IS-IS floods LSPs to advertise link states. The size of an LSP is limited by the MTU size of the link. When the content to be advertised exceeds one LSP, IS-IS will create LSP fragments to carry new link state information. According to ISO standards, an LSP fragment is identified by a one-byte LSP number. An IS-IS device can generate up to 256 LSP fragments.

Working Principle

The 256 LSP fragments are insufficient in any of the following situations:

1. New applications (such as traffic engineering [TE]) extend new TLV or Sub-TLV.
2. The network is expanded continuously.
3. Routes with reduced granularity are advertised, or other routes are redistributed to IS-IS.

After LSP fragments are used up, new routing information and neighbor information will be discarded, causing network exceptions such as routing black holes or loops. LSP fragments must be extended to carry more link state information, thus ensuring normal network operation.

You can configure an additional system ID and enable fragment extension to allow IS-IS to advertise more link state information in extended LSP fragments. Each virtual system can be considered as a virtual device that establishes a

neighbor relationship (with the path value being 0) with the originating system. Extended LSPs are published by the neighbor of the originating system, that is, the virtual system.

The following terms are related to fragment extension:

↳ Normal System ID

The system ID defined by ISO is used to establish neighbor relationships and learn routes. It is further defined as the normal system ID in order to be distinguished from the additional system ID introduced to fragment extension.

↳ Additional System ID

The additional system ID is configured by an administrator to generate extended LSPs. The additional system ID shares the usage rules of the normal system ID (for example, the additional system ID must be unique in the entire area), except that the additional system ID is not carried in Hello packets for neighbor relationship establishment.

↳ Originating System

An originating system is an IS-IS-enabled device and maps a virtual system identified by the additional system ID.

↳ Virtual System (Virtual IS)

A virtual system is identified by the additional system ID and used to generate extended LSPs. The virtual system concept is proposed by RFC for distinguishing from the originating system concept. Each virtual system can generate up to 256 LSP fragments. The administrator can configure multiple additional system IDs (virtual systems) to generate more LSP fragments.

↳ Original LSP

An original LSP is the LSP whose system ID contained in the LSP ID is a normal system ID. Original LSPs are generated by an originating system.

↳ Extended LSP

An extended LSP is the LSP whose system ID contained in the LSP ID is an additional system ID. Extended LSPs are generated by a virtual system.

Related Configuration

↳ Enabling Fragment Extension

By default, fragment extension is disabled. If you do not specify a Level when enabling fragment extension, it will take effect for Level-1 and Level-2 LSPs.

Run the **isp-fragments-extend** command to enable fragment extension.

There are up to 256 LSP fragments. When the fragments are used up, subsequent link state information, including neighbor information and IP route information, will be discarded, causing a network exception. To solve this problem, enable fragment extension at the specified Level and configure an additional system ID by using the **virtual-system** command.

4.3.7 IS-IS VRF

VRF is mainly used for local routing and packet separation. It avoids route conflict caused by use of the same prefix by multiple VPNs. IPv4 VPN and IPv6 VPN combine Multiprotocol Label Switching (MPLS) advantages in terms of Quality of Service (QoS) and security assurance, and are the primary solutions for interconnecting the geographically different office branches of an enterprise or industry user.

Working Principle

Figure 4-5 Separation of Different VPNs by VRF Tables Configured on Provider Edge (PE) Devices

In Figure 4-5, the following configuration requirements exist: Configure the two sites (CE1 and CE3) in VPN1 to access each other and the two sites (CE2 and CE4) in VPN2 to access each other, and forbid access between the sites in VPN1 and those in VPN2, because VPN1 and VPN2 belong to different customers or departments and may have identical IP addresses.

The customer edge (CE) devices connect the customer network to the PEs to exchange VPN routing information with the PEs, that is, advertise local routes to the PEs and learn remote routes from the PEs.

Each PE learns routes from directly connected CEs and exchanges the learned VPN routes with the other PE through the Border Gateway Protocol (BGP). The PEs provide access to the VPN service.

The Provider (P) device in the Service Provider (SP) network is not directly connected to the CEs. The P device only needs the MPLS forwarding capability and does not maintain VPN information.

The IS-IS protocol running between the PEs and CEs requires the VRF capability to separate routing information between VPN1 and VPN2. That is, IS-IS only learns routes through VRF.

Related Configuration

↘ Binding an IS-IS Instance with a VRF Table

By default, an IS-IS instance is not bound with any VRF table.

Run the **VRF** command to bind an IS-IS instance with a VRF table.

Note the following constraints or conventions for the binding operation:

- The IS-IS instances bound with the same non-default VRF table must be configured with different system IDs. The IS-IS instances bound with different VRF tables can be configured with the same system ID.
- One IS-IS instance can be bound with only one VRF table, but one VRF table can be bound to multiple IS-IS instances.
- When the VRF table bound to an IS-IS instance is changed, all IS-IS interfaces associated with the instance will be deleted. That is, the **ip** (or **ipv6**) **router isis** [tag] interface configuration and the redistribution configuration in routing process mode will be deleted.

4.3.8 IS-IS MTR

IS-IS MTR is an extended feature used to separate IPv4 unicast route calculation and IPv6 unicast route calculation based on topologies. It complies with the specification of IS-IS MT extension defined in RFC 5120. New TLV types are introduced to IIH PDUs and LSPs to transmit IPv6 unicast topology information. One physical network can be divided into an IPv4 unicast logical topology and an IPv6 unicast logical topology. The two topologies perform SPF calculation separately and maintain independent IPv4 and IPv6 unicast routing tables respectively. In this way, IPv4 unicast service traffic and IPv6 unicast service traffic are forwarded by different paths. The IS-IS MTR technique helps users deploy IPv6 unicast networks without the constraint on consistency between IPv4 and IPv6 unicast topology information.

IS-IS MTR is derived from IS-IS MT, which is used to separate IPv4 and IPv6 unicast topologies, unicast and multicast topologies, and topologies using different protocol stacks (such as IPv4 and Pv6). IS-IS MTR separates IPv4 and IPv6 unicast topologies based on IS-IS MT.

Working Principle

Figure 4-6 shows a typical networking application. The following implementation requirements exist: Deploy an IPv6 unicast topology in incremental mode, and upgrade some devices to support IPv4 and IPv6 dual protocol stacks while keeping other IPv4-enabled devices unchanged.

Figure 4-6 Physical Topology for IPv4-IPv6 Hybrid Deployment

In Figure 4-6, each link is marked by a number indicating its metric. RB only supports the IPv4 protocol stack, whereas other devices support IPv4 and IPv6 dual protocol stacks.

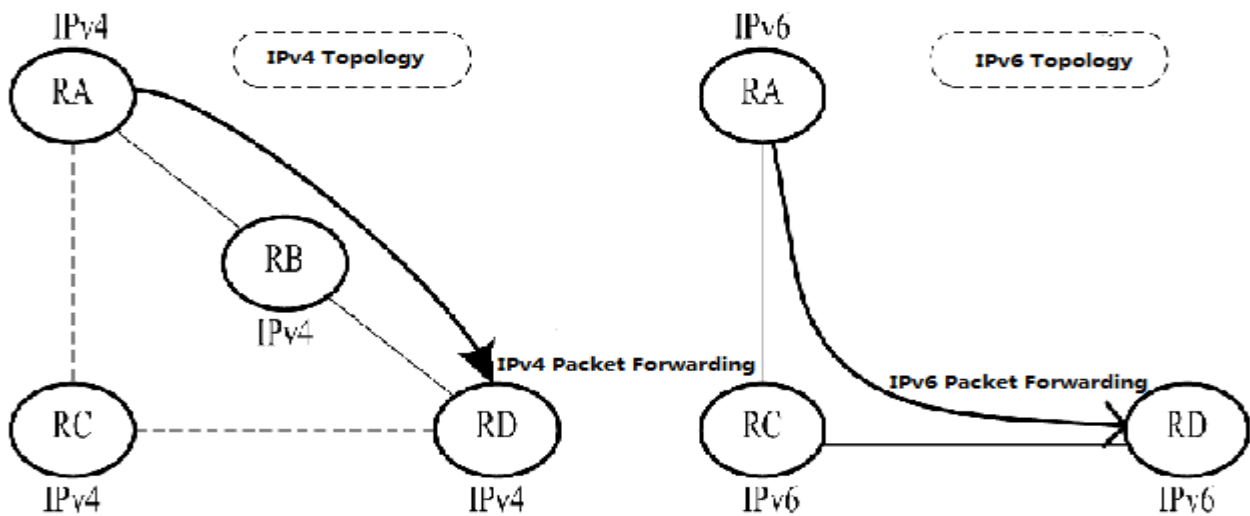

The networking constraint on consistency between IPv4 and IPv6 unicast topologies must be canceled to retain the use of RB; otherwise, RB cannot establish a neighbor relationship with RA or RD, which will cause new problems.

Figure 4-7 IPv4-IPv6 Hybrid Topology

In Figure 4-7, without IS-IS MTR support, the SPF calculations performed by RA, RB, RC, and RD only take into account the single hybrid topology. The calculated shortest path is RA -> RB -> RD, with the overhead being 20. RB will discard IPv6 packets because it does not support IPv6.

Figure 4-8 Separation of IPv4 and IPv6 Topologies

In Figure 4-8, the IS-IS MTR technique is used to separate IPv4 and IPv6 unicast topologies. RA, RB, RC, and RD establish neighbor relationships based on the IPv4 unicast topology and IPv6 unicast topology respectively. The left part shows the IPv4 topology formed by IPv4-enabled routers. The calculated IPv4 shortest path is RA -> RB -> RC, which realizes IPv4 packet forwarding. The right part shows the IPv6 topology formed by IPv6-enabled routers. The calculated IPv6 shortest path is RA -> RC -> RD, which realizes IPv6 packet forwarding.

IS-IS MTR must be deployed to avoid routing black holes when some devices support only one protocol. IS-IS MTR is not required when all devices support IPv4 and IPv6 dual protocol stacks.

- Deployment of a new network: IS-IS MTR is not required when devices only support the IPv4 protocol stack. For devices that only support the IPv6 protocol stack or devices that support IPv4 and IPv6 dual protocol stacks, enable the MT mode of IS-IS MTR. You are advised not to enable Multi-Topology Transition (MTT); otherwise, loops may occur.
- Reconstruction of an existing network with devices supporting only one protocol stack: Enable the MTT mode of IS-IS MTR on devices that support IPv4 and IPv6 dual protocol stacks in sequence (starting from the device closest to a device supporting only one protocol stack in the network topology). After the MTT mode is enabled on all new devices, switch the MTT mode to the MT mode on these devices in sequence (starting from the device farthest from a device supporting only one protocol stack in the network topology).

Related Configuration

▾ Enabling MTR for IS-IS Instances

By default, IS-IS instances are not enabled with MTR.

Run the **multi-topology** command to configure IS-IS to support IPv6 unicast topologies. After that, IPv4 and IPv6 unicast routes in IS-IS will be calculated based on different topologies.

Note the following constraints or conventions when you use the **multi-topology** command:

1. Set **metric-style** to **Wide** or **Transition** before you run the command.
2. The MTR feature will be disabled if **metric-style** is set to **Narrow** or only one Level is configured to support the Wide or Transition mode.

4.3.9 IS-IS Neighbor

The following conditions must be met for two routing devices to establish a neighbor relationship when IS-IS MTR is not configured:

- The interface addresses on both routing devices are in the same network segment.
- The interface Levels on both routing devices match.
- The routing devices are authenticated by each other.
- The routing devices support the same protocol.

The following conditions must be met for routing devices to establish a neighbor relationship when IS-IS MTR is configured:

- The interface addresses on both routing devices are in the same network segments.
- The interface Levels on both routing devices match.
- The routing devices are authenticated by each other.
- The routing devices have at least one consistent MT ID when P2P links are configured.
- There are no constraints on the MT IDs that the routing devices support when LAN links are configured.

4.4

4.5 Configuration

Configuration	Description and Command	
Enabling IS-IS	 (Mandatory) It is used to enable IS-IS on specified interfaces. You need to create an IS-IS routing process in advance.	
	router isis [<i>tag</i>]	Starts an IS-IS routing process. <i>tag</i> indicates the process name.
	net <i>areaAddress.SystemId.00</i>	Configures a NET address in IS-IS.
	ip router isis [<i>tag</i>]	Enables IS-IS on an interface. <i>tag</i> indicates the name of the IS-IS routing process.
Configuring IS-IS Hello Packets	 (Optional) It is used to configure the IS-IS Hello packet holdtime.	
	isis hello-interval { <i>interval</i> minimal } [level-1 level-2]	Configures the Hello packet interval on an interface. The value range is 1 to 65,535, in the unit of seconds.
	isis hello-multiplier <i>multiplier-number</i> [level-1 level-2]	Configures the Hello packet holdtime multiplier on an IS-IS interface. The value range is 2 to 100. The default value is 3.
Configuring IS-IS LSPs	 (Optional) It is used to perform time-related LSP configuration, determine whether to ignore LSP checksum errors, and enable/disable LSP fragment extension.	
	isis lsp-interval <i>interval</i> [level-1 level-2]	Configures the minimum LSP interval on an interface. The value range is 1 to 4,294,967,295, in the unit of milliseconds.
	isis retransmit-interval <i>interval</i> [level-1 level-2]	Configures the LSP retransmission interval by P2P links on an interface. The value range is 0 to 65,535, in the unit of seconds.
	lsp-refresh-interval <i>interval</i>	Configures the LSP refresh interval. The value range is 1 to 65,535, in the unit of seconds.
	max-lsp-lifetime <i>value</i>	Configures the LSP lifetime. The value range is 1 to 65,535, in the unit of seconds.
	ignore-lsp-errors	Configures to ignore LSP checksum errors.
	lsp-fragment-extend [level-1 level-2] [compatible rfc3786]	Enables fragment extension.
	virtual-system <i>system-id</i>	Configures an additional system ID.

Configuration	Description and Command	
Configuring IS-IS SNPs	 (Optional) It is used to configure the CSNP broadcast interval.	
	isis csnp-interval <i>interval</i> [level-1 level-2]	Configures the CSNP interval on an interface. The value range is 0 to 65,535, in the unit of seconds. The default value is 10s. No CSNPs are sent if the CSNP interval is set to 0.
Configuring the IS-IS Level Type	 (Optional) It is used to configure the system type or interface circuit type in IS-IS.	
	is-type { level-1 level-1-2 level-2-only }	Configures the system type.
	isis circuit-type { level-1 level-1-2 level-2-only [external] }	Configures the interface circuit type.
Configuring IS-IS Authentication	 (Optional) It is used to configure interface authentication, area authentication, and RD authentication.	
	isis password [0 7] <i>password</i> [send-only] [level-1 level-2]	Configures the password for plaintext authentication of Hello packets on an interface. When send-only is included, the authentication password is only used to authenticate sent Hello packets. Received Hello packets are not authenticated. If no Level is specified, the configured authentication and password take effect for all Levels. This command does not take effect if the isis authentication mode command is executed. Both commands are used to configure IS-IS interface authentication, but the isis password command has a lower priority. Before you run the isis password command, delete the isis authentication mode command configuration.

Configuration	Description and Command	
	<p>isis authentication mode { text md5 } [level-1 level-2]</p>	<p>Specifies authentication as plaintext or MD5. If no Level is specified, the authentication mode takes effect for all Levels.</p> <p>If you use this command after the isis password password [level-1 level-2] command is executed, the previous command configuration will be overwritten. Both commands are used to configure IS-IS interface authentication, but the isis authentication mode command has a higher priority.</p>
	<p>isis authentication key-chain name-of-chain [level-1 level-2]</p>	<p>Configures the password for interface authentication.</p> <p>If no Level is specified, the configured key chain takes effect for all Levels. This command must be used with the isis authentication mode command to configure IS-IS interface authentication.</p>
	<p>isis authentication send-only [level-1 level-2]</p>	<p>(Optional) Specifies that interface authentication is performed only on sent packets. Received packets are not authenticated.</p> <p>If no Level is specified, the send-only authentication mode takes effect for all Levels.</p> <p>This command is used to avoid network flapping caused by a temporary authentication failure when IS-IS authentication is configured. Before you deploy IS-IS authentication in the entire network, run the isis authentication mode { text md5 } [level-1 level-2] and isis authentication key-chain name-of-chain [level-1 level-2] commands on each device. After that, run the no isis authentication send-only command to restore the authentication of received packets. This realizes smooth authentication deployment and avoids network flapping.</p>

Configuration	Description and Command	
	<p>area-password [0 7] <i>password</i> [send-only]</p>	<p>Configures the password for area (Level-1) plaintext authentication.</p> <p>When send-only is included, the authentication password is only used to authenticate sent packets. Received packets are not authenticated.</p> <p>This command does not take effect if the authentication mode command is executed. Both commands are used to configure IS-IS area authentication, but the area-password command has a lower priority. Before you run the area-password command, delete the authentication mode command configuration.</p>
	<p>authentication mode { <i>text</i> <i>md5</i> } level-1</p>	<p>Specifies the IS-IS area authentication mode.</p> <p>If you use this command after the area-password <i>password</i> command is executed, the previous command configuration will be overwritten. Both commands are used to configure IS-IS area authentication, but the authentication mode command has a higher priority.</p>
	<p>authentication key-chain <i>name-of-chain</i> level-1</p>	<p>Configures the key chain for IS-IS area authentication.</p> <p>This command must be used with the authentication mode command to configure IS-IS area authentication.</p>

Configuration	Description and Command	
	<p>authentication send-only level-1</p>	<p>(Optional) Specifies that IS-IS area authentication is performed only on sent packets. Received packets are not authenticated.</p> <p>This command is used to avoid network flapping caused by a temporary authentication failure when IS-IS authentication is configured. Before you deploy IS-IS authentication in the entire area, run the authentication mode { text md5 } level-1 and authentication key-chain name-of-chain level-1 commands on each device. After that, run the no authentication send-only command to restore the authentication of received packets. This realizes smooth authentication deployment and avoids network flapping.</p>
	<p>domain-password [0 7] password [send-only]</p>	<p>Configures the password for RD (Level-2) plaintext authentication.</p> <p>When send-only is included, the authentication password is only used to authenticate sent packets. Received packets are not authenticated.</p> <p>This command does not take effect if the authentication mode command is executed. Both commands are used to configure IS-IS RD authentication, but the domain-password command has a lower priority. Before you run the domain-password command, delete the authentication mode command configuration.</p>
	<p>authentication mode { text md5 } level-2</p>	<p>Specifies the IS-IS RD authentication mode. If you use this command after the domain-password password command is executed, the previous command configuration will be overwritten. Both commands are used to configure IS-IS RD authentication, but the authentication mode command has a higher priority.</p>

Configuration	Description and Command	
	<p>authentication key-chain <i>name-of-chain</i> level-2</p>	<p>Configures the password for IS-IS RD authentication.</p> <p>This command must be used with the authentication mode command to configure IS-IS RD authentication.</p>
	<p>authentication send-only level-2</p>	<p>(Optional) Specifies that IS-IS RD authentication is performed only on sent packets. Received packets are not authenticated.</p> <p>This command is used to avoid network flapping caused by a temporary authentication failure when IS-IS authentication is configured. Before you deploy IS-IS authentication in the entire RD, run the authentication mode { text md5 } level-2 and authentication key-chain name-of-chain level-2 commands on each device. After that, run the no authentication send-only command to restore the authentication of received packets. This realizes smooth authentication deployment and avoids network flapping.</p>
<p>Configuring IS-IS GR</p>	<p> (Optional) It is used to enable IS-IS GR.</p>	
	<p>graceful-restart</p>	<p>Enables the GR Restart capability on the device that works as a Restarter. By default, the GR Restart capability is enabled.</p>
	<p>graceful-restart grace-period <i>seconds</i></p>	<p>(Optional) Configures the IS-IS GR time on the device that works as a Restarter. The default value is 300s.</p>
	<p>no graceful-restart helper disable</p>	<p>Enables the IS-IS GR Help capability on the device that works as a Helper. By default, the GR Help capability is enabled.</p>
<p>Configuring BFD Support for IS-IS</p>	<p> (Optional) It is used to enable BFD support for IS-IS.</p>	
	<p>bfd all-interfaces [anti-congestion]</p>	<p>Enables BFD support for IS-IS on all interfaces.</p>
	<p>isis bfd [disable anti-congestion]</p>	<p>Enables or disables BFD support for IS-IS on the current interface.</p>

Configuration	Description and Command	
Setting the IS-IS Overload Bit	 (Optional) It is used to set the overload bit in LSPs.	
	set-overload-bit [on-startup <i>seconds</i>] [suppress { [interlevel] [external] }] [level-1 level-2]	Sets the overload bit.
Configuring IS-IS VRF	 (Optional) It is used to bind an IS-IS instance with a VRF table.	
	vrf <i>vrf-name</i>	Binds an IS-IS instance with a VRF table.
Configuring IS-IS MTR	 (Optional) It is used to calculate IPv4 and IPv6 unicast routes in IS-IS based on different topologies.	
	multi-topology [transition]	Configures IS-IS to support IPv6 unicast topologies.
Configuring Simple Network Management Protocol (SNMP) for IS-IS	 (Optional) It is used to allow the SNMP software to perform Management Information Base (MIB) operations on IS-IS instances.	
	enable mib-binding	Performs MIB operations on the instance bound with Tag 1.
	configure terminal	Enters global configuration mode.
	snmp-server enable traps isis	Enables IS-IS trap globally.
	snmp-server host { <i>host-addr</i> ipv6 <i>ipv6-addr</i> } [vrf <i>vrfname</i>] [traps] [version { 1 2c 3 { auth noauth priv } }] <i>community-string</i> [udp-port <i>port-num</i>]	Configures an SNMP host in global configuration mode to receive IS-IS trap messages.
	router isis	Enters IS-IS routing process configuration mode.
	enable traps all	Allows the sending of all IS-IS trap messages to the host with the IP address 10.1.1.1.
Running ISIS on Super VLAN	 Optional.	
	isis subvlan [all <i>vid</i>]	Runs ISIS on Super VLAN.
.Configuring Other IS-IS Parameters	 Optional.	
	maximum-paths <i>maximum</i>	Configures the maximum number of IS-IS IPv4/IPv6 equal-cost paths.
	lsp-length <i>receive size</i>	Configures the maximum length allowed for received LSPs.
	lsp-length originate <i>size</i> [level-1 level-2]	Configures the maximum length allowed for sent LSPs.

Configuration	Description and Command	
	passive-interface [default] { <i>interface-type</i> <i>interface-number</i> }	Configures a passive interface.
	isis metric <i>metric</i> [level-1 level-2]	Configures the interface metric, which is valid only when metric-style is set to Narrow .
	isis wide-metric <i>metric</i> [level-1 level-2]	Configures the interface wide-metric value, which is valid only when metric-style is set to Wide .
	isis priority <i>value</i> [level-1 level-2]	Configures the priority for DIS election on an interface.
	default-information originate [route-map <i>map-name</i>]	Generates a Level-2 default route, which will be advertised through LSPs. When the command includes the route-map option, a default route is generated only if the criteria in route-map are met.
	summary-address <i>ip-address net-mask</i> [level-1 level-2 level-1-2] [metric <i>number</i>]	Configures an IPv4 summary route.
	summary-prefix <i>ipv6-prefix/prefix-length</i> [level-1 level-2 level-1-2]	Configures an IPv6 summary route.
	ignore-lsp-errors	Configures to ignore LSP checksum errors.
	log-adjacency-changes	Activates logging of IS-IS neighbor relationship changes.
	redistribute	Configures route redistribution.

4.5.1 Enabling IS-IS

Configuration Effect

- Before you run IS-IS, create an IS-IS routing process in global configuration mode. You can set the **tag** parameter after the **router isis** command to name the process. You can add different tags to configure different IS-IS routing processes. The setting of the **tag** parameter is optional.
- A system ID uniquely identifies an IS in a routing AS; therefore, the system ID must be unique across the AS. In IS-IS, each area may contain one or multiple area IDs. Normally, you only need to configure one area ID. You can configure multiple area IDs to realize area division. If an IS is configured with multiple area IDs, the system IDs must be the same.
- After an interface is added to the specified IS-IS routing process, the interface will establish a neighbor relationship.

Notes

- The Level-1 IS devices in an area must be configured with the same area ID.

- The core routing table does not distinguish the routing entries generated by different IS-IS routing processes.
- The IP addresses of interfaces connected between neighbors must be in the same network segment.
- If the two IP addresses are in different network segments, a neighbor relationship cannot be established.
- If you need to add an interface to the specified IS-IS routing process, set the **tag** parameter after the **ip router isis** command to indicate the process name.
- If you run the **no ip routing** command in global configuration mode, IS-IS will disable IPv4 routing on all interfaces. That is, the **no ip router isis [tag]** command is automatically executed on all interfaces. Other IS-IS settings remain unchanged.
- By default, CPU protection is enabled on devices. For packets mapped to the destination group addresses (AllISSystems, AllL1ISSystems, and AllL2ISSystems) in IS-IS, there is a default limit (for example, 400 pps) on the number of packets sent to the CPU. If a device has many neighbor relationships or sends Hello packets at short intervals, the IS-IS packets that the device receives may exceed the default limit, causing frequent flapping of neighbor relationships. To solve the problem, you can use the CPU protection command in global configuration mode to increase the limit.

Configuration Steps

▾ Starting an IS-IS Routing Process

- Mandatory.
- Perform this configuration in global configuration mode on each device, unless otherwise specified.

▾ Configuring a NET Address in IS-IS

- Mandatory.
- Perform this configuration in IS-IS routing process configuration mode on each device, unless otherwise specified.

▾ Enabling IS-IS on an Interfaces

- Mandatory.
- Perform this configuration in interface configuration mode on each device, unless otherwise specified.

Verification

- Check whether devices send Hello packets.
- Check whether devices establish neighbor relationships.
- Check whether devices exchange LSPs.

Related Commands

▾ Starting an IS-IS Routing Process

Command	<code>router isis [tag]</code>
---------	----------------------------------

Parameter Description	<i>tag</i> : Indicates the name of an IS-IS instance.
Command Mode	Global configuration mode
Usage Guide	<p>Use this command to initialize an IS-IS instance and enter IS-IS routing process configuration mode. An IS-IS instance will start running after a NET address is configured.</p> <p>If you set the tag parameter when you start an IS-IS routing process, you need to add the tag parameter when closing the IS-IS routing process.</p> <p>By default, CPU protection is enabled on devices. For packets mapped to the destination group addresses (AllISSystems, AllL1ISSystems, and AllL2ISSystems) in IS-IS, there is a default limit (for example, 400 pps) on the number of packets sent to the CPU. If a device has many neighbor relationships or sends Hello packets at short intervals, the IS-IS packets that the device receives may exceed the default limit, causing frequent flapping of neighbor relationships. To solve the problem, you can use the CPU protection command in global configuration mode to increase the limit.</p>

↘ Configuring a NET Address in IS-IS

Command	net <i>net-address</i>
Parameter Description	<i>net-address</i> : The NET address is in the format of XX.XXXX.YYYY.YYYY.YYYY.00. XX.XXXX indicates the area ID, and YYYY.YYYY.YYYY indicates the system ID.
Command Mode	IS-IS routing process configuration mode
Usage Guide	Use this command to configure an area ID and a system ID in IS-IS. Different NET addresses must have the same system ID.

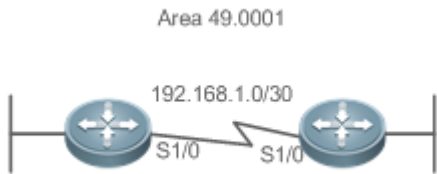

↘ Enabling IS-IS on an Interface

Command	ip router isis [<i>tag</i>]
Parameter Description	<i>tag</i> : Indicates the name of an IS-IS instance.
Command Mode	Interface configuration mode
Usage Guide	<p>Use this command to enable an interface to participate in IS-IS IPv4 routing. Use the no form of this command to disable the IS-IS routing process on the interface.</p> <p>If you run the no ip routing command in global configuration mode, IS-IS will disable IPv4 routing on all interfaces. That is, the no ip router isis [<i>tag</i>] command is automatically executed on all interfaces. Other IS-IS settings remain unchanged.</p>

Configuration Example

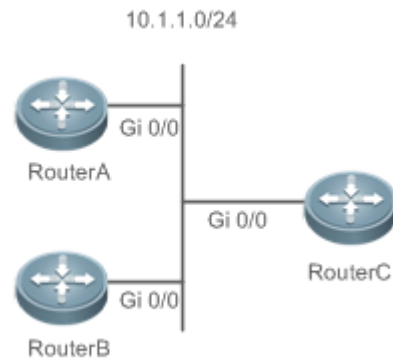

↘ Establishing a Neighbor Relationship on an IS-IS P2P Link

Scenario	Router A and Router B are connected in P2P mode.
-----------------	--

<p>Figure 4-9 P2P Link Topology</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure IS-IS. ● Configure Wide Area Network (WAN) interfaces.
<p>A</p>	<pre>A(config)# router isis A(config-router)# net 49.0001.0000.0000.0001.00 A(config)# interface Serial 1/0 A(config-if)# ip address 192.168.1.1 255.255.255.252 A(config-if)# ip router isis</pre>
<p>B</p>	<pre>B(config)# router isis B(config-router)# net 49.0001.0000.0000.0002.00 B(config)# interface Serial 1/0 B(config-if)# ip address 192.168.1.2 255.255.255.252 B(config-if)# ip router isis</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● Enable sending of Hello packets from the interface 192.168.1.1 on Router A to the interface 192.168.1.2 on Router B. ● Establish an IS-IS neighbor relationship between Router A and Router B, with the neighbor state being Up. ● Check the LSPs on Router A and Router B. The system IDs 0000.0000.0001 and 0000.0000.0002 should exist.
<p>A</p>	<pre>A# show isis neighbors A# show isis database detail</pre>
<p>B</p>	<pre>B# show isis neighbors</pre>

📌 **Establishing a Neighbor Relationship on an IS-IS Broadcast Link**

<p>Scenario</p>	<p>Router A, Router B, and Router C are interconnected through the Ethernet.</p>
------------------------	--

<p>Figure 4-10 IS-IS Broadcast Link Topology</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure IS-IS. ● Configure Ethernet interfaces.
<p>A</p>	<pre>A(config)# router isis A(config-router)# net 49.0001.0000.0000.0001.00 A(config)# interface GigabitEthernet 0/0 A(config-if)# ip address 10.1.1.1 255.255.255.0 A(config-if)# ip router isis</pre>

📌 **Performing Simple IS-ISv6 Configuration**

Scenario	Router A and Router B are connected through the Ethernet.
Figure 4-11 IS-ISv6 Broadcast Link Topology	
Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS. ● Configure Ethernet interfaces.
A	<pre>A(config)# router isis A(config-router)# net 49.0001.0000.0000.0001.00 A(config)# interface GigabitEthernet 0/0 A(config-if)# ipv6 address 1000 ::1/112 A(config-if)# ipv6 router isis</pre>
B	<pre>B(config)# router isis B(config-router)# net 49.0001.0000.0000.0002.00 B(config)# interface GigabitEthernet 0/0 B(config-if)# ipv6 address 1000 ::2/112 B(config-if)# ipv6 router isis</pre>
Verification	<p>Enable sending of Hello packets from the interface 1000 ::1 on Router A to the interface 1000 ::2 on Router B.</p> <p>Establish an IS-IS neighbor relationship between Router A and Router B, with the neighbor state being Up.</p> <p>Check the LSPs on Router A and Router B. The system IDs 0000.0000.0001 and 0000.0000.0002 should</p>

	exist.
A	<pre>A# show isis neighbors A# show isis database detail</pre>
B	<pre>B# show isis neighbors</pre>

Common Errors

- The IP addresses of the interfaces connected between neighbors are not in the same network segment.
- The **ip router isis** command is not executed on interfaces.
- No NET address is configured, or different NET addresses exist at Level-1.
- **max-area-addresses** is configured differently on both sides.
- **metric-style** is configured differently on both sides.
- The interface Levels on both sides are different. One side is Level-1, whereas the other side is Level-2.
- One side is configured with the P2P mode, whereas the other side is configured with the broadcast mode.
- One side is enabled with authentication, whereas the other side is not.

4.5.2 Configuring IS-IS Hello Packets

Configuration Effect

- Configure the Hello packet interval on an interface. The value range is 1 to 65,535, in the unit of seconds.
- Configure the Hello packet holdtime multiplier on an IS-IS interface.

Notes

- You can change the Hello packet holdtime by using the **isis hello-multiplier** command or **isis hello-interval** command or both.
- By default, CPU protection is enabled on devices. For packets mapped to the destination group addresses (AllISSystems, AllL1ISSystems, and AllL2ISSystems) in IS-IS, there is a default limit (for example, 400 pps) on the number of packets sent to the CPU. If a device has many neighbor relationships or sends Hello packets at short interval, the IS-IS packets that the device receives may exceed the default limit, causing frequent flapping of neighbor relationships. To solve the problem, you can use the CPU protection command in global mode to increase the limit.

Configuration Steps

▾ Configuring the Hello Packet Interval on an Interface

- Perform this configuration based on requirements.
- Run the **isis hello-interval** command in interface configuration mode on the desired device, unless otherwise specified.

▾ Configuring the Hello Packet Holdtime Multiplier on an Interface

- Perform this configuration based on requirements.
- Run the **isis hello-multiplier** command in interface configuration mode on the desired device, unless otherwise specified.

Verification

- Enable Router A to send Hello packets to Router B and Router C, and capture packets to check the packet interval.
- Make Router B or Router C down. After the holdtime has elapsed, check whether the corresponding neighbor relationship on Router A is invalid.

Related Commands

↘ Configuring the Hello Packet Interval on an Interface

Command	isis hello-interval { <i>interval</i> minimal } [level-1 level-2]
Parameter Description	<p><i>interval</i>: Indicates the Hello packet interval. The value range is 1 to 65,535, in the unit of seconds. The default value is 10.</p> <p>minimal: Indicates the minimum value of the holdtime, which is 1.</p> <p>level-1: Applies the setting to Level-1 Hello packets.</p> <p>level-2: Applies the setting to Level-2 Hello packets.</p>
Command Mode	Interface configuration mode
Usage Guide	<p>Use this command to change the Hello packet interval. The default interval is 10s. A DIS sends Hello packets at a frequency three times that by non-DIS devices in a broadcast network. If an IS is elected as the DIS on the interface, by default, the interface sends a Hello packet every 3.3s.</p> <p>If the keyword minimal is used, the Hello packet holdtime is set to 1. The Hello packet interval will be calculated based on the holdtime multiplier. If the holdtime multiplier is set to 4 and the isis hello-interval minimal command is executed, the Hello packet interval is equal to 1s divided by 4. The default Hello packet holdtime multiplier on an IS-IS interface is 3. The holdtime is equal to the holdtime multiplier multiplied by the packet interval. If the keyword minimal is used, the holdtime is set to 1. The packet interval is equal to 1 divided by the holdtime multiplier. If the holdtime multiplier is set to 4 and the isis hello-interval minimal command is executed, the packet interval is equal to 1 divided by 4s, which is 250 ms.</p>

↘ Configuring Hello Packet Holdtime Multiplier on an Interface

Command	isis hello-multiplier <i>multiplier-number</i> [level-1 level-2]
Parameter Description	<i>multiplier-number</i> : Indicates the Hello packet holdtime multiplier. The value range is 2 to 100. The default value is 3.
Command Mode	Interface configuration mode
Usage Guide	The Hello packet holdtime is equal to the Hello packet interval multiplied by the holdtime multiplier.

Configuration Example

▾ Configuring the Hello Packet Interval and Holdtime on an IS-IS Interface

Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS neighbors. (Omitted) ● Configure the Hello packet interval on an IS-IS interface. ● Configure the Hello packet holdtime multiplier on an IS-IS interface.
	<pre>A(config)# interface GigabitEthernet 0/0 A(config-if)# isis hello-interval 5 A(config-if)# isis hello-multiplier 5</pre>
Verification	<p>Enable Router A to send Hello packets to Router B and Router C, and capture packets to check the packet interval.</p> <p>Make Router B or Router C down. After the holdtime has elapsed, check whether the corresponding neighbor relationship on Router A is invalid.</p>
	<pre>A# show isis neighbor</pre>

4.5.3 Configuring IS-IS LSPs

Configuration Effect

- **isis lsp-interval:** Configures the LSP interval on an IS-IS interface.
- **lsp-gen-interval:** Sets the minimum number of LSP generation interval.
- **isis retransmit-interval:** After a device at one end of a P2P link sends an LSP packet, if the device receives no response within a period of time, it determines that the LSP packet is lost or dropped due to an error. The device will resend the LSP packet.
- **lsp-refresh-interval:** All current LSPs are periodically retransmitted to enable each network node to maintain the latest LSPs. The retransmission period is called the LSP refresh interval, which aims to update and synchronize LSPs in the entire area.
- **max-lsp-lifetime:** An LSP contains a field to indicate its lifetime. When a device generates an LSP, the field is set to the maximum lifetime of the LSP. After the LSP is received by the peer device, its lifetime will decrease with time. The peer device will replace the old LSP with the newly received one. If the device receives no new LSP until the existing LSP's lifetime decreases to 0, the existing LSP is still maintained in the LSDB for another 60s. If the device still receives no new LSP during this period, the existing LSP will be deleted from the LSDB. This mechanism updates and synchronizes LSPs in the entire area.
- **ignore-lsp-errors:** After receiving an LSP, the local IS-IS neighbor calculates its checksum and compares it with the checksum contained in the LSP. By default, if the two checksums are inconsistent, the LSP will be discarded. If you run the **ignore-lsp-errors** command to configure to ignore checksum errors, the LSP will be processed normally despite checksum inconsistency.

- **lsp-fragment-extend:** Enables LSP fragment extension, which is used to generate an extended LSP when the 256 fragments of the original LSP are used up.

Notes

- The LSP refresh interval must be smaller than the maximum LSP lifetime.
- The maximum LSP lifetime must be greater than the LSP refresh interval.

Configuration Steps

↘ Configuring the Minimum LSP Interval

- Perform this configuration based on requirements.
- Run the **lsp-interval** command in interface configuration mode on the desired device, unless otherwise specified.

↘ Configuring the LSP Retransmission Interval

- Perform this configuration based on requirements.
- Run the **retransmit-interval** command in interface configuration mode on the desired device, unless otherwise specified.

↘ Configuring the LSP Refresh Interval

- Perform this configuration based on requirements.
- Run the **lsp-refresh-interval** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

↘ Configuring the LSP Lifetime

- Perform this configuration based on requirements.
- Run the **max-lsp-lifetime** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

↘ Configuring to Ignore LSP Checksum Errors

- Perform this configuration based on requirements.
- Run the **ignore-lsp-errors** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

Verification

- Update LSPs continuously and capture LSPs to check the minimum LSP interval.
- Disable neighboring routes and capture LSPs to check the LSP retransmission interval.
- Capture LSPs to check the refresh interval.
- Check the LSP lifetime.

- Send an LSP with an incorrect checksum and check whether the LSP is discarded.
- Reduce the **lsp-length originate** command value, add routing information, and capture LSPs to check whether more than 256 LSP fragments are generated.

Related Commands

▾ Configuring the Minimum LSP Interval

Command	isis lsp-interval <i>interval</i> [level-1 level-2]
Parameter	<i>milliseconds</i> : Indicates the LSP interval. The value range is 1 to 4,294,967,295, in the unit of milliseconds.
Description	level-1 : Applies the setting only to Level-1 LSPs. level-2 : Applies the setting only to Level-2 LSPs.
Command Mode	Interface configuration mode
Usage Guide	N/A

▾ Configuring the LSP Retransmission Interval

Command	isis retransmit-interval <i>interval</i> [level-1 level-2]
Parameter	<i>seconds</i> : Indicates the LSP retransmission interval. The value range is 0 to 65,535, in the unit of seconds.
Description	level-1 : Applies the setting only to Level-1 LSPs. level-2 : Applies the setting only to Level-2 LSPs.
Command Mode	Interface configuration mode
Usage Guide	Use this command to configure the LSP retransmission interval. In a P2P network, after a device sends an LSP, if the device receives no PSNP response within the time specified by this command, it will resend the LSP. If the retransmission interval is set to 0, the LSP will not be resent,

▾ Configuring the LSP Refresh Interval

Command	lsp-refresh-interval <i>interval</i>
Parameter	<i>interval</i> : Indicates the LSP refresh interval. The value range is 1 to 65,535, in the unit of seconds. The default value is 900.
Command Mode	IS-IS routing process configuration mode
Usage Guide	After an LSP has remained stable for a period specified by this command, it will be refreshed and updated before being published. The LSP refresh interval must be smaller than the maximum LSP lifetime.

▾ Configuring the LSP Lifetime

Command	max-lsp-lifetime <i>value</i>
Parameter	<i>value</i> : Indicates the maximum time that LSPs keep alive. The value range is 1 to 65,535, in the unit of seconds. The default value is 1,200.
Command Mode	IS-IS routing process configuration mode

Mode	
Usage Guide	The maximum LSP lifetime must be greater than LSP refresh interval.

↘ Configuring to Ignore LSP Checksum Errors

Command	ignore-lsp-errors
Parameter Description	N/A
Command Mode	IS-IS routing process configuration mode
Usage Guide	After receiving an LSP, the local IS-IS neighbor calculates its checksum and compares it with the checksum contained in the LSP. By default, if the two checksums are inconsistent, the LSP will be discarded. If you run the ignore-lsp-errors command to configure to ignore checksum errors, the LSP will be processed normally despite checksum inconsistency.

↘ Configuring LSP Fragment Extension

Command	Lsp-fragment-extend [level-1 level-2] [compatible rfc3786]
Parameter Description	level-1: Applies the setting only to Level-1 LSPs. level-2: Applies the setting only to Level-2 LSPs. compatible: Indicates compatibility with the RFC version of extended LSPs. rfc3786: Extends the LSP old version.
Command Mode	IS-IS routing process configuration mode
Usage Guide	Use this command to enable LSP fragment extension.

↘ Configuring an Additional System ID

Command	virtual-system <i>system-id</i>
Parameter Description	<i>system-id:</i> Indicates an additional system ID (6-byte).
Command Mode	IS-IS routing process configuration mode
Usage Guide	Use this command to configure the additional system ID of an IS-IS routing process, which is used by the extended LSP that is generated after the 256 fragments of the original LSP are used up. To enable fragment extension, run the lsp fragment-extend command.

Configuration Example

↘ Configuring the Minimum LSP Interval

Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS neighbors. (Omitted) ● Configure the minimum LSP interval.
----------------------------	---

	<pre>A(config)# interface GigabitEthernet 0/1 A(config-if)# isis lsp-interval 100 level-2</pre>
Verification	Run the clear isis * command to update LSPs continuously and capture LSPs to check the minimum LSP interval.

↘ **Configuring the LSP Retransmission Interval**

Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS neighbors in P2P mode. (Omitted) ● Configure the LSP retransmission interval.
	<pre>A(config)# interface serial 0/1 A(config-if)# isis retransmit-interval 10 level-2</pre>
Verification	Disable neighboring routes and capture LSPs to check the LSP retransmission interval.

↘ **Configuring the LSP Refresh Interval**

Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS neighbors. (Omitted) ● Configure the LSP refresh interval.
	<pre>A(config)# router isis A(config-router)# lsp-refresh-interval 600</pre>
Verification	Capture LSPs to check the refresh interval.

↘ **Configuring the LSP Lifetime**

Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS neighbors. (Omitted) ● Configure the LSP lifetime.
	<pre>A(config)# router isis A(config-router)# max-lsp-lifetime 1500</pre>
Verification	Check the LSP lifetime (LSP Holdtime field).
	<pre>A# show isis database</pre>

Configuring to Ignore LSP Checksum Errors

Configuration Steps	<ul style="list-style-type: none"> Configure IS-IS neighbors. (Omitted) Configure to ignore LSP checksum errors.
	<pre>A(config)# router isis A(config-router)# ignore-lsp-errors</pre>
Verification	Send an LSP with an incorrect checksum and check whether the LSP is discarded.

Configuring LSP Fragment Extension

Configuration Steps	<ul style="list-style-type: none"> Configure IS-IS neighbors. (Omitted) Configure LSP fragment extension. Configure the additional system ID of the IS-IS routing process.
	<pre>A(config)# router isis A(config-router)# lsp-fragment-extend A(config-router)# virtual-system 0000.0000.0034</pre>
Verification	Reduce the lsp-length originate command value, add routing information, and capture LSPs to check whether more than 256 LSP fragments are generated.

4.5.4 Configuring IS-IS SNPs

Configuration Effect

- CSNPs are periodically broadcast by the DIS in a broadcast network for LSDB synchronization. In a P2P network, a CSNP is sent only after a neighbor relationship is established. An interface set to **mesh-groups** can be configured to periodically send CSNPs.
- When you need to set **mesh-group** on an IS-IS interface, run the **isis csnp-interval** command to configure the non-0 CSNP interval to ensure complete LSP synchronization between neighbors in the network. After that, CNSPs will be periodically sent to synchronize LSPs.

Configuration Steps

- Perform this configuration based on requirements.
- Run the **isis csnp-interval interval [level-1 | level-2]** command in interface configuration mode on the desired device, unless otherwise specified.

Verification

Capture CSNPs in the broadcast network to check the CSNP interval.

Related Commands

Configuring Source Registration Filter

Command	isis csnp-interval <i>interval</i> [level-1 level-2]
Parameter	<i>interval</i> : Indicates the CSNP interval. The value range is 0 to 65,535, in the unit of seconds.
Description	level-1 : Applies the setting only to Level-1 CSNPs. level-2 : Applies the setting only to Level-2 CSNPs.
Command Mode	Interface configuration mode
Usage Guide	Use this command to change the CSNP interval. By default, a DIS sends a CSNP every 10s in a broadcast network. In a P2P network, a CSNP is sent only after a neighbor relationship is established. An interface set to mesh-groups can be configured to periodically send CSNPs. No CSNPs are sent if the CSNP interval is set to 0.

Configuration Example

Configuring the CSNP Broadcast Interval

Configuration Steps	<ul style="list-style-type: none"> Configure IS-IS neighbors. (Omitted) Configure the CSNP broadcast interval.
	<pre>A(config)# interface GigabitEthernet 0/1 A(config-if)# isis csnp-interval 20</pre>
Verification	Capture packets to check the CSNP interval.

4.5.5 Configuring the IS-IS Level Type

Configuration Effect

- IS-IS supports a two-Level system to realize routing management and extensible route selection in a large network. Each Level is only concerned about maintaining the topology of the corresponding area.
- You can run the **is-type** command in IS-IS routing process configuration mode to configure an IS-IS Level, or run the **isis circuit-type** command in interface configuration mode to configure the IS-IS Level of an interface. The default Levels specified by the **is-type** and **isis circuit-type** commands are Level-1/Level-2. If you run both commands, the interface only sends the PDUs of the same Level specified by the two commands.

Notes

- If Level-1 or Level-2-only is configured using the **circuit-type** command, IS-IS will only send PDUs of the corresponding Level.
- If an interface is set to **external**, the interface will work as an external domain interface and IS-IS will not send PDUs of the corresponding Level.
- A device can have only one instance running at Level-2 (including Level-1/Level-2).

Configuration Steps

▾ Configuring the System Type

- Perform this configuration based on requirements.
- Run the **is-type** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

▾ Configuring the Interface Circuit Type

- Perform this configuration based on requirements.
- Run the **isis circuit-type** command in interface configuration mode on the desired device, unless otherwise specified.

Verification

- Check whether only the instances of the Level specified by the **is-type** command are processed, and neighbors of the corresponding Level are created.
- Check whether the interface only sends the PDUs of the same Level specified by the **is-type** and **circuit-type** commands.

Related Commands

▾ Configuring the System Type

Command	is-type { level-1 level-1-2 level-2-only }
Parameter	level-1 : Indicates that IS-IS only runs at Level-1.
Description	level-1-2 : Indicates that IS-IS runs at Level-1 and Level-2. level-2-only : Indicates that IS-IS only runs at Level-2.
Command Mode	IS-IS routing process configuration mode
Usage Guide	Changing the is-type value will enable or disable the routes of the corresponding level.

▾ Configuring the Interface Circuit Type

Command	isis circuit-type { level-1 level-1-2 level-2-only [external] }
Parameter	level-1 : Establishes a Level-1 neighbor relationship.
Description	level-2-only : Establishes a Level-2 neighbor relationship. level-1-2 : Establishes a Level-1/Level-2 neighbor relationship. external : Uses the interface as an external domain interface.

Command Mode	Interface configuration mode
Usage Guide	<p>If the circuit type is set to Level-1 or Level-2-only, IS-IS will only send PDUs of the corresponding Level.</p> <p>If the system type is set to Level-1 or Level-2-only, IS-IS only processes the instances of the corresponding Level, and the interface only sends the PDUs of the same Level specified by the is-type and circuit-type commands.</p> <p>If the interface is set to external, the interface will work as an external domain interface and IS-IS will not send PDUs of the corresponding Level.</p>

Configuration Example

Configuring IS-IS Levels

Configuration Requirements	Router A is connected to Router B and Router C by P2P serial links. Router B and Router C are connected by the Ethernet, and Router D and Router E are also connected by the Ethernet. On Router A, configure IS-IS area route summarization. Note that area route summarization can be configured only on border devices.
-----------------------------------	--

4.5.6 Configuring IS-IS Authentication

Configuration Effect

- Interface authentication is intended for establishing and maintaining neighbor relationships. A neighbor relationship cannot be established between two IS-IS devices with different interface authentication passwords. This prevents unauthorized or unauthenticated IS-IS devices from joining an IS-IS network that requires authentication. Interface authentication passwords are encapsulated in Hello packets before being sent.
- Area authentication and RD authentication in IS-IS are performed to verify LSPs, CSNPs, and PSNPs to prevent unauthorized or unauthenticated routing information from being injected into the LSDB. Authentication passwords are encapsulated in LSPs, CSNPs, and PSNPs before being sent.

Notes

- An interface authentication password is encapsulated in a Hello packet before being sent by an interface. When an interface receives a Hello packet, it checks the password in the packet against the existing one.
- Area authentication passwords are encapsulated in Level-1 LSPs, CSNPs, and PSNPs. When an interface receives an LSP, CSNP, or PSNP, it checks the password in the packet against the existing one.
- RD authentication passwords are encapsulated in Level-2 LSPs, CSNPs, and PSNPs. When an interface receives an LSP, CSNP, or PSNP, it checks the password in the packet against the existing one.

Configuration Steps

▾ Configuring Interface Authentication

- Perform this configuration based on requirements.
- Configure **isis password** in interface configuration mode on the desired device, unless otherwise specified.

▾ Configuring Area Authentication

- Perform this configuration based on requirements.
- Run the **area-password** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

▾ Configuring RD Authentication

- Perform this configuration based on requirements.
- Run the **domain-password** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

Verification

- IS-IS plaintext authentication provides only limited security because the password transferred through a packet is visible.
- IS-IS MD5 authentication provides higher security because the password transferred through a packet is encrypted using the MD5 algorithm.

Related Commands

▾ Configuring the Password for Plaintext Authentication of Hello Packets on an Interface

Command	isis password [0 7] password [send-only] [level-1 level-2]
Parameter Description	<p>0: Indicates that the key is displayed in plaintext.</p> <p>7: Indicates that the key is displayed in ciphertext.</p> <p>password-string: Indicates the password string for plaintext authentication. The string can contain up to 126 characters.</p> <p>send-only: Indicates that the plaintext authentication password is only used to authenticate sent packets. Received packets are not authenticated.</p> <p>level-1: Applies the setting to the Level-1 circuit type.</p> <p>level-2: Applies the setting to the Level-2 circuit type.</p>
Command Mode	Interface configuration mode
Usage Guide	<p>Use this command to configure the password for Hello packet authentication on an interface. Use the no form of this command to clear the password.</p> <p>If no Level is specified, by default, the password takes effect for Level-1 and Level-2 circuit types.</p> <p>This command does not take effect if the isis authentication mode command is executed. You need to first delete the previous command configuration.</p> <p>If you include the send-only parameter when deleting the isis authentication mode command configuration, only the parameter setting is canceled.</p>

▾ Specifying Interface Authentication as Plaintext or MD5

Command	isis authentication mode { md5 text } [level-1 level-2]
Parameter Description	<p>md5: Uses MD5 authentication.</p> <p>text: Uses plaintext authentication.</p> <p>level-1: Applies the setting to the Level-1 circuit type.</p> <p>level-2: Applies the setting to the Level-2 circuit type.</p>
Command Mode	Interface configuration mode
Usage Guide	<p>Use this command to specify the authentication mode before you can make the key chain configured using the isis authentication key-chain command take effect.</p> <p>If no Level is specified, the authentication mode will take effect for Level-1 and Level-2 circuit types.</p> <p>If you use the isis authentication mode command after the isis password command is executed to configure plaintext authentication, the previous command configuration will be overwritten.</p> <p>The isis password command does not take effect if the isis authentication mode command is executed.</p>

	To run the isis password command, delete the isis authentication mode command configuration first.
--	--

📌 **Configuring the Password for Interface Authentication**

Command	isis authentication key-chain <i>name-of-chain</i> [level-1 level-2]
Parameter Description	<i>name-of-chain</i> : Indicates the name of a key chain. The maximum length is 255. level-1 : Indicates that the authentication key chain takes effect for Level-1. level-2 : Indicates that the authentication key chain takes effect for Level-2.
Command Mode	Interface configuration mode
Usage Guide	<p>Authentication is not performed if no key chain is configured using the key chain command. In addition to the key chain command, you also need to run the isis authentication mode command to make IS-IS key chain authentication take effect.</p> <p>The key chain is applicable to plaintext authentication and MD5 authentication. Which authentication mode to use can be determined using the isis authentication mode command.</p> <p>For plaintext authentication, the key-string in the key chain cannot exceed 254 characters; otherwise, the key chain will be invalid.</p> <p>Only one key chain can be used at a time. After you configure a new key chain, it will replace the original one.</p> <p>If no Level is specified, the key chain takes effect for Level-1 and Level-2.</p> <p>The key chain is applicable to Hello packets. IS-IS will send or receive passwords that belong to the key chain.</p> <p>A key chain may contain multiple passwords. A password with a smaller SN is preferentially used for sending a packet. When the packet arrives at the peer device, the device will receive the packet if the packet-carried password is consistent with a password in the key chain.</p> <p>The authentication commands (for example, authentication key-chain) executed in IS-IS routing process configuration mode are intended for LSPs and SNPs. They do not take effect for IS-IS interfaces.</p>

📌 **(Optional) Applying Interface Authentication Only to Sent Packets (Received Packets Are Not Authenticated)**

Command	isis authentication send-only [level-1 level-2]
Parameter Description	level-1 : Sets send-only for Level-1 on an interface. level-2 : Sets send-only for Level-2 on an interface.
Command Mode	Interface configuration mode
Usage Guide	<p>Use this command to enable IS-IS to set an authentication password in the Hello packet sent by an interface. However, IS-IS does not authenticate the Hello packet received by the interface. You can use this command before you deploy IS-IS interface authentication on all devices in the network or before you change the authentication password or authentication mode. After you run the isis authentication send-only command, the devices will not authenticate received Hello packets to avoid network flapping when IS-IS interface authentication is deployed. After authentication is deployed in the entire network, run the no isis authentication send-only command to cancel the send-only setting.</p> <p>The isis authentication send-only command is applicable to plaintext authentication and MD5</p>

	<p>authentication. You can run the isis authentication mode command to specify the authentication mode for an IS-IS interface.</p> <p>If no Level is specified, the authentication mode will take effect for Level-1 and Level-2 on the interface.</p>
--	---

📌 Configuring the Password for Area (Level-1) Plaintext Authentication

Command	area-password [0 7] <i>password</i> [send-only]
Parameter Description	<p>0: Indicates that the key is displayed in plaintext.</p> <p>7: Indicates that the key is displayed in ciphertext.</p> <p>password-string: Indicates the password string for plaintext authentication. The string can contain up to 126 characters.</p> <p>send-only: Indicates that the plaintext authentication password is only used to authenticate sent Hello packets in Level-1 areas. Received Hello packets are not authenticate.</p>
Command Mode	IS-IS routing process configuration mode
Usage Guide	<p>Run this command to enable authentication of received LSPs, CSNPs, and PSNPs in Level-1 areas and include authentication information in these packets before they are sent. All IS-IS devices in an area must be configured with the same password.</p> <p>This command does not take effect if the authentication mode command is executed. You need to first delete the previous command configuration.</p> <p>To delete the password, run the no area-password command. If you run the no area-password send-only command, only the send-only setting is canceled. If you run the area-password psw send-only and no area-password send-only commands in sequence, the configuration is changed to area-password psw.</p>

📌 Configuring the Password for RD (Level-2) Plaintext Authentication

Command	domain-password [0 7] <i>password</i> [send-only]
Parameter Description	<p>0: Indicates that the key is displayed in plaintext.</p> <p>7: Indicates that the key is displayed in ciphertext.</p> <p>password-string: Indicates the password string for plaintext authentication. The string can contain up to 126 characters.</p> <p>send-only: Indicates that the plaintext authentication password is only used to authenticate sent Hello packets in Level-1 areas. Received Hello packets are not authenticated.</p>
Command Mode	IS-IS routing process configuration mode
Usage Guide	<p>Run this command to enable authentication of received LSPs, CSNPs, and PSNPs in Level-2 domains and include authentication information in these packets before they are sent. All IS-IS devices in a Level-2 domain must be configured with the same password.</p> <p>This command does not take effect if the authentication mode command is executed. You need to first delete the previous command configuration.</p> <p>To delete the password, run the no domain-password command. If you run the no domain-password send-only command, only the send-only setting is canceled. If you run the domain-password psw send-only and no domain-password send-only commands in sequence, the configuration is changed to</p>

	domain-password <i>psw.</i>
--	------------------------------------

▾ Specifying the IS-IS RD Authentication Mode

Command	authentication mode { md5 text } [level-1 level-2]
Parameter	md5 : Uses MD5 authentication.
Description	text : Uses plaintext authentication. level-1 : Indicates that the authentication mode takes effect for Level-1. level-2 : Indicates that the authentication mode takes effect for Level-2.
Command Mode	IS-IS routing process configuration mode
Usage Guide	Use this command to specify the authentication mode before you can make the key chain configured using the authentication key-chain command take effect. If no Level is specified, the authentication mode will take effect for Level-1 and Level-2. If you use the authentication mode command after the area-password or domain-password command is executed to configure plaintext authentication, the previous command configuration will be overwritten. The area-password or domain-password command does not take effect if the authentication mode command is executed. To run the area-password or domain-password command, delete the authentication mode command configuration first.

▾ Specifying the Key Chain for IS-IS Authentication

Command	authentication key-chain <i>name-of-chain</i> [level-1 level-2]
Parameter	<i>name-of-chain</i> : Indicates the name of a key chain. The maximum length is 255.
Description	level-1 : Indicates that the authentication key chain takes effect for Level-1. level-2 : Indicates that the authentication key chain takes effect for Level-2.
Command Mode	IS-IS routing process configuration mode
Usage Guide	Authentication is not performed if no key chain is configured using the key chain command. In addition to the key chain command, you also need to run the authentication mode command to make IS-IS key chain authentication take effect. The key chain is applicable to plaintext authentication and MD5 authentication. Which authentication mode to use can be determined using the authentication mode command. For plaintext authentication, the key-string in the key chain cannot exceed 254 characters; otherwise, the key chain will be invalid. Only one key chain can be used at a time. After you configure a new key chain, it will replace the original one. If no Level is specified, the key chain takes effect for Level-1 and Level-2. The key chain is applicable to LSPs, CSNPs, and PSNPs. IS-IS will send or receive passwords that belong to the key chain. A key chain may contain multiple passwords. A password with a SN is preferentially used for sending a packet. When the packet arrives at the peer device, the device will receive the packet if the packet-carried password is consistent with a password in the key chain.

➤ **Applying IS-IS Authentication Only to Sent Packets**

Command	authentication send-only [level-1 level-2]
Parameter	level-1: Applies the send-only setting to Level-1.
Description	level-2: Applies the send-only setting to Level-2.
Command Mode	IS-IS routing process configuration mode
Usage Guide	<p>Use this command to enable IS-IS to set an authentication password in the Hello packet to be sent. However, IS-IS does not authenticate received Hello packets. You can use this command before you deploy IS-IS authentication on all devices in the network or before you change the authentication password or authentication mode. After you run the authentication send-only command, the devices will not authenticate received packets to avoid network flapping when authentication passwords are deployed. After authentication is deployed in the entire network, run the no isis authentication send-only command to cancel the send-only setting.</p> <p>The authentication send-only command is applicable to plaintext authentication and MD5 authentication. You can run the authentication mode command to specify the authentication mode.</p> <p>If no Level is specified, the authentication mode will take effect for Level-1 and Level-2.</p>

Configuration Example

➤ **Configuring IS-IS Authentication**

Configuration Requirements	Router A, Router B, and Router C are connected through the Ethernet and run IS-IS. Router A is a Level-1 device, Router B is a Level-1/Level-2 device, and Router C is a Level-2 device. The following configuration requirements exist: Apply plaintext authentication to the Hello packets between Router A and Router B, as well as Level-1 LSPs and SNPs. Apply MD5 authentication to the Hello packets between Router B and Router C, as well as Level-2 LSPs and SNPs.
Figure 4-13 IS-IS Authentication Topology	
Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS. ● Configure Ethernet interfaces. ● Configure the password for IS-IS authentication.
A	Configure IS-IS.
	<pre>A(config)# router isis A(config-router)# net 49.0001.0000.0000.0001.00</pre>

<p>B</p>	<pre>B# show isis neighbors</pre>
<p>C</p>	<pre>C# show isis neighbors</pre>

Common Errors

- Different authentication passwords are configured between neighbors.
- Different authentication modes are configured between neighbors.

4.5.7 Configuring IS-IS GR

Configuration Effect

- IS-IS GR helps improve system reliability. On devices that separate the control plane from the forwarding plane, GR ensures that data forwarding is not interrupted during routing protocol restart.

IS-IS GR Working Mechanism

For GR to be successful, the following two conditions must be met: (1) The network topology is stable; (2) The device can ensure uninterrupted forwarding when it restarts IS-IS.

Two roles exist during the GR process: Restarter and Helper. Accordingly, IS-IS GR is divided into the IS-IS GR Restart capability and IS-IS GR Help capability. A device with the GR Restart capability can send a GR request and execute GR. A device with the GR Help capability can receive a GR request and help its neighbor with GR implementation. The GR process starts when the Restarter sends a GR request. After receiving the GR request, the neighboring device enters Help mode to help the Restarter reestablish its LSDB while maintaining the neighbor relationship with the Restarter. The main GR working mechanism is as follows:

When an IS-IS device needs to perform GR, it instructs its neighbor to maintain their neighbor relationship so that other devices in the network cannot sense the change in the topological relationship and the neighbor will not recalculate the route and update its forwarding table. The IS-IS device synchronizes and restores the LSDB to its pre-GR state with the help of the neighbor to ensure that the route and forwarding table remain unchanged before and after GR implementation and data forwarding is not interrupted.

The Restarter performs the following operations during the GR process:

1. The GR Restarter notifies the GR Helpers that it will be restarted.

Figure 4-14 Restart Notification by the GR Restarter

Switch A is a GR Restarter, and Switch B and Switch C are the GR Helpers for Switch A. Switch A sends a GR request instructing all its neighbors not to delete the neighbor relationships with Switch A when it is restarted. After receiving the GR request, the neighbors send GR responses to the GR Restarter, and will maintain their neighbor relationships with the GR Restarter during the GR time (specified by **GR grace-period**) notified by the GR Restarter.

2. The GR Restarter is restarted.

Figure 4-15 Restart Performed by the GR Restarter

When the GR Restarter is restarted, its IS-IS interface goes from Down to Up. Because the GR Helpers know that the GR Restarter is in IS-IS restart state, they maintain their neighbor relationships with the GR Restarter during the GR time and retain the routes from the GR Restarter.

3. The GR Restarter synchronizes topology and routing information from the GR Helpers.

Figure 4-16 LSDB Synchronization

After IS-IS restart, the GR Restarter synchronizes topology or routing information from the GR Helpers and recalculates its routing table. During this process, any change in the routing table is not updated to the forwarding table.

4. GR is completed when the GR Restarter finishes LSDB synchronization. Then all devices enter IS-IS interaction state.

Figure 4-17 GR Completion

After the GR Restarter synchronizes all required data, all devices enter IS-IS interaction state. The GR Restarter's routing table is updated to the forwarding table and invalid entries are cleared. Because the GR Restarter is completely restored to the pre-restart state under stable network conditions, its routing table and forwarding table remain unchanged before and after GR.

Notes

- IS-IS GR is implemented based on RFC5306: Restart Signaling for IS-IS.
- ✔ All products support the IS-IS GR Helper capability.

Configuration Steps

▾ Enabling the IS-IS GR Restart Capability

- Perform this configuration based on requirements.
- Run the **graceful-restart** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

▾ Configuring the Maximum GR Time

- Perform this configuration based on requirements.
- Run the **graceful-restart grace-period** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

▾ Enabling the IS-IS GR Help Capability

- Perform this configuration based on requirements.
- Run the **graceful-restart helper** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

Verification

- Check whether the routing table and forwarding table remain unchanged before and after GR.

Related Commands

▾ Enabling the IS-IS GR Restart Capability

Command	graceful-restart
Parameter	N/A
Description	
Command Mode	IS-IS routing process configuration mode
Usage Guide	Use this command to enable the IS-IS GR Restart capability. As long as the network conditions remain unchanged, IS-IS can be restarted and restored to the pre-restart state without impact on data forwarding.

▾ Configuring the Maximum GR Time

Command	graceful-restart grace-period <i>seconds</i>
Parameter	<i>seconds</i> : Indicates the GR time. The value range is 1s to 65,535s. The default value is 300s.
Description	
Command Mode	IS-IS routing process configuration mode
Usage Guide	N/A

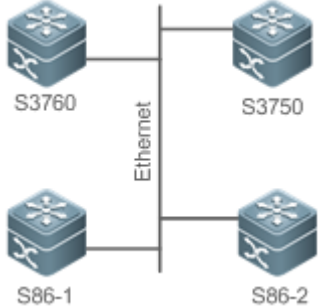

▾ Enabling the IS-IS GR Help Capability

Command	graceful-restart helper disable
Parameter	N/A
Description	
Command Mode	IS-IS routing process configuration mode
Usage Guide	Use the graceful-restart helper disable command to disable the IS-IS GR Help capability. The command enables IS-IS to ignore the GR request sent by the device to be restarted.

Configuration Example

▾ Configuring IS-IS GR

Configuration Requirements	<p>Two S8600 series high-end devices have the IS-IS GR Restart capability and are equipped with master/slave management boards for redundant backup at the control plane. IS-IS neighbor relationships are established between S86-1 and S3750/S3760 and between S86-2 and S3750/S3760. The system software of all devices supports the IS-IS GR Help capability.</p> <p>The following configuration requirements exist: Enable the IS-IS GR Restart capability with proper GR Time setting on S86-1 and S86-2 to realize uninterrupted forwarding and improve core device reliability.</p> <p>Disable the IS-IS GR Help capability on S3750 to exclude it from the Help process. By default, other device supports the IS-IS GR Help capability and require no additional configuration.</p>
-----------------------------------	---

<p>Figure 4-18 IS-IS GR Topology</p>	
<p>Configuration Steps</p>	<p>Configure IS-IS. (Omitted) Configure Ethernet interfaces. (Omitted)</p>
<p>S86-1</p>	<p>Configure IS-IS GR.</p>

<p>S86-2</p>	<pre>S86-2# show isis neighbors</pre>
<p>S3760</p>	<pre>S3760# show isis neighbors</pre>

4.5.8 Configuring BFD Support for IS-IS

Configuration Effect

- IS-IS dynamically discovers neighbors through Hello packets. After IS-IS enables the BFD function, a BFD session will be set up with the neighbor in Up state. The BFD mechanism is used to detect the neighbor state. Once a neighbor

failure is detected through BFD, IS-IS performs network convergence immediately. The convergence time can be reduced from 30s to less than 1s. By default, IS-IS Hello packets are sent at an interval of 10s in a P2P network, and the time required to detect a neighbor failure is three times the packet interval, that is 30s.

Notes

- You must set BFD session parameters before you enable BFD support for IS-IS.
- When you run the **bfd up-dampening** command on an interface with BFD support for IS-IS, you need to run the **bfd all-interfaces** command with the *[anti-congestion]* option selected.
- When you run the **bfd all-interfaces** command with the *[anti-congestion]* option selected, run the **bfd up-dampening** command on the interface.
- IP routing may cause a neighbor's interface for BFD session setup to be inconsistent with the interface for outgoing BFD packets. If this happens, the BFD session cannot be set up.
- If a neighbor's interface for BFD session setup is inconsistent with the interface for outgoing BFD packets, the BFD session cannot be set up.

Configuration Steps

↳ Enabling BFD Support for IS-IS on All Interfaces

- Perform this configuration based on requirements.
- Run the **bfd all-interfaces** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

↳ Enabling BFD Support for IS-IS on the Current Interface

- Perform this configuration based on requirements.
- Run the **isis bfd** command in interface configuration mode on the desired device, unless otherwise specified.

Verification

- Build a topology with two parallel lines. Typically, IS-IS selects one line as the master line and the other as the backup line. Enable BFD on the master line.
- Make the master line fail. Check whether IS-IS performs route convergence based on the BFD monitoring state and starts the backup line.

Related Commands

↳ Enabling BFD Support for IS-IS on the Current Interface

Command	bfd all-interfaces <i>[anti-congestion]</i>
Parameter Description	<i>anti-congestion</i> : Indicates the IS-IS BFD anti-congestion option.
Command	IS-IS routing process configuration mode

Mode	
Usage Guide	<p>You can enable or disable BFD on an IS-IS interface by using any of the following two methods:</p> <p>Method 1: Run the bfd all-interfaces command in IS-IS routing process configuration mode to enable BFD on all IS-IS interfaces, and then run the no bfd all-interfaces command to disable BFD on all IS-IS interfaces.</p> <p>Method 2: Run the isis bfd [disable] command in interface configuration mode to enable BFD on the specified IS-IS interface, and then run the isis bfd disable command to disable BFD on the interface.</p>

↘ Enabling BFD Support for IS-IS on the Current Interface

Command	isis bfd [disable anti-congestion]
Parameter	<i>disable</i> : Disables BFD support for IS-IS on the current interface.
Description	<i>anti-congestion</i> : Indicates the IS-IS BFD anti-congestion option.
Command Mode	Interface configuration mode
Usage Guide	<p>You can enable or disable BFD on an IS-IS interface by using any of the following two methods:</p> <p>Method 1: Run the [no] bfd all-interfaces [anti-congestion] command in IS-IS routing process configuration mode to enable or disable BFD on all IS-IS interfaces.</p> <p>Method 2: Run the isis bfd [disable anti-congestion] command in interface configuration mode to enable or disable BFD on the specified interface.</p> <p>Normally, BFD sends detection packets at millisecond intervals to detect the link state. When a link exception (such as a disconnected link) occurs, BFD can quickly detect it and instruct IS-IS to delete the neighbor relationship and the neighbor reachability information in LSPs. Then IS-IS recalculates and generates a new route to bypass the abnormal link, thus realizing fast convergence. With the introduction of new techniques such as the Multi-Service Transport Platform (MSTP), link congestion tends to occur during peak hours of data communication. BFD quickly detects the link exception and instructs IS-IS to delete the neighbor relationship and the neighbor reachability information in LSPs. Link switch is performed to bypass the congested link. A Hello packet for IS-IS neighbor detection is sent every 10s and its expiration time is 30s. The Hello packet can still be received normally when BFD detects an exception, and therefore an IS-IS neighbor relationship is reestablished quickly, causing the route to be restored to the congested link. Then BFD detects the abnormal link and link switch is performed again. This process is repeated, which makes the route be switched between the congested link and other links, causing repetitive flapping.</p> <p>The anti-congestion option is used to avoid routing flapping in case of link congestion. After the option is configured, the IS-IS neighbor state is still kept alive when link congestion occurs, but the neighbor reachability information in LSPs is deleted. The route is switched to a normal link. When the congested link is restored, the neighbor reachability information in LSPs is recovered and the route is switched back, which avoids route flapping.</p> <p>When you run the bfd all-interfaces [anti-congestion] command, run the bfd up-dampening command on the interface. The two commands must be used together. If you run only one command, the route flap dampening feature may not take effect or other network exceptions may occur.</p>

Configuration Example

➤ **Enabling BFD Support for IS-IS on the Current Interface**

Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS neighbors. (Omitted) ● Set BFD session parameters. (Omitted) ● Enable BFD support for IS-IS on the current interface.
	<pre>A(config)# interface GigabitEthernet 0/1 A(config-if)# isis bfd</pre>
Verification	<p>Enable S1 (192.168.1.10) and S2 (192.168.2.10) to send packets to G1 (229.1.1.1) and G2 (229.1.2.1). Add User to the G1 and G2 groups.</p> <ul style="list-style-type: none"> ● Check the multicast packet that User receives. User should only receive the (S1, G1) packet. ● Check that the PIM-SM routing table does not have the (S1, G2), (S2, G1), and (S2, G2) entries.
	<pre>A# show bfd neighbors detail</pre>

Common Errors

- BFD support for IS-IS is not enabled on neighbors.

4.5.9 Setting the IS-IS Overload Bit

Configuration Effect

The overload bit is used in the following three situations:

- Device overload

The local IS-IS node has overload issues, such as insufficient memory or full CPU load; as a result, its routing table has incomplete routes or does not have resource forwarding data. You can set the overload bit in an LSP to instruct the neighbor not to use the local node as a forwarding device.

