed. The sFlow Collector monitors the sFlow datagram on the specified port. When the vrf parameter is configured, the corresponding VRF instance must exist. When you remove the a VRF instance, the sFlow Collector address will be removed if this VRF instance is also configured for an sFlow Collector address.

↘ **Enabling sFlow Samples Output to the sFlow Collector**

- Mandatory configuration.
- You can use the **sflow flow collector** command to enable the sFlow Agent to send flow samples to the sFlow Collector.
- This function must be enabled on the interface to send flow samples to the sFlow Collector. In addition, sFlow Collector must exist, the route to it must be reachable, and the IP address of the corresponding sFlow Collector has been configured on the sFlow Agent device.

Command	sflow flow collector <i>collector-id</i>
Parameter Description	<i>collector-id</i> : sFlow Collector ID. The range is from 1 to 2.
Defaults	Sending the flow samples to the sFlow Collector is disabled by default.
Command Mode	Interface configuration mode
Configuration Usage	This command can be used for physical ports, SVI ports and sub routed ports and aggregate ports. sFlow datagrams can be output only when an IP address is configured for the corresponding sFlow Collector.

↘ **Enabling Counter Samples Output to the sFlow Collector**

- Mandatory configuration.
- You can use the **sflow counter collector** command to enable the sFlow Agent to send counter samples to the sFlow Collector.

- This must be enabled on the interface to send counter samples to the sFlow Collector. In addition, sFlow Collector must exist, the route to it must be reachable, and the IP address of the corresponding sFlow Collector has been configured on the sFlow Agent device.

Command	sflow counter collector <i>collector-id</i>
Parameter Description	<i>collector-id</i> : sFlow Collector ID. The range is from 1 to 2.
Defaults	Sending counter samples to the sFlow Collector is disabled by default.
Command Mode	Interface configuration mode
Configuration Usage	This command can be used for physical ports, SVI ports and sub routed ports and aggregate ports. sFlow datagrams can be output only when an IP address is configured for the corresponding sFlow Collector.

↘ Enabling Counter Sampling and Flow Sampling

- Mandatory configuration.
- You can use the **sflow enable** command to enable the flow sampling and counter sampling on an interface.
- The forwarding performance of an interface may be affected after flow sampling is enabled.

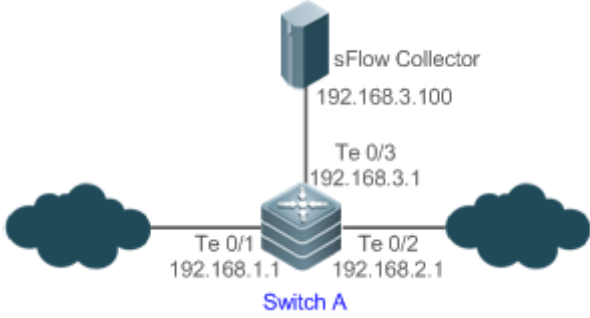

Command	sflow enable [ingress egress]
Parameter Description	ingress : Enables sFlow sampling in ingress direction. egress : Enables sFlow sampling in egress direction.
Defaults	The sFlow sampling function on an interface is disabled by default.
Command Mode	Interface configuration mode
Configuration Usage	This command can be used to enable counter sampling and flow sampling for physical ports, SVI ports, sub routed ports and aggregate ports. sFlow datagram can be output only when an IP address is configured for the corresponding sFlow Collector. If the direction parameter is not specified, sampling on both directions are enabled. The SVI ports and sub routed ports support only the ingress parameter.

Verification

- Use the **show sflow** command to display the sFlow configuration, and check whether the displayed information is consistent with the configuration.