To set the overload bit, run the **set-overload-bit** command without the **on-startup** keyword. The overload bit can be configured or canceled manually. When the local IS-IS node is restored, manually cancel the command configuration; otherwise, the node is always in overload state.

- Instantaneous black hole

In the scenario described by RFC3277, the IS-IS convergence speed is faster than the BGP speed; as a result, after an IS-IS node is restarted, a route may be instantaneously unreachable, which is called an instantaneous black hole. You can set the overload bit in an LSP to instruct the neighbor not to use the local node as a forwarding device until the specified time has elapsed.

To set the overload bit, run the **set-overload-bit** command with the **on-startup** keyword. The overload bit can be configured or canceled automatically by the IS-IS node based on the configuration. If the **on-startup** keyword is selected, the IS-IS node

automatically enters instantaneous black hole state after restart. When a neighbor relationship is established, the IS-IS node sends an LSP with the overload bit to notify the neighbor that the local node enters instantaneous black hole (or overload) state and instruct the neighbor not to use the local node as a forwarding device. After the specified time has elapsed, the IS-IS node immediately sends an LSP with the overload bit canceled to notify the neighbor that the local node has exited instantaneous black hole (or overload) state and can work as a forwarding device.

- Disabling real data forwarding on the local IS-IS node

If you only need to connect the local IS-IS node to a production network for testing or to meet other functional requirements, but does not require the node to forward real data in the network, you can set the overload bit in an LSP to instruct the neighbor not to use the local node as a forwarding device.

To set the overload bit, run the **set-overload-bit** command without the **on-startup** keyword. The overload bit can be configured or canceled manually. You can set the **suppress** keyword based on requirements to limit the routing information carried in an LSP in case of overload. For example, internal and external routes can be suppressed, and only the local direct route is advertised.

Notes

- At the same Level, the configuration with the **on-startup** keyword is mutually exclusive with the configuration without the **on-startup** keyword.

Configuration Steps

- Perform this configuration based on requirements.
- Run the **set-overload-bit** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

Verification

- Capture packets and check that the neighbor does not forward LSPs from the local node.

Related Commands

Command	set-overload-bit [on-startup seconds] [suppress { [interlevel] [external] }] [level-1 level-2]
Parameter Description	<p>on-startup seconds: Indicates the duration when an IS-IS node remains in overload state after restart. The value range is 5s to 86,400s.</p> <p>suppress: Indicates not to advertise internal routes (intra-area and inter-area routes) or external routes to neighbors when the IS-IS node is in overload state.</p> <p>interlevel: Indicates not to advertise intra-area and inter-area routes to neighbors when the IS-IS node is in overload state. It is used with the suppress keyword.</p> <p>external: Indicates not to advertise external routes to neighbors when the IS-IS node is in overload state. It is used with the suppress keyword.</p> <p>level-1: Sends LSPs with the overload bit only to Level-1 neighbors.</p> <p>level-2: Sends LSPs with the overload bit only to Level-2 neighbors.</p>
Command	IS-IS routing process configuration mode

Mode	
Usage Guide	<p>Use this command to force an IS-IS node to set the overload bit in a non-virtual LSP to instruct its IS-IS neighbors not to use the local node as a forwarding device.</p> <p>If you select the on-startup keyword, the IS-IS node automatically enters overload state after restart.</p> <p>If you do not select the on-startup keyword, the IS-IS node enters overload state immediately after restart.</p>

Configuration Example

Configuring the Overload Bit in Case of an Instantaneous Black Hole

Configuration Steps	<ul style="list-style-type: none"> Configure IS-IS neighbors. (Omitted) Verify that the IS-IS node enters instantaneous black hole state immediately after restart and remains in this state until the specified time (300s) has elapsed, and the IS-IS node only advertises local direct links to its neighbors during the specified time.
	<pre>A(config)# router isis A(config-router)#set-overload-bit on-startup 300 suppress interlevel external</pre>
Verification	<p>Capture packets to check LSPs.</p> <ul style="list-style-type: none"> Verify that the IS-IS node automatically enters instantaneous black hole state after restart. Once a neighbor relationship is established, the IS-IS node sends an LSP with the overload bit. After the specified time has elapsed, the IS-IS node immediately sends an LSP with the overload bit canceled to notify its neighbors that the local node has exited instantaneous black hole (or overload) state.
	<pre>A# show isis neighbors</pre>

Disabling Real Data Forwarding on the Local IS-IS Node

Configuration Steps	<ul style="list-style-type: none"> Configure IS-IS neighbors. (Omitted) Connect the local IS-IS node as a test device to a production network. The node is not required to forward real data in the network to avoid impact on production.
	<pre>A(config)# router isis A(config-router)#set-overload-bit suppress interlevel external</pre>
Verification	<p>Capture packets to check LSPs. Verify that the LSPs carry the overload bit and only advertise local direct routes.</p>
	<pre>A# show isis neighbors</pre>

4.5.10 Configuring IS-IS VRF

Configuration Effect

- Each VRF table can be seen as a virtual device or a dedicated PE device.
- The virtual device contains the following elements: an independent routing table, as well as an independent address space; a set of interfaces that belong to the VRF table; a set of routing protocols applicable only to the VRF table.
- Each device can maintain one or more VRF tables and a public-network routing table (also called a global routing table). Multiple VRF instances are separated from each other.

Notes

- Note the following constraints or conventions when you bind IS-IS instances and VRF tables:
- The IS-IS instances bound with the same VRF table must be configured with different system IDs. The IS-IS instances bound with different VRF tables can be configured with the same system ID.
- One IS-IS instance can be bound with only one VRF table, but one VRF table can be bound to multiple IS-IS instances.
- When the VRF table bound to an IS-IS instance is changed, all IS-IS interfaces associated with the instance will be deleted. That is, the **ip router isis [tag]** interface configuration and the redistribution configuration in routing process configuration mode will be deleted.

Configuration Steps

- Perform this configuration based on requirements.
- Run the **vrf** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

Verification

- Check whether the local device establishes neighbor relationships with other devices specified in the VRF table.

Related Commands

📌 Configuring IS-IS VRF

Command	<code>vrf vrf-name</code>
Parameter Description	<i>vrf-name</i> : Indicates the name of an existing VRF table.
Command Mode	IS-IS routing process configuration mode
Usage Guide	<p>Before you bind an IS-IS instance to a VRF table, ensure that the VRF table has been configured. If you need to establish an IS-ISv6 neighbor relationship, enable IPv6 and ensure that the table to be bound is a multiprotocol VRF table.</p> <p>Note the following constraints or conventions when you bind IS-IS instances and VRF tables:</p> <ul style="list-style-type: none"> ● The IS-IS instances bound with the same non-default VRF table must be configured with different

	<p>system IDs. The IS-IS instances bound with different VRF tables can be configured with the same system ID.</p> <ul style="list-style-type: none"> ● One IS-IS instance can be bound with only one VRF table, but one VRF table can be bound to multiple IS-IS instances. ● When the VRF table bound to an IS-IS instance is changed, all IS-IS interfaces associated with the instance will be deleted. That is, the ip (or ipv6) router isis [<i>tag</i>] interface configuration and the redistribution configuration in routing process configuration mode will be deleted.
--	--

Configuration Example

Configuring IS-IS VRF

Configuration Steps	<ul style="list-style-type: none"> ● Bind an IS-IS instance to a VRF table. ● Add interfaces to the VRF table and IS-IS instance. (Omitted)
	<pre>A(config)#vrf definition vrf_1 A(config-vrf)#address-family ipv4 A(config-vrf-af)#exit-address-family A(config)# router isis A(config-router)# vrf vrf_1</pre>
Verification	Check whether the local device establishes neighbor relationships with other devices specified in the VRF table.
	<pre>A# show isis neighbors</pre>

Common Errors

- Interfaces are not added to the VRF table.
- The IP addresses of the interfaces connected between neighbors are not in the same network segment.
- The **ip router isis** command is not executed on interfaces.
- No NET address is configured, or different NET addresses exist at Level-1.
- **max-area-addresses** is configured differently on both sides.
- **metric-style** is configured differently on both sides.
- The interface Levels on both sides are different. One side is Level-1, whereas the other side is Level-2.
- One side is configured with the P2P mode, whereas the other side is configured with the broadcast mode.
- One side is enabled with authentication, whereas the other side is not.

4.5.11 Configuring IS-IS MTR

Configuration Effect

- If the **multi-topology** command is not executed, IPv4 and IPv6 share one IS-IS physical topology, also called the default topology. If the **multi-topology** command is executed without the **transition** parameter, routing devices run in MT mode. IS-ISv4 runs in the default topology, and IS-ISv6 runs in the IPv6 unicast topology. If the **multi-topology** command is executed with the **transition** parameter, routing devices run in MTT mode. IS-ISv6 runs in the default topology and IPv6 unicast topology. The three configurations are mutually exclusive. The routing devices in MTT mode can transfer the MT TLV or the default topology TLV. The MTT mode is applicable to incremental deployment to ensure smooth network migration. The MTT mode can cause route leaking between the default topology and IPv6 unicast topology. If the MTT mode is configured improperly, network failures such as routing black holes and loops may occur.

Notes

Note the following constraints or conventions when you configure the IS-IS MTR feature:

- Set **metric-style** to **Wide** or **Transition** before you run the **multi-topology** command.
- The MTR feature will be disabled if **metric-style** is set to **Narrow** or only one Level is configured to support the Wide or Transition mode.

Configuration Steps

- Perform this configuration based on requirements.
- Configure the MTR feature in IS-IS address-family ipv6 configuration mode on the desired device, unless otherwise specified.

Verification

- Check whether the local device establishes neighbor relationships with other devices.

Related Commands

📄 Configuring IS-IS MTR

Command	multi-topology [<i>transition</i>]
Parameter Description	<i>transition</i> : Configures the MTT mode, which supports smooth migration from an IPv4-IPv6 hybrid topology to separate IPv4 and IPv6 topologies.
Command Mode	IS-IS address-family ipv6 configuration mode
Usage Guide	If the multi-topology command is not executed, IPv4 and IPv6 share one IS-IS physical topology, also called the default topology. If the multi-topology command is executed without the transition parameter, routing devices run in MT mode. IS-ISv4 runs in the default topology, and IS-ISv6 runs in the IPv6 unicast topology. If the multi-topology command is executed with the transition parameter, routing devices run in MTT mode. IS-ISv6 runs in the default topology and IPv6 unicast topology. The three configurations are mutually exclusive. The routing devices in MTT mode can transfer the MT TLV or the default topology TLV.

The MTT mode is applicable to incremental deployment to ensure smooth network migration. The MTT mode can cause route leaking between the default topology and IPv6 unicast topology. If the MTT mode is configured improperly, network failures such as routing black holes and loops may occur.

Set **metric-style** to **Wide** or **Transition** before you run the command. The MTR feature will be disabled if **metric-style** is set to **Narrow** or only one Level is configured to support the Wide or Transition mode.

Configuration Example

Configuring IS-IS MTR

Configuration Requirements

The typical application scenario of MTR is to retain devices that only support IPv4 services in a network where IPv6 service extension will be performed.

In Figure 4-19, Router 2 only supports the IPv4 protocol stack but does not support the MTR feature; therefore, it can only run IPv4 services. The network capacity needs to be scaled to support IPv6 services in order to meet service extension requirements. (Router 1, Router 3, and Router 4 that support the MTR feature will be added.) The device (Router 2) that supports only one protocol stack must be replaced to maintain the stability of the network running IPv4 and IPv6 dual protocol stacks; otherwise, IPv6 routing black holes may occur.

If you need to retain Router 2, you can configure the MTR feature on Router 1, Router 3, and Router 4. The MTR feature enables Router 2 to continue to run IPv4 services without interference on the IPv4 and IPv6 services on Router 1, Router 3, and Router 4. The MTR feature improves networking flexibility, indirectly prolongs the service life of old devices, and meets service extension requirements while maximizing the values of old devices.

The configuration requirements are as follows:

- Retain Router 2, which only supports IPv4 services.
- Add devices that support IPv4 and IPv6 dual topologies, and separate IPv4 route calculation and IPv6 route calculation based on different topologies.

Common Errors

- **metric-style** is not set to **Wide** or **Transition**.
- The protocol types used by two neighbors do not match; therefore, a neighbor relationship cannot be established.

- The IP addresses of the interfaces connected between neighbors are not in the same network segment.
- The **ip router isis** command is not executed on interfaces.
- No NET address is configured, or different NET addresses exist at Level 1.
- **max-area-addresses** is configured differently on both sides.
- **metric-style** is configured differently on both sides.
- The interface Levels on both sides are different. One side is Level-1, whereas the other side is Level-2.
- One side is configured with the P2P mode, whereas the other side is configured with the broadcast mode.
- One side is enabled with authentication, whereas the other side is not.

4.5.12 Configuring SNMP for IS-IS

Configuration Effect

- By default, the SNMP software can perform the MIB operation on the first IS-IS instance. To perform the MIB operation on other instances, you need to manually specify these instances.

Notes

- By default, the SNMP software can perform the MIB operation on the first displayed IS-IS instance.

Configuration Steps

↘ Binding the Instances on Which the IS-IS MIB Operation Will Be Performed

- Perform this configuration based on requirements.
- Run the **enable mib-binding** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

↘ Enabling IS-IS Trap Globally

- Perform this configuration based on requirements.
- Run the **snmp-server enable traps isis** command in global configuration mode on the desired device, unless otherwise specified.

↘ Configuring an SNMP Host Globally

- Perform this configuration based on requirements.
- Run the **snmp-server host** command in global configuration mode on the desired device, unless otherwise specified.

↘ Allowing the Sending of all IS-IS Trap Messages to the SNMP Host

- Perform this configuration based on requirements.
- Run the **enable traps all** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

Verification

- Use the MIB tool to read and write IS-IS settings.

Related Commands

↘ Binding the Instances on Which the IS-IS MIB Operation Will Be Performed

Command	enable mib-binding
Parameter Description	N/A
Command Mode	IS-IS routing process configuration mode
Usage Guide	The latest standards stipulate that the MIB operation can be performed on a single instance. By default, the MIB operation is performed on the first displayed IS-IS instance. Because multiple IS-IS instances can be configured, the administrator can use this command to specify the instances on which the MIB operation will be performed.

↘ Enabling IS-IS Trap Globally

Command	snmp-server enable traps [isis]
Parameter Description	<i>isis</i> : Enables IS-IS event trap.
Command Mode	Global configuration mode
Usage Guide	This command must be used with the snmp-server host command in global configuration mode so that trap messages can be sent.

↘ Configuring an SNMP Host Globally

Command	snmp-server host { host-addr ipv6 ipv6-addr } [vrf vrfname] [traps] [version { 1 2c 3 { auth noauth priv } }] community-string [udp-port port-num] [notification-type]
Parameter Description	<p><i>host-addr</i>: Indicates the address of the SNMP host.</p> <p><i>ipv6-addr</i>: Indicates the IPv6 address of the SNMP host.</p> <p><i>vrfname</i>: Indicates the name of a VRF table.</p> <p>version: Indicates the SNMP version, which can be set to V1, V2C, or V3</p> <p>auth noauth priv: Indicates the security level of V3 users.</p> <p><i>community-string</i>: Indicates the community string or user name (V3 version).</p> <p><i>port-num</i>: Indicates the port number of the SNMP host.</p> <p><i>notification-type</i>: Indicates the type of trap messages that are actively sent, for example, snmp.</p>
Command Mode	Global configuration mode
Usage Guide	This command is used with the snmp-server enable traps command to actively send trap messages to a

Network Management System (NMS). You can configure different SNMP hosts to receive trap messages. A host supports different trap types, ports, and VRF tables. For the same host (with the same port configuration and VRF configuration), the last configuration is combined with the previous configurations. That is, to send different trap messages to the same host, configure a type of trap messages each time. These configurations are finally combined.

▾ **Allowing the Sending of Trap Messages**

Command	enable traps { all traps set }
Parameter	all: Indicates all trap messages.
Description	<i>traps set.</i> Indicates a trap message type in any set.
Command Mode	IS-IS routing process configuration mode
Usage Guide	IS-IS packets are classified into 18 types of trap messages, which are grouped into several sets, with each set containing several trap message types. To enable the sending of IS-IS trap messages, run the snmp-server enable traps isis command in global configuration mode and specify the recipient host and the type of trap messages that can be sent.

Configuration Example

▾ **Configuring IS-IS SNMP**

Configuration Steps	<ul style="list-style-type: none"> ● Bind the instances on which the IS-IS MIB operation will be performed. ● Complete trap message-related settings.
	<pre>A(config)# router isis A(config-router)# enable mib-binding A# configure terminal A(config)#snmp-server enable traps isis A(config)#snmp-server host 10.1.1.1 traps version 2c public A(config)#router isis A(config-router)# enable traps all</pre>
Verification	Run the MIB tool to read and write IS-IS settings.
	<pre>A# show running-config</pre>

4.5.13 Configuring IS-IS to Enable Super VLAN

Configuration Effect

- Run the ISIS protocol on super VLANs.

Notes

- The IS-IS basic functions must be configured.
- The designated sub VLAN is connected with neighbors.

Configuration Steps

Running IS-IS on Super VLAN

- Optional. Run this command to enable IS-IS on a super VLAN if required.

Verification

- Run the **show isis neighbor** command to display the protocol status.
- Run the **show isis interface** command to view interface configuration.

Related Commands

Running IS-IS on Super VLAN

Command	isis subvlan [all vid]
Parameter Description	all: Indicates that packets are allowed to be sent to all sub VLANs. vid: Specifies the sub VLAN ID. The value ranges from 1 to 4094.
Command Mode	Interface configuration mode
Usage Guide	In normal cases, a super VLAN contains multiple sub VLANs. Multicast packets of a super VLAN are also sent to its sub VLANs. In this case, when IS-IS multicast packets are sent over a super VLAN containing multiple sub VLANs, the IS-IS multicast packets are replicated multiple times, and the device processing capability is insufficient. As a result, a large number of packets are discarded, causing the neighbor down error. In most scenarios, the IS-IS function does not need to be enabled on a super VLAN. Therefore, the IS-IS function is disabled by default. However, in some scenarios, the IS-IS function must be run on the super VLAN, but packets only need to be sent to one sub VLAN. In this case, run this command to specify a particular sub VLAN. You must be cautious in configuring packet transmission to all sub VLANs, as the large number of sub VLANs may cause a device processing bottleneck, which will lead to the neighbor down error.

Configuration Example

Scenario	<p>The diagram illustrates a network topology for IS-IS configuration. It shows two routers connected via their S1/0 interfaces. The network is labeled Area 49.0001, and the IP address 192.168.1.0/30 is shown above the connection line.</p>
-----------------	---

Configuration Steps	<ul style="list-style-type: none"> ● Configure the ISIS basic functions on all devices. ● Specify a particular sub VLAN on all devices.
A	<pre>A# configure terminal A(config)# interface VLAN 300 A(config-if-VLAN 300)# isis subvlan 1024</pre>
B	<pre>B# configure terminal B(config)# interface VLAN 300 B(config-if-VLAN 300)# isis subvlan 1024</pre>
Verification	<ul style="list-style-type: none"> ● Verify that an ISIS interface neighbor is established on Device A. ● Verify ISIS interface configuration on Device A.
A	<pre>A# show isis neighbor A# show isis interface</pre>

4.5.14 Configuring Other IS-IS Parameters

Configuration Effect

- **maximum-paths:** Configures the maximum number of IS-IS equal-cost paths to be installed to a routing table.
- **lsp-length receive:** Configures the maximum length allowed for received LSPs.
- **lsp-length originate:** Configures the maximum length allowed for sent LSPs.
- **passive-interface:** Prevents passive interfaces from receiving and sending IS-IS packets. That is, IS-IS neighbor relationships will not be established on passive interfaces. The IP addresses of passive interfaces are flooded through other interfaces.
- **isis metric:** Stores the metric, which is used in SPF calculation, in the IP reachability information TLV. The greater the metric, the greater the routing consumption of the interface and the longer the path obtained by SPF calculation.
- **isis priority:** In a broadcast network, IS-IS needs to elect a DIS among all devices. The DIS will generate a pseudonode and related LSPs. The device with the highest priority is elected as the DIS. You can configure different priorities for different Levels.
- **default-information originate:** Generates a Level-2 default route, which will be advertised through LSPs.
- **summary-address** and **summary-prefix:** Creates a summary route to represent a group of routes in a routing table. A summary route can include multiple routes of the specified Level. The interface metric of the summary route follows the smallest interface metric among all routes.
- **log-adjacency-changes:** Enables neighbor relationship event output to log IS-IS neighbor relationship changes.

- **redistribute:** Redistributes other routes to IS-IS; redistributes Level-1 routes to Level-2; redistributes Level-2 routes to Level-1.

Configuration Steps

↘ Configuring the Maximum Number of Equal-Cost Paths

- Perform this configuration based on requirements.
- Run the **maximum-paths** command in IS-IS routing process configuration mode or IS-IS address-family ipv6 configuration mode on the desired device, unless otherwise specified.

↘ Configuring the Maximum Length Allowed for Received LSPs

- Perform this configuration based on requirements.
- Run the **isp-length receive** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

↘ Configuring the Maximum Length Allowed for Sent LSPs

- Perform this configuration based on requirements.
- Run the **isp-length originate** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

↘ Configuring a Passive Interface

- Perform this configuration based on requirements.
- Run the **passive-interface** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

↘ Configuring the IS-IS Interface Metric

- Perform this configuration based on requirements.
- Run the **isis metric** command in interface configuration mode on the desired device, unless otherwise specified.

↘ Configuring the Priority of the DIS

- Perform this configuration based on requirements.
- Run the **isis priority** command in interface configuration mode on the desired device, unless otherwise specified.

↘ Generating a Default Route

- Perform this configuration based on requirements.
- Run the **default-information originate** command in IS-IS routing process configuration mode or IS-IS address-family ipv6 configuration mode on the desired device, unless otherwise specified.

↘ Configure a Summary Route

- Perform this configuration based on requirements.
- Run the **summary-address** and **summary-prefix** commands in IS-IS routing process configuration mode or IS-IS address-family ipv6 configuration mode on the desired device, unless otherwise specified.

↘ Enabling Neighbor Relationship Event Output

- Perform this configuration based on requirements.
- Run the **log-adjacency-changes** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

↘ Configuring Route Redistribution

- Perform this configuration based on requirements.
- Run the **redistribute** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

Verification

- **maximum-paths:** Check whether the maximum number of equal-cost paths displayed by routing entries is the same as the configuration.
- **lsp-length receive:** Capture packets to check the length of LSPs.
- **lsp-length originate:** Capture packets to check the length of LSPs.
- **passive-interface:** Capture packets to check whether the interface receives and sends IS-IS packets.
- **isis metric:** Check the database details of IS-IS.
- **isis priority:** Check whether the device with the changed priority setting is elected as the DIS.
- **default-information originate:** Check whether a default route is generated.
- **summary-address and summary-prefix:** Capture packets to check whether the summary route instead of detailed routes is advertised through LSPs.
- **log-adjacency-changes:** Change the neighbor state and verify that the change is recorded when debugging is disabled.
- **redistribute:** Check IS-IS routing entries.

Related Commands

↘ Configuring the Maximum Number of Equal-Cost Paths

Command	maximum-paths <i>maximum</i>
Parameter Description	<i>maximum</i> : Indicates the maximum number of IS-IS equal-cost routes to be installed to a routing table. The minimum value is 1 and the maximum value depends on the device capability.
Command Mode	IS-IS routing process configuration mode and IS-IS address-family ipv6 configuration mode

Usage Guide	This command is used by IS-IS to control the number of IS-IS equal-cost paths to be installed to a routing table. The routing table also has a command used to control the number of equal-cost paths. The number of effective equal-cost paths is determined by either of the two command values, whichever is smaller.
--------------------	--

↘ Configuring the Maximum Length Allowed for Received LSPs

Command	isp-length receive <i>size</i>
Parameter Description	<i>size</i> : Indicates the maximum length allowed for received LSPs. According to RFC, the value range is 1,492 to 16,000, in the unit of bytes.
Command Mode	IS-IS routing process configuration mode
Usage Guide	Use this command to control the maximum length allowed for LSPs received by the local device. Intermediate nodes with sufficient memory are required to receive LSPs whose maximum length is equal to the interface MTU in order to avoid a route convergence failure. From this perspective, the command is meaningless. The maximum length allowed for received LSPs cannot be smaller than that allowed for sent LSPs; otherwise, the former will be automatically adjusted to be equal to the latter.

↘ Configuring the Maximum Length Allowed for Sent LSPs

Command	isp-length originate <i>size</i> [level-1 level-2]
Parameter Description	<i>size</i> : Indicates the maximum length allowed for sent LSPs. The value range is 512 to 16,000, in the unit of bytes. level-1 : Applies the setting only to Level-1 LSPs. level-2 : Applies the setting only to Level-2 LSPs.
Command Mode	IS-IS routing process configuration mode
Usage Guide	In principle, the maximum length of LSPs and SNPs cannot be greater than the interface MTU; otherwise, the packets will be discarded when being sent.

↘ Configuring a Passive Interface

Command	passive-interface [default] { <i>interface-type</i> <i>interface-number</i> }
Parameter Description	default : Configures all IS-IS interfaces that are not enabled as passive interfaces. <i>interface-type</i> : Indicates the interface type. <i>interface-number</i> : Indicates the interface number.
Command Mode	IS-IS routing process configuration mode
Usage Guide	This command prevents the specified interface from receiving and sending IS-IS packets, but the IP address of the interface will be flooded by other interfaces. If the default option is selected and there are more than 255 IS-IS interfaces not enabled, only the first 255 interfaces will be configured as passive interfaces. The remaining interfaces are non-passive interfaces.

↘ Configuring the IS-IS Interface Metric

Command	isis metric <i>metric</i> [level-1 level-2]
Parameter Description	<i>metric</i> : Indicates the metric value. The value range is 1 to 63. The default value is 10. level-1 : Applies the setting to Level-1 circuits. level-2 : Applies the setting to Level-2 circuits.
Command Mode	Interface configuration mode
Usage Guide	The metric, which is used in SPF calculation, is stored in the IP reachability information TLV. The greater the metric, the greater the routing consumption of the interface and the longer the path obtained by SPF calculation. The metric belongs to the narrow type and is valid only when metric-style is set to Narrow .

↘ Configuring the Wide Metric of an Interface

Command	isis wide-metric <i>metric</i> [level-1 level-2]
Parameter Description	<i>metric</i> : Indicates the metric value. The value range is 1 to 16,777,214. The default value is 10. level-1 : Applies the setting to Level-1 circuits. level-2 : Applies the setting to Level-2 circuits.
Command Mode	Interface configuration mode
Usage Guide	The metric, which is used in SPF calculation, is stored in the IP reachability information TLV. The greater the metric, the greater the routing consumption of the interface and the longer the path obtained by SPF calculation. The metric is valid only when metric-style is set to Wide .

↘ Configuring the Priority of the DIS

Command	isis priority <i>value</i> [level-1 level-2]
Parameter Description	<i>value</i> : Indicates the priority. The value range is 0 to 127. The default value is 64. level-1 : Applies the setting to Level-1 circuits. level-2 : Applies the setting to Level-2 circuits.
Command Mode	Interface configuration mode
Usage Guide	Use this command to change the priority carried in Hello packets in a LAN. The device with a lower priority is less likely to be elected as the DIS. The command is invalid on a P2P network interface. The no isis priority command, with or without parameters, restores the priority to its default value. To change the configured priority, run the isis priority command with the priority specified to overwrite the existing configuration, or you can first restore the priority to its default value and then configure a new priority.

↘ Generating a Default Route

Command	default-information originate [route-map <i>map-name</i>]
Parameter	route-map <i>map-name</i> : Associates with a route map.

Description	
Command Mode	IS-IS routing process configuration mode and IS-IS address-family ipv6 configuration mode
Usage Guide	Because Level-2 domains do not generate any default route, use this command to allow a default route to enter a Level-2 domain.

▾ Configuring an IPv4 Summary Route

Command	summary-address <i>ip-address net-mask</i> [level-1 level-2 level-1-2] [<i>metric number</i>]
Parameter Description	<p><i>ip-address</i>: Indicates the IP address of the summary route.</p> <p><i>net-mask</i>: Indicates the subnet mask of the summary route.</p> <p>level-1: Applies the setting only to Level-1.</p> <p>level-2: Applies the setting only to Level-2. By default, the setting takes effect for Level-2.</p> <p>level-1-2: Applies the setting to Level-1 and Level-2.</p> <p><i>number</i>: Indicates the metric of the summary route.</p>
Command Mode	IS-IS routing process configuration mode
Usage Guide	If the configured summary route contains routing information about a reachable address or network segment, the summary route, instead of detailed routes, is advertised externally.

▾ Configuring an IPv6 Summary Route

Command	summary-prefix <i>ipv6-prefix/prefix-length</i> [level-1 level-2 level-1-2]
Parameter Description	<p><i>ipv6-prefix/prefix-length</i>: Indicates the network address of the summary route and its IPv6 prefix length. The address format is X:X:X:X:/<0-128>.</p> <p>level-1: Applies the setting only to Level-1.</p> <p>level-2: Applies the setting only to Level-2. By default, the setting takes effect for Level-2.</p> <p>level-1-2: Applies the setting to Level-1 and Level-2.</p>
Command Mode	IS-IS address-family ipv6 configuration mode
Usage Guide	If the configured summary route contains routing information about a reachable address or network segment, the summary route, instead of detailed routes, is advertised externally.

▾ Enabling Neighbor Relationship Event Output

Command	log-adjacency-changes
Parameter Description	N/A
Command Mode	IS-IS routing process configuration mode
Usage Guide	You can also use the debug command to record IS neighbor state changes, but the command consumes many system resources.

▾ Redistributing Other Routes to IS-IS

Command	redistribute { bgp ospf <i>process-id</i> [match { internal [external [1 2]] [nssa-external [1 2]] external [1 2] [internal] [nssa-external [1 2]] nssa-external [1 2] [internal] [external [1 2]] }] rip connected static } [metric <i>metric-value</i>] [metric-type <i>type-value</i>] [route-map <i>map-tag</i>] [level-1 level-1-2 level-2]
Parameter Description	<p><i>process-id</i>: Indicates the OSPF process ID. The range is 1 to 65,535.</p> <p>match { internal external [1 2] nssa-external [1 2] }: When OSPF routes are redistributed, the routes are filtered by subtype. If the match option is not selected, routes of all OSPF types will be received. If match external is not followed by the number 1 or 2, OSPF routes specified by external 1 and external 2 will be redistributed. If match nssa-external is not followed by the number 1 or 2, OSPF routes specified by nssa-external 1 and nssa-external 2 will be redistributed.</p> <p>metric <i>metric-value</i>: Indicates the metric of redistributed routes. The value range is 0 to 4,261,412,864. The metric of external routes is used when the metric option is not specified.</p> <p>metric-type { internal external }: Indicates the metric type of redistributed routes. internal: Indicates that the metric belongs to the internal type. external: Indicates that the metric belongs to the external type. If metric-type is not specified, the metric belongs to the internal type.</p> <p>route-map <i>map-tag</i>: Indicates the route map used for external route redistribution. It is used to filter redistributed routes or configure the attributes of redistributed routes. The value of <i>map-tag</i> cannot exceed 32 characters. By default, route-map is not configured.</p> <p>level-1 level-1-2 level-2: Indicates the Level of redistributed routes received by IS-IS. If no Level is specified, routes are redistributed to Level-2. level-1: Redistributes routes to Level-1. level-1-2: Redistributes routes to Level-1 and Level-2. level-2: Redistributes routes to Level-2.</p>
Command Mode	IS-IS routing process configuration mode and IS-IS address-family ipv6 configuration mode
Usage Guide	<p>The no redistribute { bgp ospf <i>process-id</i> rip connected static } command is used to cancel the redistribution of routes mapped to the specified protocol. If no redistribute is followed by other parameters, the command will restore the default parameter settings, rather than cancel route redistribution. For example, no redistribute bgp cancels BGP route redistribution, whereas no redistribute bgp route-map aa cancels the route map named aa used for BGP route redistribution.</p> <p>When external routes are redistributed in IPv4 mode, the routing information is stored in LSPs' IP External Reachability Information TLV.</p> <p>When external routes are redistributed in IPv6 mode, the routing information is stored in LSPs' IPv6 Reachable TLV.</p> <p>In the old versions of some vendors, if metric-type is set to external, the metric of redistributed routes is added by 64 during route calculation and used to determine routing. This practice does not comply with the related protocol. In the actual application, external routes may be preferred over internal routes. If this happens during interworking with old versions of some vendors, you can modify the related setting (such as metric or metric-type) of each device to ensure that internal routes are preferred over external routes.</p>

➤ **Redistributing the Level-1 Reachable Routing Information of the Specified IS-IS Instance to Level-2 of the Current Instance**

Command	redistribute isis [<i>tag</i>] level-1 into level-2 [route-map <i>route-map-name</i> distribute-list
----------------	---

	<i>access-list-name</i>]
Parameter Description	<p><i>tag</i>: Indicates the name of the IS-IS instance whose routing information will be redistributed.</p> <p>route-map <i>route-map-name</i>: Indicates the route map used for route redistribution. It is used to filter redistributed routes or configure the attributes of redistributed routes. The value of <i>route-map-name</i> cannot exceed 32 characters. By default, route-map is not configured.</p> <p>distribute-list <i>access-list-name</i>: Filters redistributed routes by using distribute-list. <i>access-list-name</i> indicates the associated prefix list, which can be a standard prefix list, an extended prefix list, or a name prefix list. It is in the format of {<1-99> <100-199> <1300-1999> <2000-2699> <i>acl-name</i> }. When the IS-IS address-family ipv6 configuration mode is applied, only the name prefix list can be used, in the format of <i>acl-name</i>.</p>
Command Mode	IS-IS routing process configuration mode and IS-IS address-family ipv6 configuration mode
Usage Guide	<p>You can use the route-map or distribute-list parameter to filter the specified instance's Level-1 routes to be redistributed. Only the routes that meet specific criteria can be redistributed to Level-2 of the current instance. The route-map and distribute-list parameters cannot be used at the same time.</p> <p>The no redistribute isis [tag] level-2 into level-1 command is used to cancel the redistribution of the specified instance's routes. If no redistribute is followed by other parameters, the command will restore the default parameter settings, rather than cancel route redistribution.</p> <p>For example, no redistribute isis tag1 level-1 into level-2 cancels the redistribution of the routes of the IS-IS instance name tag1. no redistribute isis tag1 level-1 into level-2 route-map aa cancels the use of the route map named aa to filter redistributed routes.</p>

↘ Redistributing the Level-2 Reachable Routing Information of the Specified IS-IS Instance to Level-1 of the Current Instance

Command	redistribute isis [<i>tag</i>] level-2 into level-1 [route-map <i>route-map-name</i> distribute-list <i>access-list-name</i>] (prefix <i>ip-address net-mask</i> ipv6-prefix <i>ipv6-address/length</i>)]
Parameter Description	<p><i>tag</i>: Indicates the name of the IS-IS instance whose routing information will be redistributed.</p> <p>route-map <i>route-map-name</i>: Indicates the route map used for route redistribution. It is used to filter redistributed routes or configure the attributes of redistributed routes. The value of <i>route-map-name</i> cannot exceed 32 characters. By default, route-map is not configured.</p> <p>Distribute-list <i>access-list-name</i>: Filters redistributed routes by using distribute-list. <i>access-list-name</i> indicates the associated prefix list, which can be a standard prefix list, an extended prefix list, or a name prefix list. It is in the format of {<1-99> <100-199> <1300-1999> <2000-2699> <i>acl-name</i> }. When the IS-IS address-family ipv6 configuration mode is applied, only the name prefix list can be used, in the format of <i>acl-name</i>.</p> <p>prefix <i>ip-address net-mask</i>: Determines the routes to be redistributed by address and prefix length.</p> <p>ipv6-prefix <i>ipv6-address/length</i>: Determines the IPv6 routes to be redistributed by address and prefix length.</p>
Command Mode	IS-IS routing process configuration mode and IS-IS address-family ipv6 configuration mode
Usage Guide	You can use the route-map , distribute-list , or prefix parameter to filter the specified instance's Level-2

	<p>routes to be redistributed. Only the routes that meet specific criteria can be redistributed to Level-1 of the current instance.</p> <p>The no redistribue isis [tag] level-2 into level-1 command is used to cancel the redistribution of the specified instance's routes. If no redistribute is followed by other parameters, the command will restore the default parameter settings, rather than cancel route redistribution.</p> <p>For example:</p> <p>no redistribue isis tag1 level-2 into level-1 cancels the redistribution of the routes of the IS-IS instance name tag1. no redistribue isis tag1 level-2 into level-1 route-map aa cancels the use of the route map named aa to filter redistributed routes.</p>

Configuration Example

↘ Configuring the Maximum Number of Equal-Cost Paths

Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS neighbors. (Omitted) ● Configure the maximum number of equal-cost paths.
	<pre>A(config)# router isis A(config-router)# maximum-paths 5</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the maximum number of equal-cost paths displayed by routing entries is the same as the configuration.
	<pre>A# show ip route isis</pre>

↘ Configuring the Maximum Length Allowed for Received LSPs

Configuration	<ul style="list-style-type: none"> ● Configure IS-IS neighbors. (Omitted) ● Configure the maximum length allowed for received LSPs.
	<pre>A(config)# router isis A(config-router)# lsp-length receive 512</pre>
Verification	Capture packets to check the length of received LSPs.

↘ Configuring the Maximum Length Allowed for Sent LSPs

Configurations	<ul style="list-style-type: none"> ● Configure IS-IS neighbors. (Omitted) ● Configure the maximum length allowed for sent LSPs.
-----------------------	---

	<pre>A# configure terminal A(config)# router isis 1 A(config-router)# lsp-length originate 512 level-2</pre>
Verification	Capture packets to check the length of sent LSPs.

↘ Configuring a Passive Interface

Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS neighbors. (Omitted) ● Configure a passive interface.
	<pre>A# configure terminal A(config)# router isis 1 A(config-router)# passive-interface GigabitEthernet 0/0</pre>
Verification	Capture packets to check whether the interface receives and sends IS-IS packets.

↘ Configuring the Metric of an IS-IS Interface

Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS neighbors. (Omitted) ● Configure metric of the IS-IS interface.
	<pre>A(config)# interface GigabitEthernet 0/1 A(config-if)#isis metric 1</pre>
Verification	Check the database details of IS-IS.
	<pre>A# show isis database detail</pre>

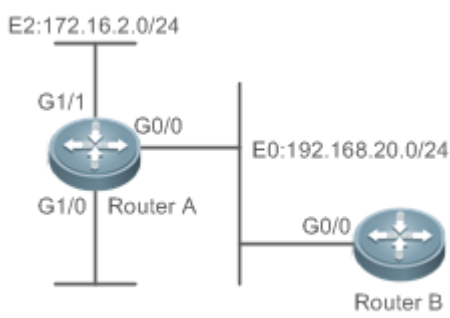

↘ Configuring the Priority of the DIS

Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS neighbors. (Omitted) ● Configure the priority of the DIS.
	<pre>A(config)# interface GigabitEthernet 0/1 A(config-if)# isis priority 127 level-1</pre>
Verification	Check whether the device with the changed priority setting is elected as the DIS.
	<pre>A# show isis database detail</pre>

➤ **Generating a Default Route**

Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS neighbors. (Omitted) ● Generate a default route.
	<pre>A(config)# router isis A(config-router)# default-information originate</pre>
Verification	<p>Capture packets to check whether the sent LSP contains a default route.</p>

➤ **Configuring an IS-IS Summary Route**

Configuration Requirements	<p>Router A and Router B are connected through the Ethernet and run IS-IS. Configure Router A to advertise only the 172.16.0.0/22 route instead of the 172.16.1.0/24 and 172.16.2.0/24 routes.</p>
Figure 4-19 IS-IS Route Summary Topology	 <p>The diagram shows two routers, Router A and Router B, connected via Ethernet. Router A is on the left and has three interfaces: G1/1 (top), G1/0 (bottom), and G0/0 (right). Router B is on the right and has one interface: G0/0 (left). The Ethernet link between Router A's G0/0 and Router B's G0/0 is labeled E0:192.168.20.0/24. There are also two other Ethernet links connected to Router A: one at the top labeled E2:172.16.2.0/24 and one at the bottom labeled G1/0.</p>
Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS. ● Configure Ethernet interfaces. ● Configure the password for IS-IS authentication.
A	<p>Configure IS-IS.</p>
	<pre>A(config)# router isis A(config-router)# net 49.0001.0000.0000.0001.00 A(config-router)# summary-address 172.16.0.0/16 level-1-2</pre>
	<p>Configure Ethernet interfaces.</p> <pre>A(config)# interface GigabitEthernet 0/0 A(config-if)# ip address 192.168.20.1 255.255.255.0 A(config-if)# ip router isis A(config)# interface GigabitEthernet 1/0</pre>

	<pre>A(config-if)# ip address 172.16.1.1 255.255.255.0 A(config-if)# ip router isis A(config)# interface GigabitEthernet 1/1 A(config-if)# ip address 172.16.2.1 255.255.255.0 A(config-if)# ip router isis</pre>
B	Configure IS-IS.
	<pre>B(config)# router isis B(config-router)# net 49.0001.0000.0000.0002.00</pre>
	Configure an Ethernet interface.
	<pre>B(config)# interface GigabitEthernet 0/0 B(config-if)# ip address 192.168.20.2 255.255.255.0 B(config-if)# ip router isis</pre>
Verification	Run the show ip route command on Router B to check whether only one summary route exists.
B	<pre>B(config)# show ip route i L1 172.16.0.0/16 [115/20] via 192.168.20.1, FastEthernet0/0</pre>

↘ **Configuring an IS-ISv6 Summary Route**

	Router A and Router B are connected through the Ethernet and run IS-ISv6. Configure Router A to advertise only the 2000::/96 route instead of the 2000::1111:0/112 and 2000::2222::0/112 routes.
Figure 4-20 IS-ISv6 Route Summary Topology	
Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS. ● Configure Ethernet interfaces. ● Configure the password for IS-IS authentication.
A	Configure IS-IS.
	<pre>A(config)# ipv6 unicast-routing</pre>

	<pre>A(config)# router isis A(config-router)# net 49.0001.0000.0000.0001.00 A(config-router)# address-family ipv6 unicast A (config-router-af)# summary-prefix 2000::/96 level-1-2 A (config-router-af)# exit-address-family</pre>
	<p>Configure Ethernet interfaces.</p> <pre>A(config)# interface GigabitEthernet 0/0 A(config-if)# ipv6 address 5000::1/64 A(config-if)# ipv6 router isis A(config)# interface GigabitEthernet 1/0 A(config-if)# ipv6 address 2000::1111:0001/112 A(config-if)# ipv6 router isis A(config)# interface GigabitEthernet 1/1 A(config-if)# ipv6 address 2000::2222:0001/112 A(config-if)# ipv6 router isis</pre>
B	<p>Configure IS-IS.</p> <pre>B(config)# ipv6 unicast-routing B(config)# router isis B(config-router)# net 49.0001.0000.0000.0002.00</pre>
	<p>Configure an Ethernet interface.</p> <pre>B(config)# interface GigabitEthernet 0/0 B(config-if)# ipv6 address 5000::2/64 B(config-if)# ipv6 router isis</pre>
Verification	<p>Run the show ipv6 route command on Router B to check whether only one summary route exists.</p>
B	<pre>B(config)# show ipv6 route I1 2000::/96 [115/20] via FE80::C800:1BFF:FEF8:1C, FastEthernet1/0</pre>

📌 **Enabling Neighbor Relationship Event Output**

Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS neighbors. (Omitted) ● Enable neighbor relationship event output.
----------------------------	--

	<pre>A(config-router)# log-adjacency-changes</pre>
Verification	Change the neighbor state and verify that the change is recorded when debugging is disabled.

↘ Configuring Route Redistribution

Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS neighbors. (Omitted) ● Configure OSPF routes. (Omitted) ● Configure route redistribution
	<pre>A(config)# router isis A(config-router)# redistribute ospf 1 metric 10 level-1</pre>
Verification	Check whether routing entries with redistributed routes exist.
	<pre>A# show ip route isis</pre>

4.6 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears all IS-IS neighbor relationship tables.	clear clns neighbors
Clears all IS-IS data structures.	clear isis *
Clears all IS-IS counters.	clear isis [tag] counter

Displaying

Description	Command
Displays all IS neighbors and inter-device neighbor relationships.	show clns [tag] is-neighbors [interface-type interface-number] [detail]
Displays all IS neighbors and provides device information and information about the neighbor relationship with ESSs.	show clns [tag] neighbors [interface-type interface-number] [detail]
Displays all IS-IS counters.	show isis [tag] counter
Displays the LSDB information.	show isis [tag] database [FLAGS] [LEVEL] [LSPID]

Displays the state information related to IS-IS GR.	show isis [tag] graceful-restart
Displays the relationship between the device name and system ID.	show isis [tag] hostname
Displays the details of an IS-IS interface.	show isis [tag] interface [interface-type interface-number] [counter]
Displays the mesh group configuration of all interfaces.	show isis [tag] mesh-groups
Displays IS-IS neighbor information.	show isis [tag] neighbors [detail]
Displays the neighbor information of virtual systems in IS-IS.	show isis [tag] virtual-neighbors
Displays IS-IS information.	show isis [tag] protocol
Displays the topology of IS-IS device connection.	show isis [tag] topology [l1 l2 level-1 level-2]
Displays information of an IS-IS IPv6 unicast topology.	show isis [tag] ipv6 topology [l1 l2 level-1 level-2]

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Enables IS-IS debugging.	debug isis { all auth events gr ifsm lsp mtr nfsm nsm pdu spf warn }

5 Configuring BGP

5.1 Overview

The Border Gateway Protocol (BGP) is an Exterior Gateway Protocol (EGP) used for communication between routers in different autonomous systems (ASs). BGP is used to exchange network accessibility information between different ASs and eliminate routing loops by using its own mechanism.

BGP uses TCP as the transmission protocol. The reliable transmission mechanism of TCP is used to ensure the transmission reliability of BGP.

Routers running BGP are called BGP speakers. BGP speakers between which a BGP session is established are called BGP peers.

Two modes can be used to establish peers between BGP speakers: Internal BGP (IBGP) and External BGP (EBGP).

- IBGP refers to a BGP connection established within an AS and completes transition of routing information within the AS.
- EBGP refers to a BGP connection established between different ASs and completes exchange of routing information between different ASs.

Rules for BGP to select an optimum route:

5. Invalid routing table entries are not involved in optimum route selection.

 Invalid entries include entries of inaccessible next hops and flapping entries.

6. Otherwise, select a route with a large value of **LOCAL_PREF**.

7. Otherwise, select a route generated by a BGP speaker.

 Routes generated by a BGP speaker include routes generated by the **network**, **redistribute** and **aggregate** commands.

8. Otherwise, select a route with the shortest AS length.

9. Otherwise, select a route with a smaller value of **ORIGIN**.

10. Otherwise, select a route with the smallest value of **MED**.
11. Otherwise, EBGp routes have higher priorities than IBGP routes and routes in the AS alliance, and the IBGP routes have the same priorities as the routes in the AS alliance.
12. Otherwise, select a route with the smallest IGP metric value to the next hop.
13. Otherwise, select an EBGp route that is received first.
14. Otherwise, select a route advertised by a BGP speaker with a smaller router ID.
15. Otherwise, select a route with a large cluster length.
16. Otherwise, select a route with a large neighbor address.

i The preceding shows the route selection process under the default configurations. By using CLI commands, you can change the route selection process. For example, you can run the **bgp bestpath as-path ignore** command to make step 4 of the route selection process lose effect or run the **bgp bestpath compare-routerid** command to make step 9 lose effect.

Protocols and Standards

- RFC4271: A Border Gateway Protocol 4 (BGP-4)
- RFC4273: Definitions of Managed Objects for BGP-4
- RFC4360: Proposed Standard: BGP Extended Communities Attribute
- RFC4364: Proposed Standard: BGP/MPLS IP Virtual Private Networks (VPNs)
- RFC4486: Proposed Standard: Subcodes for BGP Cease Notification Message

- RFC4724: Proposed Standard: Graceful Restart Mechanism for BGP
- RFC4760: Draft Standard: Multiprotocol Extensions for BGP-4
- RFC5492: Draft Standard: Capabilities Advertisement with BGP-4
- RFC7432: Proposed Standard: BGP MPLS-based Ethernet VPN

5.2 Applications

Application	Description
Inter-AS Route Advertisement	Implement inter-AS route advertisement by using BGP.
Intra-AS Route Reflection	Set up a route reflection topology within an AS to reduce BGP connections.

5.2.1 Inter-AS Route Advertisement

Scenario

BGP implements route advertisement and maintenance across different ASs.

As shown in Figure 5-1, BGP transfers the route of AS 65536 to AS 65538 through AS 65537.

Figure 5-1

Remarks	<p>R1 is a device at the network edge of AS 65536.</p> <p>R2 and R3 are devices at the network edge of AS 65537.</p> <p>R4 is a device at the network edge of AS 65538.</p>
----------------	---

Deployment

- Establish the EBGP neighborhood between R1 and R2 to implement inter-AS route advertisement.
- Establish the IBGP neighborhood between R2 and R3 to implement intra-AS route advertisement.
- The Internet runs OSPF to ensure network accessibility between R2 and R3.
- Establish the EBGP neighborhood between R3 and R4 to implement inter-AS route advertisement.

5.2.2 Intra-AS Route Reflection

Scenario

According to the BGP route advertisement principles, routes learned by an IBGP neighbor will not be advertised to the next IBGP neighbor by default. Therefore within an AS, a device running BGP must implement full-mesh. When there are many BGP devices within the AS, implementing full-mesh may cause large difficulties for network deployment. In this case, route reflection can be used to solve this problem.

As shown in Figure 5-2, route reflection is deployed to implement BGP full-mesh among R1 to R4 and RR.

Figure 5-2

Remarks	RR is a route reflector. R1 to R4 are route reflection clients.
----------------	--

Deployment

- Establish IBGP neighborships between R1 to R4 and RR respectively.
- Configure R1 to R4 as the route reflection clients of RR.

5.3 Features

Basic Concept

↘ BGP Speaker and AS Number

A router enabled with BGP is called a BGP speaker.

After a router is enabled with BGP, a local AS number must be specified for the router. An AS number is a globally unique number allocated by IANA, ranging from 1 to 4294967295.

↘ BGP Neighbor and Peer

Before a route is advertised between BGP speakers, a neighborhood must be established in advance. You need to manually configure BGP neighbors on both BGP speakers. That is, configure the peer as a neighbor on the two BGP speakers respectively. Therefore, BGP neighbors are also called BGP peers.

Neighbor Type and Route Type

BGP neighborships are classified into the following types:

- **IBGP neighborship:** The neighborship between BGP speakers within an AS is called IBGP neighborship. Routes learned from IBGP neighbors are called IBGP routes.
- **EBGP neighborship:** The neighborship between BGP speakers in different ASs is called EBGP neighborship. Routes learned from EBGP neighbors are called EBGP routes.

BGP route attribute

When a BGP speaker advertises routes to its neighbors, the BGP speaker also advertises the attributes carried by the routes.

Common BGP attributes are as follows:

- **ORIGIN:** Specifies the origin of a BGP route and can be set to **IGP**, **EGP**, or **INCOMPLETE**.
- **AS-PATH:** Lists the ASs passed by a route in a reverse order. The last AS is placed at the beginning of the list.
- **NEXT-HOP:** Specifies the IP address of the next hop to be reached by a BGP route.
- **MULTI-EXIT-DISC:** Distinguishes multiple output/input interfaces for reaching the same neighbor AS. A smaller value means a higher priority.
- **LOCAL-PREF:** Distinguishes the priorities of IBGP routes in an AS. A larger value means a higher priority.

Overview

Feature	Description
Creating a BGP Neighbor	Create a BGP neighbor.
Configuring a BGP Route Reflector	Set up a BGP route reflection topology to simplify network deployment for BGP neighbor full-mesh.
Configuring a BGP Alliance	Configure a BGP alliance to simplify network deployment for BGP neighbor full-mesh.
Re-distributing Local AS Network Information to BGP	Re-distribute routing information to BGP and advertise local routes through BGP.
Controlling Route Exchange Between BGP Peers	Configure the route exchange policy for a BGP peer and control routes to be received by and to be advertised to this peer.
Obtaining Accessible Networks of Other ASs from BGP	Re-distribute routing information in BGP into a core routing table or IGP.
Configuring Synchronization Between BGP and IGP	Configure BGP to check whether BGP routes are synchronized with IGP routes.
Configuring BGP Soft Reset	After a routing policy changes, use soft reset to apply a new policy.
Configuring the Route Attributes of BGP	Configure the route selection algorithms and routing policy control of BGP.
Configuring BGP Route Aggregation	Reduce routes by means of route aggregation.

Feature	Description
Configuring BGP Route Dampening	Reduce the impacts of route flapping on a network topology.
Configuring the Management Distance of BGP	Change the priorities of BGP routes.
Configuring Multi-path Load Balancing of BGP	Configure multi-path load balancing for BGP to enhance the network reliability and increase the network bandwidth.
Configuring BGP FRR	Configure fast rerouting for BGP to enhance the network reliability.
Configuring BGP Timers	Modify the internal timer time of BGP.
Configuring BGP Route Update Mechanisms	Disable/Enable regular scanning for BGP routes and configure the route scanning interval.
Configuring the Next-Hop Triggering Update Function of BGP	Configure the next hop triggering update function of BGP.
Configuring BGP LOCAL AS	Configure the LOCAL AS for a BGP neighbor.
Configuring BGP Capacity Protection	Avoid non-predictable running status caused by consumption of device capacity.
Configuring BGP GR	Configure the BGP GR function to enhance the network reliability.
Configuring 4-Byte AS Numbers of BGP	Configure the display mode of a 4-byte AS number.
Configuring a Regular Expression	Use a regular expression to filter routing information.
Configuring BGP Session Retention	Configure BGP to ensure that after an address family with incorrect routing attributes is detected for a neighbor, other address family routes advertised by the neighbor will not be affected.
Configuring BGP Delayed Advertisement upon System Restart	Configure BGP to delay route advertisement to a neighbor within a period after the system is restarted.
Other Related Configurations	Configure extended BGP functions.

5.3.1 Creating a BGP Neighbor

A BGP neighbor is manually configured by a user. Two connection modes are supported: IBGP and EBGP. You can identify the connection mode between BGP speakers based on the AS where the BGP peer resides and the AS where the BGP speaker resides.

-  Generally, BGP speakers between which an EBGP connection is established are directly connected whereas BGP speakers between which an IBGP connection is established can be at any location within an AS.

Working Principle

A BGP speaker can initiate a TCP connection request to a BGP peer specified by a user. After the TCP connection is successfully created, the peers will exchange BGP packets to negotiate about connection parameters. The BGP neighborhood is successfully established after the negotiation succeeds.

↘ Creating a TCP Connection

A BGP speaker initiates a TCP connection request to a neighbor. The destination IP address is the peer IP address specified by the user and the port number is fixed to 179.

The BGP speaker also listens on the port number 179 of the local TCP connection to receive connection requests from its peer.

↘ Negotiating about Protocol Parameters

After the TCP connection is successfully created, the BGP speakers exchange OPEN packets to negotiate about BGP connection parameters. The parameters for negotiation include:

- Version: Indicates the BGP version number. At present, only version 4 is supported.
- Neighbor AS number: Determines whether the AS number of the neighbor is consistent with the local AS number. If not, the connection request will be denied.
- Hold Time: Negotiates about the timeout duration for the BGP connection. The default value is 180 seconds.
- Neighbor capability: Negotiates about various extended capabilities supported by the neighbor, including the address family, dynamic route update, and GR functions.

↘ Maintaining Neighborhood

The Keepalive message is periodically sent between BGP speakers. If a new Keepalive packet is not received from the BGP neighbor after the Hold Time expires, the BGP speaker considers that the neighbor is not accessible, disconnects the TCP connection from the neighbor, and attempts to reconnect to it. The interval for a BGP speaker to send the Keepalive message is one third of the Hold Time determined through negotiation and is 60 seconds by default.

Related Configuration

↘ Creating a BGP Neighbor

By default, a BGP speaker does not specify any neighbor. You can manually configure a BGP neighbor.

You can run the **neighbor** { *peer-address* | *peer-group-name* } **remote-as** *as-number* command to manually create a BGP neighbor and specify the AS number of the neighbor.

↘ Setting the Neighbor TTL

By default, The TTL field in a TCP packet sent by an IBGP neighbor is set to the maximum value (255). It is set to 1 by an EBGP neighbor.

You can run the **neighbor** { *peer-address* | *peer-group-name* } **ebgp-multihop** [*tvl*] command to set the TTL field of a TCP packet sent by a BGP neighbor.

A larger value of TTL means a longer distance between BGP neighbors. When TTL is 1, the BGP neighbor devices must be directly connected.

▾ Setting the Source Address of TCP

By default, BGP automatically selects the source IP address of a TCP connection based on the IP address of the neighbor. Generally, the IP address of a local packet output interface is used.

You can run the **neighbor** { *peer-address* | *peer-group-name* } **update-source** {*interface-type interface-number* | *address* } command to adjust the source IP address of the neighbor's TCP connection.

▾ Setting MD5 Encryption

By default, a BGP connection is not encrypted through MD5.

You can run the **neighbor** { *peer-address* | *peer-group-name* } **password** [**0** | **7**] *string* command to set encryption for a BGP neighbor's TCP connection.

▾ Activating the Address Family Capability of a Neighbor

By default, a neighbor created in the BGP configuration mode activates only the IPv4 Unicast address family capability.

You can run the **address-family** command to enter a corresponding address family mode, and then run the **neighbor** { *peer-address* | *peer-group-name* } **activate** command to activate the address family capability for the BGP neighbor.

5.3.2 Configuring a BGP Route Reflector

According to the principle of BGP route advertisement, full mesh must be established for all BGP speakers within an AS (neighborships need to be established between each two BGP speakers). Too many BGP speakers within an AS will increase the resource overhead of the BGP speakers, increase the network administrator's workload and complexity of configuration and decrease the network expansion capability.

Using a route reflector is a method for reducing IBGP peer connections within an AS.

-
-  The methods for reducing the IBGP peer connections within an AS include using a route reflector and using an AS alliance.
-

Working Principle

Configure a BGP speaker as a route reflector which classifies IBGP peers in an AS into two types: clients and non-clients.

The rules for implementing a route reflector within an AS are as follows:

- Configure a route reflector and specify clients for the route reflector. The route reflector and its clients form a cluster. The route reflector will connect to its clients.
- The clients of a route reflector in a cluster cannot connect to other BGP speakers out of the cluster.
- Within an AS, full mesh is established among IBGP peers of non-clients. The IBGP peers of non-clients include the following situations: Multiple route reflectors in a cluster; a route reflector in a cluster and BGP speakers (generally not supporting the route reflector function) not involved in the route reflector function out of the cluster; a route reflector in a cluster and route reflectors in other clusters.

The rules for processing a route received by a route reflector are as follows:

- A route update message received by an EBGP speaker will be sent to all clients and non-clients.
- A route update message received by a client will be sent to other clients and all non-clients.
- A route update message received by an IBGP speaker will be sent to all the other clients.

-
- i** Generally, only one route reflector is configured in a cluster. In this case, the Router ID of the route reflector can be used to identify this cluster. To increase the redundancy, you can set multiple route reflectors in a cluster. In this case, you must configure the cluster ID so that a route reflector can identify the route update messages from other route reflectors in the cluster.
 - i** If multiple route reflectors are configured for a cluster, you must configure a cluster ID for the cluster.
 - i** Generally, it is unnecessary to create connections between the clients of a route reflector in a cluster because the route reflector will reflect the routes between the clients. However, if full mesh has been established among all clients, you can cancel the client route reflection function of the route reflector.
-

Related Configuration

↘ Configuring a BGP Route Reflector and Reflected Clients

By default, BGP is not configured with route reflection.

You can run the **neighbor peer-address route-reflector-client** command to configure a device as a route reflector and its neighbor devices as reflected clients.

↘ Configuring BGP Client-Client Reflection

By default, BGP client-client route reflection is enabled, which means that routes received from a reflected client can be advertised to other clients.

You can run the **bgp client-to-client reflection** command to enable or disable (using the **no** form of this command) client-client reflection.

↘ Configuring a BGP Reflection Cluster ID

By default, a BGP reflection cluster ID is the Router-ID of BGP. If multiple reflection clusters are deployed within an AS, different reflection cluster IDs must be configured for these reflection clusters.

You can run the **bgp cluster-id cluster-id** command to manually configure the cluster ID of a route reflector.

5.3.3 Configuring a BGP Alliance

An alliance is another method for reducing the IBGP peer connections within an AS.

Working Principle

Divide an AS into multiple sub ASs and configure a unified alliance ID (namely, the alliance AS NUMBER) for these sub ASs to form an alliance. Outside the alliance, the entire alliance is still considered as an AS and only the AS number of the alliance is visible. Inside the alliance, full mesh of IBGP peers can be established for BGP speakers within a sub AS, and

EBGP connections can be established for BGP speakers in different sub ASs. Though EBGP connections are established between BGP speakers within a sub AS, when information is exchanged, NEXT_HOP, MED, LOCAL_PREF and other path attributes keep unchanged.

Related Configuration

↘ Configuring a BGP Alliance ID

By default, no alliance ID is configured for a BGP speaker.

You can run the **bgp confederation identifier** *as-number* command to configure a BGP alliance ID. After the configuration is successful, the local AS (specified by the **router bgp** *as-number* command) of BGP becomes the private AS inside the alliance and is invisible to other ASs.

↘ Configuring a BGP Alliance Neighbor

By default, no alliance neighbor is configured for BGP.

You can run the **bgp confederation peers** *as-number* [... *as-number*] command to configure a BGP alliance neighbor. After the configuration succeeds, the AS specified by this command and the local AS belong to the same alliance.

5.3.4 Re-distributing Local AS Network Information to BGP

BGP cannot automatically discover or learn accessible networks. The accessible network information of a local AS must be re-distributed to BGP. Then, BGP can advertise the information to neighbors.

Working Principle

Two methods can be used to re-distribute local AS network information to BGP:

- Manual static configuration: re-distribute the accessible network information within a specified range to BGP.
- Configuring route re-distribution: re-distribute accessible IGP network information to BGP.

 In addition, you can also re-distribute local AS network information to BGP routes by configuring route aggregation.

Related Configuration

↘ Configuring a BGP Network

By default, no network is configured for BGP.

You can run the **network** *network-number* [**mask** *mask*] [**route-map** *map-tag*] [**backdoor**] command to configure a BGP network to re-distribute specified accessible network information to BGP. The prerequisite for successfully re-distributing routing information to BGP is that a route is available in the core routing table and this route can be an IGP, directly-connected or static route.

↘ Configuring BGP Route Re-distribution

By default, BGP is not configured with route re-distribution.

You can run the **redistribute** *protocol-type* command to re-distribute the routing information of other protocols to BGP, including OSPF, RIP, ISIS, static and directly-connected routes.

5.3.5 Controlling Route Exchange Between BGP Peers

BGP provides powerful route management functions. You can actively control the route exchange between BGP peers.

Working Principle

Configure the route exchange policy for a BGP peer and control routes to be received by and to be advertised to this peer.

Related Configuration

↘ Configuring the Default Route to Be Advertised to a Peer

By default, BGP does not advertise the default route.

You can run the **neighbor** { *address* | *peer-group-name* } **default-originate** [**route-map** *map-tag*] command to advertise the default route to a peer (or a peer group).

↘ Configuring Next-Hop-Self for a Peer

By default, BGP does not change the next hop of a route when it advertises the route to an IBGP neighbor and sets the next hop to the local BGP speaker when it advertises the route to an EBGP neighbor.

You can run the **neighbor** { *address* | *peer-group-name* } **next-hop-self** command to configure the next hop of a route to the local BGP speaker when distributing the route to a specified BGP peer (group).

↘ Configuring Remove-Private-AS for a Peer

By default, BGP does not delete the private AS in the AS-PATH attribute when it advertises routing information to a peer.

You can run the **neighbor** { *address* | *peer-group-name* } **remove-private-as** command to require that the private AS number recorded in the AS path attribute should be deleted when routing information is distributed to an EBGP peer (group). This command does not apply to an IBGP neighbor.

↘ Configuring Send-Community for a Peer

By default, BGP does not send the community attribute when it advertises routing information to a peer.

You can run the **neighbor** { *address* | *peer-group-name* } **send-community** command to specify that the community attribute can be sent to a specified BGP peer (group).

↘ Configuring Maximum-Prefix for a Peer

By default, BGP does not restrict the records of routing information that can be received by a peer.

You can run the **neighbor** { *address* | *peer-group-name* } **maximum-prefix** *maximum* [**warning-only**] command to specify the records of routing information received from a specified peer (group).

↘ Configuring Route Filtering for a BGP Neighbor

By default, a BGP neighbor is not enabled with any filtering policy and receives all legal routing information advertised by a neighbor.

BGP supports multiple methods of configuring the route filtering policies for a neighbor, including:

- **neighbor** { *peer-address* | *peer-group-name* } **distribute-list** { *access-list-number* | *access-list-name* } { **in** | **out** }
Use an ACL to filter routes in the input and output directions of the neighbor.
- **neighbor** { *peer-address* | *peer-group-name* } **filter-list** *access-list-number* { **in** | **out** }
Use an AS-PATH list to filter routes in the input and output directions of the neighbor.
- **neighbor** { *peer-address* | *peer-group-name* } **prefix-list** *prefix-list-name* { **in** | **out** }
Use a prefix-list to filter routes in the input and output directions of the neighbor.
- **neighbor** { *peer-address* | *peer-group-name* } **route-map** *map-tag* { **in** | **out** }
Use a route map to filter routes in the input and output directions of the neighbor.
- **neighbor** { *address* | *peer-group-name* } **unsuppress-map** *map-tag*
Allow for advertising certain routing information previously suppressed by the **aggregate-address** command when distributing routing information to a specified peer.

5.3.6 Obtaining Accessible Networks of Other ASs from BGP

Send routing information of other ASs exchanged by BGP to the routing table of a device so that the device can forward packets to other ASs.

Send routing information of other ASs exchanged by BGP to the routing table of a device so that the device can forward packets to other ASs.

Working Principle

↘ BGP Sends Routing Information to a Core Routing Table

BGP controls routing information sent to the core routing table by using **table-map**. **table-map** can modify the attributes of routing information sent to the core routing table. If the route is matched, BGP modifies the attribute of the routing information and sends the route. If the route is not matched or route matching is denied, BGP does not modify the attribute of the routing information but sends the route.

Changes of **table-map** are not reflected in the core routing table immediately, but reflected a moment later. To update the application of **table-map** immediately, you can run the **clear ip bgp** [*vrf vrf-name*] **table-map** command to update the routing information in the core routing table immediately. This command does not clear the existing routes in the core routing table, but directly applies **table-map** to send the updated routing information, thereby not causing forwarding flapping.

↘ Re-distributing BGP Routes to IGP

Re-distribute BGP routes on a BGP speaker to IGP to ensure that routers within an AS can obtain routes to other ASs.

Related Configuration

↘ Configuring table-map

By default, BGP is not configured with a table-map and allows for sending all routes without modifying the attributes of the routes.

You can run the **table-map** *route-map-name* command to set a table-map and control the routing information to be sent to the core routing table. *route-map-name* specifies a route-map to be associated.

- i** Run the **table-map** command in the BGP configuration mode or in the IPv4 address family mode.
The Match and Set statements supported in the table-map are as follows:
Match statements: as-path, community, ip address, ip next-hop, metric, origin and route-type
Set statements: metric, tag and next-hop

- i** You can run the **no table-map** command to delete the table-map configurations.

↘ Configuring BGP Route Re-distribution by IGP

By default, IGP does not re-distribute BGP routes.

You can run the **redistribute bgp** [**route-map** *map-tag*] [**metric** *metric-value*] command to re-distribute BGP routes to IGP (RIP\OSPF\ISIS).

The **bgp redistribute-internal** command controls only whether to re-distribute routes learned from IBGP to IGP. By default, routes learned from IBGP can be re-distributed to IGP.

- i** You can run the **bgp redistribute-internal** command in the BGP configuration mode, IPv4/IPv6 address family mode or the IPv4 VRF address family mode.
- i** You can run the **no bgp redistribute-internal** command to delete the configuration.

5.3.7 Configuring Synchronization Between BGP and IGP

Generally, BGP speakers working as mutual IBGP neighbors are not directly connected. IGP devices between the BGP speakers may fail to learn routing information same as that learned by the BGP speakers. When a BGP speaker at the border of an AS forwards packets received from other domains to the next-hop IBGP neighbor, the packets pass an IGP device in the middle. In this case, the packets may be lost due to no routing information on the IGP device.

Working Principle

To keep synchronization between BGP and IGP, you must ensure that all routers within an AS can learn routing information to be sent to another AS before the routing information is advertised to this AS.

Synchronization between BGP and IGP is not required only in the following cases:

- Routing information passing through an AS is not available. For example, the AS is an end AS.
- All routers within an AS run BPG. Full mesh is established among all BGP speakers (neighborship is established between each two BGP speakers).

Related Configuration

↘ Configuring BGP Route Synchronization

By default, synchronization between BGP and IBGP routes is disabled.

You can run the **synchronization** command to enable synchronization between BGP and IGP.

 You can run the **no synchronization** command to disable synchronization between BGP and IGP.

5.3.8 Configuring BGP Soft Reset

If routing policies (including **neighbor distribute-list**, **neighbor route-map**, **neighbor prefix-list** and **neighbor filter-list**) change, an effective method must be provided to implement new routing policies. A traditional method is to terminate a BGP connection and then create a new BGP connection. By configuring BGP Soft Reset, you can execute a new routing policy without terminating a BGP session connection.

Working Principle

-  Routing policies that affect inbound routing information are called inbound routing policies (such as In-route-map and In-dist-list) and routing policies that affect outbound routing information are called outbound routing policies (such as Out-route-map and Out-dist-list).
-

When outbound routing policies change, BGP soft reset will re-advertise all routing information of a BGP speaker to its neighbors.

If inbound routing policies change, the operation is more complex than that when outbound routing policies change. This is because outbound routing policies are executed in the routing table of the local BGP speaker whereas inbound routing policies are executed for routing information received from the BGP peer. To reduce cost, the local BGP speaker does not store the original routing information received from the BGP peer.

If inbound routing policies change and a neighbor device supports route update, you can configure soft reset to send a route update request to the neighbor device. After receiving the request, the neighbor device re-advertises all routing information. You can also perform configuration to ensure that each BGP peer stores original routing information on the local BGP speaker and provides original routing information basis for modifying inbound routing policies subsequently.

-  The "route update capability" allows for modifying and executing routing policies without storing original routing information. This product supports the route update capability. You can run the **show ip bgp neighbors** command to check whether a BGP peer supports route update. If yes, you do not need to run the **neighbor soft-reconfiguration inbound** command when inbound routing policies change.
-

Related Configuration

↘ Configuring BGP Soft Reset

Run the **clear ip bgp** { * | *peer-address* | **peer-group** *peer-group-name* | **external** } **soft out** command to soft reset a BGP connection. You can activate execution of a routing policy without restarting the BGP session.

↘ Saving Original Routing Information of Neighbors

By default, BGP does not save original routing information of neighbors.

Run the **neighbor { address | peer-group-name } soft-reconfiguration inbound** command to save unmodified routing information sent by a BGP peer (group).

5.3.9 Configuring the Route Attributes of BGP

BGP provides various control policies for route attributes. You can apply the policies based on actual conditions.

Working Principle

AS_PATH Attribute

BGP can control distribution of routing information in three modes:

- IP address. You can run the **neighbor distribute-list** and **neighbor prefix-list** commands for implementation.
- AS_PATH attribute. See the description in this section.
- COMMUNITY attribute. See the related configuration of the COMMUNITY attribute.

You can use an AS path-based access control list (ACL) to control the distribution of routing information. Where, the AS path-based ACL uses a regular expression to parse the AS path.

Based on the standard (RFC1771), BGP does not consider the AS path length when selecting the optimum path. Generally, a shorter AS path length means a higher path priority; therefore, Ruijie considers the AS path length when selecting the optimum path. You can determine whether to consider the AS path length when selecting the optimum path based on the actual conditions.

-  Within an AS, whether to consider the AS path should be consistent for all BGP speakers when the optimum path is selected; otherwise, the optimum paths selected by the BGP speakers may be different.

MULTI_EXIT_DISC Attribute

BGP uses the MED value as the basis for comparing priorities of paths learned from EBGP peers. A smaller MED value means a higher path priority.

- By default, the MED value is compared only for paths of peers from the same AS when the optimum path is selected.
- By default, the MED value is not compared for paths of peers from other sub ASs within an AS alliance.
- By default, if a path not configured with the MED attribute is received, it is considered that the MED value of this path is 0. Since a smaller MED value means a higher path priority, this path has the highest priority.
- By default, the MED value is not compared with paths from different ASs; instead, the sequence of receiving the paths is compared.

LOCAL_PREF Attribute

When sending routes received from EBGP peers to IBGP peers, a BGP speaker adds the LOCAL_PREF attribute. BGP uses the LOCAL_PREF attribute as the basis for comparing priorities of paths learned from IBGP peers. A larger value of LOCAL_PREF means a higher path priority.

You can also run the **set local-preference** command of a route map to modify the LOCAL_PREF attribute of the specified path.

↘ COMMUNITY Attribute

The COMMUNITY attribute is another mode for controlling distribution of routing information.

A community is a set of destination addresses. The COMMUNITY attribute is intended to facilitate execution of a routing policy based on a community and thereby simplify the configuration of routing information distribution control on BGP speakers. Each destination address may belong to multiple communities. An AS administrator can define the communities, to which a destination address belongs.

By default, all destination addresses belong to the Internet community and are carried in the community attribute of the path.

At present, four common community attribute values are pre-defined:

- **Internet:** Indicates the Internet community. All paths belong to this community.
- **no-export:** Indicates that the path is not advertised to EBGp peers.
- **no-advertise:** Indicates that the path is not advertised to any BGP peer.
- **local-as:** Indicates that a path is not advertised to other ASs. When an AS alliance is configured, the path is not advertised to other ASs or sub ASs.

By using the community attribute, you can control the receiving, prioritization and distribution of routing information. BGP speakers can set, add or modify the community attribute when learning, advertising or re-distributing routes. An aggregation path will contain the community attribute values of all aggregated paths.

-
- **i** BGP supports up to 32 COMMUNITY attributes for each route and allows for up to 32 COMMUNITY attributes when match and set COMMUNITY of a route map are configured.
-

↘ Others

During selection of the optimum path, if two paths with the same path attributes are received from different EBGp peers, the optimum path is selected based on the receiving sequence by default. You can disable comparison of the receiving sequence but use the path with a smaller router ID as the optimum path.

Related Configuration

↘ Configuring AS_PATH Attribute

- **ip as-path access-list** *path-list-name* { **permit** | **deny** } *as-regular-expression*

Defines an AS path list.

- **neighbor** { *address* | *peer-group-name* } **filter-list** *path-list-name* { **in** | **out** }

By default, no filtering policy is configured for BGP peers.

The configuration is the same as that for routing information receiving and sending for a specified BGP peer (group). Routing policies are executed based on the AS path list to advertise or receive only routes that match the policies.

- **neighbor** { *address* | *peer-group-name* } **route-map** *map-tag* { **in** | **out** }

By default, no filtering policy is configured for BGP peers.

The configuration is the same as when receiving and sending routing information for a specified BGP peer (group). Routing policies are executed based on a route map or the set rules in the route map are used to modify routing attributes.

i In the route-map configuration mode, you can run the **match as-path** command to modify AS path attributes by using an AS path list or directly run the **set as-path** command to modify AS attribute values.

- **bgp bestpath as-path ignore**

Allows BGP not to consider the AS path length when selecting the optimum path. The AS path length is compared by default.

By default, a smaller AS path length means a higher path priority.

- ▾ **Configuring MULTI_EXIT_DISC Attribute**

- **bgp always-compare-med**

Allows for comparing the MED values of paths from different ASs, which is disabled by default.

- **bgp bestpath med confed**

Allows for comparing the MED values of paths of peers from other sub ASs in the same AS alliance, which is disabled by default.

- **bgp bestpath med missing-as-worst**

Sets a path not configured with the MED attribute to the lowest priority, which is disabled by default.

- **bgp deterministic-med**

Allows for comparing the paths of peers within the same AS, which is disabled by default.

- ▾ **Configuring LOCAL_PREF Attribute**

- **bgp default local-preference** *value*

Changes the default local preference value, ranging from 0 to 4,294,967,295. A larger value means a higher priority. The default value is 100.

- ▾ **Configuring COMMUNITY Attribute**

- **ip community-list standard** *community-list-name* { **permit** | **deny** } *community-number*

Creates a community list. **community-list-name** indicates the name of the community list.

i *community-number*: Indicates a value (1 to 4,294,967,295) specified by a user or a known community attribute (internet, local-AS, no-advertise or no-export).

- **neighbor** { *address* | *peer-group-name* } **send-community**

Allows for sending the community attribute to a specified BGP peer (group), which is not configured by default.

- **neighbor** { *address* | *peer-group-name* } **route-map** *map-tag* { **in** | **out** }

The configuration is the same as that for routing information receiving and sending for a specified BGP peer (group). Routing policies are executed based on a route map. No filtering policy is configured for peers by default.

-
- **i** In the route-map configuration mode, you can run the **match community-list [exact]** and **set community-list delete** commands to modify the community attribute by using a community list or directly run the **set community** command to modify the community value.
-

↳ Others

- **bgp bestpath compare-routerid**

Allows BGP to compare the router ID when selecting the optimum path, which is disabled by default.

5.3.10 Configuring BGP Route Aggregation

BGP-4 supports CIDR and therefore allows for creating aggregation entries to reduce the size of a BGP routing table. BGP aggregation entries can be added to a BGP routing table only when valid paths are available within the aggregation range.

Working Principle

Aggregate one or more detailed BGP routes into a BGP route with a shorter network mask.

- **i** By default, BGP advertises all path information before and after aggregation. If you hope that only aggregated path information is advertised, you can run the **aggregate-address summary-only** command.
 - **i** When the **aggregate-address** command is used to configure an aggregated route, the aggregated route takes effect immediately as long as there are routes in the configured address range.
-

Related Configuration

↳ Configuring BGP Route Aggregation

- **aggregate-address address mask**

Configures BGP route aggregation. By default, BGP does not create any aggregated routing entry.

- **aggregate-address address mask as-set**

Configures an aggregation address and stores the AS path information within the aggregation address range. By default, BGP does not store AS path information.

- **aggregate-address address mask summary-only**

Configures an aggregation address and advertises only an aggregated path. By default, BGP advertises all path information within the aggregation range.

- **aggregate-address address mask as-set summary-only**

Configures an aggregation address, stores the AS path information within the aggregation address range and advertises only aggregated paths.

5.3.11 Configuring BGP Route Dampening

If a route changes between being valid and invalid, route flapping occurs.

Route flapping often causes transmission of unstable routes in a network, and thereby causes network instability. BGP route dampening is a method for reducing route flapping. It reduces possible route flapping by monitoring routing information from EBGP peers.

Working Principle

Terms used in BGP route dampening are as follows:

- **Route Flap:** A route changes between being valid and invalid.
- **Penalty:** Once route flapping occurs, a BGP speaker enabled with route dampening adds a value to the penalty for this route. The penalty is accumulated until the Suppress Limit is reached.
- **Suppress Limit:** When the penalty of a route is greater than this value, the route will be suppressed.
- **Half-life-time:** The time used for the penalty to be halved.
- **Reuse Limit:** When the penalty value of a route is smaller than this value, route suppression will be canceled.
- **Max-suppress-time:** The longest time that a route can be suppressed.

A brief description of route dampening processing: BGP speaker punishes a route once (adds to the penalty) route flapping occurs. When the penalty reaches the Suppress Limit, the route will be suppressed. When the Half-life-time reaches, the penalty is halved. When the penalty is reduced to the Reuse Limit, the route is activated again. The Max-suppress-time indicates the longest time that the route can be suppressed.

Related Configuration

▾ Configuring BGP Route Dampening

- **bgp dampening**

Enables BGP dampening, which is disabled by default.

- **bgp dampening** *half-life-time reuse suppress max-suppress-time*

Configures the parameters of route dampening.

half-life-time (1~45minutes): The default value is 15 minutes. A larger value means a longer flapping suppression and dampening period.

reuse (1~20000): The default value is 750. A smaller value means longer time for continuous stabilization before a flapping route is enabled again.

suppress (1~20000): The default value is 2,000. A smaller value means more flapping times allowed before suppression.

max-suppress-time (1~255minutes): The default value is 4**half-life-time*. A larger value means longer maximum suppression time.

▾ Displaying BGP Route Dampening

- **show ip bgp dampening flap-statistics**

Displays the flapping statistics about all routes.

- **show ip bgp dampening dampened-paths**

Displays the statistics about suppressed routes.

- ↳ **Resetting BGP Route Dampening**

- **clear ip bgp flap-statistics**

Clears the flapping statistics about all routes that are not suppressed.

- **clear ip bgp flap-statistics *address mask***

Clears the flapping statistics about specified routes (excluding suppressed routes).

- **clear ip bgp dampening [*address* [*mask*]]**

Clears the flapping statistics about all routes, including routes whose suppression is cancelled.

5.3.12 Configuring the Management Distance of BGP

The management distance is used to evaluate the reliability of various route sources. A smaller management distance means a better route.

Working Principle

- ↳ **Management Distance of BGP**

The management distance indicates the reliability of a route source, ranging from 1 to 255. A larger value means lower reliability. BGP sets different management distances for routing information learned from different sources, including External-distance, Internal-distance and Local-distance.

- External-distance: Indicates the management distance of routes learned from EBGP peers.
- Internal-distance: Indicates the management distance of routes learned from IBGP peers.
- Local-distance: Indicates the management distance for routes learned from peers but it is considered that better routes can be learned from IGP. Generally, these routes can be indicated by the **Network Backdoor** command.

i You are not advised to change the management distance of BGP. If you really need to change the management distance of BGP, please remember:

The external-distance should be shorter than the management distances of other IGP routing protocols (OSPF and RIP).

The internal-distance and local-distance should be longer than the management distances of other IGP routing protocols.

- ↳ **Backdoor Route**

If you prefer an IGP route but do not use an EBGP route, you can set the EBGP route as the backdoor route. By default, the management distance for routes learned from a BGP speaker for which an EBGP connection is established is 20. You can

run the **network backdoor** command to set the management distance of the network information to 200 so that the same network information learned from IGP has the highest priority. The networks learned from IGP are considered backdoor networks and are not advertised.

Related Configuration

▾ Configuring the Management Distance of BGP

You can run the **distance bgp** *external-distance internal-distance local-distance* command to configure the management distance of BGP. The value ranges from 1 to 255.

The default value of *external-distance* is 20; the default value of *internal-distance* is 200; the default value of *local-distance* is 200.

A longer management distance means a lower route priority.

▾ Configuring a Backdoor Route

Run the **network** *network-number mask network-mask* **backdoor** command to configure a backdoor route. By default, no backdoor route is configured.

5.3.13 Configuring Multi-path Load Balancing of BGP

Multi-path load balancing means that there are multiple paths to the same network and data packets are evenly forwarded by these paths. In a routing table, one route has multiple next hops.

According to the types of equivalent routes, multi-path load balancing of BGP is classified into the following types:

- EBGp load balancing: implement load balancing for routes learned from EBGp neighbors.
 - IBGP load balancing: implement load balancing for routes learned from IBGP neighbors.
-
- Both the IPv4 and IPv6 protocol stacks support multi-path load balancing.
 - Load balancing cannot be implemented between IBGP and EBGp routes (including EBGp routes in an alliance).

Working Principle

If a BGP routing table has multiple paths to the same network, BGP calculates the route with the highest priority by default. If there are optimum multiple routes with the same priorities, BGP still selects a unique route by using comparison rules, notifies the route to the forwarding plane and controls the forwarding of data streams. After multi-path load balancing is enabled, BGP calculates a unique optimum route and also lists paths with the same priorities as equivalent routes. Then, BGP notifies the optimum route and the equivalent routes to the forwarding plane to implement load balancing.

Equivalent routes have the same basic attributes and priorities. That is, according to the optimum path selection rules of BGP, the paths have the same priorities before router-IDs are compared.

▾ AS_PATH Loose Comparison

By default, equivalent routes must have the same AS-PATH attributes. Under such strict conditions, load balancing cannot be implemented in certain environments. In this case, you are advertised to enable the AS-PATH loose comparison mode. In the AS-PATH loose comparison mode, when other conditions for equivalent routes are met, as long as the AS-PATH lengths

of routes and the AS-PATH lengths of routes from an alliance are the same respectively, it is considered that the conditions for equivalent routes are met.

 When the next hops of multiple BGP equivalent paths recur to the same IGP output interface, load balancing cannot be implemented.

Related Configuration

▾ Configuring Multi-path Load Balancing of BGP

- **maximum-paths{ ebgp | ibgp } number**

Enables the multi-path load balancing function of BGP.

number indicates the number of equivalent next hops. The minimum value is 1 and the maximum value depends on the device capability. The default value is 1. A larger value means more equivalent next hops allowed.

- **maximum-paths ibgp number**

Enables the multi-path load balancing function of IBGP.

number indicates the number of equivalent next hops, ranging from 1 to 32. The default value is 1. A larger value means more equivalent next hops allowed.

▾ Configuring AS_PATH Loose Comparison

- **bgp bestpath as-path multipath-relax**

Enables the BGP AS-PATH loose comparison mode.

5.3.14 Configuring BGP FRR

With high-speed development of IP technologies and application of various complex services, the requirements for network security and stability become increasingly higher. Especially, certain real-time services (audios and videos) are sensitive to network running status and may be largely affected by unstable networks. Therefore, more and more focus and importance are attached to network reliability. With these requirements, the IP FRR function comes into being. It is intended to use a backup link to maintain data forwarding during route platform convergence after a faulty link is detected, in order to achieve the ideal targets of "zero delay" and "zero loss" in packet forwarding.

BGP FRR is shorted for Fast Reroute.

Working Principle

If a BGP routing table has multiple paths to the same network, BGP calculates the route with the highest priority by default. After the BGP FRR function is used, BGP selects a backup route for each optimum route. After BFD FRR detects that the master link is faulty, it switches the data to the originally calculated backup link for forwarding. After route convergence is completed, data is switched to the optimum route re-calculated for forwarding. In this way, BGP FRR can avoid route disconnection due to a link fault before BGP route convergence is completed.

 BGP FRR is supported only in the IPv4 Unicast and IPv4 VRF address families of BGP.

-  Only one backup route can be generated and the next hop of the backup route cannot be the same as that of the preferred route.
-  A backup next hop cannot be generated for an Equal-Cost Multi-Path Routing (ECMP) route.
-  In the BGP IPv4 VRF configuration mode, BGP FRR has a lower priority than VPN FRR. That is, if VPN FRR is enabled in the VRF mode, BGP FRR takes effect only when VPN FRR fails to calculate a backup route.

Related Configuration

↳ Configuring BGP FRR

Run the **bgp fast-reroute** command to enable the BGP FRR function, which is disabled by default.

↳ Configuring a BFD Session to a BGP Neighbor

Run the **neighbor peer-address fall-over bfd** command to configure a BFD session to a BGP neighbor, which is not configured by default.

↳ Manually Configuring a BGP BFD Session

If the BFD session to a BGP neighbor cannot be used to fast detect the failure of the master link, you can run the **bfd bind bgp peer-ip ip-address interface interface-type interface-index source-ip ip-address** command to configure a BGP BFD session, which is not configured by default.

5.3.15 Configuring BGP Timers

You can manually configure various timers within BGP to meet the neighbor keepalive and route management requirements in different network environments.

Working Principle

↳ BGP Neighbor Keepalive Timer

BGP uses the Keepalive timer to maintain a valid connection with a peer and uses the Holdtime timer to identify whether a peer is valid. By default, the value of the Keepalive timer is 60 seconds and the value of the Holdtime timer is 180 seconds. When a BGP connection is established between two BGP speakers, the two BGP speakers negotiate about the Holdtime timer value and select a smaller value. 1/3 of the negotiated Holdtime timer value and the configured Keepalive timer value are compared and the smaller value is used as the Keepalive timer value.

↳ Neighbor Reconnection Timer

To reduce the impacts of frequent BGP reconnection to a neighbor on the network bandwidth, after a BGP speaker detects failure of a neighbor connection, the BGP speaker attempts to reconnect the neighbor after the connect-retry timer expires. By default, the value of the connect-retry timer is 15s.

↳ Route Advertisement Timer

To reduce the impacts of route update packets on the network bandwidth, after a BGP speaker detects a network topology change, the BGP speaker does not advertise the route update to its neighbors immediately. Instead, the BGP speaker uses a regular update mechanism to advertise all changed routing information to its neighbors.

Related Configuration

▾ Configuring the BGP Neighbor Keepalive Timer

- **timers bgp *keepalive holdtime***

Adjusts the BGP *keepalive* and *holdtime* values for all peers.

The *keepalive* value ranges from 0 to 65,535. The default value is 60 seconds.

The *holdtime* value ranges from 0 to 65,535. The default value is 180 seconds.

- **neighbor { *address* | *peer-group-name* } timers *keepalive holdtime***

Configures the *keepalive* and *holdtime* values used for connecting to a specified BGP peer (group).

The *keepalive* value ranges from 0 to 65,535. The default value is 60 seconds.

The *holdtime* value ranges from 0 to 65,535. The default value is 180 seconds.

▾ Configuring the Neighbor Re-connection Timer

- **neighbor { *address* | *peer-group-name* } timers connect *connect-retry***

Configures the *connect-retry* value used for reconnecting to a specified BGP peer (group).

The value of *connect-retry* ranges from 1 to 65,535. The default value is 15 seconds.

▾ Configuring the Route Advertisement Timer

- **neighbor { *address* | *peer-group-name* } advertisement-interval *seconds***

Configures the minimum interval for sending route updates to a specified BGP peer (group). The value of *advertisement-interval* ranges from 0 to 600 seconds. The default value for IBGP peers is 0 seconds and the default value for EBGP peers is 30 seconds.

- **neighbor { *address* | *peer-group-name* } as-origination-interval *seconds***

Configures the minimum interval for sending local initial route updates to a specified BGP peer (group). The value of *As-origination-interval* ranges from 1 to 65,535. The default value is 1 second.

5.3.16 Configuring BGP Route Update Mechanisms

Working Principle

BGP provides two route update mechanisms: regular-scanning update and event-triggering update. Regular-scanning update indicates that BGP uses an internal timer to start scanning regularly and update the routing table. Event-triggering update indicates that BGP starts scanning and updates the routing table when the BGP configuration commands are changed due to user configuration or the next hop of a BGP route changes.

-  This function is configured based on address families and can be configured in the IPv4, IPv6, VPNv4, VPNv6, IPv4 vrf and IPv6 VRF address family modes.
-  If you set the BGP route update mechanism to event-triggering update (by running the **bgp scan-rib disable** command), you must disable synchronization (by running the **no synchronization** command) and enable the BGP next-hop triggering update function (by running the **bgp nexthop trigger enable** command). On the other hand, if you enable synchronization or disable the BGP next-hop triggering update function, the BGP routing table must be updated in the regular scanning mode.

Related Configuration

Configuring Route Update Mechanisms

- **bgp scan-rib disable**
Sets the BGP route update mechanism to event-triggering update. Regular-scanning update is used by default.
- **bgp scan-time** *scan-time*
Configures the regular update interval of BGP. The value of *scan-time* ranges from 5 to 60 seconds. The default value is 60 seconds.

5.3.17 Configuring the Next-Hop Triggering Update Function of BGP

The next-hop triggering update function of BGP is a method for reducing the BGP convergence time. This function is used to optimize the method for monitoring the next hop of a route to ensure that BGP can increase the BGP route convergence speed when the network topology is stable.

Working Principle

When BGP connects to a neighbor, BGP automatically monitors the next hop of the BGP route learned from the neighbor. When the next hop changes in the core routing table, BGP receives an advertisement about the next hop change and updates the BGP routing table. This optimization measure improves the BGP route convergence performance by reducing the time for detecting next-hop changes.

If this function is disabled, BGP next hop update will be discovered through regular scanning specified by scan-timer.

-  This function is configured based on address families and can be configured in the IPv4, IPv6, VPNv4, and IPv4 vrf address family modes.
-  **bgp nexthop trigger delay** and **bgp scan-time** control the same timer. When bgp scan is enabled (it is enabled by default and can be disabled by the **bgp scan-rib disable** command), if the value of **bgp nexthop trigger delay** is larger than 60s, bgp scan does not take effect because the scan timer is always triggered before the delay.
-  If the network environment is unstable (with frequent next-hop changes), especially with many routes, this function performs unnecessary route calculations, which consumes more CPU resources. Therefore, you are advised to disable this function in this environment.

Related Configuration

↘ Configuring the Next-Hop Triggering Update Function of BGP

- **bgp nexthop trigger enable**

Enables the BGP next-hop triggering function, which is enabled by default.

- **bgp nexthop trigger delay *delay-time***

Configures the delay of BGP next-hop triggering update. The value of *delay-time* ranges from 0 to 100 seconds. The default value is 5 seconds.

5.3.18 Configuring BGP LOCAL AS

The Local AS function of BGP is used to configure a local AS different from a router BGP AS for a specific peer. This is similar to deploying a new virtual AS between the peer devices. When the local router BGP AS changes, you can establish a BGP connection without changing the BGP configurations on the peer device. This function is mainly used for AS migration and merging of large networks and ensures that the device configurations in other interconnected ASs are not affected.

Working Principle

In BGP, when a local device connects to a peer, the local device advertises the local AS number to the peer by using an Open message. The peer checks whether the BGP AS number advertised is the same as the local AS number. If the AS numbers are different, the peer will deny the BGP connection. By default, the local AS in the BGP connection is a route BGP AS. However, if a local AS is configured for the peer, the configured local AS will replace the route BGP AS when a BGP connection is established between the local device and the peer.

i The **neighbor *peer-address* local-as *as-num*** command for configuring the BGP Local AS function can be followed by more options. For details, see the Command Reference.

i The BGP Local AS function is applied only to EBGP peers, but is not applied to IBGP peers and alliance EBGP peers. In addition, the BGP Local AS function has the following restrictions:

- 1) The configured local AS cannot be the same as the remote AS of a peer.
- 2) The local AS cannot be configured independently for a member of a peer group.
- 3) The configured local AS cannot be the same as the route BGP AS.
- 4) If a device is a member of an AS alliance, the local AS cannot be the same as the AS alliance number.

Related Configuration

↘ Configuring BGP LOCAL AS

- **neighbor { *address* | *peer-group-name* } local-as *as-number***

Configures a local AS for a peer. By default, no local AS is configured for any peer. The local AS of a peer is the route BGP AS.

5.3.19 Configuring BGP Capacity Protection

There are often a large number of BGP routes, which may cause overload of a device, especially for a device with small memory. Protecting BGP capacity helps avoid non-predictable running status caused by consumption of device capacity.

Working Principle

Restricting the Number of BGP Routes

Restrict the number of BGP routes by setting the maximum number of routes in a BGP address family and the maximum number of routes that can be learned by a BGP neighbor.

Entering the OVERFLOW State in case of Insufficient Memory

If the memory is insufficient, BGP can enter the OVERFLOW state. In the OVERFLOW state, BGP generates a default route pointing to a NULL interface. If a newly learned route is not a refined route other than the default route in the current routing table, the route is discarded. In other words, general newly learned routes are discarded to ensure that the system memory is stable. The purpose of not discarding all routes is to avoid route loops in the entire network. Therefore, it is safe for BGP to enter the OVERFLOW state. BGP is allowed to enter the OVERFLOW state by default.

- i** By default, BGP enters the OVERFLOW state in case of insufficient memory. If you do not want to BGP to enter the OVERFLOW state, you can run the **no overflow memory-lack** command to disable this function.
- i** In the OVERFLOW state, BGP supports only the **clear bgp { addressfamily | all } *** command at present. You can also exit from the OVERFLOW state by disabling and enabling BGP again. When the memory becomes sufficient again, BGP can also automatically exit from the OVERFLOW state.

Related Configuration

Restricting the Number of BGP Routes

- **neighbor { address | peer-group-name } maximum-prefix maximum [threshold] [warning-only]**

Restricts the maximum number of routes that can be learned from a BGP neighbor, which is not restricted by default.

- **maximum-prefix maximum**

Restricts the maximum number of routes in a BGP address family, which is not restricted by default.

Configuring BGP OVERFLOW

- **overflow memory-lack**

Enable BGP to enter the OVERFLOW state in case of insufficient memory, which is enabled by default.

5.3.20 Configuring BGP GR

Graceful Restart (GR) is intended to implement uninterrupted data forwarding during restart of BGP. During active/standby switching of the management boards, the GR function keeps the network topology stable, maintains the forwarding table and ensures that key services are not interrupted.

Working Principle

- i** Comply with RFC4724: Graceful Restart Mechanism for BGP. [BGP GR] is used in the following description to indicate the RFC.

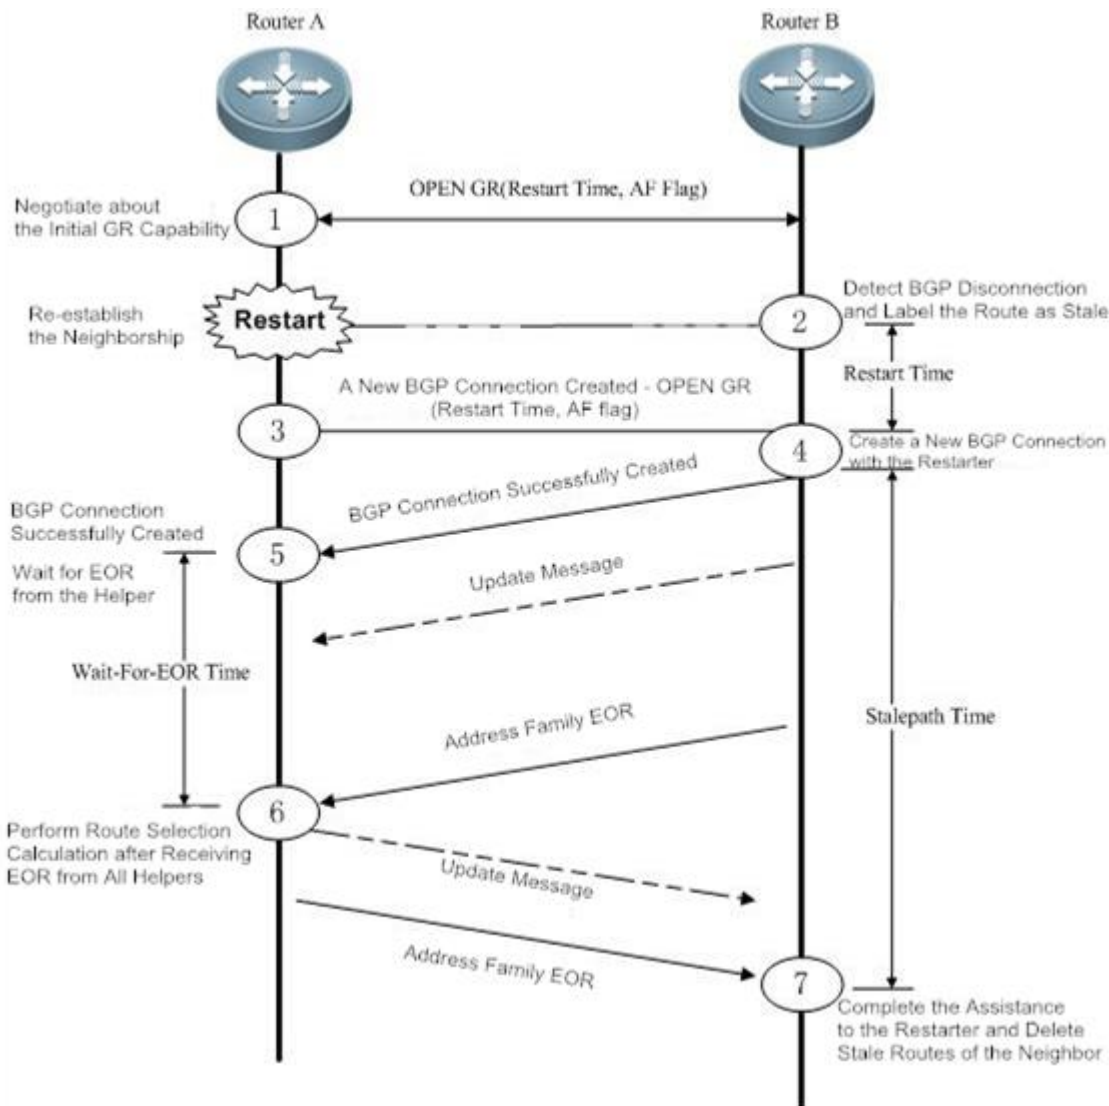

BGP GR is not an independent process, but is jointly completed by the Restarter and Helper.

- The Restarter performs restart and maintains the working capability of the route forwarding plane when the route control plane is faulty.
- The Helper is the BGP neighbor of the Restarter and helps the Restarter to complete GR.

A capability indicating GR is added to the OPEN message of BGP, which is called "Graceful Restart Capability". This capability is used by BGP to tell its neighbor it supports the graceful restart capability. During initialization of a BGP connection, two neighbors negotiate about the GR capability.

The route update end flag (End-of-RIB, shorted as EOR) is added to the Update packet of BGP, which indicates that the routing information update to the neighbor is completed.

Figure 5-3 BGP GR Interaction Process

- ① When BGP establishes neighborhood at the beginning, BGP uses the GR capability field in the OPEN message to negotiate about the GR capabilities of the two neighbors.

6. ② At a moment, the Restarter starts restart, and the BGP session is disconnected. The Helper detects the disconnection, keeps the route of the Restarter valid but adds the "Stale (aged but not updated)" flag to the route.
7. ③ and ④ The Restarter completes restart and connects to the Helper again.
8. ⑤ The Restarter waits for the route update message and EOR flag from the Helper.
9. ⑥ After receiving the EOR flag from all neighbors, the Restarter performs route calculation, update routing entries and then sends updated routes to the Helper.
10. ⑦ After receiving the updated routes, the Helper cancels the "Stale" flag of the routes. After receiving the EOR flag from the Restarter, the Helper deletes routes with the "Stale" flag (these routes are not updated), performs route calculation, and updates the routing entries. The entire GR process is completed.

BGP GR defines several extended and important timers:

- **Restart-Timer:** The GR Restarter advertises the time value to the GR Helper, which indicates the maximum waiting time that the GR Restarter hopes the Helper to wait before a new connection is established between them. You can run the **bgp graceful-restart restart-time** command to modify the time value.
- **Wait-For-EOR Timer:** Indicates the maximum time that the GR Restarter waits for the EOR flag from all GR Helpers. After receiving the EOR flag from all GR Helpers or after the Wait-For-EOR timer expires, the GR Restarter calculates the preferred route and updates the routing entries. You can run the **bgp update-delay** command to modify the time value.
- **StalePath Timer:** Indicates the maximum time that the GR-Helper waits for the EOR flag from the GR Restarter after a new connection is established between them. Within this period, the Helper keeps the original route of the Restarter valid. After receiving the EOR flag or after the StalePath timer expires, the Helper clears the routing entries still with the "Stale" tag. You can run the **bgp graceful-restart stalepath-time** command to modify the time value.

Related Configuration

Configuring BGP GR

- **bgp graceful-restart**
Enables the Restarter capability, which is enabled by default.
- **bgp graceful-restart restart-time *time***
Sets the Restart Timer. The default value is 120 seconds.
- **bgp update-delay *delay***
Sets the Wait-For-EOR Timer. The default value is 120 seconds.
- **bgp graceful-restart stalepath-time *time***
Sets the StalePath Timer. The default value is 360 seconds.
- **bgp graceful-restart disable**
Disables the address family GR capability. The address family GR capability is enabled by default. After the global BGP GR is enabled, the GR capability is automatically enabled for all address families.

- i** When BGP GR is implemented, all BGP peers must enable the BGP GR capability. If certain peers do not support or enable GR, BGP GR may fail to be implemented. GR failure may cause a short route black-hole or route loop, which may affect the network. Therefore, you are advised to verify that all neighbors are enabled with the BGP GR capability. You can run the **show ip bgp neighbors** command to display the capabilities successfully negotiated between BGP peers and verify that the GR capability negotiation is successful. In the BGP route configuration mode, run the **bgp graceful-restart** command to enable the BGP GR capability.
- i** The **bgp graceful-restart** command will not be applied to a successfully established BGP connection immediately. That is, when the BGP connection is in the Established state, the BGP peers will not re-negotiate about the GR capability immediately. To enable the BGP peers of the BGP connection to negotiate about the GR capability immediately, you need to forcibly restart the BGP peers to re-negotiate about the GR capability by running the **clear ip bgp 192.168.195.64** command (for example). To make GR enabling or disabling take effect immediately, you must restart the neighborhood for capability negotiation, which may cause network flapping and affect normal use of users. Therefore, you can explicitly control whether to restart the neighborhood.
- i** Supporting BGP GR does not mean that a device can be used as the Restarter to implement BGP GR. Whether to implement BGP GR also depends on the hardware capabilities of the device. Ruijie devices must support the dual-engine hot backup when being used as the GR Restarter.
- i** The restart period configured by the **bgp graceful-restart restart-time** command should not be longer than the Hold Time of the BGP peers; otherwise, the Hold Time will be used as the restart time to be advertised to the BGP peers during GR capability negotiation.
- i** The **bgp graceful-restart disable** command is used to disable the GR capability in an address family in the address family configuration mode, which is not configured by default.

5.3.21 Configuring 4-Byte AS Numbers of BGP

A traditional AS number consists of 2 bytes, ranging from 1 to 65,535. A newly defined AS number consists of 4 bytes, ranging from 1 to 4,294,967,295. Newly defined AS numbers are used to cope with exhaustion of AS number resources.

Working Principle

4-byte AS numbers support two expression modes: the decimal mode and dot mode. The decimal mode is the same as the original expression mode, that is, expressing the 4 bytes of an AS number as decimal digits. The dot mode is expressed as ([higher 2 bytes.]lower 2 bytes). If the higher 2 bytes are 0, they will not be displayed.

For example, an AS number is 65534 in the decimal mode and is 65,534 in the dot mode (the 0 at the beginning is not displayed).

For example, an AS number is 65,536 in the decimal mode, and is 1.0 in the dot mode.

For example, an AS number is 65,538 in the decimal mode, and is 1.2 in the dot mode.

- i** Related protocols are as follows: RFC 4893 and RFC 5396.

↘ **Configuring the Display Mode of a 4-Byte AS Number**

A 4-byte AS number is displayed in the decimal mode by default. You can manually set the display mode to the dot mode. After the setting, a regular expression will use the dot mode for matching 4-byte AS numbers.

Compatibility with Devices Supporting Only 2-Byte AS Numbers

With introduction of 4-byte AS numbers, BGP connections may be established between old BGP speakers supporting only 2-byte AS numbers and new BGP speakers supporting 4-byte AS numbers. If the AS where a new BGP speaker resides has a 4-byte AS number, when an old BGP speaker creates neighborship with the new BGP speaker, the old BGP speaker uses the reserved AS number 23,456 to replace the 4-byte AS number of the new BGP speaker. In the OPEN packets sent by the new BGP speaker to the old BGP speaker, the 4-byte AS number in the **My Autonomous System** field will be replaced by 23,456. In addition, in UPDATE packets sent to the old BGP speaker, the 4-byte AS number in the AS-PATH and AGGREGATOR attributes will also be replaced by 23,456. In addition, new optional transfer attributes AS4-PATH and AS4-AGGREGATOR will be used to record the real 4-byte AS number so that the real AS-PATH and AGGREGATOR attributes can be restored when the route reaches a next new BGP speaker.

In other cases, the real AS number of the remote end is used to create neighborship.

Related Configuration

Configuring the Display Mode of a 4-Byte AS Number

- **bgp asnotation dot**

Displays a 4-byte AS number in the dot mode. The decimal mode is used by default.

5.3.22 Configuring a Regular Expression

A regular expression is a formula that matches strings based on a template.

The formula is used to assess text data and return True or False to indicate whether the expression can correctly describe the data.

Working Principle

Regular expressions are used in BGP path attributes. The following table describes the usages of special characters in a regular expression.

Character	Symbol	Special Meaning
Period	.	Matches any single character.
Asterisk	*	Matches zero or any sequence in a string.
Plus sign	+	Matches one or any sequence in a string.
Question mark	?	Matches zero or one symbol in a string.
Caret	^	Matches the start of a string.
Dollar sign	\$	Matches the end of a string.
Underline	_	Matches the start, end and space of commas, brackets and strings.
Square brackets	[]	Matches a single character within a range.

Related Configuration

↳ Using a Regular Expression in a show Command

- **show ip bgp regexp** *regexp*
Displays the BGP routing information in a specified regular expression matched by the AS-PATH attribute.
- **show ip bgp quote-regexp** *regexp*
Displays the BGP routing information in a regular expression within the specified double quotation marks matched by the AS-PATH attribute.

5.3.23 Configuring BGP Session Retention

By default, when an UPDATE packet is received from a neighbor, a BGP session will be disconnected if an error is detected on the multi-protocol routing attribute. This will cause flapping of the routes in all address families of this neighbor. That is, the routing error in an address family will affect the route stability in other address families.

Working Principle

After the BGP session retention function is enabled, if an error occurs in the routing attribute of an address family, only the routing information in this address family related to the neighbor is deleted. In addition, the BGP session and other address families are not affected, which enhances the stability of BGP.

recovery-time is used to configure the time for waiting for automatic route recovery, which requires that a neighbor should support the route-refresh capability. After the recovery-time, BGP sends the route-refresh message of the address family to the neighbor and re-advertises all routing information in the address family to this neighbor.

 In the session retention state, you can manually reset the neighbor to exit from the session retention state.

Related Configuration

↳ Configuring BGP Session Retention

- **bgp mp-error-handle session-retain [recovery-time *time*]**
Enables the BGP session retention function, which is disabled by default.
recovery-time *time* configures the time for waiting for automatic route recovery, ranging from 10 to 4,294,967,296 seconds. The default value is 120.

5.3.24 Configuring BGP Delayed Advertisement upon System Restart

By default, after the neighborship is established after system restart, a BGP peer can advertise route information to its neighbors. This is normal in most cases. However, in certain cases, for example, there are many neighbors or routes during startup but writing entries into the hardware is slow. In this case, the neighbors have learned the routes and started forwarding traffic, but the hardware has not completed writing of entries at the local end, which causes failure of traffic forwarding.

Working Principle

The BGP delayed advertisement upon system restart ensures that routes are not advertised to neighbors immediately after the neighborship is established upon system restart and that the routes are advertised after a period. This function has no effect on other behaviors such as route receiving performed by the neighbors. If part of the routes is not affected by the delay, configure prefix-list policy to match this part of routes so that route advertisement can be more flexible.

delay-time is used to configure the waiting time before routes are advertised to the neighbors. **startup-time** is used to configure the startup time. Within the startup-time, BGP sends routing information to the neighbors at the interval specified by **delay-time**.

 After the startup-time ends, the default route advertisement behavior recovers.

Related Configuration

Configuring BGP Delayed Advertisement upon System Restart

- bgp initial-advertise-delay** *delay-time* [*startup-time*]

Enables BGP delayed advertisement upon system restart, which is disabled by default.

delay-time configures the delay time for advertising routes after the BGP neighborship is established upon system restart, ranging from 1 to 600 seconds. The default value is 1s.

startup-time configures the time range for system restart, ranging from 5 to 58,400 seconds. The delayed route advertisement mechanism is used within this range. The default value is 600s.

- bgp initial-advertise-delay prefix-list** *prefix-list-name*

By default, the BGP delayed advertisement upon system restart is disabled. If enable it, the route will be immediately sent after the prefix-list policy is matched.

prefix-list-name: indicates the name of prefix-list policy.

5.3.25 Other Related Configurations

-  For configuration and application of BGP MCE, see section "VRF Configuration Guide".
-  For configuration and application of BGP L2VPN, see section "L2VPN Configuration Guide".
-  For configuration and application of BGP/MPLS VPN, see section "BGP/MPLS VPN Configuration Guide".
-  For configuration and application of the BGP MDT address family, see section "Multicast VPN (MD Configuration Guide)".

5.4 Configuration

Configuration	Description and Command
Configuring a BGP Peer (Group)	 (Mandatory) It is used to create a BGP neighbor.
	router bgp Enables BGP.

Configuration	Description and Command	
	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>	Creates a BGP neighbor.
Configuring MD5 Authentication	 (Optional) It is used to perform encrypted authentication for the BGP neighbor.	
	neighbor { <i>peer-address</i> <i>peer-group-name</i> } password [0 7] <i>string</i>	Configures the password for encryption.
Configuring a Route Reflector	 (Optional) It is used to reduce the number of BGP neighbor connections.	
	neighbor { <i>peer-address</i> <i>peer-group-name</i> } route-reflector-client	Specifies a peer (group) as a reflector client.
Configuring an AS Alliance	 (Optional) It is used to reduce the number of BGP neighbor connections.	
	bgp confederation identifier <i>as-number</i>	Configures the BGP alliance ID.
	bgp confederation peers <i>as-number</i> [... <i>as-number</i>]	Configures a BGP alliance neighbor.
Configuring Multi-path Load Balancing of BGP	 (Optional) It is used to implement multi-path load balancing.	
	maximum-paths ibgp <i>number</i>	Configures IBGP load balancing.
	maximum-paths ebgp <i>number</i>	Configures EBGP load balancing.
	bgp bestpath as-path multipath-relax	Enables the BGP AS-PATH loose comparison mode.
Configuring EBGP FRR	 (Optional) It is used to increase the convergence speed when a network fault occurs.	
	bgp fast-reroute	Configures BGP FRR.
	neighbor { <i>peer-address</i> <i>peer-group-name</i> } fall-over bfd	Configures a BFD session to a BGP neighbor.
Configuring FRR in an IBGP Route Reflection Environment	 (Optional) It is used to increase the convergence speed when a network fault occurs.	
	bgp fast-reroute	Configures BGP FRR.
Configuring Local ASs	 (Optional) It is used for transitional deployment during network migration.	
	neighbor { <i>peer-address</i> <i>peer-group-name</i> } local-as <i>as-number</i> [no-prepend [replace-as [dual-as]]]	Configures the local AS for a BGP neighbor.
Configuring BGP GR	 (Recommended) It is used to improve the network reliability.	
	bgp graceful-restart	Enables the BGP GR capability.
	bgp graceful-restart restart-time <i>restart-time</i>	Configures the maximum time for BGP GR.
	bgp graceful-restart stalepath-time <i>time</i>	Configures the maximum retention time for BGP stable route.

Configuration	Description and Command	
Configuring a BGP IPv6 Address Family	 (Optional) It is used to deploy an IPv6 network by using BGP.	
	address-family ipv6 unicast	Enters the BGP IPv6 unicast configuration mode.
	neighbor { <i>peer-address</i> <i>peer-group-name</i> } activate	Activates the address family capability of a BGP neighbor in the current configuration mode.
Configuring Interconnection with Devices Supporting Only 2-Byte AS Numbers	 (Optional) It is used for interconnecting with an old device that supports only 2-byte AS numbers.	
	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>	Creates a BGP neighbor.

5.4.1 Configuring a BGP Peer (Group)

Configuration Effect

- Configure BGP and create IBGP and EBGP neighbors.

Notes

- If an IBGP neighbor is not directly connected, you need to configure IGP or a static routing protocol to implement interconnection.
- If an EBGP neighbor is not directly connected, you need to configure the **ebgp-multihop** parameter for the neighbor.

Configuration Steps

↘ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↘ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Configuring a Source Interface for a BGP Neighbor

- (Optional) Perform this configuration in the BGP configuration mode. By default, BGP automatically selects a local interface that reaches the destination IP address of a peer as the source interface.

 For an IBGP neighbor, you are advised to use a Loopback interface as the source interface.

Verification

- Run the **show** command to display the neighbor status.

Related Commands

↳ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↳ Creating a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↳ Creating a Source Interface for a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } update-source { <i>interface-type interface-number</i> <i>address</i> }
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>interface-type interface-number</i> : Indicates an interface name. <i>address</i> : Directly specifies the network interface address used for creating a BGP connection.
Command Mode	BGP configuration mode
Usage Guide	The source interface of a neighbor must be a local valid interface or address.

Configuration Example

↳ Configuring a BGP Peer (Group)

<p>Scenario Figure 5-4</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable BGP on all devices and set the AS numbers as shown in Figure 5-4. ● Configure a loopback interface on A, B, and C and create an IBGP neighbor based on the loopback interface. ● Create an EBGP neighborship by using the directly connected interfaces on C and D. ● Create an IBGP peer group on C.

Common Errors

- IGP is not enabled and the interconnection between the local loopback address and the loopback address on the IBGP neighbor fails, which causes that the neighbor fails to be created.
- `ebgp-multihop` is not configured when an EBGP is not directly connected, which causes that a TCP connection fails to be created.

5.4.2 Configuring MD5 Authentication

Configuration Effect

- Configure MD5 for encrypted authentication between EBGP and IBGP neighbors.

Notes

- If an IBGP neighbor is not directly connected, you need to configure IGP or a static routing protocol to implement interconnection.
- If an EBGP neighbor is not directly connected, you need to configure the **`ebgp-multihop`** parameter for the neighbor.

Configuration Steps

↘ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↘ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

Verification

- Run the **show** command to display the neighbor status.

Related Commands

↳ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Description	
Command Mode	Global configuration mode
Usage Guide	-

↳ Creating a BGP Neighbor

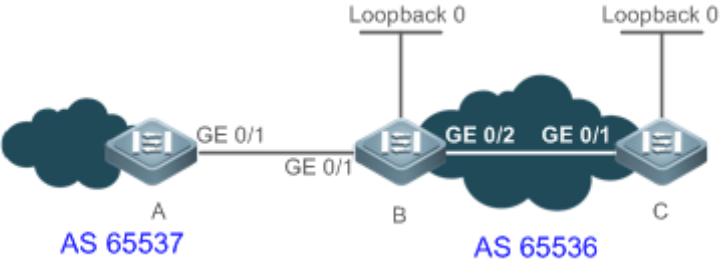

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address.
Description	<i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↳ Configuring an MD5 Password for a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } password [0 7] <i>string</i>
Parameter	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address.
Description	<i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. 0 : Displays a password not encrypted. 7 : Displays a password encrypted. <i>string</i> : Indicates a password for TCP MD5 authentication, consisting of a maximum of 80 characters.
Command Mode	BGP configuration mode
Usage Guide	The same passwords must be configured on the two ends of a BGP neighborhood.

Configuration Example

↳ Configuring BGP MD5 Authentication

Scenario Figure 5-5	
Configuration Steps	<ul style="list-style-type: none"> ● Enable BGP on all devices and set the AS numbers as shown in Figure 5-5. ● Configure a loopback interface on B and C and create an IBGP neighbor based on the loopback interface. ● Create an EBGP neighborship by using the directly connected interfaces on A and B. ● Configure the passwords on A, B and C for their neighbors.
A	<pre> A# configure terminal A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0 A(config-if-GigabitEthernet 0/1)# exit A(config)# router bgp 65537 A(config-router)# neighbor 192.168.1.2 remote-as 65536 A(config-router)# neighbor 192.168.1.2 password 7 ebgpneighbor </pre>

Common Errors

- The passwords for MD5 encrypted authentication at the two ends of a BGP neighborhood are different.

5.4.3 Configuring a Route Reflector

Configuration Effect

- Configure a route reflector in the IGP environment to reduce the number of BGP neighbor connections.

Notes

- If an IBGP neighbor is not directly connected, you need to configure IGP or a static routing protocol to implement interconnection.

Configuration Steps

↳ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↳ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

↳ Creating a BGP Reflector

- (Mandatory) Perform this configuration in the BGP configuration mode.

Verification

- Run the **show** command to display the neighbor status.

Related Commands

↳ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↳ Creating a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↳ Creating a BGP Reflector

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } route-reflector-client
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters.

Command Mode	BGP configuration mode
Usage Guide	-

Configuration Example

Configuring a BGP Route Reflector

<p>Scenario Figure 5-6</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable BGP on all devices and set the AS numbers as shown in Figure 5-6. ● Configure a loopback interface on all devices and create an IBGP neighborship by using the loopback interface according to the connection lines as shown in Figure 5-6. ● Configure route reflection on the device RR and specify A, B, C and D as reflector clients.
<p>A</p>	<pre>A# configure terminal A(config)# interface loopback 0 A(config-if-Loopback 0)# ip address 10.1.1.1 255.255.255.255 A(config-if-Loopback 0)# exit A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0 A(config-if-GigabitEthernet 0/1)# exit A(config)# router bgp 65536 A(config-router)# neighbor 10.1.1.5 remote-as 65536 A(config-router)# neighbor 10.1.1.5 update-source loopback 0 A(config-router)# network 192.168.1.0 mask 255.255.255.0</pre>

5.4.4 Configuring an AS Alliance

Configuration Effect

- Configure a BGP alliance to reduce the number of BGP neighbor connections.

Notes

- It is advised to use private AS numbers for sub ASs (also called member ASs) within an alliance. Private AS numbers range from 64,512 to 65,535.
- Within a sub AS of an alliance, full mesh must be established for all BGP speakers (route reflectors can be further configured within the sub AS).
- An EBGP neighborhood must be established between sub ASs of an alliance.
- All BGP speakers within an alliance must belong to a sub AS within the alliance.

Configuration Steps

↘ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↘ Configuring a BGP Alliance ID

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Configuring a BGP Alliance Member

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Configuring Multiple Hops for an EBGP Neighbor

- Perform this configuration in the BGP configuration mode. It is mandatory when an EBGP neighbor is not directly connected.

↘ Configuring BGP Route Re-distribution to a Network

- (Optional) Perform this configuration in the BGP configuration mode. Perform this configuration when a local route needs to be advertised. You can also configure an alternative network by means of re-distribution.

Verification

- Run the **show** command to display the BGP neighbor status.
- Run the **show** command to display the BGP routing table information.

Related Commands

↘ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↘ Enabling a BGP Alliance ID

Command	bgp confederation identifier <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	BGP configuration mode
Usage Guide	-

↘ Configuring a BGP Alliance Member

Command	bgp confederation peers <i>as-number</i> [... <i>as-number</i>]
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	BGP configuration mode
Usage Guide	All member ASs of a local EBGP alliance must be identified.

↘ Creating a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters.

	<i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↘ **Configuring Multiple Hops for an EBGP Neighbor**

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } ebgp-multihop [<i>ttl</i>]
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>ttl</i> : Indicates the maximum number of hops that are allowed, ranging from 1 to 255.
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↘ **Configuring BGP Route Re-distribution to a Network**

Command	network <i>network-number</i> [mask <i>mask</i>] [route-map <i>map-tag</i>] [backdoor]
Parameter Description	<i>network-number</i> : Indicates the network address. <i>mask</i> : Indicates the subnet mask. <i>map-tag</i> : Indicates the name of a route map, consisting of no more than 32 characters. backdoor : Indicates that the route is a backdoor route.
Command Mode	BGP configuration mode
Usage Guide	The core routing table must contain same IGP (or static and directly connected) routes.

Configuration Example

↘ **Configuring a BGP Alliance**

Scenario Figure 5-7	<p>The diagram illustrates a BGP alliance configuration. It shows two Autonomous Systems (AS) connected via BGP. AS 100 is a confederation of three member ASes: AS 65536 (routers A and B), AS 65537 (router C), and AS 65538 (routers D and E). AS 200 consists of a single router, ASBR2. The connections are as follows: <ul style="list-style-type: none"> Router A (AS 65536) is connected to Router C (AS 65537) via GE0/2. Router C (AS 65537) is connected to Router E (AS 65538) via GE0/3. Router E (AS 65538) is connected to Router ASBR2 (AS 200) via GE0/1. The connections between A-C and C-E are labeled 'Confed EBGP', and the connection between E-ASBR2 is labeled 'EBGP'. </p>
Configuration	<ul style="list-style-type: none"> Configure BGP on A and B, set the AS number to 65,536 and configure an IBGP neighborship.

Steps	<ul style="list-style-type: none"> ● Configure BGP on C and D, set the AS number to 65,537 and configure an IBGP neighborhood. ● Configure BGP on ASBR1 and E, set the AS number to 65,538 and configure an IBGP neighborhood. ● Configure an alliance ID 100 on A, B, C, D, E and ASBR1. ● Configure the alliance member 65,537 on A, configure C as an EBGP neighbor, and set the peer AS number to 65,537. ● Configure the alliance members 65,536 and 65,538 on C, configure A as an EBGP neighbor and set the peer AS number to 65,536, configure ASBR1 as an EBGP neighbor and set the peer AS number to 65,538. ● Configure the alliance members 65,537 on ASBR1, configure C as an EBGP neighbor and set the peer AS number to 65,537, configure ASBR2 as an EBGP neighbor and set the peer AS number to 200. ● Configure BGP on ASBR2 and set the AS number to 200; configure ASBR1 as an EBGP neighbor and set the peer AS number to 100.

Common Errors

- No BGP alliance neighbor is configured.
- Full mesh is not established within sub ASs of an alliance.

5.4.5 Configuring Multi-path Load Balancing of BGP

Configuration Effect

- Implement multi-path load balancing for IBGP routes.
- Support AS-PATH loose comparison.

Notes

- Routes learned from an IBGP neighbor must have the same priority (the router-ID does not need to be compared).

Configuration Steps

↘ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↘ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Configuring BGP Load Balancing

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Configuring AS-PATH Loose Comparison

- (Optional) Perform this configuration in the BGP configuration mode. Perform this configuration when load balancing needs to be implemented for routes learned from different ASs.

Verification

- Run the **show** command to display BGP routing information.
- Run the **show** command to display the core routing table information.

Related Commands

↘ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↘ Creating a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address.

Description	<i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↘ [Configuring BGP Load Balancing](#)

Command	maximum-paths { ebgp ibgp } number
Parameter Description	<i>number</i> : Indicates the maximum number of equivalent paths. The minimum value is 1 and the maximum value depends on the device capability. If the value is 1 , multi-path load balancing of IBGP will be disabled.
Command Mode	BGP configuration mode
Usage Guide	-

↘ [Configuring AS-PATH Loose Comparison](#)

Command	bgp bestpath as-path multipath-relax
Parameter Description	-
Command Mode	BGP configuration mode
Usage Guide	-

[Configuration Example](#)

↘ [Configuring Multi-path Load Balancing of IBGP](#)

<p>Scenario Figure 5-8</p>	<p>The diagram illustrates a network topology with three Autonomous Systems (AS) and five routers. AS 65530 contains Router A (10.1.1.1/16), Router B (10.1.1.2/16), and Router C (10.2.1.1/16). AS 65531 contains Router D (10.3.3.1/16). AS 65532 contains Router E (10.4.1.1/16). There is also a destination network 10.5.0.0/16. Connections are as follows: Router A is connected to Router B (10.1.1.2/16) and Router C (10.2.1.1/16). Router B is connected to Router D (10.3.3.2/16). Router C is connected to Router E (10.4.1.2/16). Router D is connected to the destination network 10.5.0.0/16. Router E is also connected to the destination network 10.5.0.0/16.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable BGP on all devices and set the AS numbers as shown in Figure 5-8. ● Establish IBGP neighborships between A and B and between A and C by using directly connected interfaces. ● Establish EBGP neighborships between B and D and between C and E by using directly connected interfaces. ● Re-distribute the same routes to D and E. ● Configure IBGP load balancing on A and enable the AS-PATH loose comparison mode.

Common Errors

- The priorities of multi-hop BGP routes are different, which causes load balancing failure.

5.4.6 Configuring EBGPFRR

Configuration Effect

- Implement EBGPFRR.

Notes

- (Optional) Configure a neighbor BFD session to implement fast link fault detection.

Configuration Steps

▾ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

▾ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

▾ Configuring BGP FRR

- (Mandatory) Perform this configuration in the BGP configuration mode.

▾ Configuring a Neighbor BFD Session

- (Mandatory) Perform this configuration in the BGP configuration mode.

Verification

- Run the **show** command to display routing information.

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address.
Description	<i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command	BGP configuration mode
Mode	
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↘ Creating a BFD Session to a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } fall-over bfd
Parameter	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address.
Description	<i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters.
Command	BGP configuration mode
Mode	
Usage Guide	-

Configuration Example

↘ Configuring EBGp FRR

Scenario Figure 5-9	
Configuration Steps	<ul style="list-style-type: none"> ● Enable BGP on all devices. ● Configure the addresses of the directly connected interfaces on A, B and C to establish EBGP neighborships. ● Configure a BFD session for the EBGP neighborship between B and C. ● Configure FRR on C.
A	<pre> A# conf terminal A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0 A(config-if-GigabitEthernet 0/1)# exit A(config)# interface GigabitEthernet 0/2 A(config-if-GigabitEthernet 0/2)# ip address 192.168.2.1 255.255.255.0 A(config-if-GigabitEthernet 0/2)# exit A(config)# router bgp 100 A(config-router)# neighbor 192.168.1.2 remote-as 300 A(config-router)# neighbor 192.168.2.2 remote-as 200 A(config-router)# redistribute connect </pre>

Common Errors

- No BFD session is configured for BGP neighbors.

5.4.7 Configuring Local ASs

Configuration Effect

- Smoothly migrate the network configurations of router A from AS 23 to AS 3600.

Notes

N/A

Configuration Steps

↘ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↘ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Configuring the Local AS for a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

Verification

- Run the **show** command to display the information.

Related Commands

↘ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↘ Creating a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↘ Configuring the Local AS for a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } local-as <i>as-number</i> [no-prepend [replace-as [dual-as]]]
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates a local AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode. no-prepend : Does not add the local AS to the AS-PATH in the routing information received by a peer. This option is not available by default. replace-as : For the AS-PATH in the routing information sent by a peer, the local AS is used to replace the BGP AS. This option is not available by default. dual-as : Enables a peer to use the BGP AS or Local AS to establish a BGP connection with a device. This option is not available by default.
Command	BGP configuration mode

Mode	
Usage Guide	-

Configuration Example

Configuring BGP Local-AS

<p>Scenario Figure 5-10</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Create an EBGP neighborhood with B on A and specify the Local-AS for the EBGP neighborhood. ● Create an EBGP neighborhood for connecting to A on B.
<p>A</p>	<pre>A# configure terminal A(config)# router bgp 3600 A(config-router)# neighbor 57.50.1.1 remote-as 5750 A(config-router)# neighbor 57.50.1.1 update-source loopback 0 A(config-router)# neighbor 57.50.1.1 ebgp-multihop 255 A(config-router)# neighbor 57.50.1.1 local-as 23 no-prepend replace-as dual-as</pre>
<p>B</p>	<pre>B# configure terminal B(config)# router bgp 5750 B(config-router)# neighbor 36.0.1.1 remote-as 23 B(config-router)# neighbor 36.0.1.1 update-source loopback 0 B(config-router)# neighbor 36.0.1.1 ebgp-multihop 255</pre>
<p>Verification</p>	<p>Run the show command to display the BGP neighbor status.</p>
<p>A</p>	<pre>A# show ip bgp neighbors 57.50.1.1</pre>

```
BGP neighbor is 57.50.1.1, remote AS 5750, local AS 23(using Peer's Local AS, no-prepend, replace-as,
dual-as), external link

```

5.4.8 Configuring BGP GR

Configuration Effect

- Configure BGP GR to implement network deployment with high reliability.

Notes

- To successfully deploy the BGP GR function, you need to use a neighbor device as the GR Helper.
- In an BGP environment, you also need to configure IGP GR.
- After BGP GR is enabled, you need to reset a BGP neighbor connection to make it take effect.

Configuration Steps

↘ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↘ Configuring BGP GR

- Perform this configuration in the BGP configuration mode, which is configured by default.

↘ Configuring a BGP GR Timer

- (Optional) Perform this configuration in the BGP configuration mode.

↘ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

Verification

- Run the **show** command to display the neighbor status.

Related Commands

Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer

end.