Configuration Examples

↘ Configuring Flow Sampling and Counter Sampling for sFlow Agent

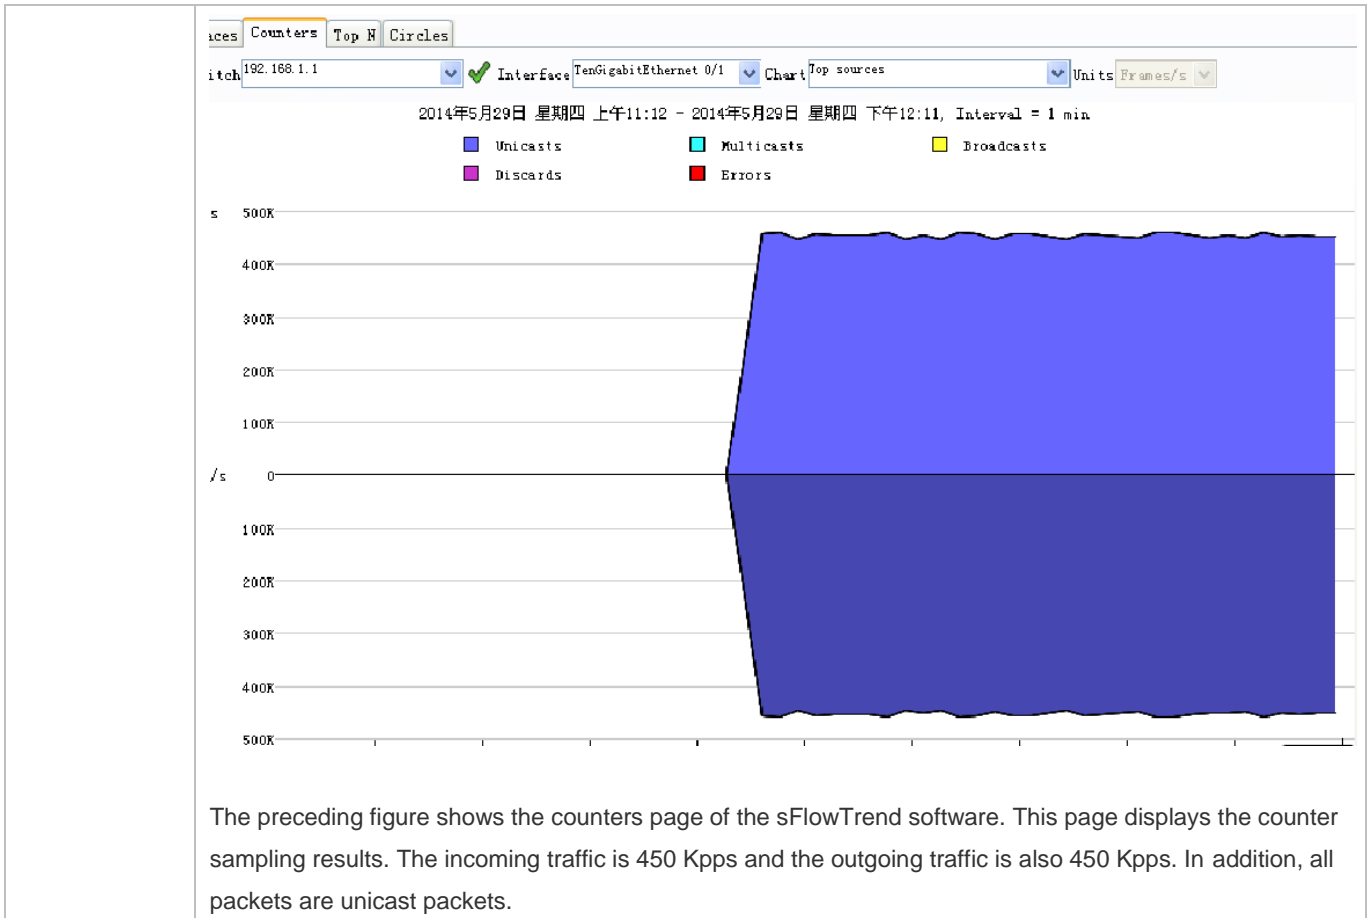

<p>Scenario</p> <p>Figure 6-6</p>	
	<p>As shown in Figure 6-6, start switch A that serves as the sFlow Agent, enable flow sampling and counter sampling on port Te 0/1, monitor the traffic in the 192.168.1.0 network segment, encapsulate the sampling traffic into sFlow datagrams at regular intervals or when the buffer is full, and send the sFlow datagrams to the sFlow Collector for traffic analysis.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure 192.168.1.1 as the sFlow Agent address. ● Configure 192.168.3.100 as the address of sFlow Collector 1, and 6343 as the port number. ● Configure interface TenGigabitEthernet 0/1 to output flow samples and counter samples to sFlow Collector 1, and enable the sFlow sampling function on this interface.
<p>Switch A</p>	<pre>Ruijie# configure terminal Ruijie(config)# sflow agent address 192.168.1.1 Ruijie(config)# sflow collector 1 destination 192.168.3.100 6343 Ruijie(config)# interface TenGigabitEthernet 0/1 Ruijie(config-if-TenGigabitEthernet 0/1)# sflow flow collector 1 Ruijie(config-if-TenGigabitEthernet 0/1)# sflow counter collector 1 Ruijie(config-if-TenGigabitEthernet 0/1)# sflow enable Ruijie(config-if-TenGigabitEthernet 0/1)# end</pre>
<p>Verification</p>	<p>Use the show sflow command to check whether the command output is consistent with the configuration.</p>
	<pre>Ruijie# show sflow sFlow datagram version 5 Global information: Agent IP: 192.168.1.1 sflow counter interval:30 sflow flow max-header:64 sflow sampling-rate:8192 Collector information: ID IP Port Size VPN 1 192.168.3.100 6343 1400</pre>

Port information			
Interface	CID	FID	Enable
TenGigabitEthernet 0/1	1	1	Y

Information displayed on the sFlowTrend software:

The preceding figure shows the Top N page of the sFlowTrend software. This page displays the flow sampling results and displays the top 5 source IP addresses that involve the largest traffic. The total incoming traffic is about 450 Kpps and the total outgoing traffic is 450 Kpps, which are consistent with the actual traffic.

6.4.2 Configuring Optional Parameters of sFlow

Configuration Effect

You can adjust the data sampling accuracy by modifying relevant parameter attributes of sFlow.

Notes

- The forwarding performance may be affected when the sampling rate is too low.

Configuration Steps

▾ Configuring the Maximum Length of the Output sFlow Datagram

- Optional configuration.
- You can use the **sflow collector** command to configure the length of the sFlow datagram, excluding the Ethernet header, IP header, and UDP header. An sFlow datagram may contain one or multiple flow samples and counter samples. Configuration of the output sFlow datagram's maximum length may lead to the result that the number of sFlow datagrams output during processing of a certain number of flow samples differs from the number of sFlow datagrams output during processing of the same number of counter packets. If the maximum length is greater than MTU, the output sFlow datagrams will be segmented.

Command	sflow collector <i>collector-id</i> max-datagram-size <i>datagram-size</i>
Parameter Description	<i>collector-id</i> : sFlow Collector ID. The range is from 1 to 2 max-datagram-size <i>datagram-size</i> : maximum length of the output sFlow datagram. The range is from 200 to 9,000.
Defaults	The default value is 1,400.
Command Mode	Global configuration mode
Configuration Usage	-

▾ Configuring the Flow Sampling Rate

- Optional configuration.
- You can use the **sflow sampling-rate** command to configure the global flow sampling rate.
- Configuration of flow sampling rate may affect the sFlow sampling accuracy. A lower sampling rate means a higher accuracy and larger CPU consumption. Therefore, the forwarding performance of the interface may be affected when the sampling rate is low.

Command	sflow sampling-rate <i>rate</i>
Parameter Description	<i>rate</i> : Sampling rate of sFlow sampling. One packet is sampled from every <i>n</i> packets (<i>n</i> equals the value of rate). The range is from 4,096 to 65,535.
Defaults	The default global flow sampling rate is 8,192.
Command Mode	Global configuration mode
Configuration Usage	This command is used to configure the global sampling rate of sFlow flow sampling, and sFlow flow sampling of all interfaces uses this sampling rate.

▾ Configuring the Maximum Length of the Packet Header Copied During Flow Sampling

- Optional configuration.
- You can use the **sflow flow max-header** command to configure the length of the packet header copied during flow sampling globally.
- Users can use this command to modify the datagram information to be sent to the sFlow Collector. For example, if a user concerns about the IP header, this user can configure the length to 56 bytes. During encapsulation of flow samples, the first 56 bytes of the sample packet are copied to the sFlow datagram.

Command	sflow flow max-header <i>length</i>
Parameter Description	<i>length</i> : maximum length of the packet header to be copied. The range is from 18 to 256.
Defaults	The default length of the packet header to be copied during global flow sampling is 64 bytes.
Command Mode	Global configuration mode
Configuration	Configure the maximum number of bytes of the packet content copied from the header of the original packet.

Usage	The copied content is recorded in the generated sample.
--------------	---

▾ Configuring the Sampling Interval

- Optional configuration.
- You can use the **sflow counter interval** command to configure the global counter sampling interval.
- Enable the counter sampling interface to send the statistics on it to the sFlow Collector at the sampling interval.

Command	sflow counter interval seconds
Parameter Description	<i>seconds</i> : time interval. The range is form 3 to 2,147,483,647. The unit is second.
Defaults	The default global counter sampling interval is 30 seconds.
Command Mode	Global configuration mode
Configuration Usage	This command is used to configure the global sFlow counter sampling interval, and sFlow Counter sampling of all interfaces uses this sampling interval.

Verification

- Check whether an sFlow datagram with the flow samples is received on the sFlow Collector.
- Use the **show sflow** command to display the sFlow configuration, and check whether the displayed information is consistent with the configuration.

Configuration Examples

▾ Configuring Optional Parameters of sFlow

Scenario	See Figure 6-6.
	<ul style="list-style-type: none"> ● Set the flow sampling rate to 4,096 in global configuration mode. ● Configure the length of the packet header copied during flow sampling to 128 bytes in global configuration mode. ● Set the sampling interval to 10 in global configuration mode.
Configuration Steps	<pre>Ruijie# configure terminal Ruijie(config)# sflow sampling-rate 4096 Ruijie(config)# sflow flow max-header 128 Ruijie(config)# sflow counter interval 10</pre>
	<p>Make traffic pass through interface TenGigabitEthernet 0/1.</p> <ul style="list-style-type: none"> ● Check whether there is traffic on interface TenGigabitEthernet 0/1 on sFlow Collector 1. ● Use the show sflow command to check whether the command output is consistent with the configuration.

Verification	<pre> Ruijie# show sflow sFlow datagram version 5 Global information: Agent IP: 10.10.10.10 sflow counter interval:10 sflow flow max-header:128 sflow sampling-rate:4096 Collector information: ID IP Port Size VPN 1 192.168.2.100 6343 1400 2 NULL 0 1400 Port information Interface CID FID Enable TenGigabitEthernet 0/1 0 1 Y </pre>

6.5 Monitoring

Displaying

Function	Command
Displays the sFlow configuration.	show sflow

Specifications and Limitations

This section lists the specifications and limitations of features supported on N18000 series products.

Feature	Description
DCB	<ol style="list-style-type: none"> 1. N18000-ED/DB products support 8 CNPV. 2. N18000-ED/DB products do not support the congestion-notification cnm-data-len command, so the 0-byte initial data is carried in the CNM. 3. For N18000-ED/DB products, PFC and ETS can be enabled on interfaces independently. 4. N18000-ED/DB products support three traffic classes.
L2GRE	<ol style="list-style-type: none"> 1. For N18000 series products, TTL is configured in the global configuration mode instead of in the L2GRE instance.
IP Multicasting	<ol style="list-style-type: none"> 1. For N18000 series products, the default CPP value of PIM packets is 1000pps and that of IGMP packets is 1000pps. Packets whose CPP value exceeds this value are discarded. If over 1000 multicast forwarding entries are to be created through the PIM protocol, it is recommended to set the CPP value of PIM packets to be equal to the entry number. If over 1000 multicast forwarding entries are to be created through the IGMP protocol, it is recommended to set the CPP value of IGMP packets to be equal to the entry number.
IPv6 Multicasting	<ol style="list-style-type: none"> 1. For N18000 series products, the default CPP value of PIMv6 packets is 1000pps and that of MLD packets is 1000pps. Packets whose CPP value exceeds this value are discarded. If over 1000 multicast forwarding entries are to be built through the PIMv6 protocol, it is recommended to set the CPP value of PIMv6 packets to be equal to the entry number. If over 1000 multicast forwarding entries are to be built through the MLD protocol, it is recommended to set the CPP value of IGMP packets to be equal to the entry number.
ISIS	<ol style="list-style-type: none"> 1. N18000 series products are enabled with CPU protection by default. There is a default limit to the number of packets corresponding to each destination group address of IS-IS (AllISSystems, AllL1ISSystems, AllL2ISSystems) that are sent to CPU. If there are many adjacencies or if Hello packets are sent at short intervals, the IS-IS packet number received by the switch may exceed the default limit, causing constant oscillation of adjacency. In this case, it is recommended to increase the limit to the IS-IS packet number by configuring CPU protection commands in the global configuration mode.
PBR	<p>For N18000 series products:</p> <ol style="list-style-type: none"> 1. If the policy-based routing (PBR) is configured with a null ACL, all packets are matched; if the policy-based routing is configured with an ACL without any ACE, the system matches the packets with the ACL of the next policy, and all packets are matched and are forwarded with common routing. 2. PBR is applied to only the packets sent to the local switch. If you do not want to apply PBR to a specific incoming IPv4/IPv6 packet, add the ACE "deny the switch IPv4/v6 address" in the ACL manually.
Network Service Module	<ol style="list-style-type: none"> 1. N18000 series products support 64 equivalent paths, and each path contains up to 32 equivalent routes. The equivalent path is a collection of routes with the same prefix that share the same next hop.