Configuration Example

Configuring BGP GR

<p>Scenario Figure 5-11</p>	<p>The diagram illustrates two Autonomous Systems (AS). AS 200 consists of a single router R1. AS 100 consists of three routers: R2, R3, and R4. R1 is connected to R2 via a solid line, representing an EBGP neighborship. R2, R3, and R4 are interconnected with each other via dashed lines, representing an IBGP neighborship. A legend indicates that solid lines represent EBGP and dashed lines represent IBGP.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable BGP on all devices and set the AS numbers as shown in Figure 5-11. ● Configure a loopback interface on R2, R3, and R4 and create an IBGP neighborship based on the loopback interface. ● Create an EBGP neighborship by using the directly connected interfaces on R1 and R2. ● Enable BGP GR on R1, R2, R3, and R4.
<p>R1</p>	<pre>R1# configure terminal R1(config-router)# exit R1(config)# router bgp 100 R1(config-router)# bgp graceful-restart</pre>

```

Common Errors

- GR is not enabled for IGP.
- GR is not enabled for a BGP neighbor device.

5.4.9 Configuring a BGP IPv6 Address Family

Configuration Effect

- Configure BGP IPv6 routes to implement IPv6 network access in different ASs.

Notes

- Generally, BGP uses IPv6 addresses to create neighborships and implement exchange of IPv6 routes.

- In special scenarios (such as the 6PE function, see the MPLS-L3VPN-SCG.doc), BGP supports exchange of IPv6 routes on the neighbors with IPv4 addresses.
- Configurations related to BGP IPv6 services must be configured in the BGP IPv6 address family mode.

Configuration Steps

↘ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↘ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Configuring the BGP IPv4 Address Family Mode

- (Optional) Perform this configuration in the BGP configuration mode.

↘ Disabling the IPv4 Address Family Capability for a BGP Neighbor

- (Optional) Perform this configuration in the BGP IPv6 configuration mode.

↘ Configuring the BGP IPv6 Address Family Mode

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Configuring the IPv6 Address Family Capability for a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP IPv6 configuration mode.

↘ Configuring IPv6 Route Advertisement in BGP

- (Optional) Perform this configuration in the BGP IPv6 configuration mode.

Verification

- Run the **show** command to display the neighbor status.
- Run the **show** command to display the routing status.

Related Commands

↘ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↘ Creating a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter	<i>peer-address</i> : Indicates the address of a peer, which is usually an IPv6 address.
Description	<i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

▾ Configuring the BGP IPv4 Address Family Mode

Command	address-family ipv4 unicast
Parameter	-
Description	
Command Mode	BGP configuration mode
Usage Guide	-

▾ Disabling the IPv4 Address Family Capability for a BGP Neighbor

Command	no neighbor { <i>peer-address</i> <i>peer-group-name</i> } activate
Parameter	<i>peer-address</i> : Indicates the address of a peer, which is usually an IPv6 address.
Description	<i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters.
Command Mode	BGP IPv4 address family mode
Usage Guide	Neighbors with IPv6 addresses are used to exchange IPv6 routes. However, when a neighbor is configured in the BGP mode, BGP automatically activates the IPv4 unicast address family capability for the neighbor. Therefore, you are advised to manually disable the IPv4 unicast address family capability.

▾ Configuring the BGP IPv6 Address Family Mode

Command	address-family ipv6 unicast
Parameter	-
Description	
Command Mode	BGP configuration mode
Usage Guide	-

▾ Configuring the IPv6 Address Family Capability for a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } activate
Parameter	<i>peer-address</i> : Indicates the address of a peer, which is usually an IPv6 address.
Description	<i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters.
Command	BGP IPv6 address family mode

Mode	
Usage Guide	-

↘ **Configuring IPv6 Route Advertisement in BGP**

Command	network <i>network-number</i> [mask <i>mask</i>] [route-map <i>map-tag</i>] [backdoor]
Parameter Description	<i>network-number</i> : Indicates the network number. <i>mask</i> : Indicates the subnet mask. <i>map-tag</i> : Indicates the name of a route map, consisting of no more than 32 characters. backdoor : Indicates that the route is a backdoor route.
Command Mode	BGP IPv6 address family mode
Usage Guide	-

Configuration Example

↘ **Configuring BGP to Implement IPv6 Route Exchange in Different ASs**

Scenario Figure 5-12	<p>The diagram shows two routers, Router A and Router B, connected by a line. Router A is on the left and is associated with AS 65530. Router B is on the right and is associated with AS 65531. Each router is represented by a blue cube with a white cross on its top face, and a cloud-like shape is positioned behind each router.</p>
Configuration Steps	<ul style="list-style-type: none"> ● Enable BGP on all devices and set the AS numbers as shown in Figure 5-12. ● Configure a BGP neighbor, disable the IPv4 address family capability for the neighbor and activate the IPv6 address family capability. ● Configure IPv6 route advertisement in BGP.
A	<pre>A# configure terminal A(config)# int loopback 0 A(config-if-Loopback)# ipv6 address 30::1/128 A(config-if-Loopback)# exit A(config)# router bgp 65530 A(config-router)# neighbor 100::1 remote-as 65531 A(config-router)# address-family ipv4 A(config-router-af)# no neighbor 100::1 activate A(config-router-af)# exit-address-family A(config-router)# address-family ipv6 A(config-router-af)# neighbor 100::1 activate</pre>

	<pre>A(config-router-af)# network 30::1/128</pre>																				
<p>B</p>	<pre>B# configure terminal B(config)# router bgp 65531 B(config-router)# neighbor 100::2 remote-as 65530 B(config-router)# address-family ipv4 B(config-router-af)# no neighbor 100::2 activate B(config-router-af)# exit-address-family B(config-router)# address-family ipv6 B(config-router-af)# neighbor 100::2 activate</pre>

	Total number of prefixes 1
--	----------------------------

Common Errors

- The IPv6 address family capability is not activated for BGP neighbors.
- In non-6PE scenarios, IPv4 addresses are used to establish IPv6 routes for exchange between neighbors.

5.4.10 Configuring Interconnection with Devices Supporting Only 2-Byte AS Numbers

Configuration Effect

- Successfully interconnect devices supporting 4-byte AS numbers with devices supporting only 2-byte AS numbers.

Configuration Steps

↳ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↳ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

↳ Configuring the Display Mode of a 4-Byte AS Number

- (Optional) Perform this configuration in the BGP configuration mode. By default, a 4-byte AS number is displayed as decimal digits.

Verification

- Run the **show** command to display the neighbor status.

Related Commands

↳ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↳ Creating a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).

Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

➤ **Configuring the Display Mode of a BGP 4-Byte AS Number**

Command	bgp asnotation dot
Parameter Description	-
Command Mode	BGP configuration mode

5.4.11 Using Local IPv6 Link Addresses to Establish BGP Neighborships

Configuration Effect

- Use local IPv6 link addresses to establish BGP neighborships.

Notes

- Generally, global IPv4 addresses need to be used for establishing BGP neighborships.
- Local IPv6 link addresses can be used for establishing only single-hop BGP neighborships.
- When local IPv6 link addresses are used for establishing neighborships, using local IPv6 link addresses as information sources must be specified on the peer end.
- When local IPv6 link addresses are used for establishing neighborships, local IPv6 link addresses must be configured on both ends.

Configuration Steps

↘ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↘ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Specifying the Message Source for a BGP Neighbor

- Perform this configuration in the BGP configuration mode. If local IPv6 link addresses are configured for a neighbor, this configuration is mandatory; otherwise, this configuration is optional.

↘ Configuring the BGP IPv4 Address Family Mode

- (Optional) Perform this configuration in the BGP configuration mode.

↘ Disabling the IPv4 Address Family Capability for a BGP Neighbor

- (Optional) Perform this configuration in the BGP IPv6 configuration mode.

↘ Configuring the BGP IPv6 Address Family Mode

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Configuring the IPv6 Address Family Capability for a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP IPv6 configuration mode.

↘ Configuring IPv6 Route Advertisement in BGP

- (Optional) Perform this configuration in the BGP IPv6 configuration mode.

Verification

- Run the **show** command to display the neighbor status.
- Run the **show** command to display the routing status.

Related Commands

↳ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↳ Creating a BGP Neighbor

Command	neighbor <i>peer-address</i> remote-as <i>as-number</i>
Parameter Description	<i>peer-address</i> : Indicates the address of a peer, which is usually an IPv6 address. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer must be the same as the BGP AS number of a BGP speaker at the peer end.

↳ Specifying the Message Source for a BGP Neighbor

Command	neighbor <i>peer-address</i> update-source <i>interface-type interface-number</i>
Parameter Description	<i>peer-address</i> : Indicates the address of a peer, which is usually an IPv6 address. <i>interface-type interface-number</i> : Indicates an interface name.
Command Mode	BGP configuration mode
Usage Guide	If the local IPv6 link address of a local interface is used when a BGP neighborhood is established with a neighbor device, this interface must be specified as the message source of the neighborhood when the BGP neighborhood is configured on the local device.

↳ Configuring the BGP IPv4 Address Family Mode

Command	address-family ipv4 unicast
Parameter	-

Description	
Command Mode	BGP configuration mode
Usage Guide	-

↘ Disabling the IPv4 Address Family Capability for a BGP Neighbor

Command	no neighbor <i>peer-address</i> activate
Parameter Description	<i>peer-address</i> : Indicates the address of a peer, which is usually an IPv6 address.
Command Mode	BGP IPv4 address family mode
Usage Guide	Neighbors with IPv6 addresses are used to exchange IPv6 routes. However, when a neighbor is configured in the BGP mode, BGP automatically activates the IPv4 unicast address family capability for the neighbor. Therefore, you are advised to manually disable the IPv4 unicast address family capability.

Network	Next Hop	Metric	LocPrf	Weight Path							
*> 30::1/128	FE80:100::2	0		0 65530 i							

Common Errors

- When a neighborhood is configured, a local IPv6 link address is used to specify the neighborhood; however, no update source is specified as the interface for this local IPv6 link address during local configuration.
- Only one end uses a local IPv6 link address for establishing a neighborhood.

5.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears BGP IPv4 unicast routes.	clear ip bgp [vrf <i>vrf-name</i>] { * <i>as-number</i> <i>peer-address</i> } [soft] [in out] clear bgp ipv4 unicast [vrf <i>vrf-name</i>] { * <i>as-number</i> <i>peer-address</i> } [soft] [in out]
Clears BGP IPv6 unicast routes.	clear bgp ipv6 unicast [vrf <i>vrf-name</i>] { * <i>as-number</i> <i>peer-address</i> } [soft] [in out]

Displaying

Description	Command
Displays BGP IPv4 unicast routes.	show ip bgp show bgp ipv4 unicast
Displays BGP IPv6 unicast routes.	show bgp ipv6 unicast

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Enables all BGP debugging.	debug ip bgp all
Debugs BGP route flapping.	debug ip bgp dampening
Debugs BGP event processing.	debug ip bgp event
Debugs BGP route filtering.	debug ip bgp filter
Debugs BGP status machine.	debug ip bgp fsm
Debugs BGP neighbor keepalive.	debug ip bgp keepalives
Debugs BGP MPLS processing.	debug ip bgp mpls
Debugs BGP core route processing.	debug ip bgp nsm
Debugs BGP UPDATE packets.	debug ip bgp update

6 Configuring PBR

6.1 Overview

Policy-based routing (PBR) is implemented by applying a route map including policies to interfaces and devices.

Similar to static routing, PBR is also manually configured and cannot automatically update with network changes. In addition, PBR is effective only for packets sent from local interfaces and devices. As compared with static and dynamic routing, PBR is more flexible. Static and dynamic routing can forward packets only based on destination addresses. PBR can forward packets based on source and destination addresses, packet length and input interface.

6.2 Applications

Application	Description
Selecting an ISP by Using PBR	Specify preferential output interfaces for packets from different subnets.
Implementing Traffic Classification by Using PBR	Specify QoS values for packets from different subnets.

6.2.1 Selecting an ISP by Using PBR

An existing user network often uses resources of multiple internet server providers (ISPs). PBR needs to be used since different bandwidths may be requested from different ISPs or the network resources for key users need to be protected. By controlling forwarding of certain data packets, you can make full use ISP resources as well as meet the requirements of flexible and diversified applications.

Scenario

Figure 6-1

A LAN has two output interfaces for connecting the Internet. PBR is configured on the layer-3 device DEV1 to enable the two output interfaces to implement load sharing and mutual backup.

The specific requirements are as follows:

- Data streams from subnet 1 are sent from GE 0/1.
- Data streams from subnet 2 are sent from GE 0/2.
- If the GE 0/1 link is disconnected, the data streams on GE 0/1 are switched to GE 0/2. Vice versa.

Deployment

- Configure two different ACLs on the layer-3 device DEV1:
ACL1: source addresses belong to subnet 1.
ACL2: source addresses belong to subnet 2.
- Configure two policies in the route map on the layer-3 device DEV1:
Policy 1: sets the next hops for packets matching ACL1 to GE0/1 and GE0/2 (Based on the configuration sequence, GE0/1 takes effect first and GE0/2 works in the backup mode).
Policy 2: sets the next hops for packets matching ACL2 to GE0/2 and GE0/1 (Based on the configuration sequence, GE0/2 takes effect first and GE0/1 works in the backup mode).
- Configure PBR on GE0/3 (by using a route map). Then, packets received on this interface are forwarded based on the policies.

6.2.2 Implementing Traffic Classification by Using PBR

Scenario

Networks of medium- and small-sized enterprises have simple structures. Different branch nodes are interconnected to the central nodes through carrier dedicated lines or the Internet VPN mode. Enterprise networks often need to implement

three-in-one integration (of audio, video and data) to maximize the utilization of existing IP networks and save costs. Since all traffic is output from a single output interface, it is necessary to adjust the QoS policies for the output interface, in order to provide preferential communication quality for bandwidth- and delay-sensitive applications.

Figure 6-2

A LAN has an output interface for connecting the Internet. PBR is configured on the layer-3 device DEV1 to change the QoS values for packets from different networks.

The specific requirements are as follows:

- For data streams from subnet 1, representing audio streams, set the DSCP value to 56.
- For data streams from subnet 2, representing video streams, set the DSCP value to 40.
- For data streams from subnet 3, representing data streams, set the DSCP value to 24.

Deployment

- Configure three different ACLs on the layer-3 device DEV1:
 - ACL1: source addresses belong to subnet 1.
 - ACL2: source addresses belong to subnet 2.
 - ACL3: source addresses belong to subnet 3.
- Configure three policies in the route map on the layer-3 device DEV1:
 - Policy 1: sets the DSCP value for packets matching ACL1 to 56.
 - Policy 2: sets the DSCP value for packets matching ACL2 to 40.
 - Policy 3: sets the DSCP value for packets matching ACL3 to 24.
- Configure PBR on GE0/3 (by using a route map). Then, the DSCP values for packets received on this interface are changed based on the policies.

6.3 Features

Feature	Description
Configuring a Policy	Before configuring PBR, configure policies in a route map.
Configuring PBR	Apply a route map including policies to interfaces and devices to implement PBR.

6.3.1 Configuring a Policy

A policy is a "match ..., set..." statement, which indicates that "if certain conditions are matched, perform certain processing actions".

 For detailed introduction to the policies, see the section "Route Map".

Executing Policies

In the global configuration mode, you can run the **route-map** *route-map-name* [**permit** | **deny**] [*sequence-number*] command to create a policy in a route map.

A route map may contain multiple policies. Each policy has a corresponding sequence number. A smaller sequence number means a higher priority. Policies are executed based on their sequence numbers. Once the matching condition of a policy is met, the processing action for this policy needs to be executed and the route map exits. If no matching condition of any policy is met, no processing action will be performed.

Policies have two working modes:

- **permit**: When the matching condition of a policy is met, perform the processing action for this policy and exit the route map.
- **deny**: When the matching condition of a policy is met, do not perform the processing action for this policy and exit the route map.

Matching conditions of policies

The matching conditions of a policy may contain 0, 1 or more matching rules.

- If 0 matching rule is contained, no packet will be matched.
- If one or more match rules are contained, all match rules must be matched at the same time to meet the matching conditions of the policy.

In the route map mode, run the **match** command to configure match rules. One **match** command is mapped to one match rule.

PBR supports the following **match** commands:

Command	Description
---------	-------------

IPv4 PBR	match ip address	The source IPv4 address (and the destination IPv4 address) is used as the matching condition.  Multiple match ip address commands can be configured in a policy.
IPv6 PBR	match ipv6 address	The source IPv6 address (and the destination IPv6 address) is used as the matching condition.  Only one match ipv6 policy command can be configured in a policy.

-  IPv4 PBR defines the source IP address (and destination IP address) ranges of packets by using the IP standard or extended ACLs. IPv6 PBR defines the source IPv6 address (and destination IPv6 address) ranges of packets by using the IPv6 extended ACLs.
-  On a switch, packet forwarding based on policies of IPv4 PBR interfaces supports expert-level and MAC name ACLs. Packet forwarding based on local policies does not support expert-level and MAC name ACLs.
-  When PBR uses an ACL that is unavailable, the route sub-map will not be matched and the next route sub-map will be matched instead. If no route sub-map is matched, a common route will be selected for forwarding. If only ACLs are configured but no ACE is configured, the PBR forwarding behavior is the same as that in a scenario where an ACL is unavailable.
-  On a non-switch device, packet forwarding based on policies of IPv4 PBR interfaces and local policies do not support expert-level and MAC name ACLs.
-  On a switch, if a route sub-map uses multiple ACLs in PBR, only the first ACL is matched.

Processing action for a policy

The processing action of a policy may contain 0, 1 or more set rules.

- If 0 set rule is contained, no processing action will be performed and the route map will directly exit.
- If one or more set rules are contained, all processing actions will be performed and the route map will exit.

 If set rules have different priorities, the set rule with the highest priority will take effect.

In the route map mode, run the **set** command to configure set rules. One **set** command is mapped to one set rule.

PBR supports the following **set** commands:

	Command	Description
IPv4 PBR	set ip tos	Modifies the tos field of an IPv4 packet.  This command cannot work with the set ip dscp command.
	set ip precedence	Modifies the precedence field of an IPv4 packet.  This command cannot work with the set ip dscp command.

	Command	Description
	set ip dscp	<p>Modifies the dscp field of an IPv4 packet.</p> <p> This command cannot work with the set ip tos and set ip precedence commands.</p>
	set ip next-hop	<p>Configures the next hop of IPv4 packet forwarding. The next hop must be directly connected; otherwise, this command is invalid.</p> <p>A packet matching the match rules will be forwarded to the next hop specified by set ip next-hop first, no matter whether the route selected for the packet in the routing table is consistent with the next hop specified by PBR.</p> <p> On a switch, the output interfaces for next hops supported by PBR include the SVI, routing and layer-3 AP interfaces.</p>
	set ip default next-hop	<p>Configures the default next hop of IPv4 packet forwarding.</p> <p>A packet matching the match rules will be forwarded to the default next hop specified by this command if a route fails to be selected or the default route is selected for this packet in the routing table.</p>
IPv6 PBR	set ipv6 precedence	<p>Modifies the precedence field of an IPv6 packet.</p> <p> IPv6 PBR does not support set ipv6 tos or set ipv6 dscp.</p>
	set ipv6 next-hop	<p>Configures the next hop of IPv6 packet forwarding.</p> <p>An IPv6 packet matching the match rules will be forwarded to the next hop specified by set ipv6 next-hop first, no matter whether the route selected for the IPv6 packet in the routing table is consistent with the next hop specified by PBR.</p> <p>The next hop must be directly connected; otherwise, this command is invalid.</p>
	set ipv6 default next-hop	<p>Configures the default next hop of IPv6 packet forwarding.</p> <p>An IPv6 packet matching the match rules will be forwarded to the default next hop specified by this command if a route fails to be selected or the default route is selected for this packet in the routing table.</p> <p>The next hop must be directly connected; otherwise, this command is invalid.</p>

-  The priority sequence is as follows: **set ip next-hop** > common route > **set ip default next-hop** > default route. The preceding **set** commands can be configured at the same time but only the command with the highest priority takes effect.
-  The priority sequence is as follows: **set ipv6 next-hop** > common route > **set ipv6 default next-hop** > default route. The preceding **set** commands can be configured at the same time but only the command with the highest priority takes effect.
-  For switches, the **set ipv6 default next-hop** command does not take effect for IPv6 addresses whose mask length exceeds 64.

6.3.2 Configuring PBR

PBR

Apply a route map including policies to interfaces or devices to implement PBR.

- Apply a route map to an interface so that packets received by the interface are routed based on the policy. The PBR is often used to control user packets received by a device. This command is effective only for forwarded packets, but not for locally initiated packets.
- Apply a route map to a device so that packets locally initiated are routed based on the policy. The PBR is often used to control protocol packets exchanged between devices (such as ping packets sent locally). This command is effective only for locally initiated packets, but not for forwarded packets.

-
-  By default, PBR is not available on a device and packets are forwarded based on a routing table.
 -  On a switch, the interfaces which support PBR are L3 Ethernet interface, SVI interface and L3 AP interface.
-

Redundant backup or load balancing

You can set multiple next hops in a policy. Either redundant backup or load balancing can be implemented among multiple next hops. Redundant backup is implemented by default.

-
-  Redundant backup or load balancing is only effective for next hops configured in the **set ip next-hop**, **set ip default next-hop**, **set ipv6 next-hop** and **set ipv6 default next-hop** commands, and only effective among multiple next hops in the same set rule.
-
- Redundant backup

Based on the configuration sequence, the first accessible next hop takes effect. When the currently effective next hop (R1) is faulty, the traffic automatically switches to the next accessible next hop (R2). When R1 becomes accessible again, the traffic automatically switches back to R1.

A newly added next hop is arranged at the last of the sequence. Assume that the original sequence of multiple next hops is R1 > R2 > R3. After R1 is deleted and added again, the sequence changes to R2 > R3 > R1.

If no next hop is accessible, packets will be discarded.
 - Load balancing

When multiple accessible next hops take effect at the same time, the Weighted Cost Multiple Path (WCMP) and Equal Cost Multiple Path (ECMP) are supported. After an accessible next hop loses effect, traffic will be balanced among the other accessible next hops.

Correlation with BFD

Correlation between PBR and BFD is effective only for next hops configured by the **set ip next-hop** or **set ipv6 next-hop** command.

The **set ip next-hop** and **set ipv6 next-hop** commands carry the **verify-availability** and **bfd [vrf vrf-name] interface-type interface-number gateway** parameters, which can establish correlation between PBR and a BFD session and monitor the accessibility of next hops.

Correlation between PBR and BFD helps enhance the PBR's perception about network environment changes. When BFD detects that the current next hop is not accessible, the BFD will immediately notify the PBR to switch the traffic to another accessible next hop (to implement redundant backup) or all the other accessible next hops (to implement load balancing).

i For the configuration and related commands for correlation between PBR and BFD, see the "BFD" section.

Correlation with Track

Correlation between PBR and Track is effective only for next hops configured by the **set ip next-hop** command.

The **set ip next-hop** command carries the **verify-availability** and **track track-obj-number** parameters, which can establish correlation between PBR and a Track session and monitor the accessibility of next hops.

Correlation between PBR and Track helps enhance the PBR's perception about network environment changes. When Track detects that the current next hop is not accessible, the Track will immediately notify the PBR to switch the traffic to another accessible next hop (to implement redundant backup) or all the other accessible next hops (to implement load balancing).

i Only IPv4 PBR supports correlation with Track.

i For the configuration and related commands for correlation between PBR and Track, see the "RNS" section.

6.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of PBR	! (Mandatory) It is used to apply PBR to forward packets.	
	ip policy route-map	Applies PBR for IPv4 packets received by an interface.
	ipv6 policy route-map	Applies PBR for IPv6 packets received by an interface.
	ip local policy route-map	Applies PBR for IPv4 packets locally initiated.
	ipv6 local policy route-map	Applies PBR for IPv6 packets locally initiated.
Setting Redundant Backup or Load Balancing	! (Optional) It is used to set whether PBR implements redundant backup or load balancing among multiple next hops.	
	ip policy { redundancy load-balance }	Sets whether IPv4 PBR implements redundant backup or load balancing among multiple next hops. The default setting is redundant backup.
	ipv6 policy { redundancy load-balance }	Sets whether IPv6 PBR implements redundant backup or load balancing among multiple next hops. The default setting is redundant backup.

Configuration	Description and Command	
	ipv6 policy-source in-interface	Applies source-address-based PBR for IPv6 packets received by an interface.

6.4.1 Configuring Basic Functions of PBR

Configuration Effect

Perform personalized routing management for user data streams by preparing flexible policies.

Perform personalized management for protocol interaction and network topologies by preparing flexible policies.

Notes

- A route map must be used when PBR is configured; therefore, you must configure a route map on a device.
- If an ACL is used when the route map is configured, you must configure the ACL on the device.

Configuration Steps

📌 Applying PBR for IPv4 packets received by an interface

- To perform personalized routing management for IPv4 user data streams passing a device, you should perform this configuration.
- Perform this configuration on the input interface for user data streams.
- Run the **ip policy route-map** command to apply a route map to an interface. Then, PBR is executed for IPv4 packets received on this interface.

Command	ip policy route-map <i>route-map-name</i>
Parameter Description	<i>route-map-name</i> : Indicates the name of a route map.
Defaults	By default, PBR is unavailable on a device and packets are forwarded based on a routing table.
Command Mode	Interface configuration mode
Usage Guide	Only one ip policy route-map command can be configured for an interface. If multiple ip policy route-map commands are configured for an interface, only the last configuration takes effect. If the route map used in PBR is unavailable, the PBR does not take effect.

📌 Applying PBR for IPv6 packets received by an interface

- To perform personalized routing management for IPv6 user data streams passing a device, you should perform this configuration.
- Perform this configuration on the input interface for user data streams.
- Run the **ipv6 policy route-map** command to apply a route map to an interface. Then, PBR is executed for IPv6 packets received on this interface.

Command	ipv6 policy route-map <i>route-map-name</i>
----------------	--

Parameter Description	<i>route-map-name</i> : Indicates the name of a route map.
Defaults	By default, PBR is unavailable on a device and packets are forwarded based on a routing table.
Command Mode	Interface configuration mode
Usage Guide	Only one ipv6 policy route-map command can be configured for an interface. If multiple ipv6 policy route-map commands are configured for an interface, only the last configuration takes effect. If the route map used in PBR is unavailable, the PBR does not take effect.

▾ Applying PBR for IPv4 packets locally initiated

- To perform personalized management for IPv4 protocol interaction and IPv4 network topologies, you should perform this configuration.
- Run the **ip local policy route-map** command to apply a route map to a device. Then, PBR is executed for IPv4 packets locally initiated.

Command	ip local policy route-map <i>route-map-name</i>
Parameter Description	<i>route-map-name</i> : Indicates the name of a route map.
Defaults	By default, PBR is unavailable on a device and packets are forwarded based on a routing table.
Command Mode	Global configuration mode
Usage Guide	Only one ip local policy route-map command can be configured for a device. If the route map used in PBR is unavailable, the PBR does not take effect.

▾ Applying PBR for IPv6 packets locally initiated

- To perform personalized management for IPv6 protocol interaction and IPv6 network topologies, you should perform this configuration.
- Run the **ipv6 local policy route-map** command to apply a route map to a device. Then, PBR is executed for IPv6 packets locally initiated.

Command	ipv6 local policy route-map <i>route-map-name</i>
Parameter Description	<i>route-map-name</i> : Indicates the name of a route map.
Defaults	By default, PBR is unavailable on a device and packets are forwarded based on a routing table.
Command Mode	Global configuration mode
Usage Guide	Only one ipv6 local policy route-map command can be configured for a device. If the route map used in PBR is unavailable, the PBR does not take effect.

Verification

- Check the configurations of PBR.

- Check the configurations of the route map used by PBR.
- If an ACL is used when the route map is configured, you should check the configurations of the ACL.

▾ Checking the configurations of IPv4 PBR

Command	show ip policy [<i>route-map-name</i>]
Parameter Description	<i>route-map-name</i> : Indicates the name of a route map.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<p>Check the interfaces configured with IPv4 PBR according to the output information and the name of the used route map.</p> <pre>Ruijie# show ip policy Banlance mode: redundance Interface Route map local RM_for_PBR_1 GigabitEthernet 0/1 RM_for_PBR_2</pre> <p>Local indicates applying policy-based routing for IPv4 packets locally initiated.</p>

▾ Checking the configurations of IPv6 PBR

Command	show ipv6 policy [<i>route-map-name</i>]
Parameter Description	<i>route-map-name</i> : Indicates the name of a route map.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<p>Check the interfaces configured with IPv6 PBR according to the output information and the name of the used route map.</p> <pre>Ruijie#show ipv6 policy Banlance mode: redundance Interface Route map local RM_for_PBR_1 VLAN 1 RM_for_PBR_2</pre> <p>Local indicates applying policy-based routing for IPv6 packets locally initiated.</p>

▾ Checking the configurations of a route map

Command	show route-map [<i>route-map-name</i>]
Parameter Description	<i>route-map-name</i> : Indicates the name of a route map.

Command Mode	Privilege, global and interface configuration modes
Usage Guide	<p>Multiple route maps may be available on a device. Focus on the route map used in PBR and check its policy settings.</p> <pre>Ruijie# show route-map route-map RM_FOR_PBR, permit, sequence 10 Match clauses: ip address acl1 Set clauses: ip next-hop 200.24.18.1 route-map RM_FOR_PBR, permit, sequence 20 Match clauses: ip address acl2 Set clauses: ip next-hop 200.24.19.1</pre>

↘ Checking the configurations of an ACL

Command	show access-lists [<i>acl-id</i> <i>acl-name</i>]
Parameter Description	<i>acl-id</i> : Indicates the ACL ID. <i>acl-name</i> : Indicates the ACL name.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<p>Multiple ACLs may be available on a device. Focus on the ACL used by a route map and check its configurations.</p> <pre>Ruijie# show access-lists 1 ip access-list standard 1 10 permit 200.24.16.0 0.0.0.255 ip access-list standard 2 10 permit 200.24.17.0 0.0.0.255</pre>

↘ Checking the routing information of IPv4 PBR

Command	show ip pbr route [<i>interface if-name</i> local]
Parameter Description	<i>if-name</i> : Indicates an interface name. local : Indicates local.
Command Mode	Privilege, global and interface configuration modes

Usage Guide	<p>Specify a local interface or device and check the routing information of IPv4 PBR.</p> <pre>Ruijie# show ip pbr route PBR IPv4 Route Summay : 1 Interface : GigabitEthernet 0/1 Sequence : 10 Min Length : None Max Length : None VRF ID : 0 Route Flags : Route Type : PBR Direct : Permit Priority : High Tos_Dscp : None Precedence : None Tos_Dscp : 0 Precedence : 0 Mode : redundance Nextthop Count : 1 Nextthop[0] : 192.168.8.100 Weight[0] : 1 Ifindex[0] : 2</pre>
--------------------	---

📌 **Checking the routing information of IPv6 PBR**

Command	show ipv6 pbr route [interface <i>if-name</i> local]
Parameter	<i>if-name</i> : Indicates an interface name.
Description	local : Indicates local.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<p>Specify a local interface or device and check the routing information of IPv6 PBR.</p> <pre>Ruijie# show ipv6 pbr route PBR IPv6 Route Summary : 1 Interface : GigabitEthernet 0/1 Sequence : 10</pre>

ACL[0]	: 2900
ACL_CLS[0]	: 5
Min Length	: None
Max Length	: None
VRF ID	: 0
Route Flags	:
Route Type	: PBR
Direct	: Permit
Priority	: High
Tos_Dscp	: None
Precedence	: None
Tos_Dscp	: 0
Precedence	: 0
Mode	: redundance
Nexthop Count	: 1
Nexthop[0]	: 10::2
Weight[0]	: 1
Ifindex[0]	: 2

📌 **Checking a route map used by IPv4 PBR**

Command	show ip pbr route-map <i>rmap-name</i>
Parameter	<i>rmap-name</i> : Indicates the route map name.
Description	
Command Mode	Privilege, global and interface configuration modes
Usage Guide	Specify a route map and check the route map used by IPv4 PBR. <pre>Ruijie# show ip pbr route-map rm PBR VRF: GLOBAL, ID: 0 Forward Mode: redundance Forwarding: On Route-map rm Route-map index: Sequence 10, permit</pre>

```

Match rule:

  ACL ID :   2900, CLS: 1, Name: ac11

Set rule:

  IPv4 nexthop: 192.168.8.100, (VRF name: , ID: 0), Weight: 0

  PBR state info ifx: 2, Connected: True, Track state: Up
    
```

📌 **Checking a route map used by IPv6 PBR**

Command	show ipv6 pbr route-map <i>rmap-name</i>
Parameter	<i>rmap-name</i> : Indicates the route map name.
Description	
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<p>Specify a route map and check the route map used by IPv6 PBR.</p> <pre> Ruijie# show ipv6 pbr route-map rm6 PBR VRF: GLOBAL, ID: 0 Forward Mode: redundance Forwarding: On Route-map rm6 Route-map index: Sequence 10, permit Match rule: ACL ID : 2901, CLS: 5, Name: ac16 Set rule: IPv6 nexthop: 10::2, (VRF name: , ID: 0), Weight: 0 PBR state info ifx: 2, Connected: True, Track state: Up </pre>

📌 **Checking the statistics about packets forwarded by IPv4 PBR**

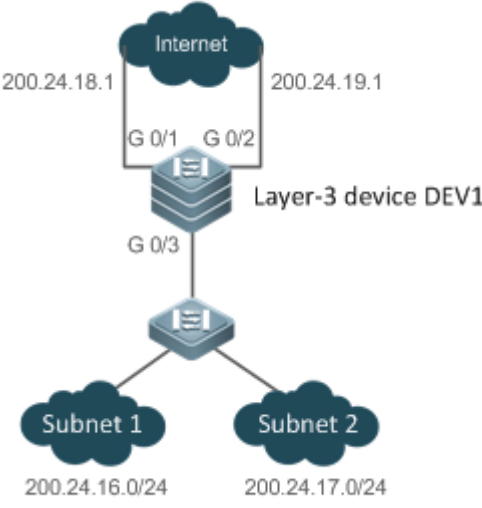

Command	show ip pbr statistics [interface <i>if-name</i> local]
Parameter	<i>if-name</i> : Indicates an interface name.
Description	local : Indicates local.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<pre> Ruijie# show ip pbr statistics IPv4 Policy-based route statistic </pre>

```
gigabitEthernet 0/1
statistics : 10
```

📌 Checking the statistics about packets forwarded by IPv6 PBR

Command	show ipv6 pbr statistics [interface <i>if-name</i> local]
Parameter	<i>if-name</i> : Indicates an interface name.
Description	local : Indicates local.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<pre>Ruijie# show ipv6 pbr statistics IPv6 Policy-based route statistic gigabitEthernet 0/1 statistics : 20</pre>

📌 Configuring correlation between IPv4 PBR and Track

<p>Scenario Figure 6-3</p>	
	<p>The layer-3 device DEV 1 is connected to subnet 1 and subnet 2 through GE0/3. The network segment where subnet 1 resides is 200.24.16.0/24 whereas the network segment where subnet 2 resides is 200.24.17.0/24.</p> <p>DEV 1 is connected to the Internet through GE0/1 and GE0/2 and their next hops are 200.24.18.1 and 200.24.19.1.</p>
	<ul style="list-style-type: none"> ● DEV1 can fast detect a faulty output link and switch to a backup link.
<p>Configuration Steps</p>	<p>When configuring IPv4 PBR and selecting an output link based on source addresses of the packets, add or modify the following configurations (red fields):</p> <ul style="list-style-type: none"> ● Set two Track objects and track the accessibility of the next hops of the two output interfaces.

	<ul style="list-style-type: none"> ● When configuring a policy, set the correlation between the next hops and the Track objects.
DEV1	<pre> DEV1(config)# ip access-list extended 101 DEV1(config-ip-acl)# permit ip 200.24.16.0 0.0.0.255 any DEV1(config-ip-acl)# exit DEV1(config)# ip access-list extended 102 DEV1(config-ip-acl)# permit ip 200.24.17.0 0.0.0.255 any DEV1(config-ip-acl)# exit DEV1(config)#ip rns 1 DEV1(config-ip-rns)#icmp-echo 200.24.18.1 DEV1(config)#ip rns schedule 1 start-time now life forever DEV1(config)#track 1 rns 1 DEV1(config)#ip rns 2 DEV1(config-ip-rns)#icmp-echo 200.24.19.1 DEV1(config)#ip rns schedule 2 start-time now life forever DEV1(config)#track 2 rns 2 DEV1(config)# route-map RM_FOR_PBR 10 DEV1(config-route-map)# match ip address 101 DEV1(config-route-map)# set ip next-hop verify-availability 200.24.18.1 track 1 DEV1(config-route-map)# set ip next-hop verify-availability 200.24.19.1 track 2 DEV1(config-route-map)# exit DEV1(config)# route-map RM_FOR_PBR 20 DEV1(config-route-map)# match ip address 102 DEV1(config-route-map)# set ip next-hop verify-availability 200.24.19.1 track 2 DEV1(config-route-map)# set ip next-hop verify-availability 200.24.18.1 track 1 DEV1(config-route-map)# exit DEV1(config)# interface GigabitEthernet 0/3 DEV1(config-if-GigabitEthernet 0/3)# ip policy route-map RM_FOR_PBR DEV1(config-if-GigabitEthernet 0/3)# exit DEV1(config)# ip policy redundance </pre>
Verification	<ul style="list-style-type: none"> ● Check whether the Track objects are up.
DEV1	<pre> DEV1#show track </pre>

```

Track 1

  Reliable Network Service 1

  The state is Up

    1 change, current state last: 120 secs

  Delay up 30 secs, down 50 secs

Track 2

  Reliable Network Service 2

  The state is Up

    1 change, current state last: 130 secs

  Delay up 30 secs, down 50 secs

```

Common Errors

- A route map is used when PBR is configured but the route map does not exist.
- An ACL is used when a route map is configured but the ACL does not exist.

6.4.2 Setting Redundant Backup or Load Balancing

Configuration Effect

- Using multiple next hops in the mutual backup mode can enhance the network reliability.
- Implementing load balancing among multiple next hops can expand the network bandwidth.

Notes

- The basic functions of PBR must be configured.
- Redundant backup and load balancing are effective only for the next hops set by the following **set** commands.

Command	Description
set ip next-hop	Configures the next hop of IPv4 packets. This command carries the <i>weight</i> parameter, which is used to set the weight of the WCMP. The default value is 1.
set ip default next-hop	Configures the default next hop of IPv4 packets. This command carries the <i>weight</i> parameter, which is used to set the weight of the WCMP. The default value is 1.
set ipv6 next-hop	Configures the next hop of IPv6 packets. This command carries the <i>weight</i> parameter, which is used to set the weight of the WCMP. The default value is 1.
set ipv6 default next-hop	Configures the default next hop of IPv6 packets. This command carries the <i>weight</i> parameter, which is used to set the weight of the WCMP. The default value is 1.

- i** Up to eight next hops can be set for WCMP whereas up to 32 next hops can be set for ECMP.

Configuration Steps

Setting whether IPv4 PBR implements redundant backup or load balancing among multiple next hops

- If load balancing needs to be implemented among multiple next hops, this configuration needs to be performed.
- If load balancing is configured at present, you also need to perform this configuration to reset redundant backup.
- This configuration is effective for all PBRs configured on a device.

Command	ip policy { redundance load-balance }
Parameter	redundance: Indicates redundant backup.
Description	load-balance: Indicates load balancing.
Defaults	Redundant backup is configured by default.
Command Mode	Global configuration mode
Usage Guide	If redundant backup is selected, the first next hop takes effect based on the configuration sequence. If load balancing is selected, all next hops take effect at the same time and share traffic by weight.

Setting whether Ipv6 PBR implements redundant backup or load balancing among multiple next hops

- If load balancing needs to be implemented among multiple next hops, this configuration needs to be performed.
- If load balancing is configured at present, you also need to perform this configuration to reset redundant backup.
- This configuration is effective for all PBRs configured on a device.

Command	ipv6 policy { redundance load-balance }
Parameter	redundance: Indicates redundant backup.
Description	load-balance: Indicates load balancing.
Defaults	Redundant backup is configured by default.
Command Mode	Global configuration mode
Usage Guide	If redundant backup is selected, the first next hop takes effect based on the configuration sequence. If load balancing is selected, all next hops take effect at the same time and share traffic by weight.

Verification

- Check whether redundant backup or load balancing is implemented among multiple next hops.

Checking whether IPv4 PBR implements redundant backup or load balancing among multiple next hops

Command	show ip policy [route-map-name]
Parameter Description	route-map-name: Specifies a route map.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	See the following example and focus on the red field. <pre>ruijie# show ip policy Banlance mode: redundance</pre>

Interface	Route map
local	test
GigabitEthernet 0/3	test

📌 **Checking whether IPv6 PBR implements redundant backup or load balancing among multiple next hops**

Command	show ipv6 policy [route-map-name]
Parameter Description	route-map-name: Specifies a route map.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	See the following example and focus on the red field. <pre>ruijie#show ipv6 policy Banlance mode: redundance Interface Route map VLAN 1 RM_for_Vlan_1 VLAN 2 RM_for_Vlan_2</pre>

Configuration Example

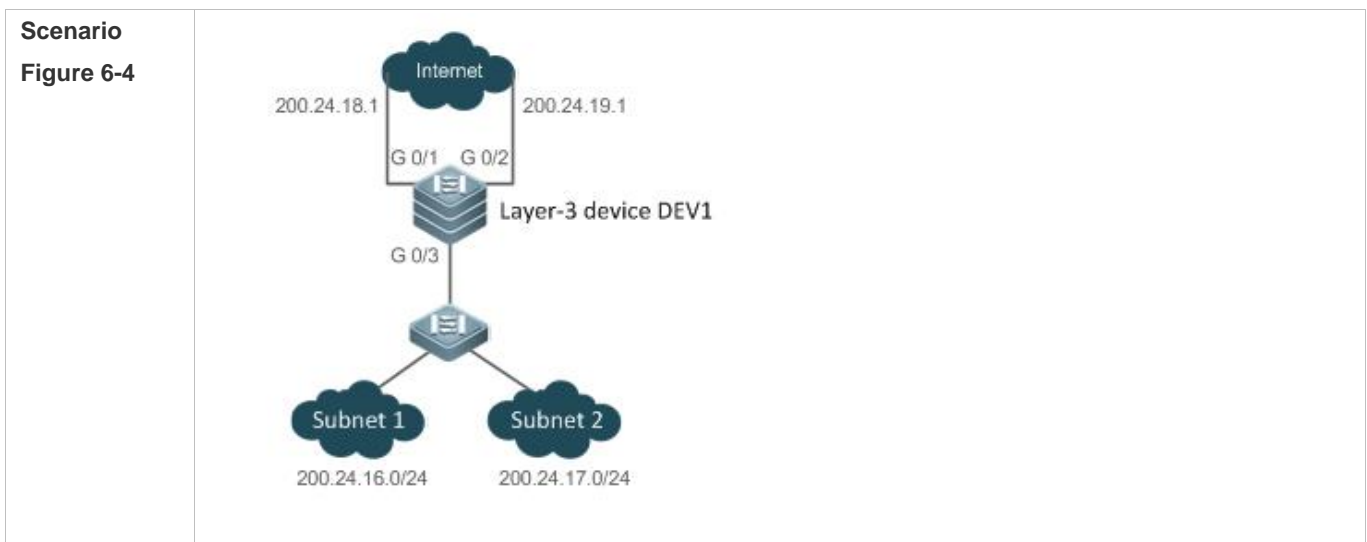

📌 **Configuring IPv4 PBR to implement redundant backup among multiple next hops**

See the preceding example: [Configuring IPv4 PBR and selecting an output link based on source addresses of packets](#)

📌 **Configuring IPv6 PBR to implement redundant backup among multiple next hops**

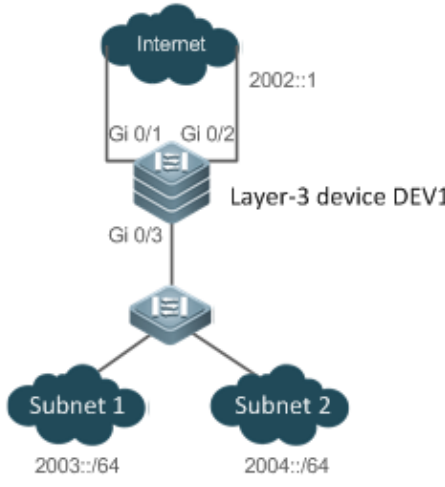

See the preceding example: [Configuring IPv6 PBR and selecting an output link based on source addresses of packets](#)

📌 **Configuring IPv4 PBR to implement load balancing among multiple next hops**

	<p>The layer-3 device DEV 1 is connected to subnet 1 and subnet 2 through GE0/3. The network segment where subnet 1 resides is 200.24.16.0/24 whereas the network segment where subnet 2 resides is 200.24.17.0/24.</p> <p>DEV 1 is connected to the Internet through GE0/1 and GE0/2 and their next hops are 200.24.18.1 and 200.24.19.1.</p>
	<p>This LAN has two output interfaces for connecting the Internet. The requirements are as follows: The traffic is equally shared by GE0/1 and GE0/2.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure basic functions of PBR. Specify multiple next hops. ● Set the load balancing mode.
	<pre> DEV1(config)# route-map RM_LOAD_PBR 10 DEV1(config-route-map)# set ip next-hop 200.24.18.1 DEV1(config-route-map)# set ip next-hop 200.24.19.1 DEV1(config-route-map)# exit DEV1(config)# interface GigabitEthernet 0/3 DEV1(config-if-GigabitEthernet 0/3)# ip policy route-map RM_LOAD_PBR DEV1(config-if-GigabitEthernet 0/3)# exit DEV1(config)# ip policy load-balance </pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● Check the configurations of IPv4 PBR. ● Check the configurations of the route map.

DEV1# show route-map

route-map PBR-VRF-Selection, permit, sequence 10

  Match clauses:

  Set clauses:

  ipv6 next-hop 2001::1

  ipv6 next-hop 2002::1
```

6.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears the statistics about packets forwarded by IPv4 PBR.	clear ip pbr statistics [interface <i>if-name</i> local]
Clears the statistics about packets forwarded by IPv6 PBR.	clear ipv6 pbr statistics [interface <i>if-name</i> local]

Displaying

Description	Command
Displays the configurations of IPv4 PBR.	show ip policy
Displays the configurations of IPv6 PBR.	show ipv6 policy
Displays the configurations of a route map.	show route-map [<i>name</i>]
Displays the configurations of an ACL.	show access-list
Displays the correlation between IPv4 PBR and BFD.	show ip pbr bfd
Displays the correlation between IPv6 PBR and BFD.	show ipv6 pbr bfd
Displays the routing information of IPv4 PBR.	show ip pbr route [interface <i>if-name</i> local]
Displays the routing information of IPv6 PBR.	show ipv6 pbr route [interface <i>if-name</i> local]
Displays a route map used by IPv4 PBR.	show ip pbr route-map <i>rmap-name</i>
Displays a route map used by IPv6 PBR.	show ipv6 pbr route-map <i>rmap-name</i>
Displays the statistics about IPv4 PBR.	show ip pbr statistics [interface <i>if-name</i> local]
Displays the statistics about IPv6 PBR.	show ipv6 pbr statistics [interface <i>if-name</i> local]

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs PBR errors.	debug pbr error
Debugs PBR events.	debug pbr events
Debugs multiple service cards supported by PBR.	debug pbr ms
Debugs PBR message communication.	debug pbr msg
Debugs interaction between PBR and NSM.	debug pbr nsm
Debugs packet forwarding of PBR.	debug pbr packet
Debugs PBR GR.	debug pbr restart

7 Configuring VRF

7.1 Overview

A Virtual Private Network (VPN) Routing and Forwarding (VRF) table is used for the forwarding of VPN packets. Each VPN corresponds to a VRF table.

A device that provides the VPN service has multiple routing tables, including a public network routing table and one or multiple VRF tables. The public-network routing table is used for the forwarding of public network packets, and the VRF tables are used for the forwarding of VPN packets. These routing tables are created to separate routes in the public network from those in VPNs and separate routes in different VPNs.

i A VPN is a private dedicated network built in the public network. "Virtual" means that the VPN is logically exclusive, instead of physically exclusive.

Protocols and Standards

- RFC4364: BGP/MPLS IP Virtual Private Networks (VPNs)

7.2 Applications

Application	Description
Local Inter-VPN Access	Provide the VPN service on a routing device and enable VPNs to access each other.
VRF only on Provider Edges (PEs)	Provide the VPN service in an IP/Multiprotocol Label Switching (MPLS) network and connect one Customer Edge (CE) to one VPN.
VRF on CEs and PEs	Provide the VPN service in an IP/ MPLS network and connect one CE to multiple VPNs.

i CE: An edge device in a customer network

i PE: An edge device in a Service Provider (SP) network

7.2.1 Local Inter-VPN Access

Scenario

Provide the VPN service on a routing device and enable VPNs to access each other.

In Figure 7-1, Sub a runs the Routing Information Protocol (RIP), Sub b runs the Open Shortest Path First (OSPF) protocol, and Servers is a network segment directly connected to C. Provide the VPN service on C to Sub a, Sub b, and Servers, and enable Sub a and Sub b to access Servers.

Figure 7-1

Related Configuration

- On C, create a VRF table for Sub a, bind the interface directly connected to A, and associate the VRF table with A by using RIP.
- On C, create a VRF table for Sub b, bind the interface directly connected to B, and associate the VRF table with B by using OSPF.
- On C, create a VRF table for Servers and bind the interface directly connected to Servers.
- On C, configure the route targets (RTs) of the VRF tables for Suba, Subb, and Servers. Import the routes in the VRF tables for Sub a and Sub b to the VRF table for Servers, and import the routes in the VRF table for Servers to the VRF tables for Sub a and Sub b.
- Configure the Border Gateway Protocol (BGP) on C. Introduce the RIP routes to the VRF table for Sub a, introduce the OSPF routes to the VRF table for Sub b, and introduce the direct routes to the VRF table for Servers.

7.2.2 VRF only on PEs

Scenario

An Internet Service Provider (ISP) provides the VPN service in an IP/MPLS backbone network.

In Figure 7-2, VPN1 runs RIP, and VPN2 runs OSPF.

- One CE is connected to one VPN, and all routes on the CE are exclusively used by the connected VPN. Therefore, no VRF table needs to be created to separate the routes.
- On each PE, VRF tables must be created to separate the routes in VPN1, those in VPN2, and those in the public network from each other.

Figure 7-2

Deployment

- On PE1, create a VRF table for VPN1 and bind the interface directly connected to CE1. On PE2, create a VRF table for VPN1 and bind the interface directly connected to CE3.
- On PE1, create a VRF table for VPN2 and bind the interface directly connected to CE2. On PE2, create a VRF table for VPN2 and bind the interface directly connected to CE4.
- On PE1, associate the VRF table for VPN1 with CE1 by using RIP. On PE2, associate the VRF table for VPN1 with CE3 by using RIP.
- On PE1, associate the VRF table for VPN2 with CE2 by using OSPF. On PE2, associate the VRF table for VPN2 with CE4 by using OSPF.
- Create a BGP neighbor (VPNv4 address family) between PE1 and PE2.
- In the VRF instance for VPN1 on PE1, redistribute RIP routes to BGP, and redistribute BGP routes to RIP. The configuration on PE2 is similar.
- In the VRF instance for VPN2 on PE1, redistribute OSPF routes to BGP, and redistribute BGP routes to OSPF. The configuration on PE2 is similar.

i For details about the application scenario, see "Configuration Guide > MPLS > L3 VPN".

7.2.3 VRF on CEs and PEs (MCE Application)

Scenario

An ISP provides the VPN service in an IP/MPLS backbone network.

In Figure 7-3, VPN a runs RIP, VPN b runs OSPF, and PE1 and PE2 are connected to BGP/MPLS VPNs.

- One Multi-VPN-Instance CE (MCE) is connected to multiple VPNs. VRF tables must be created to separate the routes in VPN a from those in VPN b.
- On each PE, VRF tables must be created to separate the routes in VPN a, those in VPN b, and those in the public network from each other.

Figure 7-3

Deployment

- On MCE1, create VRF tables for VPN a and VPN b respectively, bind the interfaces directly connected to VPN a and VPN b, and bind the VLAN interface connected to PE1. The configuration on MCE2 is similar.

- On PE1, create VRF tables for VPN a and VPN b respectively, and bind the VLAN interface connected to MCE1. The configuration on PE2 is similar.
- On MCE1, associate the VRF table for VPN a with VPN a by using RIP. The configuration on MCE2 is similar.
- On MCE1, associate the VRF table for VPN b with VPN b by using OSPF. The configuration on MCE2 is similar.
- Create a BGP neighbor (VPNv4 address family) between PE1 and PE2.
- In the VRF instance for VPN a on MCE1, redistribute RIP routes to BGP, and redistribute BGP routes to RIP. The configuration on MCE2 is similar.
- In the VRF instance for VPN b on MCE1, redistribute OSPF routes to BGP, and redistribute BGP routes to OSPF. The configuration on MCE2 is similar.

 For details about the application scenario, see "Configuration Guide > MPLS > L3 VPN".

7.3 Features

Overview

Feature	Description
VPN Instance	A VPN instance is used to provide the VPN service. It is typically represented by a VRF table.
VPN Route	A VPN route is used to forward VPN packets.
VPN Route Attribute	Route distinguisher (RD): Identifies the VPN to which a route belongs. RT: Indicates the route trade-off mode of VRF.

7.3.1 VPN Instance

A VPN instance is used to provide the VPN service. On a device that provides the VPN service, a VPN instance consists of the VRF table, interfaces, routing protocol processes, and configuration that belong to the same VPN. A VPN instance is typically represented by a VRF table.

Working Principle

A PE exchanges routes with a CE by using the related routing protocol in the corresponding VPN instance. A VRF table is bound to a specific interface to generate its interface set. Packets received on these interfaces will be associated with the VRF table and forwarded along corresponding routes.

Related Configuration

 Single-protocol VRF tables and multiprotocol VRF tables cannot be created at the same time. Single-protocol VRF tables only support IPv4, whereas multiprotocol VRF tables support IPv4 and IPv6.

[Configuring a Single-Protocol VRF Table](#)

By default, a device has no VRF table.

Run the **ip vrf** command to create a single-protocol VRF table.

Run the **ip vrf forwarding** command to bind an interface.

Currently, single-protocol VRF tables only support IPv4.

📌 **Configuring a Multiprotocol VRF Table**

By default, a device has no VRF table.

Run the **vrf definition** command to create a multiprotocol VRF table.

Run the **address-family ipv4** command to enable the IPv4 address family.

Run the **address-family ipv6** command to enable the IPv6 address family.

Run the **vrf forwarding** command to bind an interface.

Multiprotocol VRF tables support IPv4 and IPv6.

7.3.2 VPN Route

A VPN route is only used to forward VPN packets. It comes from:

- Direct route and host route on the bound interface
- Direct route and host route on the configured import interface (not bound)
- Static and dynamic routes (RIP, RIPng, OSPFv2, OSPFv3, ISIS, and BGP) in the configured VPN instance

i For details about the static routes in a VPN instance, see "Configuration Guide > IP Route".

i For details about RIP in a VPN instance, see "Configuration Guide > IP Route > RIP".

i For details about RIPng in a VPN instance, see "Configuration Guide > IP Route > RIPng".

i For details about OSPFv2 in a VPN instance, see "Configuration Guide > IP Route > OSPFv2".

i For details about OSPFv3 in a VPN instance, see "Configuration Guide > IP Route > OSPFv3".

i For details about ISIS in a VPN instance, see "Configuration Guide > IP Route > ISIS".

i For details about BGP in a VPN instance, see "Configuration Guide > IP Route > BGP".

7.3.3 VPN Route Attribute

The BGP extended attributes include two attributes specific to VPN routes: RD and RT.

Working Principle

📌 **RD**

Two routes with the same address but different RDs in two VRF tables can be advertised separately between PEs, because the routes are sent together with their RDs through multiprotocol BGP (MP-BGP).

📌 **RT**

RT in essence indicates each VRF table's route trade-off and preferences. It is mainly used to control the advertising and installation policies for VPN routes. RT is divided into the import attribute and export attribute. The import attribute indicates

the route of interest, and the export attribute indicates the advertised route. A PE advertises a route to other PEs based on the RT export rule in the corresponding VRF table. The peer PE checks all received routes against the RT import rule in each VRF table. If a route matches an RT export rule (the export rule contains the import rule), it will be added to the corresponding VRF table.

Related Configuration

RD

By default, no RD is configured in VRF mode.

Run the **rd** command to configure an RD.

RT

By default, no RT is configured in VRF mode or address family mode.

Run the **route-target { import | export | both }** command to configure an RT.

7.4 Configuration

Configuration	Description and Command	
Configuring a Single-Protocol VRF Table	 Single-protocol VRF tables and multiprotocol VRF tables cannot be created at the same time. If IPv6 is supported, configure a multiprotocol VRF table; otherwise, you can configure a single-protocol VRF table or a multiprotocol VRF table. This configuration item creates a VRF table in an IPv4 network. IPv6 is not supported.	
	ip vrf <i>vrf-name</i>	Creates a VRF table.
	rd <i>rd_value</i>	Configures an RD.
	route-target { import export both } <i>rt_value</i>	Configures an RT.
	ip vrf forwarding <i>vrf-name</i>	Binds an interface and adds the direct route and host route on the interface to a VRF table.
ip vrf receive <i>vrf_name</i>	Adds the direct route and host route on an interface to a VRF table without binding the interface.	
Configuring a Multiprotocol VRF Table	 Single-protocol VRF tables and multiprotocol VRF tables cannot be created at the same time. If IPv6 is supported, configure a multiprotocol VRF table. otherwise, you can configure a single-protocol VRF table or a multiprotocol VRF table. This configuration item creates a VRF table in an IPv4 or IPv6 network.	
	vrf definition <i>vrf-name</i>	Creates a VRF table.
	description <i>string</i>	Configures a VRF descriptor.
	rd <i>rd_value</i>	Configures an RD.
	route-target { import export both } <i>rt_value</i>	Configures an RT.

Configuration	Description and Command	
	address-family ipv4	Enables the IPv4 address family.
	address-family ipv6	Enables the IPv6 address family.
	vrf forwarding <i>vrf-name</i>	Binds an interface and adds the direct route and host route on the interface to a VRF table.
	vrf receive <i>vrf-name</i>	Adds the direct route and host route on an interface to a VRF table without binding the interface.

7.4.1 Configuring a Single-Protocol VRF Table

Configuration Effect

- Provide the VPN service on a device.
- With BGP assistance, flexibly control the separation and access between VPNs.
- With BGP assistance, provide the VPN service in an IP/MPLS backbone network.
- Only IPv4 is supported.

Notes

- No VRF table needs to be created if the device only forwards packets from one VPN or from the public network.
- If the device needs to forward public network packets and VPN packets or forward packets from multiple VPNs, VRF tables must be created to separate routes.
- In many cases, static or dynamic routes (RIP, OSPF, ISIS, and BGP) need to be added to VRF tables.

Configuration Steps

↘ Creating a VRF Table

- Mandatory.
- Create a VRF table for each VPN.

↘ Configuring an RD

- Optional.
- When routing information needs to be advertised through BGP in the backbone network, BGP may select the best route for advertising if overlapping network addresses exist in different VPNs, which will make some VPNs fail to obtain corresponding routing information. To solve this problem, you can configure RDs for routes to enable BGP to make routing decisions based on these RDs, thus ensuring that each VPN can obtain corresponding routing information.
- Run the **rd** command in single-protocol VRF mode.

↘ Configuring an RT

- Optional.
- You can run the **route-target export** command to specify the attributes of the route to be advertised, and run the **route-target import** command to specify the attributes of the route to be received. You can also run the **route-target both** command to specify the export and import attributes.
- Run the **route-target** command in single-protocol VRF mode.

↘ Binding an Interface and Adding the Direct Route and Host Route on the Interface to a VRF Table

- Mandatory.
- If the physical link for transmitting VPN packets is exclusively occupied by a VPN, bind the physical interface to the corresponding VRF table.
- If the physical link for transmitting VPN packets is shared by multiple VPNs, you need to create an independent logical link for each VPN, and bind the logical interface to the corresponding VRF table. A logical interface can be a subinterface or a VLAN interface.
- You must bind an interface to the corresponding single-protocol VRF table before you configure the IPv4 address of the interface. If you bind the interface after its IPv4 address is configured, the IPv4 address will be invalid (the IPv6 address of the interface is retained).
- If you bind an interface to the corresponding single-protocol VRF table and enable IPv6 on the interface, the device cannot forward the IPv6 packets received on the interface.

↘ Adding the Direct Route and Host Route on an Interface to a VRF Table Without Binding the Interface

- Optional.
- If policy-based routing (PBR) is required for VRF table selection, run the **ip vrf receive** command on the interface to which PBR is applied, and import the direct route and host route on the interface to each VRF table available for choice.

Verification

- Check whether VRF tables are created correctly on the router.

Related Commands

↘ Creating a VRF Table

Command	ip vrf <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Indicates the name of the VRF table to be created. It cannot exceed 31 characters.
Command Mode	Global configuration mode
Usage Guide	After you run the command, the system will enter VRF mode.

↘ Configuring an RD

Command	rd <i>rd_value</i>
----------------	---------------------------

Parameter Description	<p><i>rd_value</i> has the following three different parameter forms:</p> <p>(1) <i>rd_value</i> = as_num: nn as_num indicates the 2-byte number that identifies a public autonomous system (AS). nn is configurable in the range 0..4294967295.</p> <p>(2) <i>rd_value</i> = ip_addr: nn ip_addr must be a global IP address. nn is configurable in the range 0..65535.</p> <p>(3) <i>rd_value</i> = as4_num: nn as4_num indicates the 4-byte number that identifies a public AS. nn is configurable in the range 1..65535.</p>
Command Mode	VRF configuration mode
Usage Guide	<p>You cannot directly change the RD of an existing VRF table. You need to delete the VRF table first and then configure a new RD.</p> <p>A VRF table has only one RD. You cannot configure multiple RDs for one VRF table.</p>

📌 Configuring an RT

Command	route-target { import export both } <i>rt_value</i>
Parameter Description	<p><i>rt_value</i> has the following three different parameter forms:</p> <p>(1) <i>rt_value</i> = as_num: nn as_num indicates the 2-byte number that identifies a public AS. nn is configurable in the range 0..4294967295.</p> <p>(2) <i>rt_value</i> = ip_addr: nn ip_addr must be a global IP address. nn is configurable in the range 0..65535.</p> <p>(3) <i>rt_value</i> = as4_num: nn as4_num indicates the 4-byte number that identifies a public AS. nn is configurable in the range 1..65535.</p>
Command Mode	VRF configuration mode
Usage Guide	A VRF table can be configured with multiple import and export RT attributes.

📌 Binding an Interface

Command	ip vrf forwarding <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Indicates the name of a VRF table.
Command Mode	Interface configuration mode
Usage Guide	<p>By default, an interface does not belong to any VRF table.</p> <p>After an interface is bound to the corresponding VRF table, the direct route and host route on the interface will be automatically added to the VRF table.</p> <p>You must bind an interface to the corresponding single-protocol VRF table before you configure the IPv4 address of the interface. If you bind the interface after its IPv4 address is configured, the IPv4 address will be invalid (the IPv6 address of the interface is retained).</p>

➤ Adding the Direct Route and Host Route on an Interface to a VRF Table Without Binding the Interface

Command	<code>ip vrf receive vrf-name</code>
Parameter	<i>vrf-name</i> : Indicates the name of a VRF table.
Description	
Command Mode	Interface configuration mode
Usage Guide	This command is used to add the host route and direct route on an interface to a VRF table. If you need to add the host route and direct route on an interface to multiple VRF tables, run the command multiple times. Different from the <code>ip vrf forwarding</code> command, the <code>ip vrf receive</code> command does not bind an interface to the corresponding VRF table. The interface is still a global interface and does not belong to any VRF table. The <code>ip vrf forwarding</code> and <code>ip vrf receive</code> commands are mutually exclusive on the same interface.

➤ Displaying the VRF Information on a Device

Command	<code>show ip vrf [brief detail interfaces] [vrf-name]</code>
Parameter	brief : Displays brief information.
Description	detail : Displays detailed information. interfaces : Displays the interface binding information. <i>vrf-name</i> : Indicates the name of a VRF table.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	This command is used to display the information of a specified VRF table to check whether the VRF table is bound with the correct interface.

➤ Displaying the Routes in a VRF Table

Command	<code>show ip route vrf vrf-name</code>
Parameter	<i>vrf-name</i> : Indicates the name of a VRF table.
Description	
Command Mode	Privilege, global and interface configuration modes
Usage Guide	This command is used to check whether a specified VRF table contains corresponding routes.

Configuration Example

➤ Local Inter-VPN Access

Scenario Figure 7-4	<p>The diagram illustrates a central router labeled 'C' connected to three separate VPNs. On the left, 'Sub a' is connected to router 'A', and 'Sub b' is connected to router 'B'. Router 'C' is connected to both 'A' and 'B'. On the right, 'Servers' are connected to router 'C'. All components are represented by cloud icons.</p>
	Sub a, Sub b, and Servers are three VPNs that have separate address spaces.

	Sub a runs RIP, Sub b runs OSPF, and Servers is a network segment directly connected to C.																								
Configuration Requirements	Routes in Sub a are separated from those in Sub b, but both Sub a and Sub b can access Servers.																								
Configuration Steps	<ul style="list-style-type: none"> On C, create a VRF table for Sub a, bind the interface directly connected to A, and associate the VRF table with A by using RIP. On C, create a VRF table for Sub b, bind the interface directly connected to B, and associate the VRF table with B by using OSPF. On C, create a VRF table for Servers and bind the interface directly connected to Servers. On C, configure the RTs of the VRF tables for Sub a, Sub b, and Servers. Import the routes in the VRF tables for Sub a and Sub b to the VRF table for Servers, and import the routes in the VRF table for Servers to the VRF tables for Sub a and Sub b. Configure the Border Gateway Protocol (BGP) on C. Introduce the RIP routes to the VRF table for Sub a, introduce the OSPF routes to the VRF table for Sub b (enabled with an address family), and introduce the direct routes to the VRF table for Servers (enabled with an address family). <p> Planning of interfaces and addresses:</p> <table border="1"> <thead> <tr> <th>Interface Description</th> <th>Interface Name</th> <th>IP Address/Mask</th> <th>VRF Table</th> </tr> </thead> <tbody> <tr> <td>Interface on C connected to A</td> <td>GE0/1</td> <td>10.10.1.1/24</td> <td>VRF table for Sub a</td> </tr> <tr> <td>Interface on C connected to B</td> <td>GE0/2</td> <td>10.10.2.1/24</td> <td>VRF table for Sub b</td> </tr> <tr> <td>Interface on C connected to Servers</td> <td>GE0/3</td> <td>10.10.3.1/24</td> <td>VRF table for Servers</td> </tr> <tr> <td>Interface on A connected to C</td> <td>GE0/1</td> <td>10.10.1.2/24</td> <td>-</td> </tr> <tr> <td>Interface on B connected to C</td> <td>GE0/2</td> <td>10.10.2.2/24</td> <td>-</td> </tr> </tbody> </table>	Interface Description	Interface Name	IP Address/Mask	VRF Table	Interface on C connected to A	GE0/1	10.10.1.1/24	VRF table for Sub a	Interface on C connected to B	GE0/2	10.10.2.1/24	VRF table for Sub b	Interface on C connected to Servers	GE0/3	10.10.3.1/24	VRF table for Servers	Interface on A connected to C	GE0/1	10.10.1.2/24	-	Interface on B connected to C	GE0/2	10.10.2.2/24	-

Common Errors

- An interface is bound to a VRF table after the IP interface of the interface is configured.
- When a physical link is used to forward packets from multiple VPNs, the corresponding physical interface is bound to a VRF table.
- VPN routes are not introduced to BGP.

7.4.2 Configuring a Multiprotocol VRF Table

Configuration Effect

- Provide the VPN service on a device.
- With BGP assistance, flexibly control the separation and access between VPNs.
- With BGP assistance, provide the VPN service in an IP/MPLS backbone network.
- Support IPv4 and IPv6 through address family configuration.

Notes

- No VRF table needs to be created if the device only forwards packets from one VPN or from the public network.
- If the device needs to forward public network packets and VPN packets or forward packets from multiple VPNs, VRF tables must be created to separate routes.
- In many cases, static or dynamic routes (RIP, OSPF, ISIS, and BGP) need to be added to VRF tables.

Configuration Steps

↳ Creating a VRF Table

- Mandatory.
- Create a VRF table for each VPN.

↳ Configuring an Address Family

- Mandatory.
- Enable the corresponding address family for each created VRF table.

↳ Configuring an RD

- Optional.
- When routing information needs to be advertised through BGP in the backbone network, BGP may select the best route for advertising if overlapping network addresses exist in different VPNs, which will make some VPNs fail to obtain corresponding routing information. To solve this problem, you can configure RDs for routes to enable BGP to make routing decisions based on these RDs, thus ensuring that each VPN can obtain corresponding routing information.

↳ Configuring an RT

- Optional.
- You can run the **route-target export** command to specify the attributes of the route to be advertised, and run the **route-target import** command to specify the attributes of the route to be received. You can also run the **route-target both** command to specify the export and import attributes.
- Run the **route-target** command in multiprotocol VRF mode or multiprotocol VRF address family mode.

↳ Binding an Interface and Adding the Direct Route and Host Route on the Interface to a VRF Table

- Mandatory.
- If the physical link for transmitting VPN packets is exclusively occupied by a VPN, bind the physical interface to the corresponding VRF table.
- If the physical link for transmitting VPN packets is shared by multiple VPNs, you need to create an independent logical link for each VPN, and bind the logical interface to the corresponding VRF table. A logical interface can be a subinterface or a VLAN interface.
- Before you bind an interface to a multiprotocol VRF table, enable an address family for the table. If you do not enable the IPv4 address family in advance, you cannot configure the IPv4 address and VRRP IPv4 address of the bound interface. If you do not enable the IPv6 address family in advance, you cannot configure the IPv6 address and VRRP IPv6 address of the bound interface.
- You must bind an interface to the corresponding multiprotocol VRF table before you configure the IPv4 or IPv6 address of the interface. If you bind the interface after its IPv4 or IPv6 address is configured, the address will be invalid.

▾ Adding the Direct Route and Host Route on an Interface to a VRF Table Without Binding the Interface

- Optional.
- If PBR is required for VRF table selection, run the **ip vrf receive** command on the interface to which PBR is applied, and import the direct route and host route on the interface to each VRF table available for choice.

Verification

- Check whether multiprotocol VRF tables are created correctly on the router and corresponding address families are enabled.

Related Commands

▾ Creating a VRF Table

Command	vrf definition <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Indicates the name of the VRF table to be created. It cannot exceed 31 characters.
Command Mode	Global configuration mode
Usage Guide	After you run the command, the system will enter VRF mode.

▾ Enabling the IPv4 Address Family

Command	address-family ipv4
Parameter Description	N/A
Command Mode	VRF mode
Usage Guide	After you run the command, the system will enter VRF IPv4 address family submode.

↳ Enabling the IPv6 Address Family

Command	address-family ipv6
Parameter	N/A
Description	
Command Mode	VRF mode
Usage Guide	After you run the command, the system will enter VRF IPv6 address family submode.

↳ Configuring an RD

Command	rd rd_value
Parameter Description	<p><i>rd_value</i> has the following three different parameter forms:</p> <p>(1) <i>rd_value</i> = as_num: nn as_num indicates the 2-byte number that identifies a public AS. nn is configurable in the range 0..4294967295.</p> <p>(2) <i>rd_value</i> = ip_addr: nn ip_addr must be a global IP address. nn is configurable in the range 0..65535.</p> <p>(3) <i>rd_value</i> = as4_num: nn as4_num indicates the 4-byte number that identifies a public AS. nn is configurable in the range 1..65535.</p>
Command Mode	VRF configuration mode
Usage Guide	<p>You cannot directly change the RD of an existing VRF table. You need to delete the VRF table first and then configure a new RD.</p> <p>A VRF table has only one RD. You cannot configure multiple RDs for one VRF table.</p>

↳ Configuring an RT

Command	route-target { import export both } rt_value
Parameter Description	<p><i>rt_value</i> has the following three different parameter forms:</p> <p>(1) <i>rt_value</i> = as_num: nn as_num indicates the 2-byte number that identifies a public AS. nn is configurable in the range 0..4294967295.</p> <p>(2) <i>rt_value</i> = ip_addr: nn ip_addr must be a global IP address. nn is configurable in the range 0..65535.</p> <p>(3) <i>rt_value</i> = as4_num: nn as4_num indicates the 4-byte number that identifies a public AS. nn is configurable in the range 1..65535.</p>
Command Mode	VRF configuration mode or VRF address family submode
Usage Guide	One VRF table can be configured with multiple import and export RT attributes.

↳ Binding an Interface

Command	vrf forwarding vrf-name
----------------	--------------------------------

Parameter Description	<i>vrf-name</i> : Indicates the name of a VRF table.
Command Mode	Interface configuration mode
Usage Guide	<p>By default, an interface does not belong to any VRF table.</p> <p>After an interface is bound to the corresponding VRF table, the direct route and host route on the interface will be automatically added to the VRF table.</p> <p>Before you bind an interface to a multiprotocol VRF table, enable an address family for the table. If you do not enable the IPv4 address family in advance, you cannot configure the IPv4 address and VRRP IPv4 address of the bound interface. If you do not enable the IPv6 address family in advance, you cannot configure the IPv6 address and VRRP IPv6 address of the bound interface.</p> <p>You must bind an interface to a multiprotocol VRF table before you configure the IPv4, IPv6, VRRP IPv4, and VRRP IPv6 addresses of the interface; otherwise, these addresses will be invalid and the IPv6 protocol on the interface will be disabled.</p> <p>If the IPv4 address family is deleted from the multiprotocol VRF table, the IPv4 and VRRP IPv4 addresses of all interfaces bound to the VRF table will be deleted, and the IPv4 static routes in the VRF table or next-hop routes are also deleted. If the IPv6 address family is deleted from the multiprotocol VRF table, the IPv6 and VRRP IPv6 addresses of all interfaces bound to the VRF table will be deleted, the IPv6 protocol on the interfaces will be disabled, and the IPv6 static routes in the VRF table or next-hop routes are also deleted.</p>

✚ Adding the Direct Route and Host Route on an Interface to a VRF Table Without Binding the Interface

Command	vrf receive <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Indicates the name of a VRF table.
Command Mode	Interface configuration mode
Usage Guide	<p>This command is used to add the host route and direct route on an interface to a VRF table. If you need to add the host route and direct route on an interface to multiple VRF tables, run the command multiple times. Different from the vrf forwarding command, the vrf receive command does not bind an interface to the corresponding VRF table. The interface is still a global interface and does not belong to any VRF table.</p> <p>The vrf forwarding and vrf receive commands are mutually exclusive on the same interface.</p>

✚ Displaying the VRF Information on a Device

Command	show vrf [brief detail ipv4 ipv6] [<i>vrf-name</i>]
Parameter Description	<p>brief: Displays brief information.</p> <p>detail: Displays detailed information.</p> <p>ipv4: Displays the brief information of an IPv4 VRF table.</p> <p>ipv6: Displays the brief information of an IPv6 VRF table.</p> <p><i>vrf-name</i>: Indicates the name of a VRF table.</p>
Command Mode	Privilege, global and interface configuration modes

Usage Guide	This command is used to display the information of a specified VRF table to check whether the VRF table is bound with the correct interface.
--------------------	--

↘ **Displaying the Routes in a VRF Table**

Command	<code>show ip route vrf vrf-name</code>
Parameter Description	<i>vrf-name</i> : Indicates the name of a VRF table.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	This command is used to check whether a specified VRF table contains corresponding routes.

Configuration Example

i The following example only describes VRF-related configuration on A1, B1, MCE1, and PE1. The configuration on A2, B2, MCE2, and PE2 is similar.

↘ **VRF on CEs and PEs (MCE Application)**

Scenario Figure 7-5	
	VPN a and VPN b have independent address spaces. VPN a runs RIP and VPN b runs OSPF.
Configuration Requirements	The routes in VPN a are separated from those in VPN b. A1 and A2 can access each other, and B1 and B2 can access each other.
Configuration Steps	<ul style="list-style-type: none"> ● Connect MCE1 and A1 through RIP. Extend RIP routes on A1. On MCE1, create a VRF table for VPN a, bind the directly connected interface, and configure RIP routes. ● Connect MCE1 and B1 through OSPF. Extend OSPF routes on B1. On MCE1, create a VRF table for VPN b, bind the directly connected interface, and configure OSPF routes. ● Connect MCE1 and PE1 through BGP. On MCE1 and PE1, create a VRF table for each VPN, bind the VLAN interface, and configure BGP routes. ● Configure the physical link between MCE1 and PE1 in Trunk mode. ● In the VRF instance for VPN a on MCE1, redistribute the RIP routes to BGP, and redistribute the BGP routes to RIP. ● In the VRF instance for VPN b on MCE1, redistribute the OSPF routes to BGP, and redistribute the BGP routes to OSPF.
	i Planning of interfaces and addresses:

	Interface Description	Interface Name	IP Address/Mask	VRF Table
	Physical interface on A1 connected to MCE1	GE0/1	10.10.1.2/24	-
	Physical interface on B1 connected to MCE1	GE0/2	10.10.2.2/24	-
	Physical interface on MCE1 connected to A1	GE0/1	10.10.1.1/24	VRF table for VPN a
	Physical interface on MCE1 connected to B1	GE0/2	10.10.2.1/24	VRF table for VPN b
	Logical interface on MCE1 connected to PE1	VLAN10	10.10.10.1/24	VRF table for VPN a

	<p>#Configure BGP routes in the VRF table for VPN b.</p> <pre>PE1(config)# router bgp 200 PE1(config-router)#address-family ipv4 vrf vpnb PE1(config-router-af)#neighbor 10.10.20.1 remote-as 100 PE1(config-router-af)#exit</pre>
Verification	<ul style="list-style-type: none"> ● On A1, run the show ip route command to display the routes in VPN a. ● On B2, run the show ip route command to display the routes in VPN b. ● On MCE1, run the show ip route vrf vpna command to display the routes in VPN a, and run the show ip route vrf vpnb command to display the routes in VPN b. ● On PE1, run the show ip route vrf vpna command to display the routes in VPN a, and run the show ip route vrf vpnb command to display the routes in VPN b.

Common Errors

- A multiprotocol VRF table is configured, but no address family is enabled.
- An interface is bound to a VRF table after the IP interface of the interface is configured.
- When a physical link is used to forward packets from multiple VPNs, the corresponding physical interface is bound to a VRF table.
- VPN routes are not introduced to BGP.

7.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears the routes in a specified VRF table.	clear ip route vrf <i>vrf-name</i>

Displaying

Description	Command
Displays the information of a single-protocol VRF table.	show ip vrf [brief detail interfaces] [vrf-name]
Displays the information of a multiprotocol VRF table.	show vrf [ipv4 ipv6 brief detail] [vrf-name]

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Displays the debugging information during the processes where a VRF table is created, an address family is enabled, and an interface is bound to the VRF table.	debug vrf
Prints the information of interface-related VRF operation debugging.	debug vrf interface

8 Configuring RIPng

8.1 Overview

RIP next generation (RIPng) is a unicast routing protocol that applies to IPv6 networks. RIPng-enabled routers exchange routing information to obtain routes to remote networks.

As an Interior Gateway Protocol (IGP), RIPng can run only within the autonomous system (AS) and is applicable to small-sized networks with routes no more than 16 hops.

Protocols and Standards

- RFC2080: Defines the RIPng.

8.2 Application

RIPng is generally used on some small-sized networks, such as office networks of small companies.

As shown in the following figure, the company builds an IPv6 network, on which all routers support IPv6. The network is small in size, but the workload is still heavy if the network is maintained manually. In this case, RIPng can be configured to adapt to topological changes of the small-sized network, which reduces the workload.

Figure 8-1

8.3 Features

Basic Concepts

↘ IGP and EGP

IGP runs within an AS. For example, RIPng is a type of IGP.

Exterior Gateway Protocol (EGP) runs between ASs. For example, BGP is a type of EGP.

Feature

Feature	Description
RIPng and RIP	RIPng is an extension of RIPv2 on the basis of IPv6. Both are similar in functions and configurations.
Exchanging Routing Information	By exchanging routing information, RIPng-enabled devices can automatically obtain routes to a remote network and update routes in real time.
Routing Algorithm	RIPng is a protocol based on the distance-vector algorithm. It uses the vector addition method to compute the routing information.
Avoiding Route Loops	RIPng uses functions, such as split horizon and poison reverse, to avoid route loops.

8.3.1 RIPng and RIP

RIP applies to IPv4 networks. Two RIP versions are available, including RIPv1 and RIPv2.

RIPng is an extension of RIPv2 on the basis of IPv6. Both are similar in functions and configurations.

Working Principle

↳ RIPv2

RIPv2 packets are multicast. The multicast address is 224.0.0.9, and the UDP port ID is 520. RIPv2 can identify the subnet mask.

↳ RIPng

RIPng packets are multicast. The multicast address is FF02::9, the source address is FE80::/10, and the UDP port ID is 521. RIPng can identify the subnet mask.

i This chapter describes functions and configurations of RIPng. For details about RIPv2, see "Configuring RIP".

Related Configuration

↳ Enabling the RIPng Process

By default, the RIPng process is disabled.

Run the **ipv6 router rip** command to enable the RIPng process.

You must enable the RIPng process on a device; otherwise, all functions related to RIPng cannot take effect.

↳ Running RIPng on an Interface

By default, RIPng does not run on an interface.

Run the **ipv6 rip enable** command to run RIPng on an interface.

After RIPng runs on an interface, RIPng packets can be exchanged on the interface and RIPng can learn routes to the network segments directly connected to the device.

↘ Prohibiting an Interface from Sending or Receiving Packets

By default, a RIPng-enabled interface is allowed to send and receive RIPng packets.

Run the **passive-interface** command to prohibit an interface from sending RIPng packets.

8.3.2 Exchanging Routing Information

Compared with static routing, the dynamic routing protocol has a significant advantage, that is, by exchanging routing information, devices can automatically obtain routes to a remote network and update the routes in real time.

Working Principle

↘ Initialization

After RIPng is enabled on a router, the router sends a request packet to its neighbor router, requesting for all routing information, that is, the routing table. After receiving the request message, the neighbor router returns a response packet containing the local routing table. After receiving the response packet, the router updates the local routing table, and sends an update packet to the neighbor router, informing the neighbor router of the route update information. After receiving the update packet, the neighbor router updates the local routing table, and sends the update packet to other adjacent routers. After a series of updates, all routers can obtain and retain the latest routing information.

↘ Periodical Update

By default, periodical update is enabled for RIPng. Adjacent routers exchange complete routing information with each other every 30s (update timer), that is, the entire routing table is sent to neighbor routers.

- i** For every non-local route, if the route is not updated within 180s (invalid timer), the metric of the route is changed to 16 (unreachable). If the route is still not updated in the next 120s (flush timer), the route is deleted from the routing table.

↘ Default Route

In the routing table, a route to the destination network `::/0` is called default route.

The default route can be learned from a neighbor router, or sent to a neighbor router.

↘ Route Redistribution

For RIPng, other types of routes (such as direct routes, static routes, and routes of other routing protocols) are called external routes.

External routes (excluding the default route) can be redistributed to RIPng and advertised to neighbors.

↘ Route Filtering

Filtering conditions can be configured to limit the routing information exchanged between adjacent routers. Only the routing information that meets filtering conditions can be sent or received.

Related Configuration

↘ RIPng Timers

By default, the update timer is 30s, the invalid timer is 180s, and the flush timer is 120s.

Run the **timers basic** command to modify durations of RIPng timers.

Increasing the duration of the flush timer can reduce the route flapping. Decreasing the duration of the flush timer helps accelerate route convergence.

The durations of RIPng timers must be consistent on adjacent routers. Unless otherwise required, you are advised not to modify the RIPng timers.

↘ Default Route

Run the **ipv6 rip default-information** command to advertise the default route to neighbors on an interface.

↘ Route Redistribution

Run the **redistribute** command to redistribute external routes (excluding the default route) to RIPng and advertise them to neighbors.

↘ Route Filtering

Run the **distribute-list out** command to set filtering rules to limit the routing information sent by the device.

Run the **distribute-list in** command to set filtering rules to limit the routing information received by the device.

8.3.3 Routing Algorithm

RIPng is a protocol based on the distance-vector algorithm. It uses the vector addition method to compute the routing information.

Working Principle

↘ Distance-Vector Algorithm

RIPng is a protocol based on the distance-vector algorithm. The distance-vector algorithm treats a route as a vector that consists of the destination network and distance (metric). The router obtains a route from its neighbor and adds the distance vector from itself to the neighbor to the route to form its own route.

RIPng uses the hop count to evaluate the distance (metric) to the destination network. By default, the hop count from a router to its directly connected network is 0, the hop count from a router to a network that can be reached through a router is 1, and so on. That is, the metric is equal to the number of routers from the local network to the destination network. To restrict the convergence time, RIPng stipulates that the metric must be an integer between 0 and 15. If the metric is equal to or greater than 16, the destination network or host is unreachable. For this reason, RIPng cannot be applied to a large-scale network. As shown in the following figure, Router A is connected to the network 2::/64. Router B obtains the route (2::/64, 0) from Router A and adds the metric 1 to the route to obtain its own route (2::/64, 1), and the next hop points to Router A.

Figure 8-2

↘ **Selecting the Optimum Route**

RIPng selects an optimum route based on the following principle: If multiple routes to the same destination network is available, a router preferentially selects the route with the smallest metric.

As shown in the following figure, Router A is connected to the network 2::/64. Router C obtains the route (2::/64, 0) from Router A and the route (2::/64, 1) from Router B. Router C will select the route that is obtained from Router A and add metric 1 to this route to form its own route (2::/64, 1), and the next hop points to Router A.

Figure 8-3

i When routes coming from different sources exist on a router, the route with the smaller distance is preferentially selected.

Route Source	Default Distance
Directly-connected network	0
Static route	1
OSPF route	110
IS-IS route	115
RIPng route	120
Unreachable route	255

Related Configuration

↘ **Modifying the Distance**

By default, the distance of a RIPng route is 120.

Run the **distance** command to modify the distance of a RIPng route.

✚ Modifying the Metric

For a RIPng route that is proactively discovered by a device, the default metric is equal to the number of hops from the local network to the destination network. The metric offset of the interface is 1.

For a RIPng router that is manually configured (default route or redistributed route), the default metric is 1.

Run the **ipv6 rip metric-offset** command to modify the metric offset of the interface.

Run the **default-metric** command to modify the default metric of an external route (redistributed route).

Run the **redistribute** command to modify the metric of an external route (redistributed route) when advertising this route.

Run the **ipv6 rip default-information** command to modify the metric of a default route when advertising the default route.

8.3.4 Avoiding Route Loops

RIPng uses functions, such as split horizon and poison reverse, to avoid route loops.

Working Principle

✚ Route Loop

A RIPng route loop occurs due to inherent defects of the distance-vector algorithm.

As shown in the following figure, Router A is connected to the network 2::/64, and sends an update packet every 30s. Router B receives the route to 2::/64 from Router A every 30s. If Router A is disconnected from 2::/64, the route to 2::/64 will be deleted from the routing table on Router A. Next time, the update packet sent by Router A no longer contains this route. As Router B does not receive an update packet related to 2::/64, Router B determines that the route to 2::/64 is valid within 180s and uses the update packet to send this route to Router A. As the route to 2::/64 does not exist on Router A, the route learned from Router B is added to the routing table. Router B determines that data can reach 2::/64 through Router A, and Router A determines that data can reach 2::/64 through Router B. In this way, a route loop is formed.

Figure 8-4

✚ Split Horizon

Split horizon can prevent route loops. After split horizon is enabled, a route received on this interface will not be sent out from this interface.