MAC Address	<ol style="list-style-type: none"> For N18000-ED products, a filtering MAC address occupies space twice as large as a common MAC address does. For example, though the size of a global filtering MAC address is 10KB, the filtering MAC address takes up 20KB available space. N18000-ED/DB products neither learn nor forward the packet with both the source MAC address and the destination MAC address consisting of 0 only.
Protocol VLAN	<ol style="list-style-type: none"> N18000 series products should be configured with both frame type and Ethernet type. For N18000 series products, you can specify any Ethernet type for the profile configuration.
MSTP	<ol style="list-style-type: none"> N18000 products support 65 instances with the ID ranging from 0 to 64.
uRPF	<ol style="list-style-type: none"> N18000 products do not support the function of monitoring the uRPF packet loss information.
Global IP-MAC Binding	<ol style="list-style-type: none"> For N18000 series products, if global IP+MAC binding and port security/802.1X are both applied, all secure users can communicate with each other no matter whether the security channel is enabled or not. For N18000 series products, if IPv6 compatible mode and port security/802.1X authentication are both applied, all IPv6 packets bound with the MAC address are allowed to go through the interface.
Port Security	<ol style="list-style-type: none"> For N18000 series products, if the security port is configured with IP+MAC binding and IPv6 compatible mode, the IPv6 packets consistent with the secure address but not with IP+MAC binding are allowed to go through the interface. The control plane traffic is not allowed to go through.
QinQ	<ol style="list-style-type: none"> N18000-EB/DB products support 4 TPIDs in the global configuration mode, namely, 0x8100 and 3 any values.
Aggregated Port	<ol style="list-style-type: none"> For N18000-ED/DB products, each aggregate port supports up to 8 member ports, and the device supports up to 256 aggregate ports by default. For N18000-ED/DB products, the supported aggregate port capacity mode includes 256*8, 128*16, 64*32, and 32*64. The maximum number of the member ports of an aggregate port is 8. 16, 32, 64 corresponding to each capacity mode, and the maximum number of aggregate ports is 256, 128, 64 and 32 respectively. For N18000-ED/DB products, if you perform load balancing based on the source MAC address, the destination MAC address, or the combination of the source MAC address and the destination MAC address, the device takes fields of Ethernet type and VLAN as equivalence factors by default. For N18000-ED/DB products, in the non-enhanced mode, load balancing of IGMP Snooping and multicast packets is based on t src-ip, dst-ip or src-ip+dst-ip; traffic balancing of unknown unicast packets, multicast packets and broadcast packets is based on src-mac, dst-mac or src-mac+dst-mac. But a L3 packet (unknown unicast packets, unknown multicast packets and unknown broadcast packets) cannot achieve load balancing based on src-ip or dst-ip on a L2 port. However, the enhanced mode can address this problem with load balancing based on the packet type. In the src-dst-ip-l4port mode, modification to the L4port affects the traffic balancing of unicast packets on N18000-ED/DB products. N18000-ED/DB products support aggregate-port-based load balancing. The aggregate-port-based load balancing configuration supports SMAC, DMAC, SMAC+DMAC, SIP, DIP or SIP+DIP. N18000-ED/DB products support configuration of the following enhanced traffic balancing templates:

	<p>L2 template: src-mac dst-mac vlan l2-protocol src-port</p> <p>IPv4 template: src-ip dst-ip protocol vlan l4-src-port l4-dst-port src-port</p> <p>IPv6 template: src-ip dst-ip protocol vlan l4-src-port l4-dst-port src-port</p> <p>MPLS template: top-label 2nd-label vlan src-ip dst-ip src-port</p> <p>TRILL template: src-mac dst-mac vlan</p> <p>FCoE template: src-id dst-id ox-id</p> <p>8. For N18000-ED/DB products, if the enhanced MPLS template contains the VLAN field, the balancing algorithm takes effect only when the ingress packet is a tagged MPLS packet and the action is popping the tag.</p>
<p>SPAN-RSPAN</p>	<ol style="list-style-type: none"> 1. For N18000-ED/DB products, when traffic mirroring is applied in the output direction, if the mirrored packets are multicast routing packets, the packets that come out of the destination traffic mirroring port are the multicast packets before being routed. 2. For N18000 series products, the switching function should be forcedly enabled before configuring the destination traffic monitoring port. 3. For N18000-ED/DB products, when traffic mirroring function is applied in the output direction on the TRILL encapsulation port, if the mirrored packets are non-unicast TRILL packets, the packets that come out of the destination traffic mirroring port are the TRILL packets before being encapsulated. 4. For N18000-ED/DB products when traffic mirroring is applied in the output direction on the tunnel source port, if the mirrored packets are multicast tunnel packets, the packets that come out of the destination traffic mirroring port are the packets before being tunnel-encapsulated. 5. For N18000-ED/DB products, when traffic mirroring is applied in the output direction on the MPLS port, the packets that come out of the destination traffic mirroring port are the packets before being revised. 6. For N18000-ED/DB products, if you want to mirror the TRILL packets, the destination traffic mirroring port should be TRILL P2P port or routing port. 7. N18000-ED/DB products only mirror forwarded packets on the port. 8. N18000-ED/DB/EB products do not support VLAN-based tx mirroring.
<p>Interface</p>	<ol style="list-style-type: none"> 1. The speed 100 command is not supported on the Gigabit SFP interface of M18000-48SFP-DB module. 2. For M18000 series line cards, the inbound ports only support the speed auto and speed 10G configuration. 3. For the 10 Gigabit fiber port, the auto-negotiation function is disabled forever, that is, the status of auto-negotiation is OFF forever. 4. When you insert the optical transceiver into the 40 Gigabit fiber port, the auto-negotiation is disabled; when the copper cable is inserted, the auto-negotiation is enabled. 5. For N18000 series products, the MTU configuration applies on both the ingress ports and egress ports. 6. For all N18000 series products, the actual MTU value is 26 bytes greater than the configured value (including 14-byte preamble, 4-byte FCS and 2-byte Tag). 7. N18000-ED/DB series products support the function of blocking L3 routing between protected ports.

	<ol style="list-style-type: none"> 8. Protected port configuration is supported on N18000-ED/DB series products. 9. Only M18000-12QXS-DB/M18000-24QXS-DB/M18000-24XS4QXS-DB products support the 40G port to be divided as 4x10G ports. 10. Only M18000-12CQ-EH products support 100G interface.
Storm Control	<ol style="list-style-type: none"> 1. For N18000 series products, the storm control function is disabled and the default value of storm control is one percent of the port bandwidth. 2. For N18000-ED/DB series products, if a port is configured with multicast/broadcast/non-unicast storm control based on PPS, it cannot be configured with unicast storm control based on the bandwidth percentage/Kbps setting; if a port is configured with multicast/broadcast/non-unicast storm control based on the bandwidth percentage/Kbps setting, it cannot be configured with unicast storm control based on PPS. 3. For N18000 series products, the multicast storm control function is disabled by default and the default value of storm control is one percent of the port bandwidth. 4. For N18000-ED/DB series products, if a port is configured with unicast/broadcast storm control based on PPS, it cannot be configured with multicast storm control based on the bandwidth percentage/Kbps setting; if a port is configured with unicast/broadcast storm control based on the bandwidth percentage/Kbps setting, it cannot be configured with multicast storm control based on PPS. 5. For N18000 series products, the broadcast storm control function is disabled by default and the default value of storm control is one percent of the port bandwidth. 6. For N18000-ED/DB series products, if a port is configured with unicast/multicast storm control based on PPS, it cannot be configured with broadcast storm control based on the bandwidth percentage/Kbps setting; if a port is configured with unicast/multicast storm control based on the bandwidth percentage/Kbps setting, it cannot be configured with broadcast storm control based on PPS.
ACL	<ol style="list-style-type: none"> 1. For N18000 series products, the ACL applied in the input direction does not support the neq matching of TCP and UDP packets on L4 ports while the ACL applied in the output direction supports only the eq matching of TCP and UDP packets on L4 ports. 2. For the N18000 series products, IPv6 ACL supports the following match fields: protocol, sip, l4_src, dip, l4_dst, dip, dscp, flow_label. An IPv6 ACL supports either one of the following match fields: protocol, sip, l4_src, l4_dst, dscp, flow_label, range protocol, dip, l4_src, l4_dst, dscp, flow_label, range An ACL cannot match all the above areas. Besides, the IPv6 ACL does not support the fragment matching. The IPv6 ACL applied in the output direction does not support flow label. When sip and dip fields are matches with the only first 64 bits (the mask length is less or equal to 64), the above five IPv6 match files are supported. 3. For N18000 series products, the ACL applied to SVI also applies to intra-VLAN bridge forwarding