As shown in the following figure, after split horizon is enabled on Router B, Router B will not send the route to 2::/64 back to Router A. Router B will learn 180s later that 2::/64 is not reachable.

Figure 8-5

↳ Poison Reverse

Poison reverse can also prevent route loops. Compared with split horizon, poison reverse is more reliable, but brings more protocol packets, which makes network congestion more severe.

After poison reverse is enabled on an interface, a route received from this interface will be sent out from this interface again, but the metric of this router will be changed to 16 (unreachable).

As shown in the following figure, after poison reverse is enabled on Router A, if Router A detects a disconnection from 2::/64, Router A will not delete the route to 2::/64. Instead, Router A changes the number of hops to 16, and advertises the route through the update packet. On receiving the update packet, Router B learns that 2::/64 is not reachable.

Figure 8-6

Related Configuration

↳ Split Horizon

By default, split horizon is enabled.

Run the **no split-horizon** command to disable split horizon.

↳ Poison Reverse

By default, poison reverse is disabled.

Run the **split-horizon poisoned-reverse** command to enable poison reverse. (After poison reverse is enabled, split horizon is automatically disabled.)

8.4 Configuration

Configuration	Related Commands	
Configuring RIPng Basic Functions	 (Mandatory) It is used to build a RIPng routing domain.	
	ipv6 router rip	Enables a RIPng routing process and enters routing process configuration mode.
	ipv6 rip enable	Runs RIPng on an interface.
	split-horizon	Enables split horizon or poison reverse.
	passive-interface	Configures a passive interface.
Advertising the Default Route or External Routes	 Optional.	
	ipv6 rip default-information	Advertise the default route to neighbors on an interface.
	redistribute	Redistributes routes and advertising external routes to neighbors.
Setting Route Filtering Rules	 Optional.	
	distribute-list in	Filters the received RIPng routing information.
	distribute-list out	Filters the sent RIPng routing information.
Modifying Route Selection Parameters	 Optional.	
	distance	Modifies the administrative distance of a RIPng route.
	ipv6 rip metric-offset	Modifies the metric offset on an interface.
	default-metric	Configure the default metric for route redistribution.
Modifying Timers	 Optional.	
	timers	Modifies the update timer, invalid timer, and flush timer of RIPng.

8.4.1 Configuring RIPng Basic Functions

Configuration Effect

- Build a RIPng routing domain on the network.
- Routers in the domain obtain routes to a remote network through RIPng.

Notes

- IPv6 addresses must be configured.
- IPv6 unicast routes must be enabled.

Configuration Steps

▾ Enabling a RIPng Routing Process

- Mandatory.
- Unless otherwise required, perform this configuration on every router in the RIPng routing domain.

↳ Running RIPng on an Interface

- Mandatory.
- Unless otherwise required, perform this configuration on every interconnected interface of routers in the RIPng routing domain.

↳ Enabling Split Horizon or Poison Reverse

- By default, split horizon is enabled and poison reverse is disabled.
- Unless otherwise required, enable split horizon on every interface connected to the broadcast network, such as the Ethernet. (Retain the default setting.)
- Unless otherwise required, enable split horizon on every interface connected to the point-to-point (P2P) network, such as the PPP and HDLC. (Retain the default setting.)
- It is recommended that split horizon and poison reverse be disabled on an interface connected to a non-broadcast multi-access network, such as FR and X.25; otherwise, some devices cannot learn the complete routing information.
- If the secondary IP address is configured for an interface connected to a non-broadcast, it is recommended that split horizon and poison reverse be disabled.

↳ Configuring a Passive Interface

- This configuration is recommended.
- Use the passive interface to set the boundary of the RIPng routing domain. The network segment of the passive interface belongs to the RIPng routing domain, but RIPng packets cannot be sent over the passive interface.
- If RIPng routes need to be exchanged on an interface (such as the router interconnect interface) in the RIPng routing domain, this interface cannot be configured as a passive interface.

Verification

- Check the routing table on a router to verify that the route to a remote network can be obtained through RIPng.

Related Commands

↳ Enabling a RIPng Routing Process

Command	<code>ipv6 router rip</code>
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	This command is used to create a RIPng routing process and enter routing process configuration mode.

↳ Running RIPng on an Interface

Command	<code>ipv6 rip enable</code>
----------------	------------------------------

Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	The configuration for running the RIPng on an interface is different from that of RIPv2. In RIPv2, the network command is configured in routing process configuration mode to define an IP address range. If the IP address of an interface belongs to this IP address range, RIP automatically runs on this interface.

↳ Enabling Split Horizon

Command	split-horizon [poisoned-reverse]
Parameter Description	poisoned-reverse: Indicates that the split horizon function contains the poison reverse function.
Command Mode	Routing process configuration mode
Usage Guide	Run the show ipv6 rip command to check whether split horizon is enabled. The configuration is different from that of RIPv2. In RIPv2, the split horizon function is configured in interface configuration mode.

↳ Configuring a Passive Interface

Command	passive-interface { default interface-type interface-num }
Parameter Description	default: Indicates all interfaces. interface-type interface-num: Specifies an interface.
Command Mode	Routing process configuration mode
Usage Guide	First, run the passive-interface default command to configure all interfaces as passive interfaces. Then, run the no passive-interface interface-type interface-num command so that the interfaces used for interconnection between routers in the domain are not passive interface.

↳ Displaying the IP Routing Table

Command	show ipv6 route
Parameter Description	N/A
Command Mode	Privileged EXEC mode or global configuration mode
Usage Guide	Check whether the routing table contains any route to a remote network that is learned through RIPng.

Configuration Example

↳ Building a RIPng Routing Domain

<p>Scenario Figure 8-7</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure IPv6 addresses on all routers. ● Enable RIPng on all routers.
<p>A</p>	<pre>A# configure terminal Enter configuration commands, one per line. End with CNTL/Z. A(config)# ipv6 router rip A(config-router)# exit A(config)# interface GigabitEthernet 0/0 A(config-if-GigabitEthernet 0/0)# ipv6 address 2001:db8::1/32 A(config-if-GigabitEthernet 0/0)# ipv6 rip enable</pre>
<p>B</p>	<pre>B# configure terminal Enter configuration commands, one per line. End with CNTL/Z. B(config)# ipv6 router rip B(config-router)# exit B(config)# interface GigabitEthernet 0/0 B(config-if-GigabitEthernet 0/0)# ipv6 address 2001:db8::2/32 B(config-if-GigabitEthernet 0/0)# ipv6 rip enable</pre>
<p>C</p>	<pre>C# configure terminal Enter configuration commands, one per line. End with CNTL/Z. C(config)# ipv6 router rip C(config-router)# exit C(config)# interface GigabitEthernet 0/0 C(config-if-GigabitEthernet 0/0)#</pre>

	<pre>C(config-if-GigabitEthernet 0/0)# ipv6 address 2001:db8::3/32 C(config-if-GigabitEthernet 0/0)# ipv6 rip enable C(config)# interface GigabitEthernet 0/1 C(config-if-GigabitEthernet 0/1)# ipv6 address 2::1/64 C(config-if-GigabitEthernet 0/1)# ipv6 rip enable</pre>
Verification	<p>Check the routing tables on Router A, Router B, and Router C. The routing tables should contain routes to a remote network that are learned through RIPng.</p>
A	<pre>A# show ipv6 route IPv6 routing table name - Default - 6 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area R 2::/64 [120/2] via FE80::2D0:F8FF:FEFB:D521, GigabitEthernet 0/0 C 2001:DB8::/32 via GigabitEthernet 0/0, directly connected L 2001:DB8::1/128 via GigabitEthernet 0/0, local host C FE80::/10 via ::1, Null0 C FE80::/64 via GigabitEthernet 0/0, directly connected L FE80::2D0:F8FF:FEFB:E7CE/128 via GigabitEthernet 0/0, local host</pre>
B	<pre>B# show ipv6 route IPv6 routing table name - Default - 6 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2</pre>

	<pre> IA - Inter area R 2::/64 [120/2] via FE80::2D0:F8FF:FEFB:D521, GigabitEthernet 0/0 C 2001:DB8::/32 via GigabitEthernet 0/0, directly connected L 2001:DB8::2/128 via GigabitEthernet 0/0, local host C FE80::/64 via GigabitEthernet 0/0, directly connected L FE80::2D0:F8FF:FEFB:C9BA/128 via GigabitEthernet 0/0, local host </pre>
C	<pre> Ruijie# show ipv6 route IPv6 routing table name - Default - 9 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area C 2::/64 via GigabitEthernet 0/1, directly connected L 2::2/128 via GigabitEthernet 0/1, local host C 2001:DB8::/32 via GigabitEthernet 0/0, directly connected L 2001:DB8::3/128 via GigabitEthernet 0/0, local host C FE80::/10 via ::1, Null0 C FE80::/64 via GigabitEthernet 0/0, directly connected L FE80::2D0:F8FF:FEFB:D521/128 via GigabitEthernet 0/0, local host C FE80::/64 via GigabitEthernet 0/1, directly connected L FE80::2D0:F8FF:FEFB:D521/128 via GigabitEthernet 0/1, local host </pre>

Common Errors

- The IPv6 address is not configured on an interface.
- The interface used for interconnection between devices is configured as a passive interface.

8.4.2 Advertising the Default Route or External Routes

Configuration Effect

- In the RIPng domain, introduce a unicast route of another AS so that the unicast routing service to this AS can be provided for users in the RIPng domain.
- In the RIPng domain, inject a default route to another AS so that the unicast routing service to this AS can be provided for users in the RIPng domain.

Notes

- The RIPng basic functions must be configured.

Configuration Steps

▾ Configuring External Route Redistribution

- Optional.
- Perform this configuration if external routes of the RIPng domain should be introduced to the AS border router (ASBR).

▾ Generating a Default Route

- Optional.
- Perform this configuration if the default route should be introduced to an ASBR so that other routers in the RIPng domain access other AS domains through this ASBR by default.

Verification

- Run the **show ipv6 route rip** command on a non-ASBR to check whether the external routes of the domain and default route have been loaded.

Related Commands

▾ Advertising the Default Route to Neighbors on an Interface

Command	<code>ipv6 rip default-information { only originate } [metric <i>metric-value</i>]</code>
Parameter Description	<p>only: Advertises only IPv6 default route.</p> <p>originate: Advertises the IPv6 default route and other routes.</p> <p>metric <i>metric-value</i>: Indicates the metric of the default route. The value ranges from 1 to 15. The default value is 1.</p>
Command Mode	Interface configuration mode
Usage Guide	<p>After this command is configured on the interface, an IPv6 default route is advertised to the external devices through this interface, but the route itself is not added to the route forwarding table or the device and the RIPng route database.</p> <p>To prevent occurrence of a route loop, once this command is configured on an interface, RIPng refuses to receive the default route updates advertised by neighbors.</p>

↘ Redistributing Routes and Advertising External Routes to Neighbors

Command	<code>redistribute { bgp connected isis [area-tag] ospf process-id static } [metric metric-value route-map route-map-name]</code>
Parameter Description	<p>bgp: Indicates redistribution from BGP.</p> <p>Connected: Indicates redistribution from direct routes.</p> <p>isis [area-tag]: Indicates redistribution from IS-IS. <i>area-tag</i> indicates the IS-IS process ID.</p> <p>ospf process-id: Indicates redistribution from OSPF. <i>process-id</i> indicates the OSPF process ID. The value ranges from 1 to 65535.</p> <p>static: Indicates redistribution from static routes.</p> <p>metric metric-value: Sets the metric of the route redistributed to the RIPng domain.</p> <p>route-map route-map-name: Sets the redistribution filtering rules.</p>
Command Mode	Routing process configuration mode
Usage Guide	During route redistribution, it is not necessary to convert the metric of one routing protocol to the metric of another routing protocol because different routing protocols use completely different metric measurement methods. RIP measures the metric based on the hop count, and OSPF measures the metric based on the bandwidth. Therefore, the computed metrics cannot be compared with each other.

Configuration Example

Scenario Figure 8-8	
Configuration Steps	<ul style="list-style-type: none"> ● Configure the interface IPv6 addresses on all routers. (Omitted) ● Configure the RIPng basic functions on all routers. (Omitted) ● On Router B, configure redistribution of static routes. ● On the GE0/1 interface of Router A, configure advertisement of the default route.
A	<pre>A# configure terminal A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ipv6 rip default-information originate</pre>
B	<pre>B# configure terminal B(config)# ipv6 router rip B(config-router)# redistribute static</pre>
Verification	<ul style="list-style-type: none"> ● Check the routing tables on Router A and Router B, and confirm that Router A can learn the route 3001:10:10::/64, and Router B can learn the default route ::/0.

A	<pre>A# show ipv6 route rip IPv6 routing table name - Default - 17 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area R 3001:10:10::/64 [120/2] via FE80::2D0:F8FF:FE22:334A, GigabitEthernet 0/1</pre>
B	<pre>B# show ipv6 route rip IPv6 routing table name - Default - 17 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area R ::/0 [120/2] via FE80::21A:A9FF:FE41:5B06, GigabitEthernet 0/1</pre>

8.4.3 Setting Route Filtering Rules

Configuration Effect

- Routes that do not meet filtering criteria cannot be loaded to the routing table, or advertised to neighbors. In this way, users within the network can be prevented from accessing specified destination networks.

Notes

- The RIPng basic functions must be configured.

Configuration Steps

📌 Filtering the Received RIP Routing Information

- To refuse receiving some specified routes, you can configure the route distribution control list to process all the received route update packets. If no interface is specified, route update packets received on all interfaces will be processed.

Filtering the Sent RIP Routing Information

- If this command does not contain any optional parameter, route update advertisement control takes effect on all interfaces. If the command contains the interface parameter, route update advertisement control takes effect only on the specified interface. If the command contains other routing process parameters, route update advertisement control takes effect only on the specified routing process.

Verification

- Run the **show ipv6 route rip** command to check that the routes that have been filtered out are not loaded to the routing table.

Related Commands

Command	distribute-list prefix-list <i>prefix-list-name</i> { in out } [<i>interface-type interface-name</i>]
Parameter	prefix-list <i>prefix-list-name</i> : Indicates the name of the prefix list, which is used to filter routes.
Description	in out : Specifies update routes (received or sent routes) that are filtered. <i>interface-type interface-name</i> : Indicates that the distribution list is applied to the specified interface.
Command Mode	Routing process configuration mode
Usage Guide	N/A

Configuration Example

Scenario Figure 8-9	
Configuration Steps	<ul style="list-style-type: none"> Configure the interface IPv6 addresses on all routers. (Omitted) Configure the RIPng basic functions on all routers. (Omitted) On router A, configure route filtering.
A	<pre>A# configure terminal A(config)# ipv6 prefix-list hello permit 4001::/64 A(config)# ipv6 router rip A(config-router)# distribute-list prefix-list hello in</pre>
Verification	<ul style="list-style-type: none"> Check that Router A can learn only the route to 4001::/64.

A	<pre>A# show ipv6 route rip IPv6 routing table name - Default - 17 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area R 4001::/64 [120/2] via FE80::2D0:F8FF:FE22:334A, GigabitEthernet 0/1</pre>
----------	---

8.4.4 Modifying Route Selection Parameters

Configuration Effect

- Change the RIPng routes to enable the traffic pass through specified nodes or avoid passing through specified nodes.
- Change the sequence that a router selects various types of routes so as to change the priorities of RIPng routes.

Notes

- The RIPng basic functions must be configured.

Configuration Steps

▾ Modifying the Administrative Distance of a RIPng Route

- Optional.
- Perform this configuration if you wish to change the priorities of RIPng routes on a router that runs multiple unicast routing protocols.

▾ Modifying the Metric Offset on an Interface

- Optional.
- Unless otherwise required, perform this configuration on a router where the metrics of routes need to be adjusted.

▾ Configuring the Default Metric of an External Route Redistributed to RIPng

- Optional.
- Unless otherwise required, perform this configuration on an ASBR to which external routes are introduced.

Verification

- Run the **show ipv6 rip** command to display the administrative distance of RIPng routes.
- Run the **show ipv6 rip data** command to display the metrics of external routes redistributed to RIPng.

Related Commands

Modifying the Administrative Distance of a RIPng Route

Command	<code>distance distance</code>
Parameter Description	<i>distance</i> : Sets the administrative distance of a RIPng route. The value is an integer ranging from 1 to 254.
Command Mode	Routing process configuration mode
Usage Guide	Run this command to set the administrative distance of a RIPng route.

Modifying the Metric Offset on an Interface

Command	<code>ipv6 rip metric-offset value</code>
Parameter Description	<i>value</i> : Indicates the interface metric offset. The value ranges from 1 to 16.
Command Mode	Routing process configuration mode
Usage Guide	Before a route is added to the routing table, the metric of the route must be added with the metric offset set on the interface. You can control the use of a route by setting the interface metric offset.

Configuring the Default Metric of an External Route Redistributed to RIPng

Command	<code>default-metric metric</code>
Parameter Description	<i>metric</i> : Indicates the default metric. The valid value ranges from 1 to 16. If the value is equal to or greater than 16, the RGOS determines that this route is unreachable.
Command Mode	Global configuration mode
Usage Guide	If the metric is not specified during redistribution of a routing protocol process, RIPng uses the metric defined by the default-metric command. If the metric is specified, the metric defined by the default-metric command is overwritten by the specified metric. If this command is not configured, the value of default-metric is 1.

Configuration Example

Modifying the Administrative Distance of a RIPng Route

<p>Scenario Figure 8-10</p>	<p>The diagram shows two routers, A and B, connected via their GE 0/1 interfaces. Router A has a loopback interface with address 2001::1/64. Router B has a loopback interface with address 3001::1/64. The link between them is labeled with 2001::2/64.</p>
--	---

Configuration Steps	<ul style="list-style-type: none"> Configure the interface IPv6 addresses on all routers. (Omitted) Configure the RIPng basic functions on all routers. (Omitted) On Router A, set the administrative distance of a RIPng route to 160.
	<pre>A# configure terminal A(config)# ipv6 router rip A(config-router)# distance 160</pre>
Verification	<ul style="list-style-type: none"> On Router A, check whether the administrative distance of a RIPng route is 160.
	<pre>A# show ipv6 route rip in 3001::/64 R 3001::/64 [160/2] via FE80::2D0:F8FF:FE22:334A, GigabitEthernet 0/1</pre>

8.4.5 Modifying Timers

Configuration Effect

- Change the duration of RIPng timers to accelerate or slow down the change of the protocol state or occurrence of an event.

Notes

- The RIPng basic functions must be configured.
- Modifying the protocol control parameters may result in protocol running failures. Therefore, you are advised not to modify the timers.

Configuration Steps

✚ Modifying the Update Timer, Invalid Timer, and Flush Timer

- Mandatory.
- Unless otherwise required, perform this configuration on a router where RIPng timers need to be modified.

Verification

- Run the **show ipv6 rip** command to display settings of timers.

Related Commands

Command	<code>timers update invalid flush</code>
Parameter Description	<p><i>Update</i>: Indicates the route update time in second. It defines the interval at which the device sends the route update packet. Each time an update packet is received, the invalid timer and flush timer are reset. By default, a route update packet is sent every 30s.</p> <p><i>Invalid</i>: Indicates the route invalid time in second, counted from the last time when a valid update packet is received. It defines the time after which the route in the routing list becomes invalid because the route is not</p>

	<p>updated. The duration of the invalid timer must be at least three times the duration of the update timer. If no update packet is received before the invalid timer expires, the corresponding route enters the invalid state. If the update packet is received before the invalid timer expires, the timer is reset. The default duration of the invalid timer is 180s.</p> <p><i>Flush</i>: Indicates the route flushing time in second, counted from the time when the RIPng route enters the invalid state. When the flush timer expires, the route in the invalid state will be deleted from the routing table. The default duration of the flush timer is 120s.</p>
Command Mode	Routing process configuration mode
Usage Guide	By default, the update timer is 30s, the invalid timer is 180s, and the flush timer is 120s.

Configuration Example

Scenario Figure 8-11	
Configuration Steps	<ul style="list-style-type: none"> Configure the interface IPv6 addresses on all routers. (Omitted) Configure the RIPng basic functions on all routers. (Omitted) On Router A, configure the update timer, invalid timer, and flush timer.
B	<pre>B# configure terminal B(config)# ipv6 router rip B(config-router)# timers 10 30 90</pre>
Verification	<ul style="list-style-type: none"> On Router B, check the settings of RIPng timers.

```
B
B# show ipv6 rip

Routing Protocol is "RIPng"

  Sending updates every 10 seconds with +/-50%, next due in 12 seconds
  Timeout after 30 seconds, garbage collect after 90 seconds
  Outgoing update filter list for all interface is: not set
  Incoming update filter list for all interface is: not set
  Default redistribution metric is 1
  Default distance is 120
  Redistribution:
    Redistributing protocol connected
  Default version control:  send version 1, receive version 1
  Interface                Send   Recv
  GigabitEthernet 0/1      1     1

Routing Information Sources:
  Gateway: fe80::2d0:f8ff:fe22:334a  Distance: 120
  Last Update: 00:00:02  Bad Packets: 0  Bad Routes: 0
```

Common Errors

- Settings of RIPng timers on devices connected to the same network are inconsistent. Consequently, routes cannot be learned properly.

8.4.6 Configuring Super VLAN to Enable RIPng

Configuration Effect

- Run the RIPng protocol on super VLANs.

Notes

- The RIPng basic functions must be configured.
- The designated sub VLAN is connected with neighbors.

Configuration Steps

Running RIPng on Super VLAN

- Optional. Run this command to enable RIPng on a super VLAN if required.

Verification

- Run the **show ipv6** route rip command to display the protocol status.

Related Commands

↳ **Running RIPng on Super VLAN**

Command	<code>ipv6 rip subvlan [all vid]</code>
Parameter Description	all: Indicates that packets are allowed to be sent to all sub VLANs. vid: Specifies the sub VLAN ID. The value ranges from 1 to 4094.
Command Mode	Interface configuration mode
Usage Guide	In normal cases, a super VLAN contains multiple sub VLANs. Multicast packets of a super VLAN are also sent to its sub VLANs. In this case, when RIPng multicast packets are sent over a super VLAN containing multiple sub VLANs, the RIPng multicast packets are replicated multiple times, and the device processing capability is insufficient. As a result, a large number of packets are discarded, causing the neighbor down error. In most scenarios, the RIPng function does not need to be enabled on a super VLAN. Therefore, the RIPng function is disabled by default. However, in some scenarios, the RIPng function must be run on the super VLAN, but packets only need to be sent to one sub VLAN. In this case, run this command to specify a particular sub VLAN. You must be cautious in configuring packet transmission to all sub VLANs, as the large number of sub VLANs may cause a device processing bottleneck, which will lead to the neighbor down error.

Configuration Example

Scenario Figure 8-12	
Configuration Steps	<ul style="list-style-type: none"> ● Enable Ipv6 on interfaces of all devices. ● Configure the RIPng basic functions on all devices. ● Specify a particular sub VLAN on all devices.
A	<pre>A# configure terminal A(config)# interface VLAN 300 A(config-if-VLAN 300)# ipv6 rip subvlan 1024</pre>

B	<pre>B# configure terminal B(config)# interface VLAN 300 B(config-if-VLAN 300)# ipv6 rip subvlan 1024</pre>
Verification	<ul style="list-style-type: none"> ● Verify that the entry 4001::/64 has been loaded to the routing table on Device A. ● Verify that the entry 3001::/64 has been loaded to the routing table on Device B.
A	<pre>A# show ipv6 route rip R 4001::/64 [120/2] via FE80::2D0:F8FF:FEFB:D521, VLAN 300</pre>
B	<pre>A# show ipv6 route rip R 3001::/64 [120/2] via FE80::2D0:F8FF:FEFB:D521, VLAN 300</pre>

8.5 Monitoring

Displaying

Description	Command
Displays information about the RIPng process.	show ipv6 rip
Displays the RIPng routing table.	show ipv6 rip database

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs RIPng.	debug ipv6 rip [interface <i>interface-type interface-num</i> nsm restart event [ipsec]]

9 Managing Routes

9.1 Overview

The network service module (NSM) manages the routing table, consolidates routes sent by various routing protocols, and selects and sends preferred routes to the routing table. Routes discovered by various routing protocols are stored in the routing table. These routes are generally classified by source into three types:

- Direct route: It is the route discovered by a link-layer protocol and is also called interface route.
- Static route: It is manually configured by the network administrator. A static route is easy to configure and less demanding on the system, and therefore applicable to a small-sized network that is stable and has a simple topology. However, when the network topology changes, the static route must be manually reconfigured and cannot automatically adapt to the topological changes.
- Dynamic route: It is the route discovered by a dynamic routing protocol.

9.2 Applications

Application	Description
Basic Functions of the Static Route	Manually configure a route.
Floating Static Route	Configure a standby route in the multipath scenario.
Load Balancing Static Route	Configure load balancing static routes in the multipath scenario.
Correlation of Static Routes with BFD	Use the Bidirectional Forwarding Detection (BFD) function to test whether the next hop of a static route is reachable.
Fast Reroute of Static Routes	Use the fast reroute function to improve the switching performance in the multipath scenario.

9.2.1 Basic Functions of the Static Route

Scenario

On a network with a simple topology, you can configure only static routes to implement network interworking. Appropriate configuration and use of static routes can improve the network performance and guarantee the bandwidth for important network applications.

As shown in Figure 9-1, to implement interworking between PC 1, PC 2, and PC 3, you can configure static routes on R 1, R 2, and R 3.

- On R 1, configure a route to the network segment of PC 2 through R 2, and a route to the network segment of PC 3 through R 3.
- On R 2, configure a route to the network segment of PC 1 through R 1, and a route to the network segment of PC 3 through R 3.

- On R 3, configure a route to the network segment of PC 1 through R 1, and a route to the network segment of PC 2 through R 2.

Figure 9-1

Deployment

- Configure the address and subnet mask of each interface.
- Configure static routes on R 1, R 2, and R 3.

9.2.2 Floating Static Route

Scenario

If no dynamic routing protocol is configured, you can configure floating static routes to implement dynamic switching of routes to prevent communication interruption caused by the network connection failures.

As shown in Figure 9-2, to prevent communication interruption caused by a line failure between R 1 and R 3, you can configure a floating static route respectively on R 1 and R 3. Normally, packets are forwarded on a path with a small administrative distance. If a link on this path is down, the route is automatically switched to the path with a large administrative distance.

- On R1, configure two routes to the network segment of PC 3, including a route through R 3 (default distance = 1) and a route through R 2 (default distance = 2).
- On R 3, configure two routes to the network segment of PC 1, including a route through R 1 (default distance = 1) and a route through R 2 (default distance = 2).

Figure 9-2

Deployment

- Configure the address and subnet mask of each interface.
- Configure static routes on R 1, R 2, and R 3.

9.2.3 Load Balancing Static Route

Scenario

If there are multiple paths to the same destination, you can configure load balancing routes. Unlike floating routes, the administrative distances of load balancing routes are the same. Packets are distributed among these routes based on the balanced forwarding policy.

As shown in Figure 9-3, load balancing routes are configured respectively on R 1 and R 3 so that packets sent to the network segment of PC 3 or PC 1 are balanced between two routes, including a route through R 2 and a route through R 4.

- On R 1, configure two routes to the network segment of PC 3, including a route through R 2 and a route through R 4.
- On R 3, configure two routes to the network segment of PC 1, including a route through R 2 and a route through R 4.

Figure 9-3

Remarks	On the switch, the load is balanced based on the source IP address by default. Run the aggregateport load-balance command to configure the load balancing mode of ECMP route.
----------------	--

Deployment

- Configure the address and subnet mask of each interface.
- Configure static routes on R 1, R 2, R 3, and R 4.
- Configure the load balancing policy on R 1 and R 3.

9.2.4 Correlation of Static Routes with Track or BFD

Scenario

When the floating static routes or load balancing static routes are configured, the static routes may fail to sense the route failures if the line is faulty but the interface status is normal. To resolve this problem, the device needs to check whether the next hop of a static route is reachable. If the next hop is not reachable, the device can switch the traffic to the standby route.

You can use the Track or BFD function to check whether the next hop of a static route is reachable. The following scenario takes BFD as an example.

! You can use only one of the Track and BFD functions at a time.

As shown in Figure 9-4, to prevent communication interruption caused by a line failure between R 1 and R 3, you can configure a floating static route respectively on R 1 and R 3, and correlate static routes with BFD.

- On R 1, configure two routes to the network segment of PC 3, including a route through R 3 (default distance = 1) and a route through R 2 (default distance = 2). BFD is enabled on the first route to check whether the next hop 1.1.13.3 is reachable, and on the second route to check whether the next hop 1.1.12.2 is reachable.
- On R 3, configure two routes to the network segment of PC 1, including a route through R 1 (default distance = 1) and a route through R 2 (default distance = 2). BFD is enabled on the first route to check whether the next hop 1.1.13.1 is reachable, and on the second route to check whether the next hop 1.1.23.2 is reachable.

Figure 9-4

Deployment

- Configure the address and subnet mask of each interface.
- Configure the BFD parameters on each interface.
- Configure static routes and correlate these static routes with BFD on R 1, R 2, and R 3.

9.2.5 Fast Reroute of Static Routes

Scenario

To accelerate route switching and shorten the communication interruption time when no dynamic routing protocol is configured, you can either correlate static routes with Track or BFD to check whether the next hop is reachable. In addition, you can or configure fast reroute to further improve the convergence performance.

As shown in Figure 9-5, to prevent communication interruption caused by a line failure between R 1 and R 3, you can configure static fast reroute respectively on R 1 and R 3. Normally, packets are forwarded on the path between R 1 and R 3. When the link on this route is down, packets are automatically rerouted to R 2.

- On R 1, configure a route with the exit interface set to Gi0/3 and the next hop set to 1.1.13.3, and a standby route with the exit interface set to Gi0/2 and the next hop set to 1.1.12.2.
- On R 3, configure a route with the exit interface set to Gi0/1 and the next hop set to 1.1.13.1, and a standby route with the exit interface set to Gi0/2 and the next hop set to 1.1.23.2.

Figure 9-5

Deployment

- Configure the address and subnet mask of each interface.
- Configure static routes on R 1, R 2, and R 3.
- Configure static fast reroute on R 1, R 2, and R 3.

9.3 Features

Feature	Description
Route Computation	Generate a valid route on a device.
Optimal Route Selection	Select an optimal route to forward packets.
Default Route	Forward all packets and help reduce the size of a routing table.
Route Reliability	Quickly detect a route failure and recover communication.

9.3.1 Route Computation

Routing Function

Routing functions are classified into IPv4 and IPv6 routing functions. If the routing functions are disabled, a device is equivalent to a host and cannot forward routes.

Dynamic Route

A dynamic routing protocol learns remote routes and dynamically updates routes by exchanging routes with neighbors. If a neighbor is the next hop of a route and this neighbor fails, the route fails as well.

Static Route

On a network with a simple topology, you can configure only static routes to implement network interworking. Appropriate configuration and use of static routes can improve the network performance and guarantee the bandwidth for important network applications.

Whether a static route is active is computed based on the status of the local interface. When the exit interface of a static route is located at layer 3 (L3) and is in Up status (the link status is Up and the IP address is configured), this route is active and can be used for packet forwarding.

A static route can go across VPN routing & forwarding (VRF) instances. The next hop or exit interface of a static route of VRF 1 can be configured on VRF 2.

9.3.2 Optimal Route Selection

Administrative Distance

When multiple routing protocols generate routes to the same destination, the priorities of these routes can be determined based on the administrative distance. A smaller administrative distance indicates a higher priority.

Equal-Cost Route

If multiple routes to the same destination have different next hops but the same administrative distance, these routes are mutually equal-cost routes. Packets are distributed among these routes to implement load balancing based on the balanced forwarding policy.

On a specific device, the total number of equal-cost routes is limited. Routes beyond the limit do not participate in packet forwarding.

Floating Route

If multiple routes to the same destination have different next hops and different administrative distances, these routes are mutually floating routes. The route with the smallest administrative distance will be first selected for packet forwarding. If this route fails, a route with a larger administrative distance is further selected for forwarding, thus preventing communication interruption caused by a network line failure.

9.3.3 Default Route

In the forwarding routing table, the route with the destination network segment 0.0.0.0 and the subnet mask 0.0.0.0 is the default route. Packets that cannot be forwarded by other routes will be forwarded by the default route. The default route can be statically configured or generated by a dynamic routing protocol.

Default Gateway

On a L2 switch, the **ip default gateway** command is configured to generate a default route.

Static Default Route

On a L3 switch, a static route with the network segment 0.0.0.0 and the subnet mask 0.0.0.0 is configured to generate the default route.

Default Network

The default network is configured to generate a default route. If the **ip default-network** command is configured to specify a network (a classful network, such as a Class A, B, or C network), and this network exists in the routing table, the router will use this network as the default network and the next hop of this network is the default gateway. As the network specified by the **ip default-network** command is a classful one, if this command is used to identify a subnet in a classful network, the router automatically generates a static route of the classful network instead of any default route.

9.3.4 Route Reliability

When a device on a network is faulty, some routes become unreachable, resulting in traffic interruption. If connectivity of the next hop can be detected in real time, the route can be re-computed when a fault occurs, or traffic can be switched over to the standby route.

Correlation with Track

A track object is an abstract concept. It can be used to trace whether an IP address is reachable or whether an interface is up. If a dynamic routing protocol or a static route is correlated with the Track function, the dynamic routing protocol or the static route can quickly learn whether the next hop is reachable so as to respond quickly.

Correlation with BFD

The BFD protocol provides a light-load and fast method for detecting the connectivity of the forwarding path between two adjacent routers. If a dynamic routing protocol or a static route is correlated with the BFD function, the dynamic routing protocol or the static route can quickly learn whether the next hop is reachable so as to respond quickly.

 The detection performance of BFD is better than that of Track.

Fast Reroute

Fast reroute provides a standby route. When a dynamic routing protocol or a static route detects that the next hop is unreachable, it immediately switches traffic over to the standby route to recovery communication.

9.4 Configuration

Configuration Item	Description and Command	
Configuring a Static Route	 (Mandatory) It is used to configure a static route entry.	
	ip route	Configures an IPv4 static route.
	ipv6 route	Configures an IPv6 static route.
Configuring a Default Route	 (Optional) It is used to configure the default gateway.	
	ip default gateway	Configures an IPv4 default gateway on a L2 device.

Configuration Item	Description and Command	
	ipv6 default gateway	Configures an IPv6 default gateway on a L2 device.
	ip route 0.0.0.0 0.0.0.0 gateway	Configures an IPv4 default gateway on a L3 device.
	ipv6 route ::/0 ipv6-gateway	Configures an IPv6 default gateway on a L3 device.
	ip default network	Configures an IPv4 default network on a L3 device.
Configuring Route Limitations	 (Optional) It is used to limit the number of equal-cost routes and number of static routes, or disable routing.	
	maximum-paths	Configures the maximum number of equal-cost routes.
	ip static route-limit	Configures the maximum number of IPv4 static routes.
	ipv6 static route-limit	Configures the maximum number of IPv6 static routes.
	no ip routing	Disables IPv4 routing.
	noipv6 unicast-routing	Disables IPv6 routing.
	no ip route static inter-vrf	Prohibits static routing across VRFs.
Correlating a Static Route with BFD	 (Optional) It is used to correlate a static route with BFD.	
	ip route static bfd	Correlates an IPv4 static route with BFD.
	ipv6 route static bfd	Correlates an IPv6 static route with BFD.
Configure Static Fast Reroute	 (Optional) It is used to configure static fast reroute.	
	route-map	Configures a route map.
	set fast-reroute backup-nexthop	Configures the standby interface and standby next hop for fast reroute.
	ip fast-reroute	Configures static fast reroute.

9.4.1 Configuring a Static Route

Configuration Effect

- Generate a static route in the routing table. Use the static route to forward packets to a remote network.

Notes

- Static routes cannot be configured on a L2 switch.

- If the **no ip routing** command is configured on a L3 switch, you cannot configure IPv4 static routes on this switch, and existing IPv4 static routes will also be deleted. Before the device is restarted, reconfiguring the **ip routing** command can recover the deleted IPv4 static routes. After the device is restarted, deleted IPv4 static routes cannot be recovered.
- If the **no ipv6 unicast-routing** command is configured on a L3 switch, you cannot configure IPv6 static routes on this switch, and existing IPv6 static routes will also be deleted. Before the device is restarted, reconfiguring the **ipv6 unicast-routing** command can recover the deleted IPv6 static routes. After the device is restarted, deleted IPv6 static routes cannot be recovered.
- To correlate a static route with the Track function, you must run the **track** command to configure a track object.

Configuration Steps

▾ Configuring a Static IPv4 Route

Configure the following command on an IPv4-enabled router.

Command	ip route [<i>vrf vrf_name</i>] <i>network</i> / <i>net-mask</i> { <i>ip-address</i> <i>interface</i> [<i>ip-address</i>]} [<i>distance</i>] [tag <i>tag</i>] [permanent track <i>object-number</i>] [weight <i>number</i>] [description <i>description-text</i>] [disabled enabled] [global]	
Parameter Description	vrf <i>vrf_name</i>	(Optional) Indicates the routing VRF, which can be a single-protocol IPv4 VRF or a multi-protocol VRF of a configured IPv4 address family. The VRF is a global VRF by default.
	<i>network</i>	Indicates the address of the destination network.
	<i>net-mask</i>	Indicates the mask of the destination network.
	<i>ip-address</i>	(Optional) Indicates the next-hop address of the static route. You must specify at least one of <i>ip-address</i> and <i>interface</i> , or both of them. If <i>ip-address</i> is not specified, a static direct route is configured.
	<i>interface</i>	(Optional) Indicates the next-hop exit interface of the static route. You must specify at least one of <i>ip-address</i> and <i>interface</i> , or both of them. If <i>interface</i> is not specified, a recursive static direct route is configured. The exit interface is obtained by the next hop in the routing table.
	<i>distance</i>	(Optional) Indicates the administrative distance of the static route. The administrative distance is 1 by default.
	tag <i>tag</i>	(Optional) Indicates the tag of the static route. The tag is 0 by default.
	permanent	(Optional) Indicates the flag of the permanent route. The static route is not a permanent route by default.
	track <i>object-number</i>	(Optional) Indicates correlation with Track. <i>object-number</i> indicates the ID of the track object. By default, the static route is not correlated with the Track function.
	weight <i>number</i>	(Optional) Indicates the weight of the static route. The weight is 1 by default.
	description <i>description-text</i>	(Optional) Indicates the description of the static route. By default, no description is configured. <i>description-text</i> is a string of one to 60 characters.
	disabled/enabled	(Optional) Indicates the enable flag of the static route. The flag is enabled by default.
	global	(Optional) Indicates that the next hop belongs to a global VRF. By default, the VRF of

	the next hop is the same as the VRF specified by <i>vrf name</i> .
Defaults	By default, no static route is configured.
Command Mode	Global configuration mode
Usage Guide	The simplest configuration of this command is ip route <i>networknet-maskip-address</i> . If the static route is correlated with Track and the down status of the trace object is detected, the static route is not active and does not participate in packet forwarding.

➤ **Configuring an IPv6 Static Route**

Configure the following command on an IPv6-enabled router.

Command	ipv6 route [<i>vrf vrf-name</i>] <i>ipv6-prefix/prefix-length</i> { <i>ipv6-address</i> [nexthop-vrf { <i>vrf-name1</i> default }] <i>interface</i> [<i>ipv6-address</i> [nexthop-vrf { <i>vrf-name1</i> default }]] } [<i>distance</i>] [weightnumber] [description <i>description-text</i>]	
Parameter Description	<i>vrf vrf-name</i>	(Optional) Indicates the routing VRF, which must be a multi-protocol VRF of a configured IPv6 address family. The VRF is a global VRF by default.
	<i>ipv6-prefix</i>	Indicates the IPv6 prefix, which must comply with the address expression specified in RFC4291.
	<i>prefix-length</i>	Indicates the length of the IPv6 prefix. Note that a slash (/) must be added in front of the length.
	<i>ipv6-address</i>	(Optional) Indicates the next-hop address of the static route. You must specify at least one of <i>ipv6-address</i> and <i>interface</i> , or both of them. If <i>ipv6-address</i> is not specified, a static direct route is configured.
	<i>interface</i>	(Optional) Indicates the next-hop exit interface of the static route. You must specify at least one of <i>ipv6-address</i> and <i>interface</i> , or both of them. If <i>interface</i> is not specified, a recursive static direct route is configured. The exit interface is obtained by the next hop in the routing table.
	nexthop-vrf <i>vrf-name1</i>	(Optional) Indicates the routing VRF of the next hop, which must be a multi-protocol VRF of a configured IPv6 address family. By default, the VRF of the next hop is the same as the VRF specified by the VRF name. nexthop-vrf default indicates that the VRF of the next shop is a global VRF.
	<i>distance</i>	(Optional) Indicates the administrative distance of the static route. The administrative distance is 1 by default.
	weight number	(Optional) Indicates the weight of the static route, which must be specified when you configure equal-cost routes. The weight ranges from 1 to 8. When the weights of all equal-costroutes of a route are summed up, the sum cannot exceed the maximum number of equal-cost routes that can be configured for the route. Weighting of equal-cost routes of a route indicates the traffic ratio of these routes. The weight is 1 by default.
	description <i>descri</i> <i>ption-text</i>	(Optional) Indicates the description of the static route. By default, no description is configured. <i>description-text</i> is a string of one to 60 characters.

Defaults	By default, no static route is configured.
Command Mode	Global configuration mode
Usage Guide	The simplest configuration of this command is ipv6 route <i>ipv6-prefix / prefix-length</i> <i>ipv6-address</i> .

Verification

- Run the **show ip route** command to display the IPv4 routing table and check whether the configured IPv4 static route takes effect.
- Run the **show ipv6 route** command to display the IPv6 routing table and check whether the configured IPv6 static route takes effect.

Configuration Example

Configuring Static Routes to Implement Interworking of the IPv4 Network

<p>Scenario Figure 9-6</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure interface addresses on each device.
<p>R1</p>	<pre> R1#configure terminal R1(config)#interface gigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)# ip address 1.1.1.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/2 R1(config-if-GigabitEthernet 0/2)# ip address 1.1.12.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/3 R1(config-if-GigabitEthernet 0/3)# ip address 1.1.13.1 255.255.255.0 </pre>

<p>R2</p>	<pre>R2#configure terminal R2(config)#interface gigabitEthernet 0/0 R2(config-if-GigabitEthernet 0/0)# ip address 1.1.2.1 255.255.255.0 R2(config-if-GigabitEthernet 0/0)# exit R2(config)#interface gigabitEthernet 0/1 R2(config-if-GigabitEthernet 0/1)# ip address 1.1.12.2 255.255.255.0 R2(config-if-GigabitEthernet 0/0)# exit R2(config)#interface gigabitEthernet 0/3 R2(config-if-GigabitEthernet 0/3)# ip address 1.1.23.2 255.255.255.0</pre>
<p>R3</p>	<pre>R3#configure terminal R3(config)#interface gigabitEthernet 0/0 R3(config-if-GigabitEthernet 0/0)# ip address 1.1.3.1 255.255.255.0 R3(config-if-GigabitEthernet 0/0)# exit R3(config)#interface gigabitEthernet 0/1 R3(config-if-GigabitEthernet 0/1)# ip address 1.1.13.3 255.255.255.0 R3(config-if-GigabitEthernet 0/0)# exit R3(config)#interface gigabitEthernet 0/2 R3(config-if-GigabitEthernet 0/2)# ip address 1.1.23.3 255.255.255.0</pre>
	<ul style="list-style-type: none"> ● Configure static routes on each device.
<p>R1</p>	<pre>R1#configure terminal R1(config)#ip route 1.1.2.0 255.255.255.0 GigabitEthernet 0/2 1.1.12.2 R1(config)# ip route 1.1.3.0 255.255.255.0 GigabitEthernet 0/3 1.1.13.3</pre>
<p>R2</p>	<pre>R2#configure terminal R2(config)#ip route 1.1.1.0 255.255.255.0 GigabitEthernet 0/1 1.1.12.1 R2(config)# ip route 1.1.3.0 255.255.255.0 GigabitEthernet 0/3 1.1.23.3</pre>

Common Errors

- The link on the interface is not up.
- No IP address is configured for the interface.

- The static route is correlated with Track, but the track object is not configured.

9.4.2 Configuring a Default Route

Configuration Effect

- Generate a default route in the routing table. The default route is used to forward packets that cannot be forwarded by other routes.

Notes

- On a L2 switch, run the **ip default gateway** or **ipv6 default gateway** command to configure the default gateway.
- On a L3 switch, run the **ip route 0.0.0.0 0.0.0.0 gateway** or **ipv6 route ::/0 ipv6-gateway** command to configure the default gateway.
- If the **no ip routing** or **no ipv6 unicast-routing** command is configured on a L3 switch, you can run the **ip default gateway** or **ipv6 default gateway** command to configure the default gateway.

Configuration Steps

▾ Configuring the IPv4 Gateway on a L2 Switch

Command	ip default-gateway <i>gateway</i>	
Parameter	<i>gateway</i>	indicates the IPv4 gateway address.
Description		
Defaults	By default, no static default route is configured.	
Command Mode	Global configuration mode	
Usage Guide	N/A	

▾ Configuring the IPv6 Gateway on a L2 Switch

Command	ipv6 default-gateway <i>gateway</i>	
Parameter	<i>gateway</i>	indicates the IPv6 gateway address.
Description		
Defaults	By default, no static default route is configured.	
Command Mode	Global configuration mode	
Usage Guide	N/A	

▾ Configuring the IPv4 Default Gateway on a L3 Switch

Command	ip route [vrf <i>vrf_name</i>]0.0.0.0 0.0.0.0{<i>ip-address</i> <i>interface</i> [<i>ip-address</i>]} [<i>distance</i>] [tag <i>tag</i>] [permanent] [weight <i>number</i>] [description <i>description-text</i>] [disabled enabled] [global]	
Parameter Description	vrf <i>vrf_name</i>	(Optional) Indicates the routing VRF, which can be a single-protocol IPv4 VRF or a multi-protocol VRF of a configured IPv4 address family. The VRF is a global VRF by

		default.
	0.0.0.0	Indicates the address of the destination network.
	0.0.0.0	Indicates the mask of the destination network.
	<i>ip-address</i>	(Optional) Indicates the next-hop address of the static route. You must specify at least one of <i>ip-address</i> and <i>interface</i> , or both of them. If <i>ip-address</i> is not specified, a static direct route is configured.
	<i>interface</i>	(Optional) Indicates the next-hop exit interface of the static route. You must specify at least one of <i>ip-address</i> and <i>interface</i> , or both of them. If <i>interface</i> is not specified, a recursive static direct route is configured. The exit interface is obtained by the next hop in the routing table.
	<i>distance</i>	(Optional) Indicates the administrative distance of the static route. The administrative distance is 1 by default.
	<i>tag</i>	(Optional) Indicates the tag of the static route. The tag is 0 by default.
	permanent	(Optional) Indicates the flag of the permanent route. The static route is not a permanent route by default.
	weight number	(Optional) Indicates the weight of the static route. The weight is 1 by default.
	description <i>description-text</i>	(Optional) Indicates the description of the static route. By default, no description is configured. <i>description-text</i> is a string of one to 60 characters.
	disabled /enabled	(Optional) Indicates the enable flag of the static route. The flag is enabled by default.
	global	(Optional) Indicates that the next hop belongs to a global VRF. By default, the VRF of the next hop is the same as the VRF specified by <i>vrf name</i> .
Defaults	By default, no static default route is configured.	
Command Mode	Global configuration mode	
Usage Guide	The simplest configuration of this command is ip route 0.0.0.0 0.0.0.0 ip-address .	

📌 Configuring the IPv6 Default Gateway on a L3 Switch

Command	ipv6 route [vrf vrf-name] ::/0 { ipv6-address [nexthop-vrf {vrf-name1 default}] interface [ipv6-address [nexthop-vrf {vrf-name1 default}]] } [distance] [weight number] [description description-text]	
Parameter Description	vrf vrf-name	(Optional) Indicates the routing VRF, which must be a multi-protocol VRF of a configured IPv6 address family. The VRF is a global VRF by default.
	::	Indicates the IPv6 prefix, which must comply with the address expression specified in RFC4291.
	0	Indicates the length of the IPv6 prefix. Note that a slash (/) must be added in front of the length.
	<i>ipv6-address</i>	(Optional) Indicates the next-hop address of the static route. You must specify at least one of <i>ipv6-address</i> and <i>interface</i> , or both of them. If <i>ipv6-address</i> is not specified, a static direct route is configured.
	<i>interface</i>	(Optional) Indicates the next-hop exit interface of the static route. You must specify at least one of <i>ipv6-address</i> and <i>interface</i> , or both of them. If <i>interface</i> is not specified, a recursive static direct route is configured. The exit interface is obtained by the next

		hop in the routing table.
	nexthop-vrf <i>vrf-name1</i>	(Optional) Indicates the routing VRF of the next hop, which must be a multi-protocol VRF of a configured IPv6 address family. By default, the VRF of the next hop is the same as the VRF specified by <i>vrf name</i> . nexthop-vrf default indicates that the VRF of the next hop is a global VRF.
	<i>distance</i>	(Optional) Indicates the administrative distance of the static route. The administrative distance is 1 by default.
	weight <i>number</i>	(Optional) Indicates the weight of the static route, which must be specified when you configure equal-cost routes. The weight ranges from 1 to 8. When the weights of all equal-cost routes of a route are summed up, the sum cannot exceed the maximum number of equal-cost routes that can be configured for the route. Weighting of equal-cost routes of a route indicates the traffic ratio of these routes. The weight is 1 by default.
	description <i>descript</i> <i>ion-text</i>	(Optional) Indicates the description of the static route. By default, no description is configured. <i>description-text</i> is a string of one to 60 characters.
Defaults	By default, no static default route is configured.	
Command Mode	Global configuration mode	
Usage Guide	The simplest configuration of this command is ipv6 route <i>:::0 ipv6-gateway</i> .	

📌 Configuring the IPv4 Default Network on a L3 Switch

Command	ip default-network <i>network</i>	
Parameter Description	<i>network</i>	Indicates the address of the network. (The network must be a Class A, B, or C network.)
Defaults	By default, no default network is configured.	
Command Mode	Global configuration mode	
Usage Guide	If the network specified by the ip default-network command exists, a default route is generated and the next hop to this network is the default gateway. If the network specified by the ip default-network command does not exist, the default route is not generated.	

Verification

- On a L2 switch (or a L3 switch where routing is disabled), run the **show ip redirects** or **show ipv6 redirects** command to display the default gateway.
- On a L3 switch where routing is enabled, run the **show ip route** or **show ipv6 route** command to display the default route.

Configuration Example

📌 Configuring IPv4 Default Routes on L3 Switches to Implement Network Interworking

<p>Scenario Figure 9-9</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure IP addresses on L3 devices.
<p>R1</p>	<pre>R1#configure terminal R1(config)#interface gigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)# ip address 1.1.1.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/1 R1(config-if-GigabitEthernet 0/1)# ip address 1.1.12.1 255.255.255.0 R1(config-if-GigabitEthernet 0/1)# exit</pre>
<p>R2</p>	<pre>R2#configure terminal R2(config)#interface gigabitEthernet 0/0 R2(config-if-GigabitEthernet 0/0)# ip address 1.1.2.1 255.255.255.0 R2(config-if-GigabitEthernet 0/0)# exit R2(config)#interface gigabitEthernet 0/1 R2(config-if-GigabitEthernet 0/1)# ip address 1.1.12.2 255.255.255.0 R2(config-if-GigabitEthernet 0/1)# exit</pre>
<p>R1</p>	<ul style="list-style-type: none"> ● Configure an IPv6 default gateway on R 1. <pre>R1#configure terminal R1(config)#ip route 0.0.0.0 0.0.0.0 GigabitEthernet 0/1 1.1.12.2</pre>
<p>R2</p>	<pre>R2#configure terminal R2(config)#ip route 0.0.0.0 0.0.0.0 GigabitEthernet 0/1 1.1.12.1</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● Display the routing table.
<p>R1</p>	<pre>R1# show ip route Codes: C - Connected, L - Local, S - Static</pre>

```

R - RIP, O - OSPF, B - BGP, I - IS-IS

N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2

E1 - OSPF external type 1, E2 - OSPF external type 2

SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2

IA - Inter area, * - candidate default

Gateway of last resort is 1.1.12.2

S* 0.0.0.0/0 [1/0] via 1.1.12.2, GigabitEthernet 0/1

C 1.1.1.0/24 is directly connected, GigabitEthernet 0/0

C 1.1.1.1/32 is local host.

C 1.1.12.0/24 is directly connected, GigabitEthernet 0/1

C 1.1.12.1/32 is local host.
    
```

9.4.3 Configuring Route Limitations

Configuration Effect

- Limit the number of equal-cost routes and number of static routes, or disable routing.

Notes

Route limitations cannot be configured on a L2 switch.

Configuration Steps

▾ Configuring the Maximum Number of Equal-Cost Routes

Command	maximum-paths <i>number</i>	
Parameter	<i>number</i>	Indicates the maximum number of equal-cost routes. The value ranges from 1 to 32.
Description		
Defaults	By default, the number of equal cost routes is 32.	
Command Mode	Global configuration mode	
Usage Guide	Run this command to configure the maximum number of next hops in the equal-cost route. In load balancing mode, the number of routes on which traffic is balanced does not exceed the configured number of equal-cost routes.	

▾ Configuring the Maximum Number of IPv4 Static Routes

Command	ip static route-limit <i>number</i>	
Parameter	<i>number</i>	Indicates the upper limit of routes. The value ranges from 1 to 10,000.

Description	
Defaults	By default, a maximum of 1,024 IP static routes can be configured.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure the maximum number of IPv4 static routes. If the maximum number of IPv4 static routes is reached, no more IPv4 static route can be configured.

↘ Configuring the Maximum Number of IPv6 Static Routes

Command	ipv6 static route-limit <i>number</i>
Parameter Description	<i>number</i> Indicates the upper limit of routes. The value ranges from 1 to 10,000.
Defaults	By default, a maximum of 1,000 IPv6 static routes can be configured.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure the maximum number of IPv6 static routes. If the maximum number of IPv6 static routes is reached, no more IPv6 static route can be configured.

↘ Disabling IPv4 Routing

Command	no ip routing
Parameter Description	N/A
Defaults	By default, IPv4 routing is enabled.
Command Mode	Global configuration mode
Usage Guide	Run this command to disable IPv4 routing. If the device functions only as a bridge or a voice over IP (VoIP) gateway, the device does not need to use the IPv4 routing function of the RGOS software. In this case, you can disable the IPv4 routing function of the RGOS software.

↘ Disabling IPv6 Routing

Command	no ipv6 unicast-routing
Parameter Description	N/A
Defaults	By default, IPv6 routing is enabled.
Command Mode	Global configuration mode
Usage Guide	Run this command to disable IPv6 routing. If the device functions only as a bridge or a VoIP gateway, the device does not need to use the IPv6 routing function of the RGOS software. In this case, you can disable the IPv6 routing function of the RGOS software.

↘ Prohibiting Static Routing Across VRFs

Command	no ip route static inter-vrf
Parameter	N/A
Description	
Defaults	By default, static IP or IPv6 routing across VRFs is allowed.
Command Mode	Global configuration mode
Usage Guide	Run this command to prohibit static IP routing across VRFs. After this command is configured, the static IP route across VRFs is not active and cannot be participate in packet forwarding.

Verification

Run the **show run** command to display the configuration file and verify that the preceding configuration commands exist.

Configuration Example

Configuring at Most Two Static Routing Limitations

<p>Scenario Figure 9-10</p>	
<p>Configuration Steps</p>	<p>On R 1, configure the IP addresses, static routes, and maximum number of static routes.</p>
	<pre> R1#configure terminal R1(config)#interface gigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)# ip address 1.1.1.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/2 R1(config-if-GigabitEthernet 0/2)# ip address 1.1.12.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit </pre>

	<pre> R1(config)#interface gigabitEthernet 0/3 R1(config-if-GigabitEthernet 0/3)# ip address 1.1.13.1 255.255.255.0 R1(config-if-GigabitEthernet 0/3)# exit R1(config)#ip route 1.1.3.0 255.255.255.0 1.1.13.3 R1(config)#ip route 1.1.4.0 255.255.255.0 1.1.12.2 R1(config)#ip route 1.1.5.0 255.255.255.0 1.1.12.2 R1(config)#ip static route-limit 2 % Exceeding maximum static routes limit. </pre>
Verification	<ul style="list-style-type: none"> ● Check the static routes that really take effect in the routing table.
	<pre> R1(config)# show ip route Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area, * - candidate default Gateway of last resort is no set C 1.1.1.0/24 is directly connected, GigabitEthernet 0/0 C 1.1.1.1/32 is local host. S 1.1.3.0/24 [1/0] via 1.1.13.3 S 1.1.4.0/24 [1/0] via 1.1.12.2 C 1.1.12.0/24 is directly connected, GigabitEthernet 0/2 C 1.1.12.1/32 is local host. C 1.1.13.0/24 is directly connected, GigabitEthernet 0/3 C 1.1.13.1/32 is local host. </pre>

9.4.4 Correlating a Static Route with BFD

Configuration Effect

- A static route can quickly detect a route failure with the help of BFD.

Notes

- BFD correlation cannot be configured on a L2 switch.
- You must configure a static route.
- You must configure the BFD session parameters by running the **bfd interval xmin_rx xmultiplier x** command.

Configuration Steps

✚ Correlating an IPv4 Static Route with BFD

Command	ip route static bfd [vrf vrf-name] <i>interface-type interface-number gateway</i> [source ip-address]	
Parameter Description	vrf vrf-name	(Optional) Indicates the name of the VRF to which the static route belongs. The VRF is a global VRF by default.
	<i>interface-type</i>	Indicates the interface type.
	<i>interface-number</i>	Indicates the interface number.
	<i>gateway</i>	Indicates the IP address of the gateway, that is, the neighbor IP address of BFD. If the next hop of the static route is this neighbor, BFD is used to check the connectivity of the forwarding path.
	source ip-address	(Optional) Indicates the source IP address used for the BFD session. This parameter must be configured if the neighbor IP address involves multiple hops. By default, the source IP address is not specified.
Defaults	By default, a static route is not correlated with BFD.	
Command Mode	Global configuration mode	
Usage Guide	Run this command to correlate an IPv4 static route with BFD. If the down status of the BFD session is detected, the IPv4 static route is not active and does not participate in packet forwarding.	

✚ Correlating an IPv6 Static Route with BFD

Command	ipv6 route static bfd [vrf vrf-name] <i>interface-type interface-number gateway</i> [source ipv6-address]	
Parameter Description	vrf vrf-name	(Optional) Indicates the name of the VRF to which the static route belongs. The VRF is a global VRF by default.
	<i>interface-type</i>	Indicates the interface type.
	<i>interface-number</i>	Indicates the interface number.
	<i>gateway</i>	Indicates the IP address of the gateway, that is, the neighbor IP address of BFD. If the next hop of the static route is this neighbor, BFD is used to check the connectivity of the forwarding path.
	source ip-address	(Optional) Indicates the source IP address used for the BFD session. This parameter must be configured if the neighbor IP address involves multiple hops. By default, the neighbor IP address of the BFD session is a single hop, and the source IP address is not used.
Defaults	By default, a static route is not correlated with BFD.	
Command	Global configuration mode	

Mode	
Usage Guide	Run this command to correlate an IPv6 static route with BFD. If the down status of the BFD session is detected, the IPv6 static route is not active and does not participate in packet forwarding.

Verification

- Run the **show bfd neighbors** command to display information about BFD neighbors.
- Run the **show ip route static bfd** or **show ipv6 route static bfd** command to display information about correlation of static routes with BFD.

Configuration Example

Correlating an IPv4 Static Route with BFD

<p>Scenario Figure 9-11</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure a BFD session on the interconnect interface between R 1 and R 2. ● Configure static routes on R 1 and R 2, and specify the exit interface or next hop as the interworking interface. ● Correlate static routes with BFD on R 1 and R 2, and check the connectivity of the next hops of static routes.
<p>R1</p>	<pre>R1#configure terminal R1(config)#interface gigabitEthernet 0/1 R1(config-if-GigabitEthernet 0/1)# no switchport R1(config-if-GigabitEthernet 0/1)# ip address 1.1.12.1 255.255.255.0 R1(config-if-GigabitEthernet 0/1)#bfd interval 50 min_rx 50 multiplier 3 R1(config-if-GigabitEthernet 0/1)# exit R1(config)# ip route 1.1.2.0 255.0.0.0 FastEthernet 0/1 1.1.12.2 R1(config)#ip route static bfd gigabitEthernet 0/1 1.1.12.2</pre>
<p>R2</p>	<pre>R2#configure terminal R1(config)#interface gigabitEthernet 0/1 R1(config-if-GigabitEthernet 0/1)# no switchport R1(config-if-GigabitEthernet 0/1)# ip address 1.1.12.2 255.255.255.0</pre>

	<pre>R1(config-if-GigabitEthernet 0/1)#bfd interval 50 min_rx 50 multiplier 3 R1(config-if-GigabitEthernet 0/1)# exit R1(config)# ip route 1.1.1.0 255.0.0.0 FastEthernet 0/1 1.1.12.1 R1(config)#ip route static bfd gigabitEthernet 0/1 1.1.12.1</pre>
Verification	<ul style="list-style-type: none"> ● Display the status of BFD neighbors. ● Display the static routes correlated with BFD.
R1	<pre>R1#show bfd neighbors OurAddr NeighAddr LD/RD RH/RS Holddown(mult) State Int 1.1.12.1 1.1.12.2 8192/0 Up 0(3) Up GigabitEthernet 0/1 R1#show ip route static bfd S 1.1.2.0/24 via 1.1.12.2, GigabitEthernet 0/1, BFD state is Up</pre>

Common Errors

- The link on the interface is not up.
- No IP address is configured for the interface.
- No BFD session parameters are configured.
- No static route is configured.

9.4.5 Configure Static Fast Reroute

Configuration Effect

- Configure and enable static fast reroute.

Notes

- Static fast reroute cannot be configured on a L2 switch.
- You must configure a static route.
- You must configure a route map.

Configuration Steps

📌 Defining a Standby Route in the Route Map

Command	set fast-reroute backup-nexthop <i>interface ip-address</i>	
Parameter	<i>interface</i>	Indicates the standby exit interface.

Description	<i>ip-address</i>	Indicates the standby next hop.
Defaults	N/A	
Command Mode	Global configuration mode	
Usage Guide	<p>Run the route-map <i>name</i> [permit deny] <i>sequence</i> command to create a road map.</p> <p>Run the match command to define matching conditions.</p> <p>Run the set fast-reroute backup-nexthop <i>interface ip-address</i> command to define the standby exit interface and standby next hop.</p> <p>If a route meets matching conditions, a standby route is generated for this route. If the match command is not configured, standby routes are generated for any static route with the exit interface and next hop.</p>	

↘ **Enabling Fast Reroute and Referencing the Route Map**

Command	ip fast-reroute [vrf <i>vrf-name</i>] static route-map <i>route-map-name</i>	
Parameter Description	<i>vrf-name</i>	(Optional) Specifies a VRF. If the VRF is not specified, the command is executed on all VRFs.
	<i>route-map-name</i>	Indicates the name of the road map for the standby route.
Defaults	By default, static fast reroute is not configured.	
Command Mode	Global configuration mode	
Usage Guide	Run this command to enable fast reroute and reference the route map.	

Verification

Run the **show ip route fast-reroute** command to display the active and standby routes that take effect.

Configuration Example

↘ **Configuring Fast Re-Routing**

Configuration Steps	<p>On R 1, configure a static route to the network segment of PC 3, and the next hop of the exit interface is R 3.</p> <p>On R 1, configure static fast reroute. The next hop of the exit interface of the standby route is R2.</p>
	<pre> R1#configure terminal R1(config)#interface gigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)# ip address 1.1.1.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/2 R1(config-if-GigabitEthernet 0/2)# ip address 1.1.12.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/3 R1(config-if-GigabitEthernet 0/3)# ip address 1.1.13.1 255.255.255.0 R1(config-if-GigabitEthernet 0/3)# exit R1(config)# ip route 1.1.3.0 255.255.255.0 GigabitEthernet 0/3 1.1.13.3 R1(config)#route-map fast-reroute R1(config-route-map)# set fast-reroute backup-interface GigabitEthernet 0/2 backup-next-hop 1.1.12.2 R1(config-route-map)# exit R1(config)#ip fast-reroute static route-map fast-reroute </pre>
Verification	<p>Display the active and standby routes on R 1.</p> <pre> R1#show ip route fast-reroute Codes: C - connected, S - static, R - RIP, B - BGP O - OSPF, IA - OSPF inter area N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 ia - IS-IS inter area, * - candidate default Status codes: m - main entry, b - backup entry, a - active entry Gateway of last resort is no set S 1.1.3.0 /24 [ma] via 1.1.13.3, GigabitEthernet 0/3 </pre>

[b] via 1.1.12.2, GigabitEthernet 0/2

Common Errors

- The link on the interface is not up.
- No static route is configured.
- The matching conditions are not configured or are not properly configured in the road map.

9.5 Monitoring

Displaying

Description	Command
Displays the IPv4 routing table.	show ip route
Displays the IPv6 routing table.	show ipv6route

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs IPv4 route management.	debug nsm kernel ucast- v4
Debugs IPv6 route management.	debug nsm kernel ucast-v6
Debugs fast reroute management.	debug nsm kernel frr
Debugs default network management.	debug nsm kernel default-network
Debugs internal events of route management.	debug nsm events
Debugs sending of route management and routing protocol messages.	debug nsm packet send
Debugs receiving of route management and routing protocol messages.	debug nsm packet recv

10 Configuring Keys

10.1 Overview

Keys are a kind of parameters that are used in algorithms for conversion from plain text to cipher text or from cipher text to plain text.

Plain text and cipher text authentication are supported for packet authentication in a routing protocol, during which keys need to be used.

i At present, keys are used only for RIP and ISIS packet authentication.

10.2 Applications

Application	Description
RIP Authentication	RIP uses keys for packet authentication.

10.2.1 RIP Authentication

Scenario

Network devices run RIP and use the MD5 authentication mode to increase the protocol security.

Figure 10-1

Deployment

- Configure a key chain on A. Configure RIP to enable packet authentication and use the key chain.
- Configure a key chain on B. Configure RIP to enable packet authentication and use the key chain.

10.3 Features

Overview

Feature	Description
Key Chain	Provide a tool for authentication in a routing protocol.

10.3.1 Key Chain

Working Principle

A key chain may contain multiple different keys. Each key contains the following attributes:

- Key ID: Identifies a key. In the current key chain, keys and IDs are mapped in the one-to-one manner.
- Authentication string: Indicates a set of key characters used for verifying the consistency of authentication strings in a routing protocol.
- Lifetime: Specifies the lifetime of the current key for sending or receiving packets. Different authentication keys can be used in different periods.

Related Configuration

↘ [Creating a Key Chain and a Key](#)

In the global configuration mode, run the **key chain** *key-chain-name* command to define a key chain and enter the key chain configuration mode.

In the key chain configuration mode, run the **key** *key-id* command to define a key and enter the key chain key configuration mode.

↘ [Configuring an Authentication String](#)

In the key chain key configuration mode, run the **key-string** **[0|7]** *text* command to specify an authentication string.

- A plain text authentication string is configured by default. The value **0** indicates that a plain text authentication key is configured.
- The value **7** indicates that a cipher text authentication string is configured.
- The encryption authentication service is disabled by default. You can run the **service password-encryption** command to enable the encryption service to forcibly convert plain text authentication into cipher text.

↘ [Configuring Lifetime](#)

In the key chain key configuration mode, you can configure the lifetime of a key chain in the receiving and sending directions.

- **accept-lifetime** *start-time* { **infinite** | *end-time* | **duration** *seconds* }: Configures the lifetime of a key chain in the receiving direction.
- **send-lifetime** *start-time* { **infinite** | *end-time* | **duration** *seconds* }: Configures the lifetime of a key chain in the sending direction.

10.4 Configuration

Configuration	Description and Command
---------------	-------------------------

Configuring a Key Chain	 (Mandatory) It is used to create a key.	
	key chain	Creates a key chain.
	key	Configures a key ID.
	key-string	Configures a key string.
	accept-lifetime	Configures the lifetime in the receiving direction.
	send-lifetime	Configures the lifetime in the sending direction.

10.4.1 Configuring a Key Chain

Configuration Effect

- Define a key chain to be used by a routing protocol.

Notes

- A key chain can take effect only after it is associated with a routing protocol.

Configuration Steps

▾ **Creating a Key Chain**

- This configuration is mandatory if a key chain needs to be used.
- If there is no special requirement, you should perform this configuration on all routers for which routing protocol authentication needs to be performed.

▾ **Configuring a Key ID**

- This configuration is mandatory if a key chain needs to be used.
- If there is no special requirement, you should perform this configuration on all routers for which routing protocol authentication needs to be performed.

▾ **Configuring a Key String**

- This configuration is mandatory if a key chain needs to be used.
- If there is no special requirement, you should perform this configuration on all routers for which routing protocol authentication needs to be performed.

▾ **Configure the Lifetime in the Receiving Direction**

- Optional.
- If the lifetime in the sending direction is not configured, the key chain will be always effective.

▾ **Configure the Lifetime in the Sending Direction**

- Optional.

- If the lifetime in the sending direction is not configured, the key chain will be always effective.

Verification

- Use keys in a routing protocol and observe the neighborhood established by the routing protocol. If the keys are inconsistent, the neighborhood fails to be established.

Related Commands

▾ Configuring a Key Chain

Command	key chain <i>key-chain-name</i>
Parameter Description	<i>key-chain-name</i> : Indicates the name of a key chain.
Command Mode	Global configuration mode
Usage Guide	To make a key chain take effect, you must configure at least one key.

▾ Configuring a Key ID

Command	key <i>key-id</i>
Parameter Description	<i>key-id</i> : Indicates the authentication key ID in a key chain, ranging from 0 to 2,147,483,647.
Command Mode	Key chain configuration mode.
Usage Guide	-

▾ Configuring a Key Authentication String

Command	key-string [0 7] <i>text</i>
Parameter Description	0 : Specifies that the key is displayed in plain text. 7 : Specifies that the key is displayed in cipher text. <i>text</i> : Specifies the authentication string characters.
Command Mode	Key chain key configuration mode.
Usage Guide	-

▾ Configuring the Lifetime in the Sending Direction

Command	send-lifetime <i>start-time</i> { infinite <i>end-time</i> duration <i>seconds</i> }
Parameter Description	start-time : Indicates the start time of the lifetime. infinite : Indicates that the key is always effective. end-time : Indicates the end time of the lifetime, which must be later than start-time. duration seconds : Specifies the duration from the start time to the end time, ranging from 1 to 2,147,483,646.
Command	Key chain key configuration mode.

Mode	
Usage Guide	Run this command to define the lifetime of the key in the sending direction.

↘ **Configuring the Lifetime in the Receiving Direction**

Command	accept-lifetime <i>start-time</i> {infinite <i>end-time</i> duration <i>seconds</i> }
Parameter Description	<p>start-time: Indicates the start time of the lifetime.</p> <p>infinite: Indicates that the key is always effective.</p> <p>end-time: Indicates the end time of the lifetime, which must be later than start-time.</p> <p>duration seconds: Specifies the duration from the start time to the end time, ranging from 1 to 2,147,483,646.</p>
Command Mode	Key chain key configuration mode.
Usage Guide	Run this command to define the lifetime of the key in the receiving direction.

Configuration Example

↘ **Configuring a Key Chain and Using the Key Chain in RIP Packet Authentication**

<p>Scenario Figure 10-2</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure a key on all routers. ● Configure RIP on all routers. ● Enable RIP authentication on all routers.
<p>A</p>	<pre>A>enable A#configure terminal A(config)#key chain ripchain A(config-keychain)#key 1 A(config-keychain-key)#key-string Hello A(config-keychain-key)#accept-lifetime 16:30:00 Oct 1 2013 duration 43200 A(config-keychain-key)#send-lifetime 16:30:00 Oct 1 2013 duration 43200 A(config-keychain-key)#exit</pre>

	<pre>A(config-keychain)#key 2 A(config-keychain-key)#key-string World A(config-keychain-key)#accept-lifetime 04:00:00 Oct 2 2013 infinite A(config-keychain-key)#send-lifetime 04:00:00 Oct 2 2013 infinite A(config-keychain-key)#exit A(config)#interface gigabitEthernet 0/1 A(config-if)#ip address 192.168.27.1 255.255.255.0 A(config-if)#ip rip authentication key-chain ripchain A(config-if)#ip rip authentication mode md5 A(config-if)#exit A(config)#router rip A(config-router)#version 2 A(config-router)#network 192.168.27.0</pre>
B	<pre>B>enable B#configure terminal B(config)#key chain ripchain B(config-keychain)#key 1 B(config-keychain-key)#key-string Hello B(config-keychain-key)#accept-lifetime 16:30:00 Oct 1 2013 duration 43200 B(config-keychain-key)#send-lifetime 16:30:00 Oct 1 2013 duration 43200 B(config-keychain-key)#exit B(config-keychain)#key 2 B(config-keychain-key)#key-string World B(config-keychain-key)#accept-lifetime 04:00:00 Oct 2 2013 infinite B(config-keychain-key)#send-lifetime 04:00:00 Oct 2 2013 infinite B(config-keychain-key)#exit B(config)#interface gigabitEthernet 0/1 B(config-if)#ip address 192.168.27.2 255.255.255.0 B(config-if)#ip rip authentication key-chain ripchain B(config-if)#ip rip authentication mode md5 B(config-if)#exit</pre>

	<pre>B(config)#router rip B(config-router)#version 2 B(config-router)#network 192.168.27.0 B(config-router)#redistribute static</pre>
Verification	Run the show ip route rip command to check whether router A can receive an RIP route from router B.
A	<pre>A(config)#show ip route rip R 172.168.0.0/16 [120/1] via 192.168.27.2, 00:05:16, GigabitEthernet 0/1</pre>

Common Errors

- A key is not correctly associated with a routing protocol, which causes that authentication does not take effect.
- The keys configured on multiple routers are not consistent, which causes authentication failure.