	<p>messages and inter-VLAN routing messages, causing communication failure within the VLAN.</p> <ol style="list-style-type: none"> N18000 series products cannot identify the fragment flag field in IPv6 packets. Therefore, the fragment flag is omitted if an IPv6 ACL contains the fragment flag. That is, such an ACL is processed in the same way as an ACL without a fragment flag, and all packets including the initial fragment packet and non-initial packets are to be matched. For N18000 series products, the switchover of the fragment match modes is supported only in an IP extended ACL and expert extended ACL. For N18000 series products, ACL 80 only support the following fields: the source MAC address, the destination MAC address, VID, ETYPE, IP Protocol Number, IPv4 source IP address, IPv4 destination IP address, Destination Port Number, Source Port Number, ICMP Type and ICMP Code. 																
NTP	<ol style="list-style-type: none"> Ruijie devices support up to 1024 authentication keys and each server is allowed to configure only one authentication key for security communication. 																
QoS	<ol style="list-style-type: none"> The QoS trust mode cannot be configured on the SVI port. For N18000 series products, all member ports of a logical interface should be on the same line card. The member ports of the logical interface must be physical ports or aggregate ports. The DENY action in the ACL matched in a CLASS MAP does not take effect. N18000 series products do not support vid modification. When this command is configured on the egress port, N18000-ED/DB series products support DSCP modification for the packets whose traffic exceeds the bandwidth, but the CoS value does not change; when this command is configured on the ingress port, the CoS value changes with DSCP. N18000 series products support CoS modification for the packets whose traffic exceeds the bandwidth. When you modify the CoS value, the corresponding DSCP value is modified as well. By configuring the none-tos option, the DSCP value does not changed with CoS. QoS matching DSCP does not apply to MPLS packets. N18000 series products do not support the non-tos option when the set cos command is configured. For N18000 series products, the rate is limited by the real bandwidth, including the load taken by the preamble and IFG. (The preamble and IFG occupies 20 bytes,) N18000-ED/DB series products support the minimum rate-limiting granularity of 8Kbps. The granularity varies with the rate-limiting configuration. The following table describes the relationship between rate-limiting range and granularity. <table border="1" data-bbox="337 1541 1484 1797"> <tr> <td>Rate-limiting Range</td> <td>64Kbps-2Gbps</td> <td>2Gbps-4Gbps</td> <td>4Gbps-8Gbps</td> </tr> <tr> <td>Granularity</td> <td>8Kbps</td> <td>16Kbps</td> <td>32Kbps</td> </tr> <tr> <td>Rate-limiting Range</td> <td>8Gbps-16Gbps</td> <td>16Gbps-32Gbps</td> <td>32Gbps-40Gbps</td> </tr> <tr> <td>Granularity</td> <td>64Kbps</td> <td>128Kbps</td> <td>256Kbps</td> </tr> </table> <p>In case of traffic bursts, if the <i>burst-size</i> parameter is too small, the actual rate may be too small; if the <i>burst-size</i> parameter is too great, the actual rate may be too great. The following configuration is</p>	Rate-limiting Range	64Kbps-2Gbps	2Gbps-4Gbps	4Gbps-8Gbps	Granularity	8Kbps	16Kbps	32Kbps	Rate-limiting Range	8Gbps-16Gbps	16Gbps-32Gbps	32Gbps-40Gbps	Granularity	64Kbps	128Kbps	256Kbps
Rate-limiting Range	64Kbps-2Gbps	2Gbps-4Gbps	4Gbps-8Gbps														
Granularity	8Kbps	16Kbps	32Kbps														
Rate-limiting Range	8Gbps-16Gbps	16Gbps-32Gbps	32Gbps-40Gbps														
Granularity	64Kbps	128Kbps	256Kbps														

recommended:

- 1) If the rate-limiting value is smaller than 1024Kbps, it is recommended to set burst-size to 1024 KByte.
- 2) If the rate-limiting value is smaller than 10240Kbps, it is recommended to set burst-size equivalent to the rate-limiting value or adopt the maximum burst-size configuration supported by the device (The maximum burst-size is smaller than 10240KByte).
- 3) If the rate-limiting value is greater than 10240Kbps, it is recommended to adopt the maximum burst-size configuration supported by the device.
11. If the rate is too great, the *burst-size* parameter should be modified accordingly. Otherwise, the rate limiting might be inaccurate. The following configuration is recommended:
 - 1) For the 10 Gigabit port or 40 Gigabit port, it is recommended to set the burst-size to 32 or above.
12. You can attach a policy map to the output direction on N18000 series products.
13. For N18000 series products, when the **police** command is configured on an Aggregate Port (AP), the rate-limiting configuration can be shared by all AP member ports if the all member ports meet the following requirements:
 - 1) For the M18000-24QXS-DB products, the AP member ports must be the first 12 ports or last 12 ports on the line card.
 - 2) For other models of modules, all AP member ports must be on this line card.
14. For N18000 series products, the CLASS MAP is associated with the ACL. Therefore, QoS configuration shares the same restriction with ACL configuration. For details, see the ACL Configuration Guide. Policy maps cannot be configured on the SVI port.
15. You can configure a policy map and attach it to the output direction. The policy map is not supported on the Aggregate Port.
16. The policy maps attached to the output direction do not support CoS remarking. When the DSCP value of the packets is remarked, the CoS value is not remarked.
17. The map policy attached to the output direction is not supported on the logical interface. The CLASS MAP is associated with the ACL. Therefore, QoS configuration shares the same restriction with ACL configuration. For details, see *Configuring Access Control List*.
18. N18000-ED/DB series products adopt SP+DRR balancing algorithm on the VSL port by default. The queue 7 adopts the SP scheduling, and the priority of the other queues is 1. This scheduling configuration cannot be modified.
19. For N18000 series products, the rate is limited by the real bandwidth, including the load taken by the preamble and IFG. (The preamble and IFG occupies 20 bytes,)
20. N18000-ED/DB series products support the minimum rate-limiting granularity of 8Kbps. The granularity varies with the rate-limiting configuration. The following table describes the relationship between rate-limiting range and granularity.