10.5 Monitoring

Displaying

Description	Command
Displays the configurations of a key chain.	show key chain [<i>key-chain-name</i>]

11 Configuring Routing Policies

11.1 Overview

Routing policies are a policy set for changing the packet forwarding path or routing information and are often implemented by a filtering list and a route map. Routing policies are flexibly and widely applied in the following methods:

- Use a filtering list in a routing protocol to filter or modify routing information.
- Use a route map in a routing protocol to filter or modify routing information. Where, the route map can further use a filtering list.
- Use a route map in policy-based routing (PBR) to control packet forwarding or modify packet fields.

11.2 Applications

Application	Description
Route Filtering	Use a filtering list in a routing protocol to filter the routing information sent or received by the protocol.
Route Re-distribution	Use a route map in a routing protocol to filter or modify routing information and re-distribute RIP routes to OSPF. Only RIP routes with 4 hops can be re-distributed.
PBR	Use a route map in PBR to control packet forwarding or modify packet fields and specify optimum output interfaces for packets from different subnets.

11.2.1 Route Filtering

By default, a routing protocol advertises and learns all routing information. When a filtering list is used, the routing protocol advertises only required routes or receives only required routing information.

Scenario

Figure 11-1

As shown in Figure 11-1, router A has routes to 3 networks: 10.0.0.0, 20.0.0.0 and 30.0.0.0.

Configure a filtering list on the routers to achieve the following purposes:

- Filter the sent routing information on router A to filter routes that router A does not need to send.

- Filter the received routing information on router B to filter routes that router B does not need to learn.

Deployment

- Filter the sent routing information 30.0.0.0 on router A.
- Filter the received routing information 20.0.0.0 on router B to ensure that router B learns only routing information 10.0.0.0.

11.2.2 Route Re-distribution

By default, route re-distribution will re-distribute all routing information in a routing protocol to another routing protocol. All routing attributes will also be inherited. You can use a route map to perform conditional control for re-distribution between two routing protocols, including:

- Specify the range for re-distributing routes and re-distribute only routing information that meets certain rules.
- Set the attributes of routes generated by re-distribution.

Scenario

Figure 11-2

As shown in Figure 11-2, configure route re-distribution on the devices to achieve the following purposes:

- Re-distribute only RIP routes with 4 hops to OSPF.
- In the OSPF routing domain, the initial metric of this route is 40, the route type is the external route type-1 and the route tag value is set to 40.

Deployment

- Configure a route with 4 hops in the route map `rip_to_ospf`: match, and set the initial metric of this route to 40, the route type to the external route type-1 and the route tag value to 40.
- Configure route re-distribution to re-distribute RIP routes to OSPF and use the route map `rip_to_ospf`.

11.2.3 PBR

PBR is implemented by applying a route map including policies to interfaces and devices.

Similar to static routing, PBR is also manually configured, where recursive routing supports automatic update with network changes. As compared with static and dynamic routing, PBR is more flexible. Static and dynamic routing can forward packets only based on destination addresses. PBR can forward packets based on the source and destination addresses, packet length and input interface.

Scenario

Figure 11-3

Configure PBR on the layer-3 device DEV1 to achieve the following purposes:

- Packets from subnet 1 (200.24.16.0/24) are sent from GE0/1 first.
- Packets from subnet 2 (200.24.17.0/24) are sent from GE0/2 first.

Deployment

- Configure two different ACLs to match packets from subnets 1 and 2 respectively.
- Configure the route map RM_FOR_PBR: policy 10 is used to ensure that "packets from subnet 1 are sent from GE0/1 first"; policy 20 is used to ensure that "packets from subnet 2 are sent from GE0/2 first".
- Perform PBR for packets received from GE0/3 and use the route map RM_FOR_PBR.

11.3 Features

Overview

Feature	Description
Filtering List	Define a group of lists based on a route attribute, which can be used by a routing protocol for route filtering.
Route Map	A policy defines "if certain conditions are matched, you can perform certain processing actions".

11.3.1 Filtering List

Filtering lists are a group of lists defined based on a routing attribute and are a tool for filtering routing policies. Independent filtering lists are meaningless and can be used to filter routes only when they are applied in a routing protocol.

Working Principle

Based on different routing attributes, filtering lists are classified into the following types:

↘ Access Control List (ACL)

ACLs comprise IPv4 and IPv6 ACLs. When defining ACLs, you can specify IPv4/IPv6 addresses and masks to match the destination network segment or next-hop addresses of routing information.

For description about ACLs, see the *ACL Configuration Guide*.

↘ Address Prefix List (prefix-list)

Similar to ACLs, prefix-lists, including IPv4 prefix-lists and IPv6 prefix-lists, are used to match destination network segments of routing information during route filtering.

↘ AS-Path List

AS-path lists are used only for BGP. They are used to match AS paths during BGP route filtering.

↘ Community Attribute Filtering List (Community-List)

Community-lists are used only for BGP. They are used to match community attributes during BGP route filtering.

↘ Extended Community Attribute Filtering List (Extcommunity-List)

Extcommunity-lists are used only for BGP. They are used to match extended community attributes during BGP route filtering.

Related Configuration

↘ Creating an ACL

By default, no ACL is configured and no policy is set.

In the global configuration mode, run the **ip access-list { extended | standard } { id | name }** command to create an IPv4 ACL.

You can set multiple policies in an ACL, sorted by their sequence numbers. Policies have two working modes: permit and deny.

↘ Creating a Prefix-List

By default, no prefix-list is configured and no entry is set.

In the global configuration mode, run the **ip prefix-list prefix-list-name [seq seq-number] { deny | permit } ip-prefix [ge minimum-prefix-length] [le maximum-prefix-length]** command to create an IPv4 prefix-list and add a prefix entry to the list.

You can set multiple entries in the prefix-list, sorted by their sequence numbers. Entries have two working modes: permit and deny.

Run the **ip prefix-list prefix-list-name description description-text** command to add description to the prefix-list.

Run the **ip prefix-list sequence-number** command to enable the sorting function for the prefix-list.

↘ Creating an AS-Path List

By default, no AS-path list is configured and no entry is set.

In the global configuration mode, run the **ip as-path access-list** *path-list-num* { **permit** | **deny** } *regular-expression* command to create an AS-path list and add an entry to the list.

You can set multiple entries in the AS-path list. Entries have two working modes: permit and deny.

↳ Creating a Community-List

By default, no community-list is configured and no entry is set.

In the global configuration mode, run the **ip community-list** { { **standard** | **expanded** } *community-list-name* | *community-list-number* } { **permit** | **deny** } [*community-number..*] command to create a community-list and add an entry to the list.

You can set multiple entries in the community-list. Entries have two working modes: permit and deny.

↳ Creating an Extcommunity-List

By default, no extcommunity-list is configured and no entry is set.

In the global configuration mode, run the **ip extcommunity-list** { *standard-list* | **standard** *list-name* } { **permit** | **deny** } [*rt value*] [*soo value*] command to create a standard extcommunity list and add an entry to the list.

Run the **ip extcommunity-list** { *expanded-list* | **expanded** *list-name* } { **permit** | **deny** } [*regular-expression*] command to create an extcommunity list and add an entry to the list.

You can also run the **ip extcommunity-list** { *expanded-list* | **expanded** *list-name* | *standard-list* | **standard** *list-name* } command to create an extcommunity list and enter the configuration mode of **ip extcommunity-list** to add entries.

You can set multiple entries in the extcommunity-list. Entries have two working modes: permit and deny.

11.3.2 Route Map

A policy is a "match ..., set..." statement, which indicates that "if certain conditions are matched, you can perform some processing actions".

Working Principle

↳ Executing policies

A route map may contain multiple policies. Each policy has a corresponding sequence number. A smaller sequence number means a higher priority. Policies are executed based on their sequence numbers. Once the matching condition of a policy is met, the processing action for this policy needs to be performed and the route map exits. If no matching condition of any policy is met, no processing action will be performed.

↳ Working Modes Of Policies

Policies have two working modes:

- **permit**: When the matching condition of a policy is met, the processing action for this policy will be performed and the route map will exit.
- **deny**: When the matching condition of a policy is met, the processing action for this policy will not be performed and the route map will exit.

↘ Matching Conditions Of Policies

The matching condition of a policy may contain 0, 1 or more match rules.

- If the matching condition contains 0 match rule, no packet will be matched.
- If the matching condition contains one or more match rules, all rules must be matched.

↘ Processing Action for a Policy

The processing action of a policy may contain 0, 1 or more set rules.

- If the processing action contains 0 set rule, no processing action will be performed and the route map will directly exit.
- If the processing action contains one or more set rules, all processing actions will be performed and then the route map will exit.

 If set rules have different priorities, the set rule with the highest priority will take effect.

Related Configuration

↘ Creating a Route Map (Policy)

By default, no route map is configured and no policy is set.

In the global configuration mode, you can run the **route-map** *route-map-name* [**permit** | **deny**] [*sequence-number*] command to create a route map and add a policy to the route map.

You can set multiple policies in a route map. Each policy uses different sequence numbers.

↘ Setting Matching Conditions of a Policy

By default, no match rule is set (that is, the matching condition of a policy contains 0 match rule).

In the route map mode, run the **match** command to set match rules. One **match** command is mapped to one match rule.

RGOS provides abundant **match** commands for setting flexible matching conditions.

Command	Description
match as-path	Uses the AS_PATH attribute of a BGP route as the matching condition.
match community	Uses the community attribute of a BGP route as the matching condition.
match extcommunity	Uses the extended community attribute of a BGP route as the matching condition.
match interface	Uses the output interface of a route as the matching condition.
match ip address	Uses the destination IPv4 address of a route as the matching condition.
match ip next-hop	Uses the next-hop IPv4 address of a route as the matching condition.
match ip route-source	Uses the source IPv4 address of a route as the matching condition.
match ipv6 address	Uses the destination IPv6 address of a route as the matching condition.
match ipv6 next-hop	Uses the next-hop IPv6 address of a route as the matching condition.
match ipv6 route-source	Uses the source IPv6 address of a route as the matching condition.
match metric	Uses the metric of a route as the matching condition.

Command	Description
match mpls-label	Uses whether a route has label information as the matching condition.
match origin	Uses the source of a route as the matching condition.
match route-type	Uses the type of a route as the matching condition.
match tag	Uses the tag value of a route as the matching condition.

▾ Setting the Processing Actions of a Policy

By default, no set rule is configured (that is, the processing action of a policy contains 0 set rule).

In the route map mode, run the **set** command to configure set rules. One **set** command is mapped to one set rule.

RGOS provides abundant **set** commands for setting flexible processing actions.

Command	Description
set aggregator as	Modifies the AS attribute value of a route aggregator.
set as-path prepend	Adds a specified as-path attribute value.
set atomic-aggregate	Sets the atomic-aggregate attribute of a route.
set comm-list delete	Deletes all community attribute values from the community attribute list for a route matching the match rules.
set community	Sets the community attribute value of a route.
set dampening	Sets the flapping parameters of a route.
set extcomm-list delete	Deletes all extended community attribute values from the extcommunity attribute list for a route matching the match rules.
set extcommunity	Sets the extended community attribute value of a route.
set fast-reroute	Sets the backup output interface and next hop of a fast reroute.
set ip default nexthop	Specifies the default next hop of a route. This command has a lower priority than a common route and a higher priority than set default interface .
set ip dscp	Modifies the dscp field of an IP packet.
set ip nexthop	Specifies the next hop of a route. This command has a higher priority than set interface .
set ip next-hop verify-availability	Specifies the next-hop IP address of a route and checks the accessibility of the next hop by using a third-party protocol.
set ip precedence	Modifies the precedence field of an IP packet.
set ip tos	Modifies the tos field of an IP packet.
set ipv6 default next-hop	Specifies the default next hop of a route. This command has a lower priority than a common route and a higher priority than the default route.
set ipv6 global next-hop	Specifies the IPv6 next hop of a route, which belongs to a global VRF.
set ipv6 next-hop verify-availability	Specifies the next-hop IP address of a route and checks the accessibility of the next hop by using a third-party protocol.
set ipv6 precedence	Sets the priority of an IPv6 packet header.
set level	Sets the destination area type to which a route will be directed.
set local-preference	Sets the local-preference attribute value of a route.

Command	Description
set metric	Modifies the metric value of a route.
set metric-type	Sets the metric type of a route.
set mpls-label	Sets the MPLS label.
set next-hop	Sets the next-hop IP address of a route.
set origin	Sets the source attribute of a route.
set originator-id	Sets the originator IP address of a route.
set tag	Sets the tag value of a route.
set weight	Sets the weight value of a route.

11.4 Configuration

Configuration	Description and Command																		
Configuring a Route Map	 (Optional) It is used to define a policy.																		
	<table border="1"> <tr> <td>route-map</td> <td>Creates a policy (route map).</td> </tr> <tr> <td>match</td> <td>Sets the matching conditions of the policy.</td> </tr> <tr> <td>set</td> <td>Sets the processing actions of the policy.</td> </tr> </table>	route-map	Creates a policy (route map).	match	Sets the matching conditions of the policy.	set	Sets the processing actions of the policy.												
	route-map	Creates a policy (route map).																	
	match	Sets the matching conditions of the policy.																	
set	Sets the processing actions of the policy.																		
Configuring a Filtering List	 (Optional) It is used to define a filtering list.																		
	<table border="1"> <tr> <td>ip as-path</td> <td>Defines AS path filtering rules.</td> </tr> <tr> <td>ip community-list</td> <td>Defines a community list.</td> </tr> <tr> <td>ip extcommunity-list</td> <td>Defines an extcommunity list.</td> </tr> <tr> <td>ip prefix-list</td> <td>Creates a prefix-list.</td> </tr> <tr> <td>ip prefix-list description</td> <td>Adds description to a prefix-list.</td> </tr> <tr> <td>ip prefix-list sequence-number</td> <td>Enables the sorting function for a prefix-list.</td> </tr> <tr> <td>ipv6 prefix-list</td> <td>Creates an IPv6 prefix-list.</td> </tr> <tr> <td>ipv6 prefix-list description</td> <td>Adds description to an IPv6 prefix-list.</td> </tr> <tr> <td>ipv6 prefix-list sequence-number</td> <td>Enables the sorting function for an IPv6 prefix-list.</td> </tr> </table>	ip as-path	Defines AS path filtering rules.	ip community-list	Defines a community list.	ip extcommunity-list	Defines an extcommunity list.	ip prefix-list	Creates a prefix-list.	ip prefix-list description	Adds description to a prefix-list.	ip prefix-list sequence-number	Enables the sorting function for a prefix-list.	ipv6 prefix-list	Creates an IPv6 prefix-list.	ipv6 prefix-list description	Adds description to an IPv6 prefix-list.	ipv6 prefix-list sequence-number	Enables the sorting function for an IPv6 prefix-list.
	ip as-path	Defines AS path filtering rules.																	
	ip community-list	Defines a community list.																	
	ip extcommunity-list	Defines an extcommunity list.																	
	ip prefix-list	Creates a prefix-list.																	
	ip prefix-list description	Adds description to a prefix-list.																	
	ip prefix-list sequence-number	Enables the sorting function for a prefix-list.																	
ipv6 prefix-list	Creates an IPv6 prefix-list.																		
ipv6 prefix-list description	Adds description to an IPv6 prefix-list.																		
ipv6 prefix-list sequence-number	Enables the sorting function for an IPv6 prefix-list.																		

11.4.1 Configuring a Route Map

Configuration Effect

- Define a set of routing policies to be used by routing protocols or PBR.

Notes

- If a **match** command uses an ACL to define packet matching conditions, the ACL must be configured.
- The following **match** commands cannot be configured at the same time:

The Following match Commands	Cannot Be Configured with the Following match Commands At the Same Time
match ip address	match ip prefix-list
match ipv6 address	match ipv6 prefix-list
match ip next-hop	match ip next-hop prefix-list
match ipv6 next-hop	match ipv6 next-hop prefix-list
match ip route-source	match ip route-source prefix-list
match ipv6 route-source	match ipv6 route-source prefix-list

- The following **set** commands cannot be configured at the same time:

The Following set Commands	Cannot Be Configured with the Following set Commands At the Same Time
set next-hop	set vrf
set ip next-hop	set ip next-hop verify-availability
set ip dscp	set ip tos
set ip dscp	set ip precedence

Configuration Steps

↳ Creating a Policy (Route Map)

- Mandatory.
- Perform this configuration on a device to which a policy needs to be applied.

↳ Setting Matching Conditions of a Policy

- Optional.
- If no match rule is configured, no packet will be matched.
- If multiple match rules are configured, all the match rules must be matched.
- Perform this configuration on a device to which a policy needs to be applied.

↳ Setting the Processing Actions of a Policy

- Optional.
- If no set rule is configured, no processing action will be performed.
- If multiple set rules are configured, all set rules must be executed (if the set rules have different priorities, the set rule with the highest priority takes effect).
- Perform this configuration on a device to which a policy needs to be applied.

Verification

- Check the configurations of the route map.

Related Commands

↳ Creating a Policy (Route Map)

Command	route-map <i>route-map-name</i> [{ permit deny } <i>sequence</i>]
Parameter Description	<i>route-map-name</i> : Indicates the name of a route map, comprising not more than 32 characters. permit : Specifies the working mode of this policy as permit, which is the default mode. deny : Specifies the working mode of this policy as deny. The default mode is permit. <i>sequence</i> : Specifies the sequence number of this policy. A smaller value means a higher priority. The default value is 10.
Command Mode	Global configuration mode
Usage Guide	If this route map is unavailable, this command will create a route map and add a policy to the route map. If this route map is available, this command will add a policy to the route map.

↳ Setting Matching Conditions of a Policy

Command	match as-path <i>as-path-acl-list-number</i> [<i>as-path-acl-list-number</i>]
Parameter Description	<i>as-path-acl-list-number</i> : Indicates the AS-PATH list number, ranging from 1 to 500.
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match the AS-PATH attribute of a BGP route. Run the ip as-path access-list <i>path-list-num</i> { permit deny } <i>regular-expression</i> command to configure the AS-PATH list.

Command	match community { <i>community-list-number</i> <i>community-list-name</i> } [exact-match] [{ <i>community-list-number</i> <i>community-list-name</i> } [exact-match] ...]
Parameter Description	<i>community-list-number</i> : Indicates the community list number. For a standard community list, the value ranges from 1 to 99. For an extcommunity list, the value ranges from 100 to 199. <i>community-list-name</i> : Indicates the community list name, comprising not more than 80 characters. exact-match : Indicates the exact match list. It is a non-exact match list by default, that is, the match rule is met as long as the routing attributes contain the attributes specified by a community list.
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match the community attribute specified in a community list.

Command	match extcommunity { <i>standard-list-number</i> <i>standard-list-name</i> <i>expanded-list-num</i> <i>expanded-list-name</i> }
Parameter Description	<i>standard-list-number</i> : Indicates an ID, ranging from 1 to 99. It is used to identify a standard extcommunity list. One extcommunity list may contain multiple extcommunity values. <i>standard-list-name</i> : Indicates the name of a standard extcommunity list. It is used to identify the name of a standard extcommunity list. One extcommunity list may contain multiple extcommunity values. <i>expanded-list-num</i> : Indicates an ID, ranging from 100 to 199. It is used to identify an extcommunity list. One

	<p>extcommunity list may contain multiple extcommunity values.</p> <p><i>expanded-list-name</i>: Indicates the name of an extcommunity. It is used to identify the name of an extcommunity list. One extcommunity list may contain multiple extcommunity values.</p>
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match the extended community attribute specified in an extcommunity list.

Command	match interface <i>interface-type interface-number</i> [... <i>interface-type interface-number</i>]
Parameter Description	<i>interface-type interface-number</i> : Indicates the interface type and interface number.
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match the next-hop output interface of a route or a packet.

Command	match ip address { <i>access-list-number</i> [<i>access-list-number...</i> <i>access-list-name...</i>] <i>access-list-name</i> [<i>access-list-number...</i> <i>access-list-name</i>] prefix-list <i>prefix-list-name</i> [<i>prefix-list-name...</i>] }
Parameter Description	<p><i>access-list-number</i>: Indicates the access list number. For a standard access list, the value ranges are 1 to 99 and 1300 to 1999. For an extended access list, the value ranges are 100 to 199 and 2000 to 2699.</p> <p><i>access-list-name</i>: Indicates the access list name.</p> <p>prefix-list <i>prefix-list-name</i>: Indicates the name of a prefix-list to be matched.</p>
Command Mode	Route map configuration mode
Usage Guide	This match rule matches the destination IPv4 address of a packet or route by using an ACL or a prefix-list. An ACL and a prefix-list cannot be configured at the same time.

Command	match ip next-hop { <i>access-list-number</i> [<i>access-list-number...</i> <i>access-list-name...</i>] <i>access-list-name</i> [<i>access-list-number...</i> <i>access-list-name</i>] prefix-list <i>prefix-list-name</i> [<i>prefix-list-name...</i>] }
Parameter Description	<p><i>access-list-number</i>: Indicates the access list number. For a standard access list, the value ranges are 1 to 99 and 1300 to 1999. For an extended access list, the value ranges are 100 to 199 and 2000 to 2699.</p> <p><i>access-list-name</i>: Indicates the access list name.</p> <p>prefix-list <i>prefix-list-name</i>: Indicates the name of a prefix-list to be matched.</p>
Command Mode	Route map configuration mode
Usage Guide	This match rule matches the next-hop IPv4 address of a route by using an ACL or a prefix-list. An ACL and a prefix-list cannot be configured at the same time.

Command	match ip route-source { <i>access-list-number</i> [<i>access-list-number...</i> <i>access-list-name...</i>] <i>access-list-name</i> [<i>access-list-number...</i> <i>access-list-name</i>] prefix-list <i>prefix-list-name</i> [<i>prefix-list-name...</i>] }
----------------	---

Parameter Description	<i>access-list-number</i> : Indicates the access list number. For a standard access list, the value ranges are 1 to 99 and 1300 to 1999. For an extended access list, the value ranges are 100 to 199 and 2000 to 2699. <i>access-list-name</i> : Indicates the access list name. prefix-list <i>prefix-list-name</i> : Indicates the name of a prefix-list to be matched.
Command Mode	Route map configuration mode
Usage Guide	This match rule matches the source IPv4 address of a route by using an ACL or a prefix-list. An ACL and a prefix-list cannot be configured at the same time.

Command	match ipv6 address { <i>access-list-name</i> prefix-list <i>prefix-list-name</i> }
Parameter Description	<i>access-list-name</i> : Indicates the access list name. prefix-list <i>prefix-list-name</i> : Indicates the name of an IPv6 prefix-list to be matched.
Command Mode	Route map configuration mode
Usage Guide	This match rule matches the destination IPv6 address of a packet or route by using an ACL or a prefix-list. An ACL and a prefix list cannot be configured at the same time.

Command	match ipv6 next-hop { <i>access-list-name</i> prefix-list <i>prefix-list-name</i> }
Parameter Description	<i>access-list-name</i> : Indicates the access list name. prefix-list <i>prefix-list-name</i> : Indicates the name of an IPv6 prefix-list to be matched.
Command Mode	Route map configuration mode
Usage Guide	This match rule matches the next-hop IPv6 address of a route by using an ACL or a prefix-list. An ACL and a prefix-list cannot be configured at the same time.

Command	match ipv6 route-source { <i>access-list-name</i> prefix-list <i>prefix-list-name</i> }
Parameter Description	<i>access-list-name</i> : Indicates the access list name. prefix-list <i>prefix-list-name</i> : Indicates the name of an IPv6 prefix-list to be matched.
Command Mode	Route map configuration mode
Usage Guide	This match rule matches the source IPv6 address of a route by using an ACL or a prefix-list. An ACL and a prefix-list cannot be configured at the same time.

Command	match metric <i>metric</i>
Parameter Description	<i>metric</i> : Indicates the metric value of a route, ranging from 0 to 4,294,967,295.
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match the metric value of a route.

Command	match mpls-label
Parameter Description	-
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match routing information with labels.

Command	match origin { egp igp incomplete }
Parameter Description	egp: Indicates the source is remote EGP. igp: Indicates the source is local IGP. incomplete: Indicates that the source is an incomplete type.
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match the source of a route.

Command	match route-type { local internal external [type-1 type-2] level-1 level-2 }
Parameter Description	local: Indicates a route locally generated. Internal: Indicates an internal OSPF route. external: Indicates an external route (that of BGP or OSPF). type-1 type-2: Indicates type-1 or type-2 external route of OSPF. level-1 level-2: Indicates level-1 or level-2 route of ISIS.
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match the type of a route.

Command	match tag tag [...tag]
Parameter Description	tag: Indicates the tag value of a route.
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match the tag value of a route.

📌 Setting the Processing Actions of a Policy

Command	set aggregator as as-number ip-address
Parameter Description	as-number: Indicates the AS number of an aggregator. The AS number ranges from 1 to 4,294,967,295, which can be indicated by 1 to 65535.65535 in the dot mode. ip-address: Indicates the address of an aggregator.
Command Mode	Route map configuration mode

Usage Guide	This set rule is used to modify the AS attribute value of a route's aggregator.
--------------------	---

Command	set as-path prepend <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates the AS number to be added to the AS_PATH attribute. The AS number ranges from 1 to 4,294,967,295, which can be indicated by 1 to 65535.65535 in the dot mode.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to add a specified as-path attribute value.

Command	set atomic-aggregate
Parameter Description	-
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the atomic-aggregate attribute of a route.

Command	set comm-list { <i>community-list-number</i> <i>community-list-name</i> } delete
Parameter Description	<i>community-list-number</i> : Indicates the community list number. For a standard community list, the value ranges from 1 to 99. For an extcommunity list, the value ranges from 100 to 199. <i>community-list-name</i> : Indicates the community list name, comprising not more than 80 characters.
Command Mode	Route map configuration mode
Usage Guide	This rule is used to delete all community attribute values from the community list for a route matching the match rules.

Command	set community { <i>community-number</i> [<i>community-number</i> ...] additive none }
Parameter Description	<i>community-number</i> : Indicates the community attribute value. additive : Adds a number based on the original community attribute. none : Keeps the community attribute empty.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the community attribute value of a route.

Command	set dampening <i>half-life</i> <i>reuse</i> <i>suppress</i> <i>max-suppress-time</i>
Parameter Description	<i>half-life</i> : half-life when a route is accessible or not accessible, ranging from 1 to 45 minutes. The default value is 15 minutes. <i>reuse</i> : When the penalty value of a route is smaller than this value, route suppression will be canceled. The value ranges from 1 to 20,000 and the default value is 750. <i>suppress</i> : When the penalty value of a route is greater than this value, the route will be suppressed. The value ranges from 1 to 20,000 and the default value is 2,000.

	<i>max-suppress-time</i> : Indicates the longest time that a route can be suppressed, ranging from 1 to 255 minutes. The default value is 4 x half-life .
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the flapping parameters of a route.

Command	set extcomm-list { <i>extcommunity-list-number</i> <i>extcommunity-list-name</i> } delete
Parameter Description	<i>extcommunity-list-number</i> : Indicates the extcommunity list number. For a standard extcommunity list, the value ranges from 1 to 99. For an extended extcommunity list, the value ranges from 100 to 199. <i>extcommunity-list-name</i> : Indicates the extcommunity list name, comprising not more than 80 characters.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to delete all extended community attribute values from the extcommunity attribute list for a route matching the match rules.

Command	set extcommunity { <i>rt extend-community-value</i> soo <i>extend-community-value</i> }
Parameter Description	rt : Sets the RT attribute value of a route. soo : Sets the SOO attribute value of a route. <i>extend-community-value</i> : Indicates the value of an extended community.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the extended community attribute value of a route.

Command	set fast-reroute backup-interface <i>interface-type interface-number</i> [backup-nexthop <i>ip-address</i>]
Parameter Description	<i>interface-type interface-number</i> : Specifies a backup output interface. backup-nexthop <i>ip-address</i> : Specifies a backup next hop. For a non-point-to-point interface, a backup next hop must be specified.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the backup output interface and next hop of a fast reroute.

Command	set ip default next-hop <i>ip-address</i> [<i>weight</i>] [... <i>ip-address</i> [<i>weight</i>]]
Parameter Description	<i>ip-address</i> : Indicates the next-hop IP address. <i>weight</i> : Indicates the weight of this next hop.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to specify the default next hop of a route.

Command	set ip dscp <i>dscp_value</i>
----------------	--------------------------------------

Parameter Description	<i>dscp_value</i> : Sets the DSCP value in the IP header of an IP packet.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to modify the dscp field of an IP packet.

Command	set ip next-hop <i>ip-address</i> [<i>weight</i>] [... <i>ip-address</i> [<i>weight</i>]]
Parameter Description	<i>ip-address</i> : Indicates the next-hop IP address. <i>weight</i> : Indicates the weight of this next hop.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to specify the next hop of a route.

Command	set ip next-hop verify-availability <i>ip-address</i> [track <i>track-obj-number</i> bfd <i>interface-type interface-number gateway</i>]
Parameter Description	<i>ip-address</i> : Indicates the next-hop IP address. track : Judges whether the next hop is effective by using <i>Track</i> . <i>track-obj-number</i> : Indicates the track object number. bfd : Indicates that BFD is used for neighbor detection. <i>interface-type</i> : Configures the interface type. <i>interface-number</i> : Configures the interface number. <i>gateway</i> : Configures the gateway IP address, which is the neighbor IP address of BFD. If the next hop is configured as the neighbor, BFD will be used to detect the accessibility of the forwarding path.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to specify the next hop of a route and BFD or Track is used to fast detect the effectiveness of the next hop.

Command	set ip precedence { <i>number</i> critical flash flash-override immediate internet network priority routine }
Parameter Description	<i>number</i> : Indicates the priority of the IP header with a number, ranging from 0 to 7. 7: critical 6: flash 5: flash-override 4: immediate 3: internet 2: network 1: priority 0: routine critical flash flash-override immediate internet network priority routine : priority of an IP header.

Command Mode	Route map configuration mode
Usage Guide	This set rule is used to modify the precedence field of an IP packet header.

Command	set ip tos { <i>number</i> max-reliability max-throughput min-delay min-monetary-cost normal }
Parameter Description	<i>number</i> : Indicates the TOS value of an IP header with a number, ranging from 0 to 15. 2: max-reliability 4: max-throughput 8: min-delay 1: min-monetary-cost 0: normal max-reliability max-throughput min-delay min-monetary-cost normal : priority of an IP header.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to modify the tos field of an IP packet.

Command	set ipv6default next-hop <i>global-ipv6-address</i> [<i>weight</i>] [<i>global-ipv6-address</i> [<i>weight</i>] ...]
Parameter Description	<i>global-ipv6-address</i> : Indicates the next-hop IPv6 address for packet forwarding. The next-hop router must be a neighbor router. <i>weight</i> : Indicates the weight in the load balancing mode, ranging from 1 to 8. A larger value means larger packet traffic to be shared by the next hop.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to specify the default next hop IPv6 address of a route.

Command	set ipv6 next-hop <i>global-ipv6-address</i> [<i>weight</i>] [<i>global-ipv6-address</i> [<i>weight</i>] ...]
Parameter Description	vrf <i>vrf-name</i> : Indicates that the next hop belongs to a specified VRF, which must be a multi-protocol VRF configured with the IPv6 address family. By default, the next hop belongs to a global VRF when no VRF is specified. global : Indicates that the next hop is global. <i>global-ipv6-address</i> : Indicates the next-hop IPv6 address for packet forwarding. The next-hop router must be a neighbor router. <i>weight</i> : Indicates the weight in the load balancing mode, ranging from 1 to 8. A larger value means larger packet traffic to be shared by the next hop.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to specify the next hop IPv6 address of a route.

Command	set ipv6 next-hop verify-availability <i>global-ipv6-address</i> bfd <i>interface-type interface-number gateway</i>
Parameter Description	<i>global-ipv6-address</i> : Indicates the next-hop IPv6 address. bfd : Indicates that BFD is used for neighbor detection.

	<p><i>interface-type</i>: Configures the interface type.</p> <p><i>interface-number</i>: Configures the interface number.</p> <p><i>gateway</i>: Configures the gateway IPv6 address, which is the neighbor IPv6 address of BFD. If the next hop is configured as the neighbor, BFD will be used to detect the accessibility of the forwarding path.</p>
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to specify the next hop of a route and BFD is used to fast detect the effectiveness of the next hop.

Command	set ipv6 precedence { number critical flash flash-override immediate internet network priority routine }
Parameter Description	<p><i>number</i>: Indicates the priority of the IP header with a number, ranging from 0 to 7.</p> <p>7: critical</p> <p>6: flash</p> <p>5: flash-override</p> <p>4: immediate</p> <p>3: internet</p> <p>2: network</p> <p>1: priority</p> <p>0: routine</p> <p>critical flash flash-override immediate internet network priority routine: priority of an IP header.</p>
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the priority of an IPv6 packet header.

Command	set level { level-1 level-2 level-1-2 stub-area backbone }
Parameter Description	<p>level-1: Indicates that the re-distribution route is advertised to ISIS Level 1.</p> <p>level-2: Indicates that the re-distribution route is advertised to ISIS Level 2.</p> <p>level-1-2: Indicates that the re-distribution route is advertised to ISIS Level 1 and Level 2.</p> <p>stub-area: Indicates that the re-distribution route is advertised to OSPF Stub Area.</p> <p>backbone: Indicates that the re-distribution route is advertised to the OSPF backbone area.</p>
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the destination area type to which a route will be redirected.

Command	set local-preference number
Parameter Description	<i>number</i> : Indicates the metric value of a local priority, ranging from 0 to 4,294,967,295. A larger value means a higher priority.
Command Mode	Route map configuration mode

Usage Guide	This set rule is used to set the local-preference attribute value of a route.
--------------------	---

Command	set metric [+ <i>metric-value</i> - <i>metric-value</i> <i>metric-value</i>]
Parameter Description	+ : Increases (based on the metric value of the original route). - : Decreases (based on the metric value of the original route). <i>metric-value</i> : Sets the metric value of a re-distribution route. A larger value means a lower priority.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to modify the metric value of a route.

Command	set metric-type <i>type</i>
Parameter Description	<i>type</i> : Sets the type of a re-distribution route. The default type of an OSPF re-distribution route is type-2.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the metric type.

Command	set mpls-label
Parameter Description	-
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the MPLS label.

Command	set next-hop <i>ip-address</i>
Parameter Description	<i>ip-address</i> : Indicates the next-hop IP address.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the next-hop IP address.

Command	set origin { egp igp incomplete }
Parameter Description	egp : Indicates the source is remote EGP. igp : Indicates the source is local IGP. incomplete : Indicates that the source is the incomplete type and generally refers to a route generated due to re-distribution.
Command	Route map configuration mode

Mode	
Usage Guide	This set rule is used to set the source attribute of a route.

Command	set originator-id <i>ip-address</i>
Parameter Description	<i>ip-address</i> : Indicates the address of an originator.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the originator IP address of a route.

Command	set tag <i>tag</i>
Parameter Description	<i>tag</i> : Sets the tag of a re-distribution route.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the tag value of a route.

Command	set weight <i>number</i>
Parameter Description	<i>number</i> : Sets the weight of a route, ranging from 0 to 65,535. A larger value means a higher priority.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the weight of a route.

▾ Displaying the Configurations of a Route Map

Command	show route-map [<i>name</i>]
Parameter Description	<i>name</i> : Specifies a route map.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	Run the show route-map command to display the configurations of a route map. If an ACL is used when a route map is configured, you can run the show access-list command to display the configurations of the ACL.

Configuration Example

▾ Using a Route Map in Route Re-distribution to Filter and Modify Routing Information

Scenario Figure 11-4	As shown in Figure 11-4, a device is connected to both an OSPF routing domain and RIP routing domain.
-----------------------------	---

	
	<ul style="list-style-type: none"> ● Re-distribute only RIP routes with 4 hops to OSPF. In the OSPF route domain, if the route type is the external route type-1, set the tag value of the route to 40. ● Re-distribute only OSPF routes with the tag value 10 to RIP. In the RIP route domain, set the initial metric value of this route to 10.
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure the route map redrip: Match a route with 4 hops, set the initial metric value of the route to 40, set the route type to the external route type-1, and set the tag value of the route to 40. ● Configure the route map redospf: match a route with the tag value 10 and set the initial metric value of the route to 10. ● Configure re-distribution of the RIP route to OSPF and apply the route map redrip. ● Configure re-distribution of the OSPF route to RIP and apply the route map redospf.
	<pre>Ruijie(config)# route-map redrip permit 10 Ruijie(config-route-map)# match metric 4 Ruijie(config-route-map)# set metric-type type-1 Ruijie(config-route-map)# set tag 40 Ruijie(config-route-map)# exit Ruijie(config)# route-map redospf permit 10 Ruijie(config-route-map)# match tag 10 Ruijie(config-route-map)# set metric 10 Ruijie(config-route-map)# exit Ruijie(config)# router ospf 1 Ruijie(config-router)# redistribute rip subnets route-map redrip Ruijie(config-router)# exit Ruijie(config)# router rip Ruijie(config-router)# redistribute ospf 1 route-map redospf Ruijie(config-router)# exit</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● Check the configurations of the route map to verify the policy rules. ● Check the OSPF routing information library to verify that the rules matching the policy rules are re-distributed.
	<pre>Ruijie# show route-map route-map redrip, permit, sequence 10 Match clauses:</pre>

```
metric 4

Set clauses:

metric 40

metric-type type-1

tag 40

route-map redospf, permit, sequence 10

Match clauses:

tag 10

Set clauses:

metric 10
```

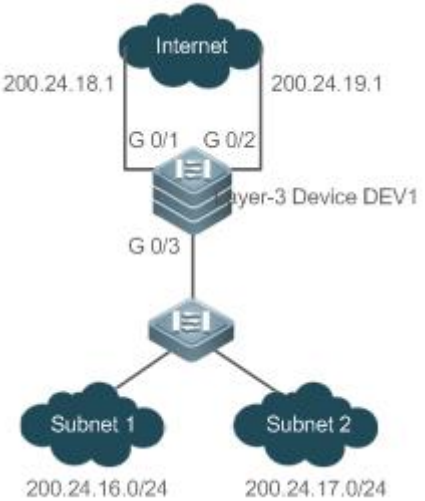

```
Ruijie# show ip ospf database external

          OSPF Router with ID (192.100.1.9) (Process ID 1)

          AS External Link States

LS age: 5

Metric Type: 1
TOS: 0
Metric: 4
Forward Address: 0.0.0.0
External Route Tag: 40
```

<p>Scenario Figure 11-5</p>	 <p>The diagram illustrates a network topology. At the top, a cloud labeled 'Internet' is connected to a 'Layer-3 Device DEV1' through two interfaces: G 0/1 with IP address 200.24.18.1 and G 0/2 with IP address 200.24.19.1. The Layer-3 Device DEV1 is also connected to two subnets: Subnet 1 (200.24.16.0/24) and Subnet 2 (200.24.17.0/24) through interface G 0/3.</p>
	<p>Configure PBR on the device DEV1 to achieve the following purposes:</p> <ul style="list-style-type: none"> ● Packets from subnet 1 (200.24.16.0/24) are sent from GE0/1 first. ● Packets from subnet 2 (200.24.17.0/24) are sent from GE0/2 first. ● The two output links work in the mutual backup mode.
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure two different ACLs to match packets from subnets 1 and 2 respectively. ● Configure the route map RM_FOR_PBR: policy 10 is used to ensure that "packets from subnet 1 are sent from GE0/1 first"; policy 20 is used to ensure that "packets from subnet 2 are sent from GE0/2 first". ● Configure PBR for packets received from GE0/3 and apply the route map RM_FOR_PBR. ● Set PBR to implement redundant backup among multiple next hops. <p> In the redundant backup mode, the sequence of multiple set next hops is the sequence of the priorities for taking effect.</p>

	<pre> Ruijie(config)# access-list 1 permit 200.24.16.0 0.0.0.255 Ruijie(config)# access-list 2 permit 200.24.17.0 0.0.0.255 Ruijie(config)# route-map RM_FOR_PBR 10 Ruijie(config-route-map)# match ip address 1 Ruijie(config-route-map)# set ip next-hop 200.24.18.1 Ruijie(config-route-map)# set ip next-hop 200.24.19.1 Ruijie(config-route-map)# exit Ruijie(config)# route-map RM_FOR_PBR 20 Ruijie(config-route-map)# match ip address 2 Ruijie(config-route-map)# set ip next-hop 200.24.19.1 Ruijie(config-route-map)# set ip next-hop 200.24.18.1 Ruijie(config-route-map)# exit Ruijie(config)# interface GigabitEthernet 0/3 Ruijie(config-if)# ip policy route-map RM_FOR_PBR Ruijie(config)# ip policy redundance </pre>
Verification	<ul style="list-style-type: none"> ● Check the configurations of PBR to verify that the route map is applied to the interfaces. ● Check the configurations of the route map to verify the policy rules. ● Check the ACL configurations to verify the packet filtering rules.
	<pre> Ruijie# show ip policy Balance mode: redundance Interface Route map GigabitEthernet 0/3 RM_FOR_PBR ! </pre>
	<pre> Ruijie# show route-map route-map RM_FOR_PBR, permit, sequence 10 Match clauses: ip address 1 Set clauses: ip next-hop 200.24.18.1 ip next-hop 200.24.19.1 route-map RM_FOR_PBR, permit, sequence 20 </pre>

	<pre>Match clauses: ip address 2 Set clauses: ip next-hop 200.24.19.1 ip next-hop 200.24.18.1</pre>
	<pre>Ruijie# show access-lists ip access-list standard 1 10 permit 200.24.16.0 0.0.0.255 10 permit 200.24.16.0 0.0.0.255 ip access-list standard 2 10 permit 200.24.17.0 0.0.0.255</pre>

Common Errors

- After matching of ACLs and prefix-lists is configured, the corresponding ACLs and prefix lists are not defined.

11.4.2 Configuring a Filtering List

Configuration Effect

- Define a set of route filtering rules to be used by routing protocols.

Notes

- A configured filtering list can take effect only after it is associated with a routing protocol.

Configuration Steps

▾ Configuring a Prefix-List

- To filter address prefixes, you should perform this configuration.
- If there is no special requirement, you should perform this configuration on a route for which filtering based on a prefix-list needs to be performed.

▾ Configuring an AS Path List

- To filter address prefixes, you should perform this configuration.
- If there is no special requirement, you should perform this configuration on a route for which filtering based on an AS path needs to be performed.

▾ Configuring a Community List

- To filter community attributes, you should perform this configuration.

- If there is no special requirement, you should perform this configuration on a route for which community attributes need to be filtered.

↘ Configuring an Extcommunity List

- To filter extended community attributes, you should perform this configuration.
- If there is no special requirement, you should perform this configuration on a route for which extended community attributes need to be filtered.

Verification

- Check whether the filtering list is correctly configured.
- Check the routing table to verify that routes can be correctly filtered.

Related Commands

↘ Defining AS Path Filtering Rules

Command	<code>ip as-path access-list path-list-num { permit deny } regular-expression</code>
Parameter Description	<p>path-list-num: Indicates an AS-path ACL name based on a regular expression and is an AS path list identifier, ranging from 1 to 500.</p> <p>permit: Permits access.</p> <p>deny: Denies access.</p> <p>regular-expression: Indicates a regular expression, ranging from 1 to 255.</p>
Command Mode	Global configuration mode
Usage Guide	-

↘ Defining a Community List

Command	<code>ip community-list { { standard expanded } community-list-name community-list-number } { permit deny } [community-number..]</code>
Parameter Description	<p>standard: Indicates a standard community list.</p> <p>expanded: Indicates an extended community list.</p> <p>community-list-name: Indicates the community list name, comprising not more than 80 characters.</p> <p>community-list-number: Indicates the community list number. For a standard community list, the value ranges from 1 to 99. For an extended community list, the value ranges from 100 to 199.</p> <p>permit: Permits access.</p> <p>deny: Denies access.</p> <p>community-number: Indicates the community attribute value.</p>
Command Mode	Global configuration mode
Usage Guide	Use this command to define a community list used for BGP.

↘ Defining an Extcommunity List

Command	ip extcommunity-list { <i>expanded-list</i> expanded <i>list-name</i> } { permit deny } [<i>regular-expression</i>]
Parameter Description	<p>expand-list: Indicates an extended extcommunity list, ranging from 100 to 199. One extcommunity list may contain multiple rules.</p> <p>standard-list: Indicates a standard extcommunity list, ranging from 1 to 99. One extcommunity list may contain multiple rules.</p> <p>expanded list-name: Indicates the name of an extended extcommunity, comprising not more than 32 characters. When using this parameter, you enter the extcommunity list configuration mode.</p> <p>standard list-name: Indicates the name of a standard extcommunity list, comprising not more than 32 characters. When using this parameter, you enter the extcommunity list configuration mode.</p> <p>permit: Defines an extcommunity rule for permitting.</p> <p>deny: Defines an extcommunity rule for denying.</p> <p>regular-expression: (optional) Defines a matching template that is used to match an extcommunity.</p> <p>sequence-number: (Optional) Defines the sequence number of a rule, ranging from 1 to 2,147,483,647. If no sequence number is specified, the sequence number automatically increases by 10 when a rule is added by default. The initial number is 10.</p> <p>rt: (Optional) Sets the RT attribute value. This command can be used only for the standard extcommunity configuration, but not for the extended extcommunity configuration.</p> <p>soo: (Optional) Sets the SOO attribute value. This command can be used only for the standard extcommunity configuration, but not for the extended extcommunity configuration.</p> <p>value: Indicates the value of an extended community (extend_community_value).</p>
Command Mode	Global configuration mode and ip extcommunity-list configuration mode
Usage Guide	-

📄 Creating a Prefix-List

Command	ip prefix-list <i>prefix-list-name</i> [seq <i>seq-number</i>] { deny permit } <i>ip-prefix</i> [ge <i>minimum-prefix-length</i>] [le <i>maximum-prefix-length</i>]
Parameter Description	<p>prefix-list-name: Indicates the prefix-list name.</p> <p>seq-number: Assigns a sequence number to an prefix-list entry, ranging from 1 to 2,147,483,647. If this command does not contain the sequence number, the system will assign a default sequence number to the prefix-list entry. The default sequence number of the first entry is 5. Subsequently, the default sequence number of each entry not assigned with a value is the first multiple of 5 greater than the previous sequence number.</p> <p>deny: Denies access when certain conditions are matched.</p> <p>permit: Permits access when certain conditions are matched.</p> <p>ip-prefix: Configures the IP address and mask, ranging from 0 to 32 digits.</p> <p>minimum-prefix-length: Specifies the minimum range (namely, the start length of a range).</p> <p>maximum-prefix-length: Specifies the maximum range (namely, the end length of a range).</p>
Command Mode	Global configuration mode
Usage Guide	-

▾ Adding Description to a Prefix-List

Command	<code>ip prefix-list <i>prefix-list-name</i> description <i>descripton-text</i></code>
Parameter	<i>prefix-list-name</i> : Indicates the prefix-list name.
Description	<i>descripton-text</i> : Describes the prefix-list.
Command Mode	Global configuration mode
Usage Guide	-

▾ Enabling the Sorting Function for a Prefix-List

Command	<code>ip prefix-list sequence-number</code>
Parameter	-
Description	
Command Mode	Global configuration mode
Usage Guide	-

▾ Creating an IPv6 Prefix-List

Command	<code>ipv6 prefix-list <i>prefix-list-name</i> [seq <i>seq-number</i>] { deny permit } <i>ipv6-prefix</i> [ge <i>minimum-prefix-length</i>] [le <i>maximum-prefix-length</i>]</code>
Parameter	<i>prefix-list-name</i> : Indicates the prefix-list name.
Description	<p><i>seq-number</i>: Assigns a sequence number to an prefix-list entry, ranging from 1 to 2,147,483,647. If this command does not contain the sequence number, the system will assign a default sequence number to the prefix-list entry. The default sequence number of the first entry is 5. Subsequently, the default sequence number of each entry not assigned with a value is the first multiple of 5 greater than the previous sequence number.</p> <p><i>deny</i>: Denies access when certain conditions are matched.</p> <p><i>permit</i>: Permits access when certain conditions are matched.</p> <p><i>ipv6-prefix</i>: Configures the IP address and mask, ranging from 0 to 128 digits.</p> <p><i>minimum-prefix-length</i>: Specifies the minimum range (namely, the start length of a range).</p> <p><i>maximum-prefix-length</i>: Specifies the maximum range (namely, the end length of a range).</p>
Command Mode	Global configuration mode
Usage Guide	-

▾ Adding Description to an IPv6 Prefix List

Command	<code>ipv6 prefix-list <i>prefix-list-name</i> description <i>descripton-text</i></code>
Parameter	<i>prefix-list-name</i> : Indicates the prefix list name.
Description	<i>descripton-text</i> : Describes the prefix list.
Command Mode	Global configuration mode

Usage Guide	-
-------------	---

➤ **Enabling the Sorting Function for an IPv6 Prefix-List**

Command	ipv6 prefix-list sequence-number
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	-

Configuration Example

➤ **Configuring a Prefix-List**

<p>Scenario Figure 11-6</p>	<p>The diagram illustrates a network topology within AS 100. At the top is Router B, and at the bottom is Router A. They are connected via a link labeled 'IBGP' with interface 'G0/1' and IP addresses '1.1.1.2/24' on Router B and '1.1.1.1/24' on Router A. Router A is connected to three subnets: Subnet 1 (192.168.1.0/24), Subnet 2 (192.168.2.0/24), and Subnet 3 (192.168.3.0/24).</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure an IBGP neighbor and advertise the neighbor to the three connected subnets. ● Configure a prefix-list. ● Associate a prefix-list with A to filter sent routes.
<p>A</p>	<pre>A# configure terminal A(config)# ip prefix-list pre1 permit 192.168.1.0/24 A(config)# router bgp 100 A(config-router)# neighbor 1.1.1.2 prefix-list pre1 out A(config-router)# end</pre>

<p>Verification</p>	<ul style="list-style-type: none"> ● Run the show command to display the prefix-list. ● Run the show command to display the BGP routing table to check whether the filtering behavior is correct.
<p>A</p>	<pre>A# show ip prefix-list ip prefix-list prel: 1 entries seq 5 permit 192.168.1.0/24 A# show ip bgp BGP table version is 2, local router ID is 1.1.1.1 Status codes: s suppressed, d damped, h history, * valid, > best, i - internal, S Stale, b - backup entry Origin codes: i - IGP, e - EGP, ? - incomplete Network Next Hop Metric LocPrf Weight Path *> 192.168.1.0 0.0.0.0 0 32768 i *> 192.168.2.0 0.0.0.0 0 32768 i *> 192.168.3.0 0.0.0.0 0 32768 i Total number of prefixes 3</pre>
<p>B</p>	<pre>B# show ip bgp BGP table version is 4, local router ID is 1.1.1.2 Status codes: s suppressed, d damped, h history, * valid, > best, i - internal, S Stale Origin codes: i - IGP, e - EGP, ? - incomplete Network Next Hop Metric LocPrf Weight Path *>i192.168.1.0 1.1.1.1 0 100 0 i Total number of prefixes 1</pre>

➤ **Configuring an AS Path List**

<p>Scenario Figure 11-7</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Create an AS-path filtering rule to match path information including only AS 200. ● Establish EBGP neighborhood on A with B and C. ● Associate an AS-path list with A to filter the routes received from B and C.
<p>A</p>	<pre>A(config)# ip as-path access-list 123 permit ^200\$ A(config)# router bgp 100 A(config)# neighbor 192.168.1.2 filter-list 123 in A(config)# neighbor 192.168.2.2 filter-list 123 in</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● Run the show command to display the AS-path list. ● Run the show command to display the BGP routing table to check whether the filtering behavior is correct.
<p>A</p>	<pre>A# show ip as-path-access-list AS path access list 123 permit ^200\$ //When no AS-path list is associated with A, run the show command to check the BGP routing table. A(config)# show ip bgp BGP table version is 1, local router ID is 1.1.1.1 Status codes: s suppressed, d damped, h history, * valid, > best, i - internal, S Stale, b - backup entry Origin codes: i - IGP, e - EGP, ? - incomplete Network Next Hop Metric LocPrf Weight Path *> 10.0.0.0/24 192.168.1.2 0 0 200 i</pre>

1 Configuring IP Multicast

1.1 Overview

IP multicasting is abstracted hardware multicasting and an extended multicast routing protocol on the standard IP network layer.

In traditional IP transmission, only one host can send packets to a single host (unicast communication) or all hosts (broadcast communication). However, the multicast technology provides the third choice: a host can send packets to certain specified hosts.

IP multicasting is applicable to one-to-many multimedia applications.

1.2 Applications

Application	Description
PIM-DM Applications	The PIM-DM multicast service is provided on the same network.
PIM-SM Applications	The PIM-SM multicast service is provided on the same network.

1.2.1 PIM-DM Applications

Scenario

The PIM-DM multicast service is provided on the same network.

As shown in Figure 1-1:

- A multicast source sends a multicast packet, and receiver A and receiver B on the same network receive the multicast packet.

Figure 1-1

Remark	A and B are layer-3 devices and C is a layer-2 access device.
---------------	---

s	Source is connected to the Gi 0/1 interface of A, and receiver A and receiver B are connected to the Gi 0/2 and Gi 0/3 interfaces of C.
----------	---

Deployment

- Run the Open Shortest Path First (OSPF) protocol on the same network to implement unicast routing.
- Run PIM-DM on the same network to implement multicast routing.
- Run the Internet Group Membership Protocol (IGMP) in a user host network segment to implement group member management.

1.2.2 PIM-SM Applications

Scenario

The PIM-SM multicast service is provided on the same network.

As shown in Figure 1-2:

- A multicast source sends a multicast packet, and receiver A and receiver B on the same network receive the multicast packet.

Figure 1-2

Remark	A, B, and C are layer-3 routers.
s	The multicast source is connected to the Gi 0/1 interface of A, receiver B is connected to the Gi 0/1 interface of B, and receiver B is connected to the Gi 0/1 interface of C.

Deployment

- Run OSPF on the same network to implement unicast routing.
- Run PIM-SM on the same network to implement multicast routing.
- Run IGMP in a user host network segment to implement group member management.

1.3 Features

Basic Concepts

📄 PIM Routers and PIM Interfaces

Routers enabled with PIM are called PIM routers. Interfaces enabled with PIM protocol are called PIM interfaces.

Multicast packets are forwarded on PIM routers. The PIM interfaces for receiving multicast packets are called upstream interfaces, and the PIM interfaces for sending multicast packets are called downstream interfaces.

The network segments where upstream interfaces are located are called upstream network segments. The network segments where downstream interfaces are located are called downstream network segments.

↘ PIM Network and PIM Domain

PIM routers are connected through PIM interfaces and form a PIM network.

On certain PIM interfaces, borders are configured to divide a large PIM network into multiple PIM domains. Borders may reject specified multicast packets or limit transmission of PIM messages.

↘ Multicast Distribution Tree, DR and RP

Multicast packets are transmitted from one point to multiple points. The forwarding path is in a tree structure. This forwarding path is called a multicast distribution tree (MDT) and has the following types:

- Rendezvous Point Tree (RPT): The RP is regarded as the root and the designated router (DR) that connects group members is regarded as a leaf.
- Shortest Path Tree (SPT): The DR that connects multicast sources is regarded as the root, and RP or DR that connects group members is regarded as a leaf.

The DR and RP are functional roles for a PIM router.

- The RP collects multicast sources and group member information on the network.
- The DR that connects multicast sources reports multicast source information to the RP. The DR that connects group members reports group member information to the RP.

↘ (*,G) and (S,G)

- (*,G): Packets sent from any source to group G, routing entries corresponding to the packets, and forwarding path (RPT) corresponding to the packets.
- (S,G): Packets sent from source S to group G, routing entries corresponding to the packets, and forwarding path (SPT) corresponding to the packets.

↘ ASM and SSM

PIM-SM supports the following multicast models that are applicable to different multicast address segments:

- Any-Source Multicast (ASM): In the ASM model, user hosts cannot select multicast sources. User hosts join a group and receive packets sent from all sources to the group.
- Source-Specific Multicast (SSM): In the SSM model, user hosts can select multicast sources. User hosts specify source addresses when joining a group and receive only packets sent from specified sources to the group.

i SSM model requirements: User hosts must know the multicast source address in advance using other network services so that the hosts can select multicast sources.

Overview

Feature	Description
---------	-------------

Feature	Description
Configuring Basic Functions of IP Multicasting	Creates a PIM network and provides data sources and user terminals on the network with the IPv4 multicast service.
Configuring a TTL Threshold	Configures a TTL threshold for an interface, that is, the minimum TTL value of multicast packets allowed on an interface.
Configuring the Number of Entries That Can Be Added to the Multicast Routing Table	Limits the number of entries that can be added to the multicast routing table.
Configuring an IP Multicasting Border	Configures an interface as a multicast border for a specified group.
Configuring an IP Multicasting Static Route	Allows the multicast forwarding path to be different from the unicast path.
Configuring Layer-2 Direction Control for Multicast Streams	Allows a specified multicast stream to be configured with multiple commands, that is, to be configured with multiple ports that can forward the stream. Once direction control is configured for a multicast stream, the stream can be forwarded only by these configured interfaces. Other interfaces are not permitted to forward the stream.
Configuring RPF Route Selection Based on the Longest Match Rule	Selects an optimal route respectively from the multicast static routing table, MBGP routing table, and unicast routing table according to RPF rules. Among these three routes, the one with the longest match mask is selected as the RPF route.
Configuring Multicast Non-Stop Forwarding Parameters	During normal running, SSP synchronizes the hardware multicast forwarding table to the management board in real time. After the management board is switched, the command for configuring the multicast control plane of the original slave management board is loaded, and the multicast protocol (such as PIM-SM or IGMP Snooping) re-converges. The multicast non-stop forwarding function ensures continuous forwarding of multicast data streams during re-convergence of the multicast protocol.
Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries	Deletes the earliest hardware entries and adds new entries if the hardware forwarding table overflows when you create multicast forwarding entries.

1.3.1 Configuring Basic Functions of IP Multicasting

Create a PIM network and provide data sources and user terminals on the network with the IPv4 multicast service.

Working Principle

A device maintains the routing table for forwarding multicast packets through multicast routing protocols (such as PIM-DM or PIM-SM) and learns the states of group members in the directly connected network segment through IGMP. A host sends IGMP Report messages to join a specified IGMP group.

Related Configuration

↳ Enabling IPv4 Multicast Routing

By default, IPv4 multicast routing is disabled.

Run **ip multicast-routing** to enable IPv4 multicast routing.

↳ Configuring IP Multicasting on an Interface

By default, IP multicasting is disabled on an interface.

Run **ip pim sparse-mode** or **ip pim dense-mode** to enable IP multicasting on an interface.

1.3.2 Configuring a TTL Threshold

Configure a TTL threshold for an interface, that is, the minimum TTL value of multicast packets allowed on an interface.

Working Principle

Configure a TTL threshold for an interface and check the TTL values of multicast packets. Multicast packets whose TTL values are larger than the TTL threshold of the interface are forwarded and those whose TTL values are smaller are discarded.

Related Configuration

↳ Configuring a TTL Threshold

By default, the TTL threshold of an interface is 0.

Run **ip multicast ttl-threshold *ttl-value*** to change the TTL threshold of an interface. The value ranges from 0 to 255.

A larger value of *ttl-value* means a larger TTL value of multicast packets to be forwarded.

1.3.3 Configuring the Number of Entries That Can Be Added to the Multicast Routing Table

Each multicast data packet received on the device maintains a corresponding IP multicast route forwarding entry. However, excess multicast routing entries may exhaust device memory and deteriorate device performance. You can limit the number of entries in the IP multicast routing table based on the actual network and service performance requirements.

Working Principle

The number of entries in the IP multicasting routing table is limited based on the actual network and service performance requirements to ensure device performance.

Related Configuration

↳ Configuring the Number of Entries That Can Be Added to the Multicast Routing Table

By default, a maximum of 1024 entries can be added to an IP multicast routing table.

Run **ip multicast route-limit** *limit* [*threshold*] to change the number of entries that can be added to the IP multicasting routing table. The value ranges from 1 to 65536.

A larger value of *limit* means a larger number of entries that can be added to the IP multicasting routing table.

1.3.4 Configuring an IP Multicasting Border

Configure an IP multicasting border to specify the transmission range of multicast packets.

Working Principle

An IP multicasting border is configured to specify the transmission range of multicast packets. When an IP multicasting border is configured on an interface, this interface cannot forward or receive multicast packets, including those sent from the local host.

Related Configuration

↳ [Configuring an IP Multicasting Border](#)

By default, no IP multicasting border is configured.

Run **ip multicast boundary** *access-list* [*in* | *out*] to configure an IP multicasting border.

1.3.5 Configuring an IP Multicasting Static Route

Configure an IP multicasting static route to specify an RPF interface or RPF neighbor for multicast packets from specified multicast sources.

Working Principle

An RPF check is performed once multicast packets are forwarded. An IP multicasting static route can be configured to specify an RPF interface or RPF neighbor for multicast packets from specified multicast sources.

Related Configuration

↳ [Configuring an IP Multicasting Static Route](#)

By default, no IP multicasting static route is configured.

Run **ip mroute** *source-address* *mask* | [**bgp** | **isis** | **ospf** | **rip** | **static**] { *v4rpf-address* | *interface-type* *interface-number* } [*distance*] to configure an IP multicasting static route.

1.3.6 Configuring Layer-2 Direction Control for Multicast Streams

Configure layer-2 direction control for multicast streams to control the forwarding of multicast streams on an interface.

Working Principle

Configure layer-2 direction control for multicast streams and a forwarding interface so that multicast streams can be forwarded only through configured interfaces. In this case, layer-2 forwarding of multicast streams can be controlled.

Related Configuration

↳ Configuring Layer-2 Direction Control for Multicast Streams

By default, layer-2 direction control for multicast streams is disabled.

Run **ip multicast static** *source-address group-address interface-type interface-number* to configure layer-2 direction control for multicast streams.

1.3.7 Configuring RPF Route Selection Based on the Longest Match Rule

Select an optimal route respectively from the multicast static routing table, MBGP routing table, and unicast routing table and select the one with the longest match mask as the RPF route from the three optimal routes.

Working Principle

A multicast static route, an MBGP route, and a unicast route that can be used for RPF check are selected respectively from the multicast static routing table, MBGP routing table, and unicast routing table according to RPF rules.

- If the longest match rule is used, the route with the longest match mask is selected as the RPF route. If the three routes have the same mask, the one with the highest priority is selected as the RPF route. If they have the same priority, the RPF routes are selected in the sequence of multicast static route, MBGP route, and unicast route.
- Otherwise, the one with the highest priority is selected as the RPF route. If they have the same priority, the RPF routes are selected in the sequence of multicast static route, MBGP route, and unicast route.

Related Configuration

↳ Configuring RPF Route Selection Based on the Longest Match Rule

By default, the route with the highest priority is selected as the RPF route. If they have the same priority, the RPF routes are selected in the sequence of multicast static route, MBGP route, and unicast route.

Run **ip multicast [vrf *vrf-name*] rpf longest-match** to configure RPF route selection based on the longest match rule.

Configuring an RPF Proxy

This function is used when inter-AS SPT is created. Configure an RPF proxy to request PIM-SM to send a Join message with RPF Vector to establish an SPT.

Working Principle

After configuring an RPF proxy, PIM-SM queries a proxy address connected to the multicast source, uses this proxy address as the destination address to query an RPF neighbor, and sends a Join message to the neighbor. In addition, PIM-SM adds the proxy address to the Join message so that the RPF neighbor can use this proxy address for RPF check.

Related Configuration

↳ Configuring an RPF Proxy

By default, RPF vector is not used and is allowed to be received.

Run **ip multicast rpf proxy [rd] { vector | disable }** to configure an RPF proxy.

1.3.8 Configuring Multicast Non-Stop Forwarding Parameters

The non-stop forwarding function ensures continuous forwarding of multicast data streams during the re-convergence of multicast protocols.

Working Principle

During normal running, SSP synchronizes the hardware multicast forwarding table to the management board in real time. After the management board is switched, the command for configuring the multicast control plane of the original slave management board is loaded, and the multicast protocol (such as PIM-SM or IGMP Snooping) re-converges. The multicast non-stop forwarding function ensures continuous forwarding of multicast data streams during re-convergence of multicast protocols.

After the configured protocol convergence period times out, all multicast forwarding table entries that are not updated during the convergence period are deleted.

Related Configuration

↘ [Configuring the Maximum Period for Multicast Protocol Convergence](#)

By default, the maximum period for multicast protocol convergence is 20s.

Run **msf nsf convergence-time** *time* to configure the maximum period for multicast protocol convergence. The value ranges from 0 to 3600s.

A larger value of *time* means a longer maximum period for multicast protocol convergence.

↘ [Configuring the Multicast Packet Leakage Period](#)

By default, the multicast packet leakage period is 30s.

Run **msf nsf leak** *interval* to configure the multicast packet leakage period. The value ranges from 0 to 3600s.

A larger value of *interval* means a longer leakage period.

1.3.9 Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries

Delete the earliest hardware entries and adds new entries if the hardware forwarding table overflows when you create multicast forwarding entries.

Working Principle

Delete the earliest hardware entries and adds new entries if the hardware forwarding table overflows when you create multicast forwarding entries .

Related Configuration

↘ [Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries](#)

By default, the overwriting mechanism upon the overflow of multicast hardware forwarding entries is disabled.

Run **msf ipmc-overflow override** to configure the overwriting mechanism upon overflow of multicast hardware forwarding entries.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of IP Multicasting	 (Mandatory) It is used to configure the multicast service.	
	ip multicast-routing	Enables the IPv4 multicast routing function.
Configuring a TTL Threshold	 Optional.	
	ip multicast ttl-threshold <i>ttl-value</i>	Configures a TTL threshold for an interface.
Configuring the Number of Entries That Can Be Added to the Multicast Routing Table	ip multicast route-limit <i>limit</i> [<i>threshold</i>]	Limits the number of entries that can be added to the multicast routing table.
Configuring an IP Multicasting Border	ip multicast boundary <i>access-list</i> [in out]	Configures an interface as a multicast border for a specified group.
Configuring an IP Multicasting Static Route	ip mroute <i>source-address mask</i> [bgp isis ospf rip static] { <i>v4rpf-address</i> <i>interface-type interface-number</i> } [<i>distance</i>]	Configures an IP multicasting static route.
Configuring Layer-2 Direction Control for Multicast Streams	ip multicast static <i>source-address group-address</i> <i>interface-type interface-number</i>	Controls the direction of data streams on layer-2 interfaces.
Configuring RPF Route Selection Based on the Longest Match Rule	ip multicast rpf longest-match	Configures RPF route selection based on the longest match rule.
Configuring Multicast Non-Stop Forwarding Parameters	msf nsf convergence-time <i>time</i>	Configures the maximum period for multicast protocol convergence.
	msf nsf leak <i>time</i>	Configures the multicast packet leakage period.
Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries	msf ipmc-overflow override	Configures the overwriting mechanism upon overflow of multicast hardware forwarding entries.

1.4.1 Configuring Basic Functions of IP Multicasting

Configuration Effect

- Create a PIM network and provide data sources and user terminals on the network with the IPv4 multicast service.

Notes

- A PIM network needs to use existing unicast routes on the network. Therefore, IPv4 routes must be configured on the network.

Configuration Steps

↳ Enabling IPv4 Multicast Routing

- Mandatory.
- IPv4 multicast routing should be enabled on each router unless otherwise specified.

↳ Enabling IP Multicasting for an Interface

- Mandatory.
- IP multicasting protocol should be enabled on interfaces unless otherwise specified:

Verification

Enable multicast sources to send multicast packets and user hosts to join the groups.

- Check whether the user hosts can successfully receive packets from each group.

Related Commands

↳ Enabling IPv4 Multicast Routing

Command	ip multicast-routing
Parameter Description	.
Command Mode	Global configuration mode
Usage Guide	-

↳ Configuring IP Multicasting

-  For IGMP configuration, see the IGMP section.
-  For PIM-DM configuration, see the PIM-DM section.
-  For PIM-SM configuration, see the PIM-SM section.
-  For DVMRP configuration, see the DVMRP section.
-  After layer-3 multicasting is enabled in the private VLAN and super VLAN and a multicast source exists in the sub-VLAN, an extra entry whose ingress is the sub-VLAN into which the multicast stream enters needs to be copied due to the validity check during multicast forwarding. This results in occupation of one more multicast hardware entry and one less in the multicast capacity.

↳ Displaying Information About the Multicast Forwarding Table

Command	show ip mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]] [dense sparse] [summary count]
Parameter Description	<i>group-or-source-address</i> : Specifies a group address or source address.

	<p>group-or-source-address: Specifies a group address or source address.</p> <p>dense: Displays the core entry of PIM-DM multicast.</p> <p>sparse: Displays the core entry of PIM-SM multicast.</p> <p>summary: Displays summary information about multicast routing entries.</p> <p>count: Displays counting information about multicast routing entries.</p>
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<p>The three parameters are optional, and the source address and group address must be specified simultaneously.</p> <p>When no source address or group address is specified, all MFC entries are displayed.</p> <p>When only the source address and group address are specified, MFC entries of the source address and group address are displayed.</p>

Configuration Example

Creating the IP Multicast Service on the IPv4 Network and Supporting PIM-DM

<p>Scenario</p> <p>Figure 1-3</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> Configure an IPv4 unicast routing protocol (such as OSPF) on a router. Enable IPv4 multicast routing on all routers. Enable PIM-DM on device interconnection interfaces and interfaces for connecting user hosts and multicast sources.
<p>A</p>	<pre>A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if)# ip pim dense-mode A(config-if)# exit A(config)# interface GigabitEthernet 0/2 A(config-if)# ip pim dense-mode A(config-if)# exit</pre>
<p>B</p>	<pre>B# configure terminal</pre>

	<pre> B(config)# ip multicast-routing B(config)# interface GigabitEthernet 0/1 B(config-if)# ip pim dense-mode B(config-if)# exit B(config)# interface GigabitEthernet 0/2 B(config-if)# ip pim dense-mode B(config-if)# exit </pre>
Verification	<p>Enable the multicast source (192.168.1.100) to send packets to G (233.3.3.3). Enable receiver A to join G.</p> <ul style="list-style-type: none"> ● Check multicast packets received by receiver A. Receiver A should be able to receive multicast packets from G. ● Check multicast forwarding tables on A and B.
A	<pre> A# show ip mroute IP Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (TTL) (192.168.1.100, 233.3.3.3), uptime 00:01:55, stat expires 00:02:19 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 (1) </pre>
B	<pre> B# show ip mroute IP Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (TTL) </pre>

```
(192.168.1.100, 233.3.3.3), uptime 00:00:35, stat expires 00:02:55
Owner PIMDM, Flags: TFS
  Incoming interface: GigabitEthernet 0/2
  Outgoing interface list:
    GigabitEthernet 0/1 (1)
```

Common Errors

- An IPv4 unicast route is incorrectly configured.
- IPv4 multicast routing is not enabled on a router.
- IP multicasting is not enabled on an interface.

1.4.2 Configuring a TTL Threshold

Configuration Effect

- Configure a TTL threshold for an interface and check the TTL values of multicast packets. Multicast packets whose TTL values are larger than the TTL threshold of the interface are forwarded and those whose TTL values are smaller are discarded.

Notes

- The basic functions of IP multicasting must be configured.

Configuration Steps

- Set a TTL threshold on PIM router interfaces unless otherwise specified.

Verification

Enable multicast sources to send multicast packets and user hosts to join the groups.

- Set a TTL threshold to a value that is larger than the TTL value of the multicast packet on the PIM router interface directly connected to the user host and check whether the user can receive the multicast packet.

Related Commands

↘ Configuring a TTL Threshold

Command	ip multicast ttl-threshold <i>ttl-value</i>
Parameter Description	<i>ttl-value</i> : Specifies a TTL threshold for an interface. The value ranges from 0 to 255. The default value is 0.
Command Mode	Interface configuration mode
Usage Guide	A multicast-enabled device can retain a TTL threshold for each interface. Multicast packets whose TTL values are larger than the TTL threshold of the interface are forwarded and those whose TTL values are smaller are discarded. A TTL threshold takes effect only for multicast frames and must be configured on layer-3 interfaces.