	<table border="1"> <tr> <td>Rate-limiting Range</td> <td>64Kbps-2Gbps</td> <td>2Gbps-4Gbps</td> <td>4Gbps-8Gbps</td> </tr> <tr> <td>Granularity</td> <td>8Kbps</td> <td>16Kbps</td> <td>32Kbps</td> </tr> <tr> <td>Rate-limiting Range</td> <td>8Gbps-16Gbps</td> <td>16Gbps-32Gbps</td> <td>32Gbps-40Gbps</td> </tr> <tr> <td>Granularity</td> <td>64Kbps</td> <td>128Kbps</td> <td>256Kbps</td> </tr> </table>	Rate-limiting Range	64Kbps-2Gbps	2Gbps-4Gbps	4Gbps-8Gbps	Granularity	8Kbps	16Kbps	32Kbps	Rate-limiting Range	8Gbps-16Gbps	16Gbps-32Gbps	32Gbps-40Gbps	Granularity	64Kbps	128Kbps	256Kbps
Rate-limiting Range	64Kbps-2Gbps	2Gbps-4Gbps	4Gbps-8Gbps														
Granularity	8Kbps	16Kbps	32Kbps														
Rate-limiting Range	8Gbps-16Gbps	16Gbps-32Gbps	32Gbps-40Gbps														
Granularity	64Kbps	128Kbps	256Kbps														
	<p>21. If the rate is too great, the <i>burst-size</i> parameter should be modified accordingly. Otherwise, the rate limiting might be inaccurate. The following configuration is recommended:</p> <p>1) For the 10 Gigabit port or 40 Gigabit port, it is recommended to set the burst-size to 32 or above.</p> <p>22. You can only use the show run command to verify whether the WRED function is enabled in the global configuration mode,</p> <p>23. The lower threshold and the maximum loss rate are called a set of WRED configuration. N18000-ED/DB products support 120 sets of WRED configuration.</p> <p>24. When the lower limit is 100%, the WRED is disabled.</p> <p>25. N18000-ED/DB series products support the mapping configuration on the physical port.</p> <p>26. The administrator can configure the DSCP-threshold mapping by mapping DSCP-CoS to CoS-Threshold.</p> <p>27. The administrator can configure the Queue-threshold mapping by mapping CoS-Threshold to CoS-Queue.</p> <p>28. In VSU mode, the management packets go to the queue 8 with default priority 7. It is recommended not to modify this mapping.</p>																
sFlow	<p>1. N18000-ED/DB products support the sFlow statistics function.</p> <p>2. N18000-ED/DB products adopt the same sFlow sampling rate range from 4096 to 65535.</p> <p>3. The sFlow sampling rate is implemented by setting the sampling threshold register of the chip. The value of the sampling threshold register is the rounded value of the maximum sampling base (0xffff) dividing the sFlow sampling rate. The sampling rate is accurate only if the remainder is an integer. Therefore, a larger sampling ratio indicates a larger error. Within the sampling rate range, any sampling ratio error of the N18000-ED/DB series cannot exceed 10%.</p> <p>4. N18000-ED/EF products do not support sFlow sampling of cross linecard. That is, if the packets are forwarded to the ED/EF line card from the other line card, the sFlow sampling function on the ED/EF line card does not take effect.</p>																
UFT	<p>1. Only N18000-ED/EF/EH/DB/DC products support the UFT mode, including default, bridge, gateway, gateway-max, gateway-ndmax, route-v4max, route-v6max, label, acl, acl-ipv4 and mc.</p> <p>2. For N18000-ED/EF products, when the UFT mode is set to gateway-ndmax, the available space for the static MAC address and the filtering address is 1KB.</p>																
CPP	<p>1. DoS	<p>1. For N18000-ED/DB/EF products have the following restriction: There are four types of invalid TCP packets as follows:</p> <ol style="list-style-type: none"> 1) TCP packets with both SYN bit and FIN bit. 2) TCP packets without any flag. 3) TCP packets with FIN flag but without ACK flag. 4) TCP packets with SYN flag and source port number ranging from 0 to 1023. <p>2. When protection against invalid TCP packet attack is enabled, N18000-ED/DB/EF series products can</p>																																																																																																							

	<p>filter invalid TCP packets of the first and fourth types. For the second type of invalid TCP packets, SW-6200 series products can only filter TCP packets configured without any flag and the sequence number 0. For the third type of invalid TCP packets, N18000-ED/DB/EF series products can only filter TCP packets configured with the FIN flag, URG flag and PSH flag and the sequence number 0.</p>
MTU	<ol style="list-style-type: none"> 1. Please note the reasonability of MTU configuration. The IP/IPv6 MTU must be less than the interface MTU. The Layer interface includes the routed port, Layer AP port and SVI.
PoE	<ol style="list-style-type: none"> 1. Only the M18000-48GT-P-ED/M8600E-48GT-ED/M7800E-48GT-P-ED products support PoE.
RMON	<ol style="list-style-type: none"> 1. Ruijie Networks products support only the Ethernet port statistics. 2. Ruijie Networks products support only the Ethernet port recording.
Syslog	<ol style="list-style-type: none"> 1. For the chassis device working in VSU mode with the log redirection enabled, the log information on the backup supervisor module is redirected to the master supervisor module for display. When it is displayed, a corresponding role mark string ("device number/supervisor module name") is added to the very front of the log content to identify the log information as the redirected log information. In the VSU environment, if four supervisor modules exist at the same time, there can be four role mark strings, i.e. (*1/M1), (*1/M2), (*2/M1), (*2/M2). 2. The <i>buffer-size</i> parameter of the logging buffered command ranges from 4KB to 10MB, and the default value is 1MB.
MPLS-BASE	<ol style="list-style-type: none"> 1. For N18000 series products, the MPLS MTU configured on an interface cannot exceed the size of packets transmitted on the interface. For the switches adopting ASIC forwarding, this configuration is invalid. The switches forward packets based on the MTU configured on actual interfaces and directly discard the packet whose size exceeds the MTU. To modify the MTU of an interface, you can use the mtu command in the interface configuration mode. Fragmentation is supported by only process forwarding and router forwarding. You should adjust the MTU value according to the actual application to avoid performance degradation due to fragmentation. 2. For N18000 series products, TTL in the inner header is copied after TTL replication is enabled, whether it is smaller than the TTL in the outer header. 3. For N18000 series products, the mpls ip command (global configuration mode) is not used to control the chip forwarding but to control the software forwarding.
MPLS-L2VPN	<ol style="list-style-type: none"> 1. After enabling the port protection mode on the member ports of the AC in L2VPN, the port protection mode does not take effect for the non-Trunk member ports. 2. For N18000-ED/DB products, the DHCP packets cannot be transmitted transparently after the ip dhcp snooping command is enabled. 3. The QoS policy for the DSCP matching does not take effect for the MPLS packets. 4. For switches, the VLAN bound with VPWS has only one member port, which cannot be changed. After the VLAN member port is changed, the VLAN should be bound with VPWS again. 5. It is recommended to set PW as the ethernetvlan mode if VPLS service is provided on switches through Trunk access or on routers through sub-interface access. 6. For N18000-ED/DB series products, DHCP packets cannot be transmitted transparently after the ip

	<p>dhcp snooping command is enabled.</p> <ol style="list-style-type: none"> 7. For N18000 series products, VPLS can be bound to only one port. 8. For N18000 series products, VPLS instances are only supported by SVI interfaces and a VPLS instance can be bound to only one SVI interface. 9. For N18000 series products, one VPLS instance can be configured with mixed access modes. For example, PEs in one VPLS instance are configured with both Access and Trunk access modes. In such case, it is recommended to set the VPLS PW encapsulation mode on the PEs to the ethernetvlan mode. 10. For N18000 series products enabled with VPLS forwarding, the aging time of MAC addresses is configured by executing the mac-address-table aging-time command in global configuration. It cannot be configured separately for each VPLS instance. 11. Switches do not support the mac-limit command. 12. Switches do not support the forwarding statistics function. 13. It is not allowed to bind VPLS and VPWS with the default VLAN (VLAN1) when switches adopt L2 VPN service through Trunk ports. 14. The SVI member ports of VPLS and VPWS bound with switches are Trunk ports or Hybrid ports. The member ports belong to all SVIs and cannot be enabled with IPv4/IPv6 multicast routing, IGMP Snooping or MLD Snooping. 15. For switches, the VLAN port bound with the VPLS service cannot be configured with Subvlan, flexible QinQ, mac-vlan, private-vlan and supper-vlan. 16. For switches, the Kompella VPLS can be bound to only one port.
MPLS-L3VPN	<ol style="list-style-type: none"> 1. By default, tag assignment is performed based on each VRF, The PE removes the tag from the tagged packets and then forwards it based on the IP routing table.
Intelligent Monitoring	<ol style="list-style-type: none"> 1. The default priority of the line card is specified as follows: <ol style="list-style-type: none"> 1) The priority of the VSL line card is higher than that of other line cards. 2) The smaller the slot number is, the higher priority the line card enjoys. 2. The default priority of the line card power supply is specified as follows: <p>The management board enjoys the highest priority,</p> <p>The priority of N18000-FE products is higher than that of the other line cards (including N18000-VSL products).</p> <p>The priority of N18000-VSL products is higher than that of the other line cards.</p> <p>The smaller the line card slot number or the FE slot number is, the higher priority the slot enjoys.</p> <p>When a non-smart line card is inserted in a slot, the slot is automatically powered on and the priority configuration does not take effect.</p> 3. Information displayed by executing the show power command varies with various products. <p>For N18000 series product, the following information is displayed: power supply redundancy mode, the power module of each slot and its status, rated power, output power, output voltage, input/output voltage, fail/alarm status; the total power, assigned power, and remaining power of the system, the name, required power, assigned power and power supply status of each slot.</p> 4. For N18000 series products, the temperature is measured at the following places: the air intake vent on

	<p>the board, the air exhaust vent on the board, the hottest position on the board (two for each board), CPU (two for multi-service card), MAC(if the engine does not have any MAC chip, "N/A" will be displayed; if the board has multiple MAC chips, each MAC chip is displayed with one temperature) The show temperature command is used to display the alarm temperature.\</p>												
Hot Swapping	<p>1. N18010 and N18014 products support multiple switch fabric modules. The switch fabric module is used to forward data among line cards, The device without switch fabric module is not functional. When all the switch fabric modules are removed, the device will be automatically reset to switch the traffic on the network to the backup line.</p>												
VSU	<p>1. For N18000 products, the chassis of CMII module cannot form a VSU with the chassis of CMII Lite module.</p> <p>2. At least one 10 Gigabit port or one 40 Gigabit port should be specified as the VSL member port. The 10 Gigabit port and the 40 Gigabit port can be the VSL member ports at the same time. The connection modes between VSL member ports of two chassis:</p> <ul style="list-style-type: none"> ● Connect 10 Gigabit ports through the XFP (or SFP+) module with the optical fiber cable. ● Connect 40 Gigabit ports through the QXFP module with the optical fiber cable or copper cable. ● A 10 Gigabit port cannot be connected to a 40 Gigabit port. <p>3. N18000 series products support up to 32 VSL member ports.</p> <ul style="list-style-type: none"> ● There is no need to configure VSL AP when configuring the VSL port. The VSL AP performs auto-negotiation. ● The VSL heartbeat detection cannot be configured. ● The four separated 10 Gigabit ports broken out from the 40 Gigabit port cannot be configured to the VSL port. <p>4. For N18000 series products, any 10 Gigabit port can be configured as the VSL port.</p> <table border="1" data-bbox="337 1291 1458 1444"> <thead> <tr> <th>Product</th> <th>Stack Module</th> <th>Common Port</th> <th>Linear Topology</th> <th>Ring Topology</th> <th>Maximum Member Device Number</th> </tr> </thead> <tbody> <tr> <td>N18000 series</td> <td>Unsupported</td> <td>Supported</td> <td>Supported</td> <td>Unsupported</td> <td>2</td> </tr> </tbody> </table> <p>5. For N18000 series products, in order to avoid the connection error when there are multiple BFD sessions, please configure BFD on one of the paired devices instead of on both devices.</p>	Product	Stack Module	Common Port	Linear Topology	Ring Topology	Maximum Member Device Number	N18000 series	Unsupported	Supported	Supported	Unsupported	2