Configuration Example

Creating the IP Multicast Service on the IPv4 Network and Configuring a TTL Threshold

<p>Scenario</p> <p>Figure 1-4</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> Configure the basic functions of IP multicasting. (Omitted) Configure the TTL threshold as 100 on the Gi 0/2 interface of device A.
<p>A</p>	<pre>A# configure terminal A(config)#int gigabitEthernet 0/2 A(config-if-GigabitEthernet 0/2)#ip multicast ttl-threshold 100 A(config-if-GigabitEthernet 0/2)# exit</pre>
<p>Verification</p>	<p>Enable the multicast source (192.168.1.100) to send packets to G (233.3.3.3). Enable receiver A to join G.</p> <ul style="list-style-type: none"> Configure the TTL threshold as 100 on the Gi 0/2 interface of device A, which is larger than the TTL value of the multicast packet. Check the difference between the route forwarding entries before and after the TTL threshold is configured.
<p>Before Configuring the TTL Threshold</p>	<pre>A# show ip mroute IP Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (TTL) (192.168.1.100, 233.3.3.3), uptime 00:00:08, stat expires 00:03:29 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/1</pre>

	<pre>Outgoing interface list: GigabitEthernet 0/2 (1)</pre>
<p>After Configuring the TTL Threshold</p>	<pre>A# show ip mroute IP Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (TTL) (192.168.1.100, 233.3.3.3), uptime 00:00:01, stat expires 00:03:29 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 (100)</pre>

1.4.3 Configuring the Number of Entries That Can Be Added to the Multicast Routing Table

Configuration Effect

- Each multicast data packet received on the device maintains a corresponding IP multicast route forwarding entry. However, excess multicast routing entries may exhaust device memory and deteriorate device performance. You can limit the number of entries in the IP multicast routing table based on the actual network and service performance requirements.

Notes

- The basic functions of IP multicasting must be configured.

Configuration Steps

- Limit the number of entries in the IP multicast routing table based on the actual network and service performance requirements.

Verification

Send N groups of multicast packets from the multicast source on the network, configure user hosts to join the groups, configure the number of entries that can be added to the IP multicast routing table as N-1, and check whether the multicast packet received by the user host is that of the N-1 group.

Related Commands

- ↳ [Configuring the Number of Entries That Can Be Added to the Multicast Routing Table](#)

Command	ip multicast route-limit <i>limit</i> [<i>threshold</i>]
Parameter Description	<i>limit</i> : Specifies the number of entries in the multicast routing table. The value ranges from 1 to 65536. The default value is 1024. <i>threshold</i> : Specifies the number of entries in the multicast routing table that triggers the warning message. The default value is 65536.
Command Mode	Global configuration mode
Usage Guide	Due to limitations on hardware resources, routing entries that exceed the range permitted by hardware can be forwarded only by software, deteriorating the performance.

Configuration Example

Creating the IP Multicast Service on the IPv4 Network and Configuring the Number of Entries That Can Be Added to the Multicast Routing Table

Scenario Figure 1-5	
Configuration Steps	<ul style="list-style-type: none"> Configure basic the functions of IP multicasting. (Omitted) Configure the number of entries that can be added to the multicast routing table on device B as 2.
B	<pre>B# configure terminal B(config)# ip multicast route-limit 2</pre>
Verification	<p>Enable the multicast source (192.168.1.100) to send packets to G1 (233.3.3.1), G2 (233.3.3.2), and G3 (233.3.3.3). Enable receiver A to join G1, G2, and G3.</p> <ul style="list-style-type: none"> Check multicast packets received by receiver A. Receiver A should be able to receive multicast packets from two groups among G1, G2, and G3. Check multicast routing entries on A and B. When the number of entries in the IP multicasting routing table reaches the upper threshold, a prompt message is displayed.
A	<pre>A# show ip mroute IP Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group</pre>

	<pre> Timers: Uptime/Stat Expiry Interface State: Interface (TTL) (192.168.1.100, 233.3.3.1), uptime 00:00:06, stat expires 00:03:24 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 (1) (192.168.1.100, 233.3.3.2), uptime 00:00:05, stat expires 00:03:25 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 (1) (192.168.1.100, 233.3.3.3), uptime 00:00:00, stat expires 00:03:30 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 (1) </pre>

	<pre>(192.168.1.100, 233.3.3.3), uptime 00:06:08, stat expires 00:03:23 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/2 Outgoing interface list: GigabitEthernet 0/1 (1)</pre>
	<p>When the number of entries in the IP multicasting routing table reaches the upper threshold, a prompt message is displayed.</p> <pre>B#*Dec 26 10:43:07: %MROUTE-4-ROUTELIMIT: IPv4 Multicast route limit 2 exceeded - VRF default.</pre>

Common Errors

- An IPv4 unicast route is incorrectly configured.

1.4.4 Configuring an IP Multicasting Border

Configuration Effect

- Configure an IP multicasting border to specify the transmission range of multicast packets.

Notes

- The basic functions of IP multicasting must be configured.

Configuration Steps

- Configure an IP multicasting border on PIM router interfaces unless otherwise specified.

Verification

Enable multicast sources to send multicast packets and user hosts to join the groups. Configure an IP multicasting border on the PIM router interface connected to the user host and check whether the user can receive the multicast packet.

Related Commands

↳ Enabling IPv4 Multicast Routing

Command	ip multicast boundary <i>access-list</i> [in out]
Parameter Description	<i>access-list</i> : Indicates the group address range defined by ACL. in : Indicates that the IP multicasting border takes effect in the incoming direction of the multicast stream. out : Indicates that the IP multicasting border takes effect in the outgoing direction of the multicast stream.
Command Mode	Interface configuration mode
Usage Guide	After this command is executed, IGMP and PIM-SM packets in the group range are filtered on this interface and multicast data streams are not going in and out through this interface. The ACL associated with this command can be a standard ACL or an extended ACL. For extended ACLs, only the destination address is matched and the source address is matched.

Configuration Example

Creating the IP Multicast Service on the IPv4 Network and Configuring an IP Multicasting Border

<p>Scenario</p> <p>Figure 1-6</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> Configure the basic functions of IP multicasting. (Omitted) Configure an ACL on device A. Configure an IP multicasting border on the Gi 0/1 interface of device A.
<p>A</p>	<pre>A# configure terminal A(config)#ip access-list standard ip_multicast A(config-std-nacl)#deny any A(config-std-nacl)#exit A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)#ip multicast boundary ip_multicast A A(config-if-GigabitEthernet 0/1)# exit</pre>
<p>Verification</p>	<p>Enable the multicast source (192.168.1.100) to send packets to G (233.3.3.3). Enable receiver A to join G.</p> <ul style="list-style-type: none"> Run debug ip pim sparse-mode events.
<p>A</p>	<pre>A# debug ip pim sparse-mode events Jan 1 20:58:34: %7: VRF(0): No cache message: src 192.168.1.100 for 233.3.3.3 vif 2 *Jan 1 20:58:34: %7: VRF(0): Ignore No cache message: src 192.168.1.100 for 233.3.3.3 vif 2 in PIM_BOUNDARY_FLT_BOTH range</pre>

Common Errors

- An IPv4 unicast route is incorrectly configured.

1.4.5 Configuring an IP Multicasting Static Route

Configuration Effect

- Configure an IP multicasting static route to specify an RPF interface or RPF neighbor for multicast packets from specified multicast sources.

Notes

- The basic functions of IP multicasting must be configured.

Configuration Steps

- An IP multicasting static route can be configured on each device unless otherwise specified.

Verification

Run **show ip rpf** { *source-address* [*group-address*] [**rd** *route-distinguisher*] } [**metric**] to check the RPF information of a specified source.

Related Commands

▾ Configuring Basic Functions of IP Multicasting

Command	ip mroute <i>source-address</i> <i>mask</i> { [bgp isis ospf rip static] { <i>v4rpf-address</i> <i>interface-type interface-number</i> } } [<i>distance</i>]
Parameter Description	<p><i>source-address</i>: Specifies the multicast source address.</p> <p><i>mask</i>: Specifies the mask of the multicast source address.</p> <p><i>protocol</i>: Indicates the unicast routing protocol currently used.</p> <p><i>rpf-address</i>: Specifies the address of the RPF neighbor (next hop of the multicast source).</p> <p><i>interface-type interface-number</i>: Indicates the RPF interface (outgoing interface of the multicast source).</p> <p><i>distance</i>: Specifies the route management distance. The value ranges from 0 to 255. The default value is 0.</p>
Command Mode	Global configuration mode
Usage Guide	<p>Multicast static routes are applicable only to RPF check.</p> <p>If the IP address of the outgoing interface, but not the next hop, of the static multicast route needs to be specified, the outgoing interface must be a point-to-point type.</p>

▾ Displaying the RFP Information of a Specified Source Address

Command	show ip rpf { <i>source-address</i>
Parameter Description	<p><i>source-address</i>: Specifies the source IP address.</p> <p><i>group-address</i>: Specifies the group IP address.</p>
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<p>The three parameters are optional, and the source address and group address must be specified simultaneously.</p> <p>When no source address or group address is specified, all MFC entries are displayed.</p> <p>When only the source address and group address are specified, MFC entries of the source address and group address are displayed.</p>

Configuration Example

Creating the IP Multicast Service on the IPv4 Network and Supporting PIM-DM

<p>Scenario Figure 1-7</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> Configure the basic functions of IP multicasting. (Omitted) Configure a static route to the receiver on device B.
<p>A</p>	<pre>B# configure terminal B(config)# ip mroute 10.10.10.10 255.255.255.255 ospf 192.168.1.1 1</pre>
<p>Verification</p>	<p>Run show ip rpf to view the RPF information to the receiver before and after the configuration.</p>
<p>Before Configuration</p>	<pre>B# show ip rpf 10.10.10.10 RPF information for 10.10.10.10 RPF interface: GigabitEthernet 0/2 RPF neighbor: 192.168.2.1 RPF route: 10.10.10.10/32 RPF type: unicast (ospf) RPF recursion count: 0 Doing distance-preferred lookups across tables Distance: 110 Metric: 1</pre>
<p>After Configuration</p>	<pre>B# show ip rpf 10.10.10.10 RPF information for 10.10.10.10 RPF interface: GigabitEthernet 0/0 RPF neighbor: 192.168.1.1 RPF route: 10.10.10.10/32 RPF type: static RPF recursion count: 0 Doing distance-preferred lookups across tables Distance: 1 Metric: 0</pre>

Common Errors

- An IPv4 unicast route is incorrectly configured.
- IPv4 multicast routing is not enabled on a device.

1.4.6 Configuring Layer-2 Direction Control for Multicast Streams

Configuration Effect

Configure layer-2 direction control for multicast streams to control the forwarding of multicast streams on an interface.

Notes

- The basic functions of IP multicasting must be configured.

Configuration Steps

- Layer-2 direction control for multicast streams can be configured on layer-2 devices unless otherwise specified.

Verification

Send multicast packets on the network containing layer-2 device A, connect multiple user hosts to VLAN 1 of layer-2 device A to receive the group, configure layer-2 direction control for multicast streams on device A, and check whether multicast packets are sent to the configured layer-2 interface.

Related Commands

▾ Configuring Layer-2 Direction Control for Multicast Streams

Command	<code>ip multicast static source-address group-address interface-type interface-number</code>
Parameter Description	<p><i>source -address</i>: Specifies the multicast source address.</p> <p><i>group-address</i>: Specifies the multicast group address.</p> <p><i>interface-type interface-number</i>: Specifies a layer-2 interface that is allowed to forward the multicast flow.</p>
Command Mode	Global configuration mode
Usage Guide	<p>Allow a specified multicast flow to be configured with multiple commands, that is, to be configured with multiple interfaces. Once direction control is configured for a multicast stream, the stream can be forwarded only by these configured interfaces. Other interfaces are not permitted to forward the stream.</p> <p>This command controls only the forwarding of multicast streams on the interface, but does not directly affect the processing of multicast protocols on the protocol packets. However, since certain features of the multicast protocol are driven by multicast data streams, behaviors of the multicast routing protocols may also be affected.</p>

Configuration Example

▾ Creating the IP Multicast Service on the IPv4 Network and Configuring Layer-2 Direction Control for Multicast Streams

<p>Scenario Figure 1-8</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> Configure the basic functions of IP multicasting. (Omitted) Configure layer-2 direction control for multicast streams on device B so that the streams are sent only to the Gi 0/2 interface.
<p>B</p>	<pre>A# configure terminal A(config)# ip multicast static 192.168.1.100 233.3.3.3 gigabitEthernet0/2</pre>
<p>Verification</p>	<p>Enable the multicast source (192.168.1.100) to send packets to G (233.3.3.1). Enable receivers A and B to join G.</p> <ul style="list-style-type: none"> Check multicast packets received by receiver A. Receiver B should not be able to receive multicast packets from G.

Common Errors

- An IPv4 unicast route is incorrectly configured.

1.4.7 Configuring RPF Route Selection Based on the Longest Match Rule

Configuration Effect

- Select an optimal route respectively from the multicast static routing table, MBGP routing table, and unicast routing table and select the one with the longest match mask as the RPF route from the three optimal routes.

Notes

- The basic functions of IP multicasting must be configured.

Configuration Steps

- Configure RPF route selection based on the longest match rule on each device unless otherwise specified.

Verification

Configure a multicast static route and a unicast static route to have the same priority and configure the unicast static route to have a longer mask length.

- Run **show ip rpf source-address** to check the RPF information of a specified source.

Related Commands

↳ **Configuring RPF Route Selection Based on the Longest Match Rule**

Command	ip multicast rpf longest-match
Parameter Description	
Command Mode	Global configuration mode
Usage Guide	<p>The steps for selecting RPF routes are as follows:</p> <ol style="list-style-type: none"> 1. Select an optimal route respectively from the multicast static routing table, MBGP routing table, and unicast routing table for RPF check. 2. Select one from the three routes as the RPF route. <p>If the longest match rule is used, the route with the longest match mask is selected. If the three routes have the same mask, the one with the highest priority is selected. If they have the same priority, the RPF routes are selected in the sequence of multicast static route, MBGP route, and unicast route.</p> <p>If the longest match rule is not used, the route with the longest match mask is selected. If they have the same priority, the RPF routes are selected in the sequence of multicast static route, MBGP route, and unicast route.</p>

Configuration Example

↳ **Creating the IP Multicast Service on the IPv4 Network and Configuring RPF Route Selection Based on the Longest Match Rule**

Scenario Figure 1-9	
Configuration Steps	<ul style="list-style-type: none"> ● Configure the basic functions of IP multicasting. (Omitted) ● On device B, configure an IP multicast static route whose mask length is smaller than that of the unicast static route. ● Configure RPF route selection based on the longest match rule on device B.
B	<pre>B# configure terminal B(config)# ip multicast-routing B(config)# ip mroute 10.10.10.10 255.255.0.0 ospf 192.168.1.1 B(config)# ip multicast rpf longest-match</pre>
Verification	Run show ip rpf to check the RPF information of the multicast source before and after configuring RPF route selection based on the longest match rule.

Before configuration	<pre> B#show ip rpf 10.10.10.10 RPF information for 10.10.10.10 RPF interface: GigabitEthernet 0/0 RPF neighbor: 192.168.1.1 RPF route: 10.10.0.0/16 RPF type: static RPF recursion count: 0 Doing distance-preferred lookups across tables Distance: 0 Metric: 0 </pre>
After configuration	<pre> B# show ip rpf 10.10.10.10 RPF information for 10.10.10.10 RPF interface: GigabitEthernet 0/2 RPF neighbor: 192.168.2.1 RPF route: 10.10.10.10/32 RPF type: unicast (ospf) RPF recursion count: 0 Doing prefix-length-preferred lookups across tables Distance: 110 Metric: 1 </pre>

Common Errors

- An IPv4 unicast route is incorrectly configured.
- IPv4 multicast routing is not enabled on a router.

1.4.8 Configuring Multicast Non-Stop Forwarding Parameters

Configuration Effect

- The non-stop forwarding function ensures continuous forwarding of multicast data streams during re-convergence of multicast protocols.

Notes

- The basic functions of IP multicasting must be configured.

Configuration Steps

📌 Configuring the Maximum Period for Multicast Protocol Convergence

- The maximum period for multicast protocol convergence can be specified on each device unless otherwise specified.

↘ Configuring the Multicast Packet Leakage Period

- The multicast leakage period can be configured on each device unless otherwise specified.

Verification

Run **show msf nsf** to check the configured multicast non-stop forwarding parameters.

Related Commands

↘ Configuring the Maximum Period for Multicast Protocol Convergence

Command	msf nsf convergence-time <i>time</i>
Parameter Description	convergence-time <i>time</i> : Specifies the maximum period for multicast protocol convergence. The value ranges from 0 to 3600s. The default value is 20s.
Command Mode	Global configuration mode
Usage Guide	-

↘ Configuring the Multicast Packet Leakage Period

Command	msf nsf leak <i>interval</i>
Parameter Description	leak <i>interval</i> : Specifies the multicast packet leakage period. The value ranges from 0 to 3600s. The default value is 30s.

Configuration Example

↘ Creating the IP Multicast Service on the IPv4 Network and Supporting PIM-DM

Scenario	Basic environment of the IP multicasting service (Omitted)
Configuration Steps	<ul style="list-style-type: none"> ● Configure the basic functions of IP multicasting. (Omitted) ● Configure the maximum period for multicast protocol convergence. ● Configure the multicast packet leakage period.

A	<pre>A# configure terminal A(config)# msf nsf convergence-time 200 A(config)# msf nsf leak 300</pre>
Verification	Run show msf nsf to display multicast non-stop forwarding configurations.
A	<pre>A# show msf nsf Multicast HA Parameters -----+-----+ protocol convergence timeout 200 secs flow leak interval 300 secs</pre>

1.4.9 Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries

Configuration Effect

- Delete the earliest hardware entries and adds new entries if the hardware forwarding table overflows when you create multicast forwarding entries.

Notes

- The basic functions of IP multicasting must be configured.

Configuration Steps

- The overwriting mechanism upon overflow of multicast hardware forwarding entries can be configured on each device unless otherwise specified.

Verification

Run **show running-config** to check whether the overwriting mechanism upon overflow of multicast hardware forwarding entries is configured.

Related Commands

↳ Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries

Command	msf ipmc-overflow override
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	-

Configuration Example

Creating the IP Multicast Service on the IPv4 Network and Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries

Scenario	Basic environment of the IP multicasting service (Omitted)
Configuration Steps	<ul style="list-style-type: none"> Configure the basic functions of IP multicasting. (Omitted) Configure the overwriting mechanism upon overflow of multicast hardware forwarding entries.
A	<pre>A# configure terminal A(config)#msf ipmc-overflow override</pre>
Verification	Run show running-config to check whether the overwriting mechanism upon overflow of multicast hardware forwarding entries is configured.
A	<pre>A# show running-config ... msf ipmc-overflow override ...</pre>

1.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and interrupt services.

Description	Command
Clears the IPv4 multicast forwarding table.	clear ip mroute { * <i>v4group-address</i> [<i>v4source-address</i>] }
Resets statistics in the IPv4 multicast forwarding table.	clear ip mroute tatistics { * <i>v4group-address</i> [<i>v4source-address</i>] }

Displaying

Description	Command
Displays the IPv4 multicast forwarding table.	show ip mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]] [dense sparse] [summary count]
Displays IPv4 static multicast route information.	show ip mroute static
Displays the RFP Information of a specified IPv4 source address.	show ip rpf <i>source-address</i> [

Description	Command
Displays information about IPv4 multicast interfaces.	show ip mvif [<i>interface-type interface-number</i>]
Displays the IPv4 layer-3 multicast forwarding table.	show ip mrf mfc
Displays the IPv4 multi-layer multicast forwarding table.	show msf msc
Displays IPv4 multicast non-stop forwarding configurations.	show msf nsf

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs running of the multicast core.	debug nsm mcast all
Debugs communication between the IPv4 multicast core and the protocol module.	debug nsm mcast fib-msg
Debugs the interface running of the IPv4 multicast core.	debug nsm mcast vif
Debugs the interface and entry statistics processing of the IPv4 multicast core.	debug nsm mcast stats
Debugs the processing of IPv4 layer-3 multicast packet forwarding.	debug ip mrf forwarding
Debugs the operation on layer-3 multicast forwarding entries on an IPv4 network.	debug ip mrf mfc
Debugs the processing of layer-3 multicast forwarding events on an IPv4 network.	debug ip mrf event
Debugs the processing of IPv4 multi-layer multicast packet forwarding.	debug msf forwarding
Debugs the operation on multi-layer multicast forwarding entries on an IPv4 network.	debug msf mfc
Debugs the bottom-layer hardware processing of IPv4 multi-layer multicast packet forwarding.	debug msf ssp

Description	Command
Debugs the invocation of API interfaces provided by IPv4 multi-layer multicast forwarding.	debug msf api
Debugs the processing of multi-layer multicast forwarding events on an IPv4 network.	debug msf event

2 Configuring IPv6 Multicast

2.1 Overview

IPv6 multicast is enrichment and enhancement of IPv4 multicast. In comparison with IPv4 multicast, the IPv6 multicast address mechanism is greatly enriched.

In traditional IP transmission, a host is allowed to send packets only to a single host (unicast communication) or all hosts (broadcast communication). The multicast technology provides a third choice: A host is allowed to send packets to certain hosts.

The IP multicast technology is applicable to one-to-many multimedia applications.

Protocols and Standards

IPv6 multicast covers the following protocols:

- Multicast Listener Discovery (MLD): Runs between a multicast device and a host, and tracks and learns relationships of group members.
- Protocol Independent Multicast – Sparse Mode for IPv6 (PIM-SMv6): Runs between devices and implements multicast packet forwarding by establishing a multicast routing table.

2.2 Applications

Application	Description
Typical Application of PIM-SMv6	The PIM-SMv6 multicast service is provided in the same network.

2.2.1 Typical Application of PIM-SMv6

Scenario

The PIM-SMv6 multicast service is provided in the same network.

As shown in the following figure:

- R1 and the multicast source are in the same network, R2 is configured as a rendezvous point (RP), R3 is in the same network as Receiver A, and R4 is in the same network as Receiver B. Assume that devices and hosts are correctly connected, IPv6 is enabled on each interface, and IPv6 unicast is enabled on each device.

Figure 2-1

Remarks	<p>R1, R2, R3, and R4 are Layer-3 devices and R2 functions as an RP.</p> <p>The multicast source is directly connected to R1, Receiver A is directly connected to R3, and Receiver B is directly connected to R4.</p>
----------------	---

Deployment

- Run the Open Shortest Path First for IPv6 (OSPFv6) protocol in the same network to implement unicast routing.
- Run the PIM-SMv6 protocol in the same network to implement multicast routing.

2.3 Features

Basic Concepts

↘ PIM Router and PIM Interface

Routers where the PIM protocol is enabled are called PIM routers. Interfaces where the PIM protocol is enabled are called PIM interfaces.

Multicast packets are forwarded by PIM routers. The PIM interfaces for receiving multicast packets are called upstream interfaces, and the PIM interfaces for transmitting multicast packets are called downstream interfaces.

Network segments where upstream interfaces are located are called upstream network segments. Network segments where downstream interfaces are located are called downstream network segments.

↘ PIM Network and PIM Domain

PIM routers are connected through PIM interfaces and form a PIM network.

On some PIM interfaces, borders are set to divide a large PIM network into multiple PIM domains. The borders may reject specific multicast packets or limit transmission of PIM messages.

↘ Multicast Distribution Tree, DR, RP

Multicast packets are transmitted from one point to multiple points. The forwarding path presents a tree structure. This forwarding path is called a multicast distribution tree (MDT). MDTs are classified into two types:

- Rendezvous point tree (RPT): Uses the rendezvous point (RP) as the root and designated routers (DRs) connected to group members as leaves.
- Shortest path tree (SPT): Use the DR connected to a multicast source as the root and the RPs or DRs connected to group members as leaves.

DRs and RPs are function roles of PIM routers.

- RPs collect information about multicast sources and group members in the network.
- The DR connected to a multicast source reports multicast source information to the RP and the DRs connected to group members report the group member information to the RP.

↳ **(*,G), (S,G)**

- (*,G): Indicates the packets transmitted from any source to Group G, routing entries corresponding to the packets, and forwarding path (RPT) corresponding to the packets.
- (S,G): Indicates the packets transmitted from Source S to Group G, routing entries corresponding to the packets, and forwarding path (SPT) corresponding to the packets.

↳ **ASM, SSM**

PIM-SM supports two multicast service models: any-source multicast (ASM) and source-specific multicast (SSM), which are applicable to different multicast address segments.

- ASM: In the ASM model, a user host cannot select a multicast source. The user host joins a multicast group and receives all packets sent from all sources to the multicast group.
- SSM: In the SSM model, a user host can select a multicast source. The user host specifies the source address when joining a multicast group, and then receives packets only from the specified source to the multicast group.

i SSM model requirement: Other network services must be used to enable a user host to know the position of a multicast source in advance so that the user host selects the multicast source.

Overview

Feature	Description
Configuring IPv6 Multicast Basic Functions	Creates a PIM network to provide the IPv6 multicast service for data sources and user terminals in the network.
Configuring the Number of Entries That Can Be Added to the IPv6 Multicast Routing Table	Restricts the number of entries that can be added to the multicast routing table.
Configuring the IPv6 Multicast Border	Sets an interface as the multicast border of a specific group range.
Configuring IPv6 Multicast Static Routing	Configures multicast static routing to adopt multicast forwarding paths different from unicast forwarding paths.

Feature	Description
Configuring Layer-2 Flow Direction Control for Multicast Streams	Multiple commands can be configured for a multicast stream, that is, multiple ports can be allowed to forward the multicast stream. If flow direction control is configured for a multicast stream, the multicast stream can be forwarded only by the configured ports. Other ports are not allowed to forward the multicast stream.
Configuring RPF Route Selection According to the Longest Matching Principle	One optimal route is selected from each of the multicast static routing table, MBGP routing table, and unicast routing table according to RPF rules. Among the three optimal routes, the route with the longest subnet mask matching is selected as the RPF route.

2.3.1 Configuring IPv6 Multicast Basic Functions

Create a PIM network to provide the IPv6 multicast service for data sources and user terminals in the network.

[Working Principle](#)

A device maintains the routing table used for multicast packet forwarding over an IPv6 multicast routing protocol (such as PIM-SMv6), and learns information about the status of group members in the directly-connected network segments over the MLDv1/v2 protocol. A host joins a specific IPv6 multicast group by transmitting the MLD REPORT message.

[Related Configuration](#)

[Enabling the IPv6 Multicast Routing Function](#)

The IPv6 multicast routing function is disabled by default.

Run the **ipv6 multicast-routing** command to enable the IPv6 multicast routing function.

[Configuring an IP Multicast Protocol on an Interface](#)

The IPv6 multicast protocol is disabled on an interface by default.

Run the **ipv6 pim dense-mode** command to enable the IPv6 multicast protocol on an interface.

2.3.2 Configuring the Number of Entries That Can Be Added to the IPv6 Multicast Routing Table

Every multicast data packet received by the device is used to maintain relevant IPv6 multicast routing entries. Excessive multicast routing entries, however, may deplete the device memory and degrade the device performance. Users can restrict the number of entries in the IPv6 multicast routing table based on the actual networking conditions and service performance requirements.

[Working Principle](#)

Restrict the number of entries in the IPv6 multicast routing table based on the actual networking conditions and service performance requirements, so as to sustain the device performance.

[Related Configuration](#)

[Configuring the Number of Entries That Can Be Added to the IPv6 Multicast Routing Table](#)

By default, 1,024 entries can be added to the IP multicast routing table.

Run the **ipv6 multicast route-limit** *limit* [*threshold*] command to adjust the number of entries that can be added to the IPv6 multicast routing table. The value ranges from 1 to 65,536.

A larger value of *limit* means that more entries can be added to the IPv6 multicast routing table, and a smaller value of *limit* means that fewer entries can be added to the IPv6 multicast routing table.

2.3.3 Configuring the IPv6 Multicast Border

Configure the IPv6 multicast border to restrict the transmission scope of multicast packets.

Working Principle

Configure the multicast border to specify the transmission scope of multicast packets. When the multicast forwarding border is configured on an interface, multicast packets including multicast packets sent by the local device cannot be forwarded or received by this interface.

Related Configuration

↳ [Configuring the IPv6 Multicast Border](#)

No multicast border is configured by default.

Run the **ipv6 multicast boundary** *access-list-name* [*in* | *out*] command to configure the multicast border.

2.3.4 Configuring IPv6 Multicast Static Routing

Configure IPv6 multicast static routing to specify a reverse path forwarding (RPF) interface or RPF neighbor for multicast packets from a specific multicast source.

Working Principle

The RPF check is conducted during forwarding of multicast packets. IPv6 multicast static routing can be configured to specify an RPF interface or RPF neighbor for multicast packets from a specific multicast source.

Related Configuration

↳ [Configuring IPv6 Multicast Static Routing](#)

No multicast static routing is configured by default.

Run the **ipv6 mroute** *ipv6-prefix/prefix-length* [*bgp* | *isis* | *ospfv3* | *ripng* | *static*] { *ipv6-prefix* | *interface-type interface-number* } [*distance*] command to configure IPv6 multicast static routing.

2.3.5 Configuring Layer-2 Flow Direction Control for Multicast Streams

Configure Layer-2 flow direction control for multicast streams to control the forwarding behavior of multicast streams on ports.

Working Principle

Configure Layer-2 flow direction control for multicast streams to configure the ports that are allowed to forward multicast streams. Then, multicast streams are forwarded only by the configured ports, thereby controlling Layer-2 forwarding of multicast streams.

Related Configuration

Configuring Layer-2 Flow Direction Control for Multicast Streams

Layer-2 flow direction control is disabled for multicast streams by default.

Run the **ipv6 multicast static** *source-address group-address interface-type interface-number* command to configure the Layer-2 flow direction control for multicast streams.

2.3.6 Configuring RPF Route Selection According to the Longest Matching Principle

Among the three optimal routes selected from the multicast static routing table, Multiprotocol Border Gateway Protocol (MBGP) routing table, and unicast routing table, select the optimal route with the longest subnet mask matching as the RPF route.

Working Principle

According to RPF rules, select a multicast static route, MBGP route, and unicast route used for the RPF check respectively from the multicast static routing table, MBGP routing table, and unicast routing table.

- If route selection according to the longest matching principle is configured, the route with the longest subnet mask matching is selected out of the three routes as the RPF route. If the three routes share the same subnet mask, the route with the highest priority is selected. If the three routes have the same priority, the RPF route is selected according to the sequence of multicast static route, MBGP route, and unicast route.
- If route selection according to the longest matching principle is not configured, the route with the highest priority is selected. If the three routes have the same priority, the RPF route is selected according to the sequence of multicast static route, MBGP route, and unicast route.

Related Configuration

Configuring RPF Route Selection According to the Longest Matching Principle

A route with the highest priority is selected as the RPF route by default. If the routes have the same priority, the RPF route is selected according to the sequence of multicast static route, MBGP route, and unicast route.

Run the **ipv6 multicast rpf longest-match** command to configure RPF route selection according to the longest matching principle.

2.4 Configuration

Configuration	Description and Command
Configuring IPv6 Multicast Basic Functions	 (Mandatory) It is used to create a multicast service.
	ipv6 multicast-routing Enables the IPv6 multicast routing function.
Configuring the Number of Entries That Can Be Added to the IPv6 Multicast Routing Table	 Optional.
	ipv6 multicast route-limit limit [<i>threshold</i>] Restricts the number of entries that can be added to the multicast routing table.

Configuring the IPv6 Multicast Border	ipv6 multicast boundary <i>access-list-name [in out]</i>	Sets an interface as the multicast border of a specific group range.
Configuring IPv6 Multicast Static Routing	ipv6 mroute <i>ipv6-prefix/prefix-length</i> [<i>protocol</i>] { <i>v6rpf-address</i> <i>interface-type interface-number</i> } [<i>distance</i>]	Configures IPv6 multicast static routing.
Configuring Layer-2 Flow Direction Control for Multicast Streams	ipv6 multicast static <i>source-address</i> <i>group-address interface-type</i> <i>interface-number</i>	Controls the flow direction of data streams on Layer-2 ports.
Configuring RPF Route Selection According to the Longest Matching Principle	ipv6 multicast rpf longest-match	Configures RPF route selection according to the longest matching principle.

2.4.1 Configuring IPv6 Multicast Basic Functions

Configuration Effect

- Create a PIM network to provide the IPv6 multicast service for data sources and user terminals in the network.

Notes

- The PIM network needs to use existing unicast routing in the network. Therefore, IPv6 unicast routing must be configured in the network.

Configuration Steps

▾ Enabling the IPv6 Multicast Routing Function

- Mandatory.
- Enable the IPv6 multicast routing function on each router unless otherwise specified.

▾ Enabling an IP Multicast Protocol on Interfaces

- Mandatory.
- Enable the IPv6 multicast protocol function on interfaces unless otherwise specified.

Verification

Make multicast sources in the network send multicast packets and make a user host join the groups.

- Check whether the user host can successfully receive packets from each group.

Related Commands

▾ Enabling the IPv6 Multicast Routing Function

Command	ipv6 multicast-routing
Parameter Description	N/A

Command Mode	Global configuration mode
Usage Guide	The IPv6 multicast routing function must be enabled before various IPv6 multicast protocols are enabled. The IPv6 multicast routing function and the MLD snooping function are mutually exclusive.

📄 **Configuring IPv6 Multicast Protocols**

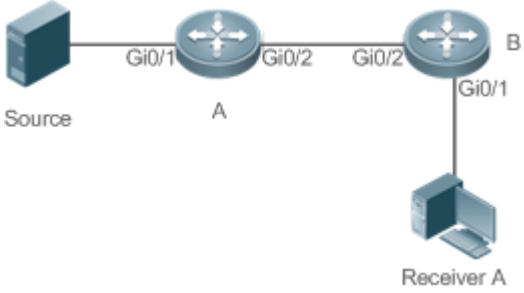

- ❗ For details about the MLD configuration method, see the *Configuring MLD*.
- ❗ For details about the PIM-SMv6 configuration method, see the *Configuring PIM-SMv6*.
- ❗ After the Layer-3 multicast function is enabled on a private VLAN and Super VLAN, if there is a multicast source in the sub-VLAN, an entry needs to be additionally copied, with the inlet of the sub-VLAN where multicast streams enter because the validity check needs to be conducted at the inlet during multicast packet forwarding. As a result, one more multicast hardware entry is occupied, and the multicast capacity needs to be decreased by one.

📄 **Displaying Multicast Forwarding Table Information**

Command	show ipv6 mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]] [sparse] [summary count]
Parameter Description	<i>group-or-source-address</i> : Indicates the group address or source address. <i>group-or-source-address</i> : Indicates the group address or source address. sparse : Displays the core entry of the PIM-SMv6 multicast routing table. summary : Displays the summary of IPv6 multicast routing entries. count : Displays the count information about IPv6 multicast routing entries.
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	N/A

Configuration Example

📄 **Creating the IPv6 Multicast Service on an IPv6 Network to Support PIMv6-SM**

Scenario Figure 2-2	 <p>The diagram illustrates a network topology for IPv6 multicast. A Source is connected to Router A via interface Gi0/1. Router A is connected to Router B via interface Gi0/2. Router B is connected to Receiver A via interface Gi0/1.</p>
Configuration Steps	<ul style="list-style-type: none"> ● Configure an IPv6 unicast routing protocol (for example, OSPFv3) on routers. ● Enable the IPv6 multicast routing function on all routers.

	<ul style="list-style-type: none"> ● Enable the PIMv6-SM function on device interconnection interfaces, interface for connecting to the user host, and interface for connecting to the multicast source.
A	<pre>A# configure terminal A(config)# ipv6 multicast-routing A(config)# interface gigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)#ipv6 pim sparse-mode A(config-if)# exit A(config)# interface gigabitEthernet 0/2 A(config-if-GigabitEthernet 0/2)#ipv6 pim sparse-mode A(config-if)# exit</pre>
B	<pre>B# configure terminal B(config)# ipv6 multicast-routing B(config)# interface gigabitEthernet 0/1 B(config-if-GigabitEthernet 0/1)#ipv6 pim sparse-mode B(config-if)# exit B(config)# interface GigabitEthernet 0/2 B(config-if-GigabitEthernet 0/2)#ipv6 pim sparse-mode B(config-if)# exit</pre>
Verification	<p>Make Multicast Source (2001::1) send packets to G(ff16::16) and make Receiver A join G.</p> <ul style="list-style-type: none"> ● Check multicast packets received by Receiver A. Receiver A should be able to receive multicast packets from G. ● Check the multicast forwarding table on Receiver A and Device B.
A	<pre>A# show ipv6 mroute IPv6 Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (2001::1, ff16::16), uptime 00:03:12, stat expires 00:02:03 Owner PIMSMV6, Flags: TFS Incoming interface: GigabitEthernet 0/1</pre>

	<pre> Outgoing interface list: GigabitEthernet 0/2 </pre>
B	<pre> B# show ipv6 mroute IPv6 Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (2001::1, ff16::16), uptime 00:00:23, stat expires 00:03:07 Owner PIMSMV6, Flags: TFR Incoming interface: GigabitEthernet 0/2 Outgoing interface list: GigabitEthernet 0/1 </pre>

Common Errors

- IPv6 unicast routing is incorrectly configured.
- IPv6 multicast routing is not enabled on a router.
- No IPv6 multicast protocol is enabled on an interface.

2.4.2 Configuring the Number of Entries That Can Be Added to the IPv6 Multicast Routing Table

Configuration Effect

- Every multicast data packet received by the device is used to maintain relevant IPv6 multicast routing entries. Excessive multicast routing entries, however, may deplete the device memory and degrade the device performance. Users can restrict the number of entries in the IPv6 multicast routing table based on the actual networking conditions and service performance requirements.

Notes

- The IPv6 multicast basic functions must be configured.

Configuration Steps

- Restrict the number of entries in the IPv6 multicast routing table based on the actual networking conditions and service performance requirements.

Verification

Make multicast sources in the network send multicast packets to N different multicast groups and make a user host join these groups. Set the number of entries that can be added to the IPv6 multicast routing table to N-1 on the device and check that multicast packets received by the user host are from N-1 groups.

Related Commands

Configuring the Number of Entries That Can Be Added to the IP Multicast Routing Table

Command	<code>ipv6 multicast route-limit limit [threshold]</code>
Parameter Description	<p><i>limit</i>: Indicates the number of multicast routing entries. The value ranges from 1 to 65,536 and the default value is 1,024.</p> <p><i>threshold</i>: Indicates the multicast routing entry quantity for triggering an alarm. The default value is 65,536.</p>
Command Mode	Global configuration mode
Usage Guide	Routing entries that are beyond the allowable range of hardware can be forwarded only by software due to hardware resource restrictions, making the performance deteriorate.

Configuration Example

Creating the IPv6 Multicast Service on an IPv6 Network and Configuring the Number of Entries That Can Be Added to the IPv6 Multicast Routing Table

Scenario Figure 2-3	
Configuration Steps	<ul style="list-style-type: none"> Configure IP multicast basic functions (omitted). Set the number of entries that can be added to the IP multicast routing table to 2 on Device B.
B	<pre>B# configure terminal B(config)# ipv6 multicast route-limit 2</pre>
Verification	<p>Make Multicast Source (2001::1) send packets to G1(ff16::16), G2(ff16::17), and G3(ff16::18) and make Receiver A join G1, G2, and G3.</p> <ul style="list-style-type: none"> Check multicast packets received by Receiver A. Receiver A should be able to receive multicast packets from two groups of G1, G2, and G3.

	<ul style="list-style-type: none"> ● Check multicast routing entries on Receiver A and Device B. ● A prompt is displayed when the number of entries in the multicast routing table reaches the upper limit.
<p>A</p>	<pre> A# show ipv6 mroute IPv6 Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (2001::1, ff16::16), uptime 00:01:01, stat expires 00:02:29 Owner PIMSMV6, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 (2001::1, ff16::17), uptime 00:01:01, stat expires 00:02:29 Owner PIMSMV6, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 (2001::1, ff16::18), uptime 00:00:57, stat expires 00:02:33 Owner PIMSMV6, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 </pre>
<p>B</p>	<pre> B# show ipv6 mroute IPv6 Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group </pre>

<pre> Timers: Uptime/Stat Expiry Interface State: Interface (2001::1, ff16::16), uptime 00:00:29, stat expires 00:03:01 Owner PIMSMV6, Flags: TFR Incoming interface: GigabitEthernet 0/2 Outgoing interface list: GigabitEthernet 0/1 (2001::1, ff16::17), uptime 00:00:29, stat expires 00:03:01 Owner PIMSMV6, Flags: TFR Incoming interface: GigabitEthernet 0/2 Outgoing interface list: GigabitEthernet 0/1 </pre>
<p>A prompt is displayed when the number of entries in the multicast routing table reaches the upper limit.</p> <pre>B#* Jan 3 21:40:07: %MROUTE-4-ROU TELIMIT: IPv6 Multicast route limit 2 exceeded..</pre>

Common Errors

- IPv6 unicast routing is incorrectly configured.

2.4.3 Configuring the IPv6 Multicast Border

Configuration Effect

- Configure the IPv6 multicast border to restrict the transmission scope of multicast packets.

Notes

- The IPv6 multicast basic functions must be configured.

Configuration Steps

- Configure the IPv6 multicast border on each PIM router interface unless otherwise specified.

Verification

Make multicast sources send multicast packets to multicast groups and make a user host join these multicast groups. Configure the IPv6 multicast border on the PIM router interface connected to the user host and check whether the user host can receive multicast packets.

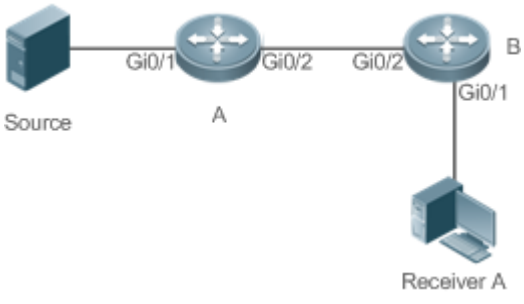

Related Commands

↳ Enabling the IPv6 Multicast Routing Function

Command	ipv6 multicast boundary <i>access-list-name</i> [in out]
Parameter Description	<i>access-list-name</i> : Uses the group address range defined by an access control list (ACL). in : Indicates that the multicast border takes effect in the incoming direction of multicast streams. out : Indicates that the multicast border takes effect in the outgoing direction of multicast streams.
Command Mode	Interface configuration mode
Usage Guide	The ACL referenced in this command can be a standard ACL or an extended ACL. If an extended ACL is used, only destination addresses need to be matched. This command can be used to filter MLD and PIM-SMv6 protocol packets relevant to the IPv6 multicast group range. Multicast data streams are not transmitted or received by multicast border interfaces.

Configuration Example

Creating the IPv6 Multicast Service on an IPv6 Network and Configuring the IPv6 Multicast Border

Scenario Figure 2-4	
Configuration Steps	<ul style="list-style-type: none"> Configure IP multicast basic functions (omitted). Configure an ACL on Device A. Configure the IP multicast border on Interface Gi0/1 of Device A.
A	<pre>A# configure terminal A(config)# ipv6 access-list ip_multicast A(config-ipv6-acl)#deny udp any any A(config-ipv6-acl)#exit A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)#ip multicast boundary ip_multicast A A(config-if-GigabitEthernet 0/1)# exit</pre>
Verification	<p>Make Multicast Source (192.168.1.100) send packets to G (233.3.3.3) and make Receiver A join G.</p> <ul style="list-style-type: none"> Run the debug ipv6 pim sparse-mode events command to debug multicast events in SM mode.
A	<pre>A# debug ipv6 pim sparse-mode events Dec 28 11:54:07: %7: No cache message: src 2001::1 for ff16::16 vif 1</pre>

```
*Dec 28 11:54:07: %7: Ignore No cache message: src 2001::1 for ff16::16 vif 1 in
PIM6_BOUNDARY_FLT_BOTH range
```

Common Errors

- IPv6 unicast routing is incorrectly configured.

2.4.4 Configuring IPv6 Multicast Static Routing

Configuration Effect

- Configure IPv6 multicast static routing to specify an RPF interface or RPF neighbor for multicast packets from a specific multicast source.

Notes

- The IPv6 multicast basic functions must be configured.

Configuration Steps

- Configure IPv6 multicast static routing on each device unless otherwise specified.

Verification

Configure IPv6 multicast static routing and then run the **show ipv6 rpf v6source-address** command to check RPF information about a specific multicast source.

Related Commands

↳ Configuring IPv6 Multicast Static Routing

Command	ipv6 mroute <i>ipv6-prefix/prefix-length</i> [<i>protocol</i>] { <i>v6rpf-addrress</i> <i>interface-type interface-number</i> } [<i>distance</i>]
Parameter Description	<p><i>ipv6-prefix</i>: Indicates the IPv6 address of a multicast source.</p> <p><i>prefix-length</i>: Indicates the subnet mask of the IPv6 address of the multicast source.</p> <p>fallback-lookup { global vrf <i>vrf-name</i> }: Specifies the VRF used for RPF search.</p> <p><i>protocol</i>: Indicates the unicast routing protocol that is being used currently.</p> <p><i>v6rpf-addrress</i>: Indicates the IPv6 address of the RPF neighbor (next hop to the multicast source).</p> <p><i>interface-type interface-number</i>: Indicates the RPF interface (outbound interface to the multicast source).</p> <p><i>distance</i>: Indicates the route management distance. The value ranges from 0 to 255 and the default value is 0.</p>
Command Mode	Global configuration mode
Usage Guide	<p>IPv6 multicast static routing is used only for the RPF check.</p> <p>To specify the outbound interface rather than the next-hop IP address of IPv6 static multicast routing, the outbound interface must be of the point-to-point type.</p>

↳ Displaying RPF Information About a Specific Source Address

Command	show ipv6 rpf v6source-address
Parameter Description	v6source-address: Indicates the IPv6 source address.
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	N/A

Configuration Example

Creating the IPv6 Multicast Service on an IPv6 Network and Configuring IPv6 Multicast Static Routing

Scenario Figure 2-5	<p>The diagram illustrates a network topology. On the left is a 'Source' represented by a server icon. A line connects the Source to Device A, labeled 'Gi0/2'. Device A is a blue cube with a cross on top. Device B is another blue cube with a cross on top. Device A is connected to Device B via two lines: one labeled 'Gi0/1' at the top and one labeled 'Gi0/2' at the bottom.</p>
Configuration Steps	<ul style="list-style-type: none"> Configure IPv6 multicast basic functions (omitted). Configure a static route to the receiver on Device B.
A	<pre>B# configure terminal B(config)# ipv6 mroute 2005::/64 ospfv3 2002::2</pre>
Verification	Run the show ipv6 rpf command to display the RPF information received by the receiver before and after configuration.
Before Configuration	<pre>B# show ipv6 rpf 2005::1 RPF information for 2005::1 RPF interface: GigabitEthernet 0/1 RPF neighbor: fe80::2d0:f8ff:fe22:341b RPF route: 2005::1/128 RPF type: unicast (ospf) RPF recursion count: 0 Doing distance-preferred lookups across tables Distance: 110 Metric: 1</pre>
After Configuration	<pre>B# show ipv6 rpf 2005::1 RPF information for 2005::1 RPF interface: GigabitEthernet 0/2</pre>

```
RPF neighbor: 2002::2
RPF route: 2005::/64
RPF type: unicast (ospf)
RPF recursion count: 0
Doing distance-preferred lookups across tables
Distance: 110
Metric: 1
```

Common Errors

- IPv6 unicast routing is incorrectly configured.
- IPv6 multicast routing is not enabled on a router.

2.4.5 Configuring Layer-2 Flow Direction Control for Multicast Streams

Configuration Effect

Configure Layer-2 flow direction control for multicast streams to control the forwarding behavior of multicast streams on ports.

Notes

- The IPv6 multicast basic functions must be configured.

Configuration Steps

- Configure Layer-2 flow direction control for multicast streams on devices unless otherwise specified.

Verification

Make Device A send multicast packets to multicast groups in the network. Multiple user hosts connected to VLAN 1 of Device A receive multicast packets from these multicast groups. Configure Layer-2 flow direction control for multicast streams on Device A so that multicast packets are sent to configured ports.

Related Commands

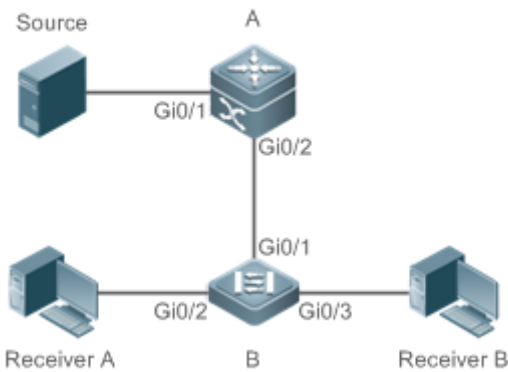

↳ **Configuring Layer-2 Flow Direction Control for Multicast Streams**

Command	ipv6 multicast static <i>source-address group-address interface-type interface-number</i>
Parameter Description	<i>source -address</i> : Indicates the multicast source address. <i>group-address</i> : Indicates the multicast group address. <i>interface-type interface-number</i> : Indicates a Layer-2 port that is allowed to forward multicast streams.
Command Mode	Global configuration mode
Usage Guide	Multiple commands can be configured for a multicast stream, that is, multiple ports can be allowed to forward the multicast stream. If flow direction control is configured for a multicast stream, the multicast stream can be forwarded only by the configured ports. Other ports are not allowed to forward the multicast

stream.
 This command controls only the forwarding behavior of multicast streams on ports. It does not directly affect processing of protocol packets by multicast protocols. Some features of multicast protocols (such as PIM-SMv6) are driven by multicast data streams, and therefore, the behavior of the multicast routing protocols may still be affected.

Configuration Example

Creating the IPv6 Multicast Service on an IPv6 Network and Configuring Layer-2 Flow Direction Control for Multicast Streams

<p>Scenario Figure 2-6</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> Configure IP multicast basic functions (omitted). Configure Layer-2 flow direction control for multicast streams on Device B so that multicast streams are transmitted only to Interface Gi0/2.
<p>B</p>	<pre>A# configure terminal A(config)# ipv6 multicast static 2001::1 ff16::16 gigabitEthernet 0/2</pre>
<p>Verification</p>	<p>Make Multicast Source (2001::1) send packets to G (ff16::16) and make Receiver A and Receiver B join G.</p> <ul style="list-style-type: none"> Receiver A should be able to receive multicast packets from G but Receiver B cannot receive multicast packets from G.

Common Errors

- IPv6 unicast routing is incorrectly configured.

2.4.6 Configuring RPF Route Selection According to the Longest Matching Principle

Configuration Effect

Among the three optimal routes selected from the multicast static routing table, MBGP routing table, and unicast routing table, select the optimal route with the longest subnet mask matching as the RPF route.

Notes

- The IP multicast basic functions must be configured.

Configuration Steps

- Configure RPF route selection according to the longest matching principle on each device unless otherwise specified.

Verification

Configure a multicast static route and a unicast static route with the same priority and configure the unicast static route to have the longest subnet mask matching.

- Run the **show ipv6 rpf v6source-address** command to check RPF information about a specific source.

Related Commands

↳ **Configuring RPF Route Selection According to the Longest Matching Principle**

Command	ipv6 multicast rpf longest-match
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	<p>The steps of selecting an RPF route are as follows:</p> <p>Select one optimal route used for the RPF check from each of the IPv6 multicast static routing table, IPv6 MBGP routing table, and IPv6 unicast routing table.</p> <p>Select one route out of the three optimal routes as the RPF route.</p> <p>If the command for selecting the RPF route according to the longest matching principle is configured, the route with the longest subnet mask matching is selected out of the three optimal routes as the RPF route. If the three routes share the same subnet mask, the route with the highest priority is selected. If the routes have the same priority, the RPF route is selected according to the sequence of IPv6 multicast static route, IPv6 MBGP route, and IPv6 unicast route.</p> <p>If the command for selecting the RPF route according to the longest matching principle is not configured, the route with the highest priority is selected out of the three optimal routes as the RPF route. If the routes have the same priority, the RPF route is selected according to the sequence of IPv6 multicast static route, IPv6 MBGP route, and IPv6 unicast route.</p>

Configuration Example

↳ **Creating the IPv6 Multicast Service on the IPv6 Network and Configuring the RPF Route Selection According to the Longest Matching Principle**

Configuration Steps	<ul style="list-style-type: none"> ● Configure IP multicast basic functions (omitted). ● Configure an IPv6 multicast static route with the subnet mask length smaller than that of the unicast route on Device B. ● Configure the RPF route selection according to the longest matching principle on Device B.
B	<pre>B# configure terminal B(config)# ipv6 multicast-routing B(config)# ipv6 mroute 2005::/64 ospfv3 2002::2 B(config)# ipv6 multicast rpf longest-match</pre>
Verification	Run the show ipv6 rpf command to display the RPF information about the multicast source before and after RPF route selection according to the longest matching principle is configured.
Before Configuration	<pre>B# show ipv6 rpf 2005::1 RPF information for 2005::1 RPF interface: GigabitEthernet 0/2 RPF neighbor: 2002::2 RPF route: 2005::/64 RPF type: unicast (ospf) RPF recursion count: 0 Doing distance-preferred lookups across tables Distance: 110 Metric: 1</pre>
After Configuration	<pre>B# show ipv6 rpf 2005::1 RPF information for 2005::1 RPF interface: GigabitEthernet 0/1 RPF neighbor: fe80::2d0:f8ff:fe22:341b RPF route: 2005::1/128 RPF type: unicast (ospf) RPF recursion count: 0 Doing distance-preferred lookups across tables Distance: 110 Metric: 1</pre>

Common Errors

- IPv6 unicast routing is incorrectly configured.

- IPv6 multicast routing is not enabled on a router.

2.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears the IPv6 multicast forwarding table.	clear ipv6 mroute { * <i>v6group-address</i> [<i>v6source-address</i>] }
Clears the statistics in the IPv6 multicast forwarding table.	clear ipv6 mroute statistics { * <i>v6group-address</i> [<i>v6source-address</i>] }

Displaying

Description	Command
Displays the IPv6 multicast forwarding table information.	show ipv6 mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]] [sparse] [summary count]
Displays RPF information about a specific IPv6 source address.	show ipv6 rpf <i>v6source-address</i>
Displays information the IPv6 static multicast route.	show ipv6 mroute static
Displays information about the configured IPv6 multicast interface that takes effect.	show ipv6 mvif [<i>interface-type interface-number</i>]
Displays the IPv6 Layer-3 multicast forwarding table.	show ipv6 mrf mfc
Displays the IPv6 multi-layer multicast forwarding table.	show msf6 msc

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs all running processes of the IPv6 multicast.	debug nsm mcast6 all
Debugs the communication between the IPv6 multicast and the protocol module.	debug nsm mcast6 fib-msg
Debugs the interface running of the IPv6 multicast.	debug nsm mcast6 mif

Description	Command

3 Configuring IGMP

3.1 Overview

The Internet Group Management Protocol (IGMP) is a member of TCP/IP protocol family. It manages IP multicast members and is used to establish and maintain multicast group membership between hosts and directly neighboring multicast routers. IGMP behaviors are classified into host behaviors and device behaviors.

- At present, three IGMP versions are available, which are IGMPv1, IGMPv2 and IGMPv3.
- All IGMP versions support the Any-Source Multicast (ASM) model.
- IGMPv3 can be directly used for the Source-Specific Multicast (SSM) model.
- IGMPv1 and IGMPv2 can be used for the SSM model only when the IGMP SSM Mapping technology is supported.

Protocols and Standards

- RFC 1112: Host Extensions for IP Multicasting
- RFC 2236: Internet Group Management Protocol, Version 2
- RFC 3376: Internet Group Management Protocol, Version 3
- RFC 4605: Internet Group Management Protocol (IGMP) / Multicast Listener Discovery (MLD)-Based Multicast Forwarding ("IGMP/MLD Proxying")

3.2 Applications

Application	Description
Local IGMP Service	Implements the IGMP service in a local network.
IGMP Proxy Service	In a simple tree network topology, use the IGMP proxy service instead of the PIM service.

3.2.1 Local IGMP Service

Scenario

As shown in figure 3-1, receivers 1 and 2 and routers A and B form a local network.

Query packets sent by router A or B are valid in the LAN, whereas Report packets sent by receivers 1 and 2 are also valid locally.

Figure 3-1

Remark	C is the egress gateway (EG) device.
s	A and B are core routers.

Deployment

- Routers A, B and C run OSPF.
- The interfaces of A, B and C run multicast protocols (PIM-SM or PIM-DM).

3.2.2 IGMP Proxy Service

Scenario

As shown in figure 3-2, router A implements the proxy function working as a host and forms a local network group with router B. Router A forwards Report packets sent by receivers 1 and 2.

Figure 3-2

Remark	Router A implements the proxy function.
s	Router B provides the PIM service.

Deployment

- Routers A and B run OSPF.
- The interfaces of A and B run multicast protocols (PIM-SM or PIM-DM).
- The multicast proxy function is implemented on the interfaces Gi0/0 and Gi0/1 of router A.

3.3 Features

Basic Concepts

Host Behavior and Device Behavior

- Layer-3 multicast devices that run multicast management protocols are called devices and their behaviors are called device behaviors.
- PCs or simulated PCs that run multicast management protocols are called hosts and their behaviors are called host behaviors.

Querier

- Devices compete against each other by comparing IP addresses. Devices with lower IP addresses become queriers and send Query packets regularly.

IGMP Proxy-Service Interface

- This interface performs host behaviors, receives Query packets sent by upstream devices (hence also called uplink interface), and sends Report information collected by the router proxy.

IGMP Mroute-Proxy Interface

- This interface implements the router functions, sends packets received by the IGMP PROXY-SERVICE interface (hence also called downlink interface), and collects host information and sends the host information to the IGMP PROXY-SERVICE interface.

IGMP SSM Mapping

- Mapping of the SSM model. IGMPv1 and IGMPv2 do not support the SSM model, but can enable the SSM-MAP function to support the SSM model.

Overview

Feature	Description
IGMP Router	Sends Query packets and obtains local member information.
IGMP Group Filtering	Filters group members and limit the number of group members.
Static IGMP Group	Static group information is available on a router; therefore, it is unnecessary for the host to send a Report packet to obtain the static group information.
Simulating Hosts to Join IGMP Groups	Simulates the host behavior to directly join a multicast group on an interface.
IGMP Proxy	Use this function in a simple tree network topology where no complex multicast route protocols (such as PIM) need to be executed.
IGMP SSM Mapping	Provides the SSM model support for IGMPv1 and IGMPv2. When a host joins a group, you can specify a source to save bandwidth and prevent unwanted and invalid multicast data streams from occupying network bandwidth, especially in a network environment where multiple multicast sources share one multicast address.

Feature	Description
Router Alert Option	<p>Checks whether IGMP packets contain the Router Alert option and discards the packets without the Router Alert option.</p> <p>Sends IGMP packets with the Router Alert option.</p>

3.3.1 IGMP Router

- This function is used to send Query packets and obtain local member information.

Working Principle

- In a multicast network running the IGMP, a multicast device periodically sends IGMP Query packets and confirms information about local members based on responses.
- Only one multicast device sends IGMP Query packets in one network segment and this device is called querier. The querier is determined by means of selection. Initially, all multicast devices are in the Querier state. When a device receives a membership query from a device with a lower IP address, the device changes from the Querier state to the Non-querier state. Therefore, only one device is in the Querier state finally. This device has the lowest IP address among all multicast devices in the network.
- The querier sends IGMP packets of different versions based on the IGMP version settings. In addition, the following querier parameters can be modified: frequency for the querier to send IGMP Query packets, query times and query interval for the last member, maximum response time of IGMP Query packets, and keepalive time of the existing querier.

Related Configuration

↳ [Enabling IGMP](#)

IGMP is disabled on an interface by default.

You can run the **ip pim { sparse-mode| dense-mode }** command to enable or disable IGMP for an interface.

IGMP can be enabled only when Sparse Mode (SM) or Dense Mode (DM) is configured on the interface.

↳ [Specifying the IGMP Version](#)

IGMPv2 is enabled by default.

You can run the **ip igmp version { 1 | 2 | 3 }** command to set or reset the IGMP version.

↳ [Configuring the Last-Member Query Interval](#)

The interval for sending the last-member Query packets is 1s by default.

You can run the **ip igmp last-member-query-interval interval** command to set or reset the interval for an interface to send Query packets.

A larger value means a larger interval; a smaller value means a smaller interval.

↳ [Configuring the Last-Member Query Times](#)

The number of the last-member query times is 2 by default.

You can run the **ip igmp last-member-query-count** *count* command to set or reset the number of the last-member query times.

A larger value means more last-member query times; a smaller value means fewer last-member query times.

↘ **Configuring the Common Member Query Interval**

The common member query interval is 125s by default.

You can run the **ip igmp query-interval** *seconds* command to set or reset the common member query interval.

A larger value means a larger common query interval; a smaller value means a smaller common query interval.

↘ **Configuring the Maximum Response Time**

The maximum response time is 10s by default.

You can run the **ip igmp query-max-response-time** *seconds* command to set or reset the maximum response time.

A larger value means longer response time; a smaller value means shorter response time.

↘ **Configuring the Querier Timeout**

The querier timeout is 255s by default.

You can run the **ip igmp query-timeout** *seconds* command to set the querier timeout.

A larger value means longer survival time; a smaller value means shorter survival time.

3.3.2 IGMP Group Filtering

Filter group members and limit the number of group members.

Working Principle

To prevent hosts in a network segment where an interface resides from joining a multicast group, you can configure an ACL on this interface as a filter. The interface will filter the received IGMP membership Report packets based on this ACL, maintain group membership only for multicast groups allowed by this ACL and set the maximum number of router members.

Related Configuration

↘ **Configuring the IGMP Group ACL**

By default, no ACL is used and any group is allowed to join.

You can run the **ip igmp access-group** *access-list-name* command to set or reset the multicast group ACL.

After the ACL is configured, a router receives only packets set in the ACL.

↘ **Configuring the Maximum Number of IGMP Group Members**

The maximum number of IGMP group members is 1,024 by default.

You can run the **ip igmp limit** *number* command to set or reset the maximum number of multicast group members.

A larger value means more members; a smaller value means fewer members.

3.3.3 Static IGMP Group

When static IGMP groups are available on a router, it is unnecessary for the host to send a Report packet to obtain the static group information. The router can directly exchange group information with a PIM router.

Working Principle

You need to set static group information manually.

Related Configuration

↳ [Configuring a Static Group](#)

No static group is configured by default.

You can run the **ip igmp static-group** *group-address* command to configure a static group.

3.3.4 Simulating Hosts to Join IGMP Groups

Simulate the host behavior to directly join a multicast group on an interface.

Related Configuration

↳ [Configuring the Join-Group function](#)

No join-group information is set by default.

You can run the **ip igmp join-group** *group-address* command to configure the address of the multicast group to be joined by the simulated host.

3.3.5 IGMP Proxy

Use this function in a simple tree network topology where no complex multicast route protocols (such as PIM) need to be executed. In this way, a downstream proxy host can send IGMP packets and maintain the membership.

Working Principle

When an upstream router is configured as an IGMP proxy-service interface, it is equal to a host that can receive Query packets sent by upstream routers or forward group information sent by downstream hosts. When a downstream router is configured as an IGMP multicast proxy interface, it is equal to a router that can forward Query packets sent by upstream routers or receive Report packets sent by downstream routers.

Related Configuration

↳ [Configuring the IGMP Proxy Service](#)

The IGMP proxy service function is disabled by default.

You can run the **ip igmp proxy-service** command to enable the IGMP proxy service.

This function is mandatory when a proxy is to be used.

↳ [Configuring the IGMP Mroute Proxy](#)

The IGMP mroute proxy function is disabled by default.

You can run the **ip igmp mroute-proxy** *interfacename* command to enable the IGMP mroute proxy.

This function is mandatory when a proxy is to be used.

3.3.6 IGMP SSM Mapping

Provide the SSM model support for IGMPv1 and IGMPv2. When a host joins a group, you can specify a source to save bandwidth and prevent unwanted and invalid multicast data streams from occupying network bandwidth, especially in a network environment where multiple multicast sources share one multicast address.

Working Principle

Based on IGMP v1/v2, IGMPv3 provides an extra function, namely, the multicast source filter function. In IGMPv1/v2, a host determines to join a group only based on the group address and then receive multicast streams sent to this group address from any source. A host using IGMPv3 advertises the multicast group that the host wants to join and the addresses of multicast sources from which this host wants to receive packets. IGMPv1 and IGMPv2 also implement "source address filtering" in some sense; however, they implement this function on the multicast receivers by enabling the SSM mapping function and configuring the static SSM mapping group.

Related Configuration

↳ Enabling IGMP SSM Mapping

The SSM mapping function is disabled by default.

You can run the **ip igmp ssm-map enable** command to enable the function.

Mandatory.

↳ Configuring Static IGMP SSM Mapping

No static SSM mapping is set by default.

You can run the **ip igmp ssm-map static** *access-list-num A.B.C.D* command to configure static SSM mapping.

3.3.7 Router Alert Option

Check whether IGMP packets contain the Router Alert option and discard packets without the Router Alert option.

Support sending IGMP packets containing the Router Alert option.

Working Principle

If a packet contains the Router Alert option, the device needs to check the packet in depth and updates the control data accordingly. If the packet does not contain the option, the device does not check the packet.

After Router Alert option check is enabled, the IGMP packets not containing the Router Alert option are discarded.

After enabled with the function of sending packets with Router Alert option, the device sends IGMP packets with Router Alert option encapsulated.

Related Configuration

↳ Checking Router Alert Option

Router Alert option check is disabled by default.

You can run the **ip igmp enforce-router-alert** command to enable the function.

📌 Sending IGMP Packets with Router Alert Option Encapsulated

Packets are sent without the Router Alert option by default.

You can run the **ip igmp send-router-alert** command to enable the function.

3.4 Configuration

Configuration	Description and Command	
Configuring IGMP Basic Functions	⚠️ (Mandatory) It is used to set up the multicast service.	
	ip multicast-routing	Enables the IPv4 multicast routing function.
	ip pim { sparse-mode dense-mode }	Enables the PIM-SM or PIM-DM function.
Configuring IGMP Routers	ip igmp version { 1 2 3 }	Specifies the IGMP version.
	ip igmp last-member-query-interval interval	Configures the last-member query interval.
	ip igmp last-member-query-count count	Configures the last-member query times.
	ip igmp query-interval seconds	Configures the membership query interval.
	ip igmp query-max-response-time seconds	Configures the maximum response time.
	ip igmp query-timeout seconds	Configures the querier timeout.
Configuring IGMP Group Filtering	ip igmp access-group access-list	Configures the IGMP group ACL.
	ip igmp limit number [except access-list]	Configures the maximum number of IGMP group members.
Configuring IGMP Proxy	ip igmp proxy-service	Configures the IGMP proxy service.
	ip igmp mroute-proxy interface-type interface-number	Configures the IGMP mroute proxy.
Configuring IGMP SSM Mapping	ip igmp ssm-map enable	Enables IGMP SSM mapping.
	ip igmp ssm-map static access-list source-address	Configures static IGMP SSM mapping.
Configuring Alert Option	ip igmp enforce-router-alert	Checks the Router Alert option.
	ip igmp send-router-alert	Sends IGMP packets containing the Router Alert option.

3.4.1 Configuring IGMP Basic Functions

Configuration Effect

- Enable the multicast routing function of a local network and collect group information of the local network.

Notes

- An interface must be enabled with the PIM-SM or PIM-DM function.

Configuration Steps

↳ Enabling the IPv4 Multicast Routing Function

- Mandatory.
- If there is no special requirement, the IPv4 multicast routing function should be enabled on each router in the local network.

↳ Enabling the PIM-SM or PIM-DM Function

- Mandatory.
- If there is no special requirement, the PIM-SM or PIM-DM function should be directly enabled on an interface of the local network.

Verification

Run the **show ip igmp interface** *interface-type interface-number* command to check whether IGMP is enabled on the interface.

Related Commands

↳ Enabling the IPv4 Multicast Routing Function

Command	ip multicast-routing
Parameter Description	
Command Mode	Global configuration mode
Usage Guide	N/A

↳ Enabling the PIM-SM or PIM-DM Function

Command	ip pim { sparse-mode dense-mode }
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	PIM interfaces must be layer-3 interfaces, including routing interfaces, L3AP, SVI and loopback interfaces. All PIM interfaces should be accessible to IPv4 unicast routes.

Configuration Example

↳ Enabling IGMP for a Local Network

Scenario	<ul style="list-style-type: none"> ● Configure an IPv4 unicast routing protocol (such as OSPF) on a router and ensure that the loopback interface is accessible to a unicast route. ● Enable the IPv4 multicast route function on all routers. ● Enable the PIM-SM or PIM-DM function on interfaces interconnecting devices and interfaces connecting user hosts and multicast sources.
	<pre>VSU(config)#ip multicast-routing VSU(config)#int gi 0/5 VSU(config-if-GigabitEthernet 0/5)#ip add 192.168.1.90 255.255.255.0 VSU(config-if-GigabitEthernet 0/5)#ip pim sparse-mode</pre>
Verification	Run the show ip igmp interface <i>interface-type interface-number</i> command to check whether IGMP is enabled on the interface.
	<pre>VSU#show ip igmp interface gigabitEthernet 0/5 Interface GigabitEthernet 0/5 (Index 5) IGMP Active, Querier, Version 2 (default) Internet address is 192.168.1.90 IGMP interface limit is 1024 IGMP interface has 1 group-record states IGMP interface has 0 static-group records IGMP activity: 3 joins, 0 leaves IGMP query interval is 125 seconds IGMP querier timeout is 255 seconds IGMP max query response time is 10 seconds Last member query response interval is 10 Last member query count is 2 Group Membership interval is 260 seconds Robustness Variable is 2</pre>

Common Errors

- Routers in the network are not enabled with the multicast routing function.
- No multicast interface is available in the network.

3.4.2 Configuring IGMP Routers

Configuration Effect

- Modify the querier timeout and IGMP router parameters will affect the type of packets to be sent and the sending method.

Notes

- The basic functions of IGMP must be configured.

Configuration Steps

▾ Specifying the IGMP Version

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

▾ Configuring the Last-Member Query Interval

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

▾ Configuring the Last-Member Query Times

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

▾ Configuring the Common Member Query Interval

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

▾ Configuring the Maximum Response Time

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

Verification

Run the **show ip igmp interface** *interface-type interface-number* command to display the interface configurations.

Related Commands

▾ Specifying the IGMP Version

Command	ip igmp version { 1 2 3 }
Parameter Description	1: Indicates IGMPv 1. 2: Indicates IGMPv 2. 3: Indicates IGMPv 3.
Command Mode	Interface configuration mode

Usage Guide	After this command is configured, IGMP will automatically restart.
--------------------	--

↘ Configuring the Last-Member Query Interval

Command	ip igmp last-member-query-interval <i>interval</i>
Parameter Description	<i>Interval</i> : Indicates the interval for sending the Query packets of a specific group. The value ranges from 1 to 255 in the unit of 0.1s, and the default value is 10 (namely, 1s).
Command Mode	Interface configuration mode
Usage Guide	This command applies only to IGMPv2 or IGMPv3. When an interface receives a Leave packet, the interface sends Query packets of the group continually and waits for a response from the host. After timeout occurs, the IGMP router assumes that the group member does not exist in the directly connected network segment and deletes the interface from the IGMP group. The timeout duration is equal to the value of last-member-query-interval multiplied by last-member-query-count plus 1/2 of query-max-response-time .

↘ Configuring the Last-Member Query Times

Command	ip igmp last-member-query-count <i>count</i>
Parameter Description	<i>count</i> : Indicates the times for sending the Query packets of a specific group, ranging from 2 to 7. The default value is 2.
Command Mode	Interface configuration mode
Usage Guide	This command applies only to IGMPv2 or IGMPv3. When an interface receives a Leave packet, the interface sends Query packets of the group continually and waits for a response from the host. After timeout occurs, the IGMP router assumes that the group member does not exist in the directly connected network segment and deletes the interface from the IGMP group. The timeout duration is equal to the value of last-member-query-interval multiplied by last-member-query-count plus 1/2 of query-max-response-time .

↘ Configuring the Common Member Query Interval

Command	ip igmp query-interval <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the common member query interval, ranging from 1 to 18,000s. The default value is 125.
Command Mode	Interface configuration mode
Usage Guide	N/A

↘ Configuring the Maximum Response Time

Command	ip igmp query-max-response-time <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the maximum response time, ranging from 1 to 25s. The default value is 10.

Command Mode	Interface configuration mode
Usage Guide	After sending Query packets, the interface waits for a response. If timeout occurs, the IGMP router assumes that the group member does not exist in the directly connected network segment and deletes the group information.

↘ **Configuring the Querier Timeout**

Command	ip igmp query-timeout <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the keepalive time of the querier, ranging from 60s to 300s. The default value is 255s.
Command Mode	Interface configuration mode
Usage Guide	After sending Query packets, an interface waits for Query packets sent by other devices. If timeout occurs, the IGMP router assumes that the querier is unique in the directly connected network segment.

Configuration Example

↘ **Configuring Basic Router Parameters**

Scenario	<ul style="list-style-type: none"> ● Configure basic functions of IGMP. ● Specify the IGMPv3. ● Configure the last-member query interval to 15 (1.5s). ● Configure the number of the last-member queries to 3. ● Configure the common member query interval to 130s. ● Configure the maximum response time to 15s. ● Configure the querier timeout to 280s.
	<pre>VSU(config-if-GigabitEthernet 0/5)#ip igmp version 3 VSU(config-if-GigabitEthernet 0/5)#ip igmp last-member-query-count 3 VSU(config-if-GigabitEthernet 0/5)#ip igmp last-member-query-interval 15 VSU(config-if-GigabitEthernet 0/5)#ip igmp query-interval 130 VSU(config-if-GigabitEthernet 0/5)#ip igmp query-max-response-time 15 VSU(config-if-GigabitEthernet 0/5)#ip igmp query-timeout 280</pre>
Verification	Run the show ip igmp interface <i>interface-type interface-number</i> command to check the IGMP functions of the interface.

```
VSU#show ip igmp interface gigabitEthernet 0/5
Interface GigabitEthernet 0/5 (Index 5)
  IGMP Enabled, Active, Querier, Version 3
  Internet address is 192.168.1.90
  IGMP interface limit is 1024
  IGMP interface has 1 group-record states
  IGMP interface has 0 static-group records
  IGMP activity: 3 joins, 0 leaves
  IGMP query interval is 130 seconds
  IGMP querier timeout is 280 seconds
  IGMP max query response time is 15 seconds
  Last member query response interval is 15
  Last member query count is 3
  Group Membership interval is 275 seconds
  Robustness Variable is 2
VSU#
```

Common Errors

- The basic functions of IGMP are not enabled.

3.4.3 Configuring IGMP Group Filtering

Configuration Effect

- A router filters IGMP group members.

Notes

- The basic functions of IGMP must be configured.

Configuration Steps

📄 Configuring the IGMP Group ACL

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

📄 Configuring the Maximum Number of IGMP Group Members

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

Verification

IGMP Group ACL

- Configure an interface to allow only groups in ACL 1 to join. The access addresses of ACL 1 are 225.0.0.1~225.0.0.255.
- Configure the interface to join a group whose address is 225.0.0.5.
- Configure the interface to join a group whose address is 236.0.0.5.
- View the group information of the current interface.

Maximum Number of IGMP Group Members

- Set the maximum member quantity to 5 on an interface.
- Configure the interface to join a group whose address is from 225.0.0.5 to 225.0.0.10.
- View the group information of the interface.

Related Commands

Configuring the IGMP Group ACL

Command	ip igmp access-group <i>access-list</i>
Parameter Description	<i>access-list</i> : Defines a group address range by using a standard IP ACL or an extended ACL. The value ranges from 1 to 199, 1300 to 2699 and characters.
Command Mode	Interface configuration mode
Usage Guide	Configure this command on an interface to control the groups that hosts in a directly connected network segment can join. Use an ACL to limit the group address range. If Report packets denied by the ACL are received, the packets will be discarded. When IGMPv3 is enabled, this command supports an extended ACL. If the received IGMP Report information is (S1,S2,S3...Sn,G), this command will apply the corresponding ACL to the (0,G) information for matching. Therefore, you must configure a (0,G) record explicitly for the extended ACL in order to normally filter (S1,S2,S3...Sn,G).

Configuring the Maximum Number of IGMP Group Members

Command	ip igmp limit <i>number</i> [except <i>access-list</i>]
Parameter Description	<i>number</i> : Indicates the maximum number of IGMP group members, whose value range varies with devices. The default value is 1,024 for an interface and 65,536 globally. except <i>access-list</i> : Indicates that the groups in the ACL are not counted. access-list indicates a standard IP ACL. The value ranges from 1 to 99, 1300 to 1999 and words.
Command Mode	Interface configuration mode
Usage Guide	Global configuration mode: Limits the maximum quantity of the IGMP group members in a system. Interface configuration mode: limits the maximum quantity of IGMP group members on an interface. If the quantity of group members exceeds the interface or global limit, the Report packets received

subsequently will be ignored.

If an Except ACL is configured, Report packets within a specified range can be normally processed; therefore, the generated group members are not counted.

The interface and global configurations can be performed independently. If the global quantity limit is smaller than that for an interface, the global configuration shall be used.

Configuration Example

Configuring IGMP Group Filtering

Scenario	<ul style="list-style-type: none"> ● Configure the basic functions of IGMP. ● Configure the access address range of ACL 1 from 225.0.0.1 to 225.0.0.255. ● Set the address of the group to be joined to 225.0.0.5. ● Set the address of the group to be joined to 236.0.0.5.
	<pre>VSU(config)#access-list 1 permit 225.0.0.1 225.0.0.255 VSU(config-if-GigabitEthernet 0/5)#ip igmp access-group 1 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.5 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 236.0.0.5</pre>
Verification	Run the show ip igmp groups [interface-type interface-number] [group-address] [detail] command to display the group information of the interface.
	<pre>VSU(config-if-GigabitEthernet 0/5)#show ip igmp groups IGMP Connected Group Membership Group Address Interface Uptime Expires Last Reporter 225.0.0.5 GigabitEthernet 0/5 00:14:00 00:02:45 192.168.1.90</pre>

Configuring the Maximum Number of IGMP Group Members

Scenario	<ul style="list-style-type: none"> ● Configure the basic functions of IGMP. ● Configure the maximum number of IGMP group members for the interface to 5. ● Add group information (225.0.0.5~225.0.0.12). ● View group information.
	<pre>VSU(config-if-GigabitEthernet 0/5)#ip igmp limit 5 VSU(config-if-GigabitEthernet 0/5)# VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.5 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.6 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.7 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.8 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.9 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.10 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.11</pre>

	<pre>VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.12</pre>
Verification	Run the show ip igmp groups [<i>interface-type interface-number</i>] [<i>group-address</i>] [detail] command to display the group information of the interface.
	<pre>VSU(config-if-GigabitEthernet 0/5)#show ip igmp groups IGMP Connected Group Membership Group Address Interface Uptime Expires Last Reporter 225.0.0.5 GigabitEthernet 0/5 00:20:15 00:03:09 192.168.1.90 225.0.0.6 GigabitEthernet 0/5 00:20:24 00:02:58 192.168.1.90 225.0.0.7 GigabitEthernet 0/5 00:00:15 00:04:29 192.168.1.90 225.0.0.8 GigabitEthernet 0/5 00:00:13 00:04:34 192.168.1.90 225.0.0.9 GigabitEthernet 0/5 00:00:11 00:04:33 192.168.1.90</pre>

Common Errors

- The basic functions of IGMP are not enabled.

3.4.4 Configuring IGMP Proxy

Configuration Effect

- Configure the router proxy function and collect local member information.

Notes

- The basic functions of IGMP must be configured.

Configuration Steps

▾ Configuring the IGMP Proxy Service

- Optional.
- If there is no special requirement, you can perform this configuration on directly connected upstream router interfaces.

▾ Configuring the IGMP Mroute Proxy

- Optional.
- If there is no special requirement, you can perform this configuration on directly connected downstream host interfaces.

Verification

- Set interface 7 for directly connecting to an upstream router as a multicast proxy server.
- Set interface 1 for directly connecting to a downstream host as a multicast proxy.
- Set interface 1 to be joined by groups whose addresses are 225.0.0.6 and 225.5.5.5.
- View the current group information.

Related Commands

Configuring the IGMP Proxy Service

Command	ip igmp proxy-service
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	<p>Run the ip igmp proxy-service command to set the uplink interface as a Proxy-Service interface.</p> <p>Run the ip igmp mroute-proxy command to set the downlink interface as a Mroute-Proxy interface.</p> <p>Forward IGMP Query packets from the Proxy-Service interface to the Mroute-Proxy interface. Forward IGMP Report packets from the Mroute-Proxy interface to the Proxy-Service interface.</p> <p>A device allows a maximum of 32 Proxy-Service interfaces. After a Proxy-Service interface receives an IGMP Query packet, the interface sends a response based on the IGMP group member records.</p> <p>If the switchport command is executed on the Proxy-Service interface, the ip igmp mroute-proxy command configured on the Mroute-Proxy interface will be deleted automatically.</p>

Configuring the IGMP Mroute Proxy

Command	ip igmp mroute-proxy <i>interface-type interface-number</i>
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	<p>Run the ip igmp proxy-service command to set the uplink interface as a Proxy-Service interface.</p> <p>Run the ip igmp mroute-proxy command to set the downlink interface as a Mroute-Proxy interface.</p> <p>Forward IGMP Query packets from the Proxy-Service interface to the Mroute-Proxy interface. Common Errors

- The basic functions of IGMP are not enabled.

3.4.5 Configuring IGMP SSM Mapping

Configuration Effect

- IGMPv3 supports source filtering; however, IGMPv1 and IGMPv2 do not support source filtering, but provides the SSM mapping function to filter sources.

Notes

- The basic functions of IGMP must be configured.

Configuration Steps

▾ Enabling SSM Mapping

(Mandatory) Enable the SSM mapping function.

Enable the SSM mapping function on a router.

▾ Configuring Static SSM Mapping

Optional.

Configure this function on routers enabled with SSM mapping.

Verification

Run the **show ip igmp ssm-mapping** [*group-address*] command to display SSM mapping information.

Related Commands

↳ Enabling SSM Mapping

Command	ip igmp ssm-map enable
Parameter Description	
Command Mode	Global configuration mode
Usage Guide	<p>Run the ip igmp ssm-map enable command to enable the SSM mapping function.</p> <p>Run the ip igmp ssm-map static command to set static mapping entries.</p> <p>Run IGMPv3 on the interface. When IGMPv1 or IGMPv2 Report packets are received, source addresses of static mappings can be added.</p>

↳ Configuring Static SSM Mapping

Command	ip igmp ssm-map static <i>access-list source-address</i>
Parameter Description	<p><i>access-list</i>: Indicates the group address range set by a standard IP ACL. The value ranges from 1 to 99, 1300 to 1999 and words.</p> <p><i>source-address</i>: Indicates the source address.</p>
Command Mode	Global configuration mode
Usage Guide	<p>Run the ip igmp ssm-map enable command to enable the SSM mapping function.</p> <p>Run the ip igmp ssm-map static command to set static mapping entries.</p> <p>Run IGMPv3 on the interface. When IGMPv1 or IGMPv2 Report packets are received, source addresses of static mappings can be added.</p>

Scenario	<ul style="list-style-type: none"> ● Configure the basic functions of IGMP. ● Enable SSM mapping. ● Configure static SSM mapping ACL 1.
	<pre>VSU(config)#ip igmp ssm-map enable VSU(config)#ip igmp ssm-map static 1 192.168.5.9</pre>
Verification	Run the show ip igmp ssm-mapping [group-address] command to display SSM mapping information.
	<pre>VSU#show ip igmp ssm-mapping SSM Mapping : Enabled Database : Static mappings configured</pre>

Common Errors

- The basic functions of IGMP are not enabled.

3.4.6 Configuring Alert Option

Configuration Effect

- Check whether IGMP packets contain the Router Alert option and discards the packets without the Router Alert option.
- Support sending IGMP packets with the Router Alert option.

Notes

- The basic functions of IGMP must be configured.

Configuration Steps

▾ Checking Router Alert Option

Optional.

▾ Sending IGMP Packets with Router Alert Option Encapsulated

Optional,

Verification

▾ Checking Router Alert Option

Check whether the IGMP-enabled interface discards the IGMP packets without the Router Alert option.

▾ Sending IGMP Packets with Router Alert Option Encapsulated

Check whether the IGMP-enabled interface sends the IGMP packets containing the Router Alert option.

Related Commands

▾ Checking Router Alert Option

Command	ip igmp enforce-router-alert
Parameter Description	
Command Mode	Global configuration mode
Usage Guide	Run the ip igmp enforce-router-alert command to enable Router Alert option check. Run the no ip igmp enforce-router-alert command to disable Router Alert option check.

▾ Sending IGMP Packets with Router Alert Option Encapsulated

Command	ip igmp send-router-alert
Parameter Description	

Command Mode	Global configuration mode
Usage Guide	Run the ip igmp send-router-alert command to enable the function of sending IGMP packets containing Router Alert option. Run the no ip igmp send-router-alert command to disable the function.

Configuration Example

↘ Checking Router Alert Option

Scenario	<ul style="list-style-type: none"> Configure the basic functions of IGMP. Configure Router Alert option check.
	<pre>VSU(config)#ip igmp enforce-router-alert</pre>
Verification	IGMP packets containing Router Alert option 225.1.1.1 are sent to the IGMP-enabled interface and these packets are processed. Run the show ip igmp groups command and you will see 225.1.1.1. IGMP packets not containing Router Alert option 225.1.1.1 are sent to the IGMP-enabled interface and these packets are discarded. Run the show ip igmp groups command and you will not see 225.1.1.1

↘ Sending IGMP Packets with Router Alert Option Encapsulated

Scenario	<ul style="list-style-type: none"> Configure the basic functions of IGMP. Configure the function of sending IGMP packets containing router alert option.
	<pre>VSU(config)#ip igmp send-router-alert</pre>
Verification	Check whether the IGMP-enabled interface sends the IGMP packets containing the Router Alert option.

3.5 Monitoring

Clearing

Description	Command
Clears dynamic group membership from the IGMP buffer.	clear ip igmp group
Clears interface information from the IGMP buffer.	clear ip igmp interface <i>interface-type interface-number</i>

Displaying

Description	Command
Displays all groups in a directly connected subnet.	show ip igmp groups

Displays details about all groups in a directly connected subnet.	show ip igmp groups detail
Displays specified groups in a directly connected subnet.	show ip igmp groups A.B.C.D
Displays details about specified groups in a directly connected subnet.	show ip igmp groups A.B.C.D detail
Displays IGMP configurations of a specified interface in a directly connected subnet.	show ip igmp interface <i>interface-type interface-number</i>
Displays details about all groups of a specified interface in a directly connected subnet.	show ip igmp groups <i>interface-type interface-number</i> detail
Displays information about a specified group of a specified interface in a directly connected subnet.	show ip igmp groups <i>interface-type interface-number</i> A.B.C.D
Displays details about a specified group of a specified interface in a directly connected subnet.	show ip igmp groups <i>interface-type interface-number</i> A.B.C.D detail
Displays configurations of an IGMP interface.	show ip igmp interface [<i>interface-type interface-number</i>]
Displays configurations of all IGMP interfaces.	show ip igmp interface
Displays configurations of IGMP SSM mapping.	show ip igmp ssm-mapping
Displays the information of IGMP SSM mapping to A.B.C.D.	show ip igmp ssm-mapping A.B.C.D

Debugging

Description	Command
Displays whether IGMP debugging is enabled.	show debugging
Debugs all IGMP information.	debug ip igmp all
Debugs IGMP packet decoding.	debug ip igmp decode
Debugs IGMP packet encoding.	debug ip igmp encode
Debugs IGMP events.	debug ip igmp events
Debugs IGMP FSM.	debug ip igmp fsm
Debugs IGMP state machine.	debug ip igmp tib
Debugs IGMP warning.	debug ip igmp warning

4 Configuring MLD

4.1 Overview

Multicast Listener Discovery (MLD) is a protocol used in the multicast technology.

This protocol receives the multicast member relationship between hosts and routers to determine multicast flow forwarding. Using information obtained from MLD, a device maintains an interface-based multicast listener status table. The multicast listener status table is activated only when at least one host in the link of the interface is a group member.

Currently, MLD has two versions: MLDv1 and MLDv2.

- MLD of both versions supports the Any-Source Multicast (ASM) model.
- MLDv2 can be directly applied to the Source-Specific Multicast (SSM) model.
- MLDv1 can be applied to the SSM model only when MLD SSM mapping is configured.

Protocols and Standards

- RFC2710: Multicast Listener Discovery (MLDv1) for IPv6
- RFC3810: Multicast Listener Discovery Version 2 (MLDv2) for IPv6

4.2 Applications

Application	Description
Configuring the MLD Service on the Local Network	Implements the MLD service on the local network.
Configuring the MLD Proxy Service	In the simple tree topology, the MLD proxy service, instead of the PIM service, is used.

4.2.1 Configuring the MLD Service on the Local Network

Scenario

As shown in figure 4-1, the local network consists of receiver 1, receiver 2, router A, and router B.

Query messages sent by router A or router B are valid on the local network, and Report messages sent by receiver A and receiver B are also valid on the local network.

Figure 4-1

Remark	Router C is the egress gateway.
s	Routers A and B are local routers.

Deployment

- Routers A, B, and C run the OSPFv6 protocol.
- Interfaces on routers A, B, and C run the multicast protocol (PIM SMv6 or PIM DMv6).

4.2.2 Configuring the MLD Proxy Service

Scenario

As shown figure 4-2, the proxy function is enabled on router A. Router A functions as a host and forms a local management group with router B. Router A forwards Report messages from receivers 1 and 2.

Figure 4-2

Remark	Router A functions as the proxy.
s	Router B provides the PIM service.

Deployment

- Routers A and B run the OSPFv6 protocol.
- Interfaces on routers A and B run the multicast protocol (PIM SMv6 or PIM DMv6).
- The multicast proxy service is enabled on Gi 0/0 and Gi 0/1 of router A.

4.3 Features

Basic Concepts

Host Behaviors and Device Behaviors

Layer-3 multicast devices running multicast management protocols are referred to as devices and their behaviors are device behaviors.

PCs or simulated PCs running multicast management protocols are referred to as hosts and their behaviors are host behaviors.

Querier

Devices interact and compete with each other. After IP address comparison, the device with a lower IP address becomes the querier and periodically sends Query messages.

MLD PROXY-SERVICE Interface

This interface, also called uplink interface, implements host behaviors. It receives Query messages sent by upstream devices and sends Report messages collected by the router proxy.

MLD MROUTE-PROXY Interface

This interface, also called downlink interface, implements router functions. It sends messages received by the proxy service interface and collects and sends host information to the proxy service interface.

MLD SSM-MAP

SSM mapping refers to mapping of source-specific multicast. MLDv1 does not support the SSM model until the SSM-MAP function is enabled.

Overview

Feature	Description
Setting MLD Router Parameters	Sends Query messages to obtain local member information.
Querier Selection Process or Timeout Mechanism	Selects the unique querier in the current network segment.
Filtering MLD Groups	Filters group members and limits the number of group members.
Supporting Static MLD Groups	Stores static group information on the local router instead of obtaining group information by sending Report messages.
Configuring Simulated Host Group Information	Simulates host behaviors to directly configure group joining information.
Supporting MLD Proxy	Uses this function in the simple tree topology instead of complex multicast routing protocols, such as the PIM.

Feature	Description
Supporting SSM-MAP	Provides the SSM model for MLDv1. When a host is added to a group, a specific source can be specified to avoid network bandwidth occupation by unnecessary and invalid multicast data streams. This function is especially useful on a network where multiple multicast sources share the same multicast address.

4.3.1 Setting MLD Router Parameters

Sends Query messages to obtain local member information.

[Working Principle](#)

A device periodically sends Query messages to ensure that a group has at least one host. If no host is available in a group, the group will be deleted.

[Related Configuration](#)

↳ [Enabling MLD](#)

By default, MLD is disabled on an interface.

Run the **ipv6 pim { sparse-mode| dense-mode }** command to enable or disable MLD on an interface.

MLD can be enabled only after PIM SM or PIM DM is enabled on the interface.

↳ [Configuring MLD Version](#)

By default, the MLD version is 2.

Run the **ipv6 mld version { 1 | 2 }** command to configure or restore the MLD version of an interface.

↳ [Configuring the Query Interval of the Last Member](#)

By default, the interval for sending Query messages is 1s.

Run the **ipv6 mld last-member-query-interval interval** command to configure or restore the interval for sending Query messages.

A larger value means a longer interval for sending Query messages.

↳ [Configuring the Number of Times for Querying the Last Member](#)

By default, the number of times for querying the last member is 2.

Run the **ipv6 mld last-member-query-count count** command to configure or restore the number of times for querying the last member.

A larger value means a larger number of times for querying the last member.

↳ [Configuring the Interval for Querying a Common Member](#)

By default, the interval for querying a common member is 125s.

Run the **ipv6 mld query-interval seconds** command to configure or restore the interval for querying a common member.

A larger value means a longer interval for querying a common member.

↳ [Configuring the Maximum Response Time](#)

By default, the maximum response time is 10s.

Run the **ipv6 mld query-max-response-time** *seconds* command to configure or restore the maximum response time.

A larger value means a longer maximum response time.

4.3.2 Querier Selection Process or Timeout Mechanism

Selects the unique querier in the current network segment. The querier sends a Query message to obtain group information on the local network.

Working Principle

On a multicast network running MLD, a multicast device dedicated to query sends MLD Query messages. The device is determined by election. Initially, all devices are in the querier state. When receiving member relationship Query messages from devices with lower IP addresses, the devices switch from the receiver state to non-querier state. Therefore, there is only one device in the query state in the end. This device has the lowest IP address among all multicast devices on the network. When the querier device does not work, MLD also works. Non-querier devices maintain the keepalive interval timer for other queriers. The timer is reset once the device receives a member relationship query message. If the timer times out, the device starts to send Query messages and a new querier election starts.

Related Configuration

↳ [Configuring the Keepalive Interval of the Querier](#)

By default, the keepalive interval of the querier is 255s.

Run the **ipv6 mld querier-timeout** *seconds* command to configure or restore the keepalive interval of the querier.

A larger value means a longer keepalive interval of the querier.

4.3.3 Filtering MLD Groups

Filters group members and limits the number of group members.

Working Principle

If you do not want hosts in the network segment where an interface resides to be added to certain multicast groups, you can configure ACL rules on the interface as a filter. The interface will filter received MLD member relationship Report messages based on the ACL rules and maintain member relationships only for multicast groups permitted by the rules. The largest number of router members can also be set.

Related Configuration

↳ [Configuring Access Control for Multicast Groups](#)

By default, no access control is configured and hosts can be added to any groups.

Run the **ipv6 mld access-group** *access-list-name* command to configure or restore access control for multicast groups.

After the configuration, the router can receive messages only from hosts in groups specified in the access list.

↳ [Configuring the Maximum Number of MLD Group Members](#)

By default, an MLD group has a maximum of 1024 members.

Run the **ipv6 mld limt** *number* command to configure or restore the maximum number of MLD group members.

A larger value means a larger number of group members.

4.3.4 Supporting Static MLD Groups

Stores static group information on a local router instead of obtaining group information by sending Report messages. The local router can directly exchange group information with the PIM router.

Working Principle

Manually configure static group information.

Related Configuration

↳ **Configuring Static-Group**

By default, no static group information is configured.

Run the **ipv6 mld static-group** *group-address* command to configure or cancel static group information.

4.3.5 Configuring Simulated Host Group Information

Simulates host behaviors to directly configure group joining information.

Related Configuration

↳ **Configuring Join-Group**

By default, no join-group information is configured.

Run the **ipv6 mld join-group** *group-address* command to configure or cancel join-group information.

4.3.6 Supporting MLD Proxy

In the simply tree topology, it is not necessary to run complex multicast routing protocols (such as PIM). In this case, MLD proxy can be used to send MLD messages for downstream hosts and maintain member relationships.

Working Principle

When an upstream router is configured as an MLD proxy service interface, it functions as a host and can receive Query messages from upstream routers as well as forward group information of downstream hosts. When a downstream router is configured as an MLD multicast proxy interface, it functions as a router and can forward Query messages of upstream routers as well as receive Report messages from downstream routers.

Related Configuration

↳ **Configuring MLD PROXY-SERVICE**

By default, the MLD proxy service is disabled on an interface.

Run the **ipv6 mld proxy-service** command to configure or cancel the MLD proxy function on an interface.

This function must be configured when proxy is used.

↳ **Configuring MLD MROUTE-PROXY**

By default, the multicast proxy service is disabled on an interface.

Run the **ipv6 mld mroute-proxy** *interfacename* command to configure or cancel the multicast proxy function on an interface.

This function must be configured when proxy is used.

4.3.7 Supporting SSM-MAP

This function provides the SSM model for MLDv1. When a host is added to a group, a specific source can be specified to avoid network bandwidth occupation by unnecessary and invalid multicast data streams. This function is especially useful on a network where multiple multicast sources share the same multicast address.

Working Principle

Based on MLDv1, MLDv2 provides an extra function, that is, source filtering multicast. In MLDv1, a host determines to join a group only based on the group address and receives multicast streams sent to the group address from any source. However, an MLDv2 host advertises the multicast group that the host wants to join and the address of the multicast source that it wants to receive. In MLDv1, source address filtering can be implemented to some extent, but filtering is implemented by enabling SSM-MAP and configuring SSM-MAP static groups on multicast flow receivers.

Related Configuration

▾ Enabling MLD SSM-MAP

By default, SSM-MAP is disabled.

Run the **ipv6 mld [vrf *vrf-name*] ssm-map enable** command to enable or disable the SSM-MAP function.

This function must be enabled when SSM-MAP is used.

▾ Configuring MLD SSM-MAP STATIC

By default, no SSM-MAP static link table is configured.

Run the **ipv6 mld [vrf *vrf-name*] ssm-map static *access-list-num* A.B.C.D** command to enable or disable the SSM-MAP static link table.

4.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of MLD	 (Mandatory) It is used to configure the multicast service.	
	ipv6 multicast-routing [vrf <i>vid</i>]	Enables the IPv6 multicast routing function.
	ipv6 pim sparse-mode	Enables the PIM-SM function.
Configuring MLD Router	ipv6 mld version { 1 2 }	Configures the MLD version.

	ipv6 mld last-member-query-interval <i>interval</i>	Configures the interval for querying the last member.
	ipv6 mld last-member-query-count <i>count</i>	Configures the number of times for querying the last member.
	ipv6 mld query-interval <i>seconds</i>	Configures the interval for querying a common member.
	ipv6 mld query-max-response-time <i>seconds</i>	Configures the maximum response interval.
Querier Selection Process or Timeout Mechanism	ipv6 mld querier-timeout <i>seconds</i>	Configures the keepalive interval of the querier.
Filtering MLD Groups	ipv6 mld access-group <i>access-list</i>	Filters MLD group members.
MLD Proxy	ipv6 mld proxy-service	Configures the MLD PROXY-SERVICE.
	ipv6 mld mroute-proxy <i>interface-type interface-number</i>	Configures the MLD MROUTE-PROXY.
Supporting SSM-MAP	ipv6 mld ssm-map enable	Enables the SSM-MAP function.
	ipv6 mld ssm-map static <i>access-list</i> <i>source-address</i>	Configures the SSM-MAP static link table.

4.4.1 Configuring Basic Functions of MLD

Configuration Effect

- Enable the multicast routing function and collect group information on the local network.

Notes

- The PIM SM or PIM DM function must be enabled on an interface.

Configuration Steps

▾ Enabling the IPv6 Multicast Routing Function

- Mandatory.
- The IPv6 multicast routing function should be enabled on all routers on the local network unless otherwise specified.

▾ Enabling the PIM SM or PIM DM Function

- Mandatory.
- The PIM SM or PIM DM function should be directly enabled on an interface on the local network unless otherwise specified.

Verification

Run the **show ipv6 mld [vrf *vrf-name*] interface *interface-type* *interface-number*** command to check whether MLD is enabled on the interface.

Related Commands

↳ Enabling the IPv6 Multicast Routing Function

Command	ipv6 multicast-routing [vrf vid]
Parameter Description	vrf vid: specifies a VRF.
Command Mode	Global configuration mode
Usage Guide	-

↳ Enabling the PIM SM or PIM DM Function

Command	ipv6 pim { sparse-mode dense-mode }
Parameter Description	-
Command Mode	Interface configuration mode
Usage Guide	PIM interfaces must be layer-3 interfaces, including: routing, L3AP, SVI, and loopback interfaces. IPv6 unicast routes should be accessible to all PIM interfaces.

Configuration Example

↳ Enabling MLD on the Local Network

Configuration Steps	<ul style="list-style-type: none"> Configure an IPv6 unicast routing protocol (such as OSPF) on a router and ensure that unicast routes are accessible to the loopback interface. (Omitted) Enable the IPv6 multicast routing function on all routers. Enable the PIM SM or PIM DM function on device interconnection interfaces and interfaces for connecting user hosts and multicast sources.
	<pre>VSU(config)#ipv6 multicast-routing VSU(config)#int gi 0/1 VSU(config-if-GigabitEthernet 0/1)# ipv6 address 2001::1/64 VSU(config-if-GigabitEthernet 0/1)#ipv6 pim sparse-mode</pre>
Verification	Run the show ipv6 mld [vrf vrf-name] interface interface-type interface-number command to check whether MLD is enabled on the interface.
	<pre>VSU#show ipv6 mld interface gigabitEthernet 0/1 Interface GigabitEthernet 0/1 (Index 1) MLD Active, Querier, Version 2 (default) Internet address is fe80::2d0:f8ff:fe22:33b1 MLD interface limit is 1024</pre>

```
MLD interface has 0 group-record states
MLD interface has 0 join-group records
MLD interface has 0 static-group records
MLD activity: 0 joins, 0 leaves
MLD query interval is 125 seconds
MLD querier timeout is 255 seconds
MLD max query response time is 10 seconds
Last member query response interval is 10 (1/10s)
Last member query count is 2
Group Membership interval is 260
Robustness Variable is 2
```

Common Errors

- Multicast routing is disabled on routers on the network.
- No multicast interface is available on the network.

4.4.2 Configuring MLD Router Parameters

Configuration Effect

- Modify MLD router parameters to change the message type or sending mode.

Notes

- The basic functions of MLD must be configured.

Configuration Steps

▾ Configuring MLD Version

Optional.

This parameter can be configured on all router interfaces directly connected to the local network unless otherwise specified.

▾ Configuring the Interval for Querying the Last Member

Optional.

This parameter can be configured on all router interfaces directly connected to the local network unless otherwise specified.

▾ Configuring the Number of Times for Querying the Last Member

Optional.

This parameter can be configured on all router interfaces directly connected to the local network unless otherwise specified.

▾ Configuring the Interval for Querying a Common Member

Optional.

This parameter can be configured on all router interfaces directly connected to the local network unless otherwise specified.

↳ Configuring the Maximum Response Interval

Optional.

This parameter can be configured on all router interfaces directly connected to the local network unless otherwise specified.

Verification

Run the **show ipv6 mld [vrf *vrf-name*] interface *interface-type* *interface-number*** command to view the configuration information.

Related Commands

↳ Configuring the MLD Version

Command	ipv6 mld version { 1 2 }
Parameter Description	1: Indicates version 1. 2: Indicates version 2.
Command Mode	Interface configuration mode
Usage Guide	After this command is executed, MLD will automatically restart.

↳ Configuring the Interval for Querying the Last Member

Command	ipv6 mld last-member-query-interval <i>interval</i>
Parameter Description	<i>Interval</i> : Specifies the interval for sending Query messages of a specified group. The unit is 0.1s, the value ranges from 1 to 255, and the default value is 10 (1s).
Command Mode	Interface configuration mode
Usage Guide	After receiving the Done message, the interface will continuously send Query messages of a specified group and wait for responses from the host. After timeout, it is considered that the no group member exists in the directly-connected network segment and the interface is deleted from the MLD group member record. The timeout interval is calculated as follows: Timeout interval = last-member-query-interval x last-member-query-count + query-max-response-time/2.

↳ Configuring the Number of Times for Querying the Last Member

Command	ipv6 mld last-member-query-count <i>count</i>
Parameter Description	<i>count</i> : Specifies the number of times for sending Query messages of a specified group. The value ranges from 2 to 7. The default value is 2.
Command Mode	Interface configuration mode
Usage Guide	After receiving the Done message, the interface will continuously send Query messages of a specified

	<p>group and wait for responses from the host. After timeout, it is considered that the no group member exists in the directly-connected network segment and the interface is deleted from the MLD group member record. The timeout interval is calculated as follows:</p> <p>Timeout interval = last-member-query-interval x last-member-query-count + query-max-response-time/2</p>
--	---

📌 Configuring the Interval for Querying a Common Member

Command	<code>ipv6 mld query-interval seconds</code>
Parameter Description	<i>seconds</i> : Specifies the interval for querying a common member. The unit is s, the value ranges from 1 to 18000, and the default value is 125.
Command Mode	Interface configuration mode
Usage Guide	-

📌 Configuring the Maximum Response Interval

Command	<code>ipv6 mld query-max-response-time seconds</code>
Parameter Description	<i>seconds</i> : Specifies the maximum response time. The unit is s, the value ranges from 1 to 25, and the default value is 10.
Command Mode	Interface configuration mode
Usage Guide	After sending Query messages, the interface waits for responses. After timeout, it is considered that no group member exists in the directly-connected network segment and group information is deleted.

Configuration Example

📌 Configuring Basic Router Parameters

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic functions of MLD. (Omitted) ● Configure MLD version 2. ● Configure the interval for querying the last member as 15 (1.5s). ● Configure the number of times for querying the last member as 3. ● Configure the interval for querying the common member as 130s. ● Configure the maximum response time as 15s.
	<pre>VSU(config-if-GigabitEthernet 0/1)#ipv6 mld version 2 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld last-member-query-count 3 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld last-member-query-interval 15 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld query-interval 130 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld query-max-response-time 15</pre>
Verification	Run the <code>show ipv6 mld [vrf vrf-name] interface interface-type interface-number</code> command to check whether MLD is enabled on the interface.

```
VSU(config-if-GigabitEthernet 0/1)# show ipv6 mld interface gi 0/1
Interface GigabitEthernet 0/1 (Index 1)
  MLD Enabled, Active, Querier, Version 2 (default)
  Internet address is fe80::2d0:f8ff:fe22:33b1
  MLD interface limit is 1024
  MLD interface has 0 group-record states
  MLD interface has 0 join-group records
  MLD interface has 0 static-group records
  MLD activity: 0 joins, 0 leaves
  MLD query interval is 130 seconds
  MLD querier timeout is 267 seconds
  MLD max query response time is 15 seconds
  Last member query response interval is 15 (1/10s)
  Last member query count is 3
  Group Membership interval is 275
  Robustness Variable is 2
```

Common Errors

- Basic functions of MLD are not enabled.

4.4.3 Querier Selection Process or Timeout Mechanism

Configuration Effect

- Select the unique querier on the local network.

Notes

- The basic functions of MLD must be configured.

Configuration Steps

- This function must be configured if the querier keepalive interval needs to be configured.
- This function can be configured on all MLD-enabled interfaces on the local network.

Verification

Run the **show ipv6 mld [vrf *vrf-name*] interface *interface-type* *interface-number*** command to view the configuration information of the interface.

Related Commands

- ↳ [Configuring the Keepalive Interval of Other Queriers](#)

Command	<code>ipv6 mld querier-timeout seconds</code>
Parameter Description	<i>seconds</i> : Specifies the keepalive interval for other queriers. The unit is s, the value ranges from 60 to 300, and the default value is 255.
Command Mode	Interface configuration mode
Usage Guide	After sending Query messages, the interface waits for Query messages from other devices. After timeout, it is considered that it is the unique querier in the directly-connected network segment.

Configuration Example

Configuring the Keepalive Interval of Other Queriers

Configuration Steps	<ul style="list-style-type: none"> Configure the basic functions of MLD. (Omitted) Configure the keepalive interval of a querier as 280s.
	<pre>VSU(config-if-GigabitEthernet 0/1)#ipv6 mld querier-timeout 280</pre>
Verification	Run the <code>show ipv6 mld [vrf vrf-name] interface interface-type interface-number</code> command to check whether MLD is enabled on the interface.
	<pre>VSU#show ipv6 mld interface gigabitEthernet 0/1 Interface GigabitEthernet 0/1 (Index 1) MLD Enabled, Active, Querier, Version 2 (default) Internet address is fe80::2d0:f8ff:fe22:33b1 MLD interface limit is 1024 MLD interface has 0 group-record states MLD interface has 0 join-group records MLD interface has 0 static-group records MLD activity: 0 joins, 0 leaves MLD query interval is 130 seconds MLD querier timeout is 280 seconds MLD max query response time is 15 seconds Last member query response interval is 15 (1/10s) Last member query count is 3 Group Membership interval is 275 Robustness Variable is 2</pre>

Common Errors

- The basic functions of MLD are not enabled.

4.4.4 Filtering MLD Groups

Configuration Effect

- A router filters MLD group information.

Notes

- The basic functions of MLD must be configured.

Configuration Steps

↳ Configuring Access Control for Multicast Groups

Optional.

This function can be configured on all router interfaces directly connected to the local network unless otherwise specified.

↳ Configuring the Maximum Number of MLD Group Members

Optional.

This function can be configured on all router interfaces directly connected to the local network unless otherwise specified.

Verification

↳ Filtering MLD Groups

Configure the interface to allow for only groups in link table 1. The access address of link table 1 is (FF66::100/64).

Configure the interface to add a group FF66::05.

Configure the interface to add a group FF65::05.

Check group information on the interface.

↳ Configuring the Maximum Number of MLD Group Members

Configure the number of group members as 5 on the interface.

Configure the interface to add a group (FF66::05-FF65::0B).

Check group information on the interface.

Related Commands

↳ Configuring Access Control for Multicast Groups

Command	ipv6 mld access-group <i>access-list</i>
Parameter Description	<i>access-list</i> : Specifies the group address range by using IP standard ACLs or IP extended ACLs. The value ranges from 1 to 199, 1300 to 2699, and WORD.
Command Mode	Interface configuration mode
Usage Guide	After running this command on the interface, you can control the groups that hosts in the directly-connected network segment can join. Use ACLs to limit the group address range. Report messages denied by the ACLs will be discarded.

	When MLDv2 is enabled, this command supports extended ACLs to precisely filter source record information in MLDv2 messages. When the received MLD Report message is (S1,S2,S3...Sn,G), this command will match (0,G) using the corresponding ACLs. Therefore, to normally use this command, you must explicitly configure a (0, G) in the extended ACLs to filter (S1,S2,S3...Sn,G).
--	--

📄 **Configuring the Maximum Number of MLD Group Members**

Command	ipv6 mld limit <i>number</i> [except <i>access-list</i>]
Parameter Description	<i>number</i> : Specifies the maximum number of MLD group members. The value range depends on the specific device. The interface default value is 1024 and the global one is 65536. except <i>access-list</i> : Groups in the access list are not counted. The access list is an IP standard ACL. The value ranges from 1 to 99, 1300 to 1999, and WORD.
Command Mode	Interface configuration mode
Usage Guide	Global configuration mode: Limits the number of MLD group members on the whole device. Interface configuration mode: Limits the number of MLD group members of the interface. If the number of group members exceeds the interface limit or global limit, subsequent Report messages will be ignored. If an except list is configured, Report messages in a specified range can be normally processed. Therefore, the group members are not counted. Interface and global limits can be configured separately. If the global limit is smaller than the interface limit, use the global limit.

Configuration Example

📄 **Configuring Group Filtering**

Configuration Steps	<ul style="list-style-type: none"> ● Configure the basic functions of MLD. (Omitted) ● Configure the access address of link table 1 as (FF66::100/64). ● Configure the group to join as FF66::05. ● Configure the group to join as FF65::05.
	<pre> VSU(config)#ipv6 access-list acl VSU(config-ipv6-acl)#permit ipv6 ::/64 ff66::100/64 VSU(config-ipv6-acl)#permit ipv6 2222::3333/64 ff66::100/64 VSU(config-ipv6-acl)#exit VSU(config)# VSU(config)#int gi 0/1 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld access-group acl VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff66::5 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff65::5 </pre>
Verification	Run the show ipv6 mld [vrf <i>vrf-name</i>] groups [<i>interface-type interface-number</i>] [<i>group-address</i>]

	[detail] command to view the group information on the interface.
	<pre> VSU#show ipv6 mld groups MLD Connected Group Membership Group Address Interface Uptime Expires Last Reporter ff66::5 GigabitEthernet 0/1 00:05:07 00:03:46 fe80::2d0:f8ff:fe22:33b1 </pre>

📌 **Configuring the Maximum Number of MLD Group Members**

Configuration Steps	<ul style="list-style-type: none"> ● Configure the basic functions of MLD. (Omitted) ● Configure the maximum number of group members on the interface as 5. ● Add group information (FF66::5 ~ FF66::0B). ● View the group information.
	<pre> VSU(config-if-GigabitEthernet 0/1)#ipv6 mld limit 5 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff66::5 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff66::6 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff66::7 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff66::8 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff66::9 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff66::A VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff66::B </pre>
Verification	Run the show ipv6 mld [vrf vrf-name] groups [interface-type interface-number] [group-address] [detail] command to view group information on the interface.
	<pre> MLD Connected Group Membership Group Address Interface Uptime Expires Last Reporter ff66::5 GigabitEthernet 0/1 00:00:36 00:04:00 fe80::2d0:f8ff:fe22:33b1 ff66::6 GigabitEthernet 0/1 00:00:34 00:04:01 fe80::2d0:f8ff:fe22:33b1 ff66::7 GigabitEthernet 0/1 00:00:22 00:04:13 fe80::2d0:f8ff:fe22:33b1 ff66::8 GigabitEthernet 0/1 00:00:18 00:04:19 fe80::2d0:f8ff:fe22:33b1 ff66::9 GigabitEthernet 0/1 00:00:14 00:04:21 fe80::2d0:f8ff:fe22:33b1 </pre>

Common Errors

- The basic functions of MLD are not enabled.

4.4.5 MLD Proxy

Configuration Effect

- Configure the router proxy function and collect local member information.

Notes

- The basic functions of MLD must be configured.

Configuration Steps

▾ Configuring MLD PROXY-SERVICE

Optional.

This function can be configured on the interface of routers directly connected to the upstream devices unless otherwise specified.

▾ Configuring MLD MROUTE-PROXY

Optional

This function can be configured on the interface of hosts directly connected to the downstream devices unless otherwise specified.

Verification

- Configure the interface that directly connects interface 7 and upstream router as the multicast proxy service.
- Configure the interface that directly connects interface 1 and downstream host as the multicast proxy.
- Configure groups FF66::05 and FF66::06 to be added to interface 1.
- Check information of the current group.

Related Commands

▾ Configuring MLD PROXY-SERVICE

Command	ipv6 mld proxy-service
Parameter Description	-
Command Mode	Interface configuration mode
Usage Guide	Run the ipv6 mld proxy-service command to configure the upstream interface as the proxy-service interface. Run the ipv6 mld mroute-proxy command to configure the downstream interface as the mroute-proxy interface. Configure the proxy-service interface to forward MLD Query messages to the mroute-proxy interface.

Configure the mroute-proxy interface to forward MLD Reports messages to the proxy-service interface. A maximum of 32 proxy-service interfaces can be configured on a device. After receiving MLD Query messages, the proxy-service interface sends a response based on the MLD group member records. If you run **switchport** command on the proxy-service interface, the **ipv6 mld mroute-proxy** command configured on the mroute-proxy interface will be automatically deleted.

↳ **Configuring MLD MROUTE-PROXY**

Command	ipv6 mld mroute-proxy <i>interface-type interface-number</i>
Parameter Description	-
Command Mode	Interface configuration mode
Usage Guide	Run the ipv6 mld proxy-service command to configure the upstream interface as the proxy-service interface. Run the ipv6 mld mroute-proxy command to configure the downstream interface as the mroute-proxy interface. Configure the proxy-service interface to forward MLD Query messages to the mroute-proxy interface. Configure the mroute-proxy interface to forward MLD Reports messages to the proxy-service interface.

Configuration Example

Configuration Steps	<ul style="list-style-type: none"> ● Configure MLD basic functions. (Omitted) ● Configure interface 7 as the proxy server. ● Configure interface 1 as the multicast proxy. ● Configure groups FF66::05 and FF66::06 to be added to interface 1.
	<pre>VSU(config-if-GigabitEthernet 0/7)#ipv6 mld proxy-service VSU(config-if-GigabitEthernet 0/7)#exit VSU(config)#int gi 0/1 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld mroute-proxy gigabitEthernet 0/7 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff66::05 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff66::06</pre>
Verification	Run the show ipv6 mld [vrf vrf-name] groups [interface-type interface-number] [group-address] [detail] command to view the group information on the interface.
	<pre>VSU(config-if-GigabitEthernet 0/1)#show ipv6 mld groups MLD Connected Group Membership Group Address Interface Uptime Expires Last Reporter ff66::5 GigabitEthernet 0/1 00:00:11 00:04:31 fe80::2d0:f8ff:fe22:33b1</pre>

ff66::6	GigabitEthernet 0/1	00:00:11	00:04:33
fe80::2d0:f8ff:fe22:33b1			
MLD Proxy-server Connected Group Membership			
Group Address	Interface	Uptime	
ff66::5	GigabitEthernet 0/7	00:00:11	
ff66::6	GigabitEthernet 0/7	00:00:11	

Common Errors

- The basic functions of MLD are not enabled.

4.4.6 Supporting SSM-MAP

Configuration Effect

- MLDv2 supports source filtering while MLDv1 does not. However, MLDv1 provides the SSM-MAP function to implement source filtering.

Notes

- The basic functions of MLD must be configured.

Configuration Steps

↳ Enabling SSM-MAP

This function must be configured if SSM-MAP.

This function must be enabled on a router where SSM-MAP is enabled.

↳ Configuring an SSM-MAP Static Link Table

Optional.

This function must be enabled on a router where SSM-MAP is enabled.

Verification

Run the **show ipv6 mld [vrf vrf-name] ssm-mapping [group-address]** command to display SSM-MAP information.

Related Commands

↳ Enabling SSM-MAP

Command	ipv6 mld ssm-map enable
Parameter Description	-
Command Mode	Global configuration mode

Usage Guide	<p>Run the ipv6 mld ssm-map enable command to enable the SSM-MAP function.</p> <p>Run the ipv6 mld ssm-map static command to configure static mapping table items.</p> <p>The interface runs MLDv2. When receiving Report messages from MLDv1, the interface adds the static mapping source address.</p>
--------------------	--

📌 **Configuring an SSM-MAP Static Link Table**

Command	ipv6 mld ssm-map static access-list source-address
Parameter Description	<p>access-list: Specifies the group address range configured by the ACL.</p> <p>source-address: Source address</p>
Command Mode	Global configuration mode
Usage Guide	<p>Run the ipv6 mld ssm-map enable command to enable the SSM-MAP function.</p> <p>Run the ipv6 mld ssm-map static command to configure static mapping table items.</p> <p>The interface runs MLDv2. When receiving Report messages from MLDv1, the interface adds the static mapping source address.</p>

Configuration Example

Configuration Steps	<ul style="list-style-type: none"> ● Configure the basic functions of MLD. (Omitted) ● Enable SSM-MAP. ● Configure SSM-MAP static link table 3.
	<pre>VSU(config)#ipv6 mld ssm-map enable VSU(config)#ipv6 mld ssm-map static 3 1500::5</pre>
Verification	Run the show ipv6 mld [vrf vrf-name] ssm-mapping [group-address] command to view SSM mapping information.
	<pre>VSU(config)#show ipv6 mld ssm-mapping SSM Mapping : Enabled Database : Static mappings configured</pre>

Common Errors

- The basic functions of MLD are not enabled.

4.5 Monitoring

Clearing

Description	Command
Clears dynamic group member records in the MLD cache.	clear ipv6 mld group [group-address] [interface-type interface-number]

Clears all MLD statistics and group member records on the interface.	clear ipv6 mld interface <i>interface-type interface-number</i>
--	--

Displaying

Description	Command
Displays groups directly connected to the device and group information learned from MLD.	show ipv6 mld groups [<i>group-address</i> <i>interface-type interface-number</i>] [detail]
Displays configurations of the interface.	show ipv6 mld interface [<i>interface-type interface-number</i>]
Displays SSM-MAP information.	show ipv6 mld ssm-mapping [<i>group-address</i>]

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Displays the MLD debugging switch status.	show debugging
Debugs all MLD information.	debug ipv6 mld [<i>vrf vrf-name</i>] all
Debugs MLD packet resolution.	debug ipv6 mld [<i>vrf vrf-name</i>] decode

Debugs MLD state machine information.	debug ipv6 mld [<i>vrf vrf-name</i>] tib
Debugs MLD warning.	debug ipv6 mld [<i>vrf vrf-name</i>] warning

5 Configuring PIM-DM

5.1 Overview

Protocol Independent Multicast (PIM) is an intra-domain multicast routing protocol.

A multicast source sends a packet to a group address. The packet is forwarded by network devices hop by hop and finally reaches the group members. On layer-3 network devices, PIM is used to create and maintain multicast routing entries, so as to support multicast forwarding.

PIM works in two modes: Protocol Independent Multicast - Sparse Mode (PIM-SM) and Protocol Independent Multicast - Dense Mode (PIM-DM).

- PIM-SM is applicable to large-scale networks where group members are sparsely distributed in a wide scope.
- PIM-DM is applicable to small networks where group members are densely distributed.

Protocols and Standards

- RFC3973: Protocol Independent Multicast - Dense Mode (PIM-DM)
- RFC2715: Interoperability Rules for Multicast Routing Protocols

5.2 Applications

Application	Description
Providing the Multicast Service in the Same Network	The multicast service is provided in the same network.
PIM-DM Application in a Hot Backup Environment	The multicast PIM-DM protocol runs in a hot backup environment.

5.2.1 Providing the Multicast Service in the Same Network

Scenario

The multicast service is provided in the same network.

The following figure is taken as an example:

- A multicast source sends a multicast packet, and Receiver A and Receiver B in the same network receive the multicast packet.

Figure 5-1

Remark	A, B, and C are Layer-3 routers.
s	The multicast source is connected to the Gi0/1 interface of A, Receiver A is connected to the Gi0/1 interface of B, and Receiver B is connected to Gi0/1 of C.

Deployment

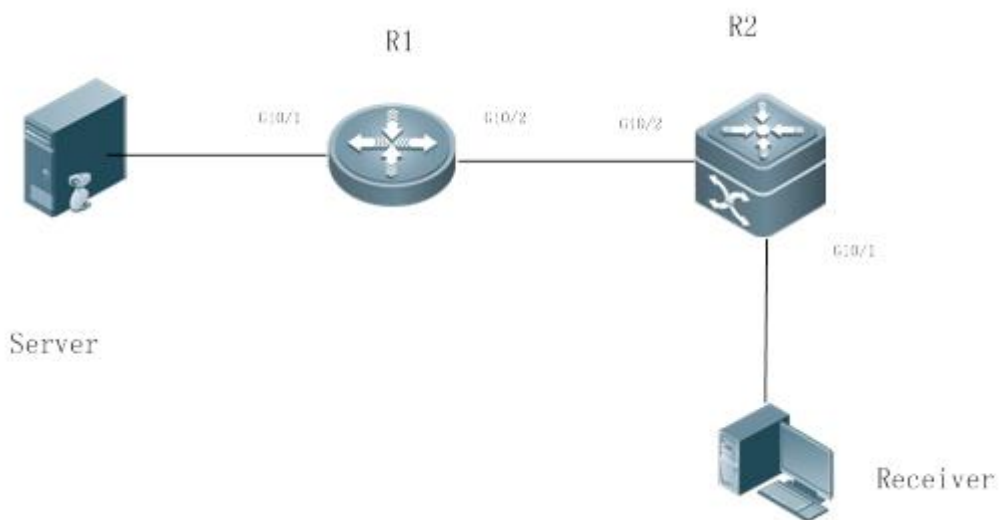

- Run the Open Shortest Path First (OSPF) protocol in the same network to implement unicast routing.
- Run the PIM-DM protocol in the same network to implement multicast routing.
- Run the Internet Group Management Protocol (IGMP) in a user host network segment to implement group member management.

5.2.2 PIM-DM Application in a Hot Backup Environment

Scenario

In a hot backup environment, run PIM-DM. A device performs hot backup switching to ensure that traffic is not interrupted.

Figure 5-2

Remark	R1 is connected to the video server, R2 is directly connected to the receiver, and R2 runs in hot backup mode.
---------------	--

s	A Layer-3 multicast protocol runs on R1 and R2.
----------	---

Deployment

- Run OSPF on R1 and R2 to implement unicast routing.
- Run PIM-DM on R1 and R2 to implement multicast routing.
- Make R2 run in a hot backup environment.

Remark	R2 may perform hot backup switching in the hot backup environment. In this case, the query interval of PIM Hello packets (the default value is 30 seconds) needs to be adjusted on R2 because the keepalive timer of the neighbor in PIM Hello packets of R1 may have expired (the default value is 3.5 times the query interval, that is, 105 seconds). The multicast function relies on the unicast function currently, and the multicast function starts convergence after the unicast function convergence is complete. For example, the default graceful restart (GR) convergence time of the unicast function is 120 seconds. It is recommended that the query interval of PIM Hello packets be set to 60 seconds. The keepalive time of the neighbor in PIM Hello packets is 210 seconds. In this scenario, the query interval of PIM Hello packets need to be set with a reference to the GR convergence time of the unicast function and the value of 3.5 times the query interval of PIM Hello packets must be larger than the GR convergence time of the unicast function. In a hot backup environment, it is recommended that the query interval of PIM Hello packets be larger than the default value (30 seconds). Otherwise, the keepalive timer of the neighbor in PIM Hello packets of the peer end times out during hot backup switching.
---------------	---

5.3 Features

Basic Concepts

↳ PIM Router and PIM Interface

Routers where the PIM protocol is enabled are called PIM Routers. Interfaces where the PIM protocol is enabled are called PIM interfaces.

Multicast packets are forwarded on PIM routers. The PIM interfaces where multicast packets are received are called Upstream Interfaces, and the PIM interfaces where multicast packets are sent are called Downstream Interfaces.

The network segments where upstream interfaces are located are called Upstream Network Segments. The network segments where downstream interfaces are located are called Downstream Network Segments.

↳ PIM Network and PIM Domain

PIM routers are connected through PIM interfaces and form a PIM network.

On some PIM interfaces, borders can be set to divide a large PIM network into multiple PIM domains. The borders are able to reject specified multicast packets or limit the transmission of PIM messages.

↳ Multicast Distribution Tree

Multicast packets are packets transmitted from one point to multiple points. The forwarding path is in a tree structure. This forwarding path is called the Multicast Distribution Tree (MDT).

↳ (*,G), (S,G)

- (*,G): Packets sent from any source to Group G, the corresponding routing entries, and the forwarding path called Rendezvous Point Tree (RPT).
- (S,G): Packets sent from Source S to Group G, the corresponding routing entries, and the forwarding path called Shortest Path Tree (SPT).

Overview

Feature	Description
PIM-DM Neighbor	Neighbor relationships are established between PIM routers to form a PIM network.
PIM-DM MDT	PIM-DM creates the MDT by using flooding, pruning, and grafting.
PIM-DM SRM	PIM-DM uses a State Refresh Message (SRM) to update the network state.
MIB	The Simple Network Management Protocol (SNMP) manager uses information in the Management Information Base (MIB) to directly manage the PIM-DM function.

5.3.1 PIM-DM Neighbor

Neighbor relationships are established between PIM routers to form a PIM network. Neighbor relationships must be established between PIM routers before PIM control messages can be exchanged or multicast packets can be forwarded.

Working Principle

A Hello message is sent from a PIM interface. For the IPv4 multicast packet with the Hello message encapsulated, the destination address is 224.0.0.13 (indicating all PIM routers in the same network segment), the source address is the IP address of the PIM interface, and the Time To Live (TTL) value is 1. For the IPv6 multicast packet with the Hello message encapsulated, the destination address is ff02::d.

Function of a Hello message: It is used to discover neighbors, coordinate protocol parameters, and maintain neighbor relationships.

📌 Discovering Neighbors

PIM routers in the same network segment receive multicast packets from the destination address 224.0.0.13 or ff02::d. In this way, the PIM routers obtain neighbor information and establish neighbor relationships.

When a PIM interface is enabled or detects a new neighbor, a Triggered-Hello-Delay message is used to generate a random time. Within the time, the interface sends Hello packets.

📌 Coordinating Protocol Parameters

A Hello message includes multiple protocol parameters, which are described as follows:

- DR_Priority: Router interfaces contend for the designated router (DR) based on their DR priorities. A higher priority means a higher chance of winning.
- Holdtime: Time in which a neighbor is held in the reachable state
- LAN_Delay: LAN delay for transmitting a Prune message in a shared network segment
- Override-Interval: Prune override time carried in a Hello message.

When a PIM router receives a Prune message from an upstream interface, it indicates that downstream interfaces exist in the shared network segment. If the PIM router still needs to receive multicast data, the PIM router must send a Prune Override message to the upstream interface within the Override-Interval.

$\text{LAN_Delay} + \text{Override-Interval} = \text{PPT}$ (Prune-Pending Timer). After a PIM router receives a Prune message from a downstream interface, the PIM router will not immediately perform pruning until PPT times out. Within the time of PPT, if the PIM router receives a Prune rejection message from the downstream interface, the PIM router cancels pruning.

↘ Maintaining Neighbor Relationships

A Hello message is sent periodically between PIM routers. If a Hello packet is not received from a PIM neighbor within Holdtime, the neighbor is considered unreachable and is deleted from the neighbor list. Any change of PIM neighbors will cause change of the multicast topology in the network. If an upstream or downstream neighbor in an MDT is unreachable, multicast routes converge again and the MDT is reshaped.

Related Configuration

↘ Enabling PIM-DM on an Interface

By default, PIM-DM is disabled on an interface.

Use the **ip pim dense-mode** command to enable or disable PIM-DM on an interface.

PIM-DM must be enabled on an interface to involve the interface in the PIM protocol.

↘ Setting the Interval of Hello Messages on an Interface

By default, a Hello message is sent at an interval of 30 seconds.

The **ip pim query-interval *interval-seconds*** command is used to adjust the interval of Hello messages. The value of the interval ranges from 1 to 65,535.

A Hello message is transmitted less frequently when the value of *interval-seconds* is larger.

5.3.2 PIM-DM MDT

The three basic mechanisms dense-mode PIM uses to build multicast forwarding trees are: flood, prune, and graft.

Working Principle

When a multicast source sends multicast packets, the system forwards them to the outgoing interfaces of multicast neighbors and local members. The Reverse Path Forwarding (RPF) check needs to be conducted on all packets received through the upstream interface of the device. Packets that fail the RPF check will be discarded. Multicast packets that pass the RPF check are further forwarded if there is an outgoing interface. If no outgoing interface is available, the device sends a prune packet to the upstream interface. After receiving the prune packet, the upstream interface identifies the source interface of the prune packet as the Pruned state and sets the Pruned Timer (PI). In this way, a multicast forwarding tree with the multicast source as the root is created.

When the system receives a Join message from a local member, if a downstream device in the Pruned state sends a Graft message to the upstream device, the upstream device returns a Graft-Ack message and resumes forwarding of multicast data to the interface of the downstream device after receiving the Graft message.

-
- i** In environment deployment, when multiple PIM-DM neighbors are created through multiple links between devices and downstream devices need to receive no or few packets, the CPU usage may be high. In this scenario, PIM-SM is recommended for the environment deployment
-

Related Configuration

Configuring the Prune Override Interval on an Interface

By default, the prune override interval is 500 ms.

Run the **ip pim override-interval *interval-milliseconds*** command to change the prune override interval.

5.3.3 PIM-DM SRM

PIM-DM uses an SRM to refresh the network state.

Working Principle

Devices connected to a multicast source periodically send SRMs to downstream devices to notify changes of the network topology. After receiving the SRMs, the adjacent devices receiving the SRMs add the local topology state information to the messages by modifying some fields in SRMs, and send the messages to downstream devices. When the messages reach leaf devices, the state information of the entire network is updated.

Related Configuration

Disabling the Processing and Forwarding of SRMs

By default, the processing and forwarding of SRMs are enabled.

The **ip pim state-refresh disable** command is used to disable the processing and forwarding of SRMs.

-
- i** Disabling the SRM function may cause the converged PIM-DM MDT to re-converge, which leads to unnecessary bandwidth waste and multicast routing table flapping. Therefore, it is recommended not to disable SRM in general conditions.
-

Setting the Interval of SRMs

By default, an SRM is sent at an interval of 60 seconds.

The **ip pim state-refresh origination-interval *interval-seconds*** command is used to adjust the interval of SRMs. The value of the interval ranges from 1 to 100.

SRMs are transmitted less frequently when the value of *interval-seconds* is larger.

-
- i** Only devices that are directly connected to a multicast source will periodically send a PIM SRM to downstream interfaces. For a device not directly connected to the multicast source, the interval of SRMs on its downstream interfaces is invalid.
-

5.3.4 MIB

Connected to other agents, the Simple Network Management Protocol (SNMP) manager uses information in the Management Information Base (MIB) to directly manage the PIM-DM function.

Working Principle

The MIB specifies variables (namely information that can be queried and set by the management process) maintained by network elements and directly manages the PIM-DM function.

Related Configuration

↳ Enabling PIM-DM MIB

By default, the PIM-DM MIB function is enabled.

The `ip pim mib dense-mode` command is used to enable the PIM-DM MIB function.

5.4 Configuration

Configuration	Description and Command	
Configuring PIM-DM Basic Functions	 (Mandatory) It is used to create the multicast service.	
	<code>ip multicast-routing</code>	Enables IPv4 multicast routing.
	<code>ip pim dense-mode</code>	Enables PIM-DM.
Configuring PIM-DM Neighbors	 (Optional) It is used to limit the (S,G) pairs of legitimate multicast packets in Any Source Multicast (ASM) model.	
	<code>ip pim query-interval interval-seconds</code>	Sets the Interval of Hello messages on an interface.
	<code>ip pim propagation-delay interval-milliseconds</code>	Sets the prune propagation delay on an interface.
	<code>ip pim override-interval interval-milliseconds</code>	Sets the prune override interval on an Interface.
Configuring PIM-DM SRMs	<code>ip pim state-refresh disable</code>	Disables the processing and forwarding of SRMs.
	<code>ip pim state-refresh origination-interval interval-seconds</code>	Sets the Interval of SRMs on an interface.
Configuring PIM-DM MIB	<code>ip pim mib dense-mode</code>	Enables PIM-DM MIB.
Configuring the PIM-DM Sub VLAN Function	<code>ip pim dense-mode subvlan [all vid]</code>	Specifies, on an interface of a super VLAN, the sub VLAN to which packets are sent.

5.4.1 Configuring PIM-DM Basic Functions

Configuration Effect

- Create a PIM-DM network and provide data sources and user terminals in the network with the IPv4 multicast service.

Notes

- PIM-DM needs to use the unicast routes existing in the network. Therefore, IPv4 unicast routing must be configured in the network.

Configuration Steps

↳ Enabling IPv4 Multicast Routing

- Mandatory
- IPv4 multicast routing should be enabled on each router unless otherwise specified.

↳ Enabling PIM-DM

- Mandatory
- PIM-DM should be enabled on the following interfaces unless otherwise specified: interconnected interfaces on routers and interfaces connecting multicast sources and user hosts.

↳ Configuring the PIM-DM Sub VLAN Function

- In most scenarios on the PIM network, the PIM DM protocol does not need to be enabled on interfaces of a super VLAN. In general, a super VLAN includes many sub VLANs. If the PIM DM protocol is enabled on the interfaces of the super VLAN, multicast packets will be replicated and sent to all sub VLANs. As a result, traffic generated easily exceeds the device processing capability, causing protocol flapping. In some scenarios that require the PIM DM protocol to be enabled on the interfaces of the super VLAN, the PIM-DM sub VLAN function may be configured, to send packets to a specified sub VLAN or all sub VLANs.
- This function is available only on the interfaces of the super VLAN.

Verification

Make multicast sources send multicast packets and make user hosts join the groups.

- Check whether the user hosts can successfully receive packets from each group.
- Check whether correct PIM-DM routing entries are created on routers.

Related Commands

↳ Enabling IPv4 Multicast Routing

Command	ip multicast-routing [vrf vid]
Parameter Description	vrf vid: Specifies a Virtual Routing and Forwarding (VRF).
Command Mode	Global configuration mode
Usage Guide	N/A

↳ Enabling PIM-DM

Command	ip pim dense-mode
----------------	--------------------------

Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	PIM interfaces must be at Layer-3, including: routing interfaces, aggregate ports(APs), switch virtual interfaces (SVIs), and loopback interfaces. For all PIM interfaces, IPv4 unicast routes should be reachable.

↳ **Enabling the PIM-DM Sub VLAN Function**

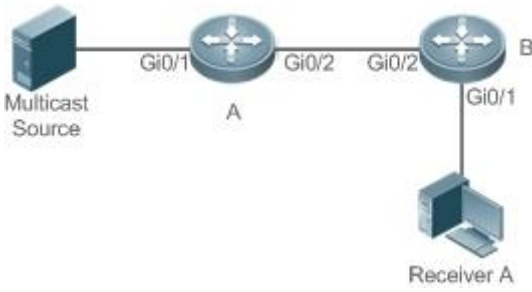

Command	ip pim dense-mode subvlan [all vid]
Parameter Description	all: sends packets to all sub VLANs. vid: sends packets to a specified sub VLAN.
Command Mode	Interface configuration mode
Usage Guide	The PIM interface must be an interface of the super VLAN.

↳ **Displaying the PIM-DM Routing Table**

Command	show ip pim dense-mode mroute [group-or-source-address [group-or-source-address]] [summary]
Parameter Description	<i>group-or-source-address:</i> Indicates a group address or source address. <i>group-or-source-address:</i> Indicates a group address or source address (The two addresses cannot be group addresses or source addresses at the same time). summary: Displays the routing table summary.
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	Check whether sufficient routing entries are provided. Check the upstream and downstream interface lists and ensure that a correct SPT tree is created.

Configuration Example

↳ **Enabling IPv4 Multicast Routing on the IPv4 Network**

Scenario Figure 5-3	 <p>The diagram illustrates a network topology for IPv4 multicast routing. On the left, a 'Multicast Source' is connected to Router A via interface Gi0/1. Router A is connected to Router B via interface Gi0/2. Router B is connected to 'Receiver A' via interface Gi0/1.</p>
Configuratio	<ul style="list-style-type: none"> Configure IPv4 unicast routing protocols (for example, OSPF) on all the routers.

n Steps	<ul style="list-style-type: none"> ● Enable the IPv4 multicast routing function on all the routers. ● Enable the PIM-DM function on all the interconnected interfaces of the routers, Source, and Receiver..
A	<pre>A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if)# ip pim dense-mode A(config-if)# exit A(config)# interface GigabitEthernet 0/2 A(config-if)# ip pim dense-mode A(config-if)# exit</pre>
B	<pre>B# configure terminal B(config)# ip multicast-routing B(config)# interface GigabitEthernet 0/1 B(config-if)# ip pim dense-mode B(config-if)# exit B(config)# interface GigabitEthernet 0/2 B(config-if)# ip pim dense-mode B(config-if)# exit</pre>
Verification	<p>Configure the multicast source (192.168.1.10) to send packets to G (229.1.1.1). Make Receiver A join G.</p> <ul style="list-style-type: none"> ● Check whether the multicast packets from Source G are received by Receiver A.. ● Check PIM-DM routing tables on Router A and Router B.
A	<pre>A# show ip pim dense-mode mroute PIM-DM Multicast Routing Table (192.168.1.10, 229.1.1.1) MRT lifetime expires in 182 seconds Source directly connected on GigabitEthernet 0/1 State-Refresh Originator State: Originator SRT:57, SAT:147 Upstream IF: GigabitEthernet 0/1 Upstream State: Forwarding Assert State: NoInfo Downstream IF List:</pre>

	<pre>GigabitEthernet 0/2, in 'olist': Downstream State: NoInfo Assert State: NoInfo</pre>
B	<pre>B# show ip pim dense-mode mroute PIM-DM Multicast Routing Table (192.168.1.10, 229.1.1.1) MRT lifetime expires in 130 seconds RPF Neighbor: 192.168.2.1, Nexthop: 192.168.2.1, GigabitEthernet 0/2 Upstream IF: GigabitEthernet 0/2 Upstream State: Forwarding Assert State: Loser, AT:125 Downstream IF List: GigabitEthernet 0/1, in 'olist': Downstream State: NoInfo Assert State: NoInfo</pre>

Common Errors

- IPv4 unicast routing is incorrectly configured.
- IPv4 multicast routing is not enabled on a certain router.
- PIM-DM is not enabled on a certain interface.

5.4.2 Configuring PIM-DM Neighbors

Configuration Effect

- Coordinate protocol parameters and adjust parameters in the Hello packet.
- Enable neighbor filtering to improve network security.

Notes

- Basic functions of PIM-DM must be configured.

Configuration Steps

- Set parameters on PIM router interfaces unless otherwise specified.

Verification

- Set parameters in a Hello packet on an interface and run the **debug ip pim dense-mode encode** command to check parameters.
- Enable neighbor filtering and run the **show ip pim dense-mode decode** command to display neighbor filtering information.

- Run the **show running-config interface** [*interface-type interface-number*] command to display configurations on an interface.

Related Commands

Setting the Interval of Hello Messages

Command	ip pim query-interval <i>interval-seconds</i>
Parameter Description	<i>interval-seconds</i> : The value ranges from 1 to 65,535 in the unit of seconds.
Command Mode	Interface configuration mode
Usage Guide	When the Hello interval is set, the holdtime value will be updated as its 3.5 times.
<p> Every time when the interval of Hello messages is updated, the holdtime value is automatically updated as 3.5 times of the interval. If the result of the interval of Hello messages multiplied by 3.5 is greater than 65,535, the holdtime value is updated as 65,535.</p>	

Setting the Prune Propagation Delay

Command	ip pim propagation-delay <i>interval-milliseconds</i>
Parameter Description	<i>interval-milliseconds</i> : The value ranges from 1 to 32,767 in the unit of milliseconds.
Command Mode	Interface configuration mode
Usage Guide	Set propagation-delay of an interface, that is, configure the prune propagation delay of an interface.

Setting the Prune Override Interval

Command	ip pim override-interval <i>interval-milliseconds</i>
Parameter Description	<i>interval-milliseconds</i> : The value ranges from 1 to 32,767 in the unit of milliseconds.
Command Mode	Interface configuration mode
Usage Guide	Set override-interval of an interface, that is, configure the prune override time of an interface.

Configuring PIM-DM Neighbor Filtering

Command	ip pim neighbor-filter <i>access-list</i>
Parameter Description	<i>access-list</i> : The supported ACL ranges from 1 to 99. Naming an ACL is also supported.
Command Mode	Interface configuration mode
Usage Guide	Only addresses that meet ACL filtering conditions can be used as PIM neighbors of the current interface. Otherwise, the addresses filtered out cannot be neighbors.

Peering refers to exchange of protocol packets between PIM neighbors. If peering with a PIM device is suspended, the neighbor relationship with it cannot be formed so that PIM protocol packets will not be received from the device.

Configuration Example

Configuring PIM-DM Neighbors on the IPv4 Network

<p>Scenario Figure 5-4</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> Configure basic functions of PIM-DM (omitted). Set protocol parameters in a Hello packet on the Gi0/1 interface of device A.
<p>A</p>	<pre>A# configure terminal A(config)# interface GigabitEthernet 0/1 A(config-if)# ip pim query-interval 60 A(config-if)# ip pim propagation-delay 800 A(config-if)# ip pim override-interval 1000 A(config-if)# exit</pre>
<p>Verification</p>	<ul style="list-style-type: none"> Run the show running-config interface [interface-type interface-number] command to display configurations on an interface. Run the debug ip pim dense-mode encode command to debug parameters in a Hello packet.

Common Errors

- IPv4 unicast routing is incorrectly configured.
- IPv4 multicast routing is not enabled on a certain router.
- PIM-DM is not enabled on a certain interface.

5.4.3 Configuring PIM-DM SRMs

Configuration Effect

- Enable or disable the PIM-DM SRM function.
- Adjust the interval of SRMs.

Notes

- Basic functions of PIM-DM must be configured.

Configuration Steps

- The interval of SRMs is only applicable only to the PIM router interfaces that are directly connected to the multicast source.

Verification

- Configure the PIM-DM SRMs and run the **show running-config** command to display the SRM status.
- Run the **show ip pim dense-mode track** command to display the SRM number.
- Run the **show running-config interface [interface-type interface-number]** command to display interface configurations.

Related Commands

↳ Disabling the Processing and Forwarding of SRMs

Command	ip pim state-refresh disable
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	When the processing and forwarding of SRMs are disabled, the State Refresh Capable option is not included in a Hello packet, and is not processed when the Hello packet is received. Disabling the SRM function may cause the converged PIM-DM MDT to re-converge, which leads to unnecessary bandwidth waste and multicast routing table flapping. Therefore, it is recommended not to disable this function in general conditions.

↳ Setting the Interval of SRMs

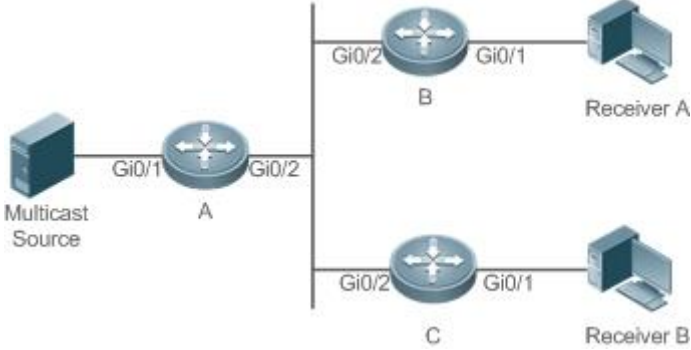

Command	ip pim state-refresh origination-interval <i>interval-seconds</i>
Parameter Description	<i>interval-seconds</i> : The value ranges from 1 to 100 in the unit of second.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

Displays PIM-DM information of an interface.	show ip pim dense-mode interface [<i>interface-type interface-number</i>] [detail]
Displays the PIM-DM neighbors.	show ip pim dense-mode neighbor [<i>interface-type interface-number</i>]
Displays the PIM-DM next-hop information .	show ip pim dense-mode nexthop
Displays the PIM-DM routing table.	show ip pim dense-mode mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]] [summary]
Displays the number of PIM-DM packets sent and received since the statistic start time.	show ip pim dense-mode track

6 Configuring PIM-SM

6.1 Overview

Protocol Independent Multicast (PIM) is an intra-domain multicast routing protocol.

A multicast source sends a packet to a group address. The packet is forwarded by network devices hop by hop and finally reaches the group members. On Layer-3 network devices, PIM is used to create and maintain multicast routing entries, so as to support multicast forwarding.

PIM works in two modes: Protocol Independent Multicast - Sparse Mode (PIM-SM) and Protocol Independent Multicast - Dense Mode (PIM-DM).

- PIM-SM is applicable to large-scale networks where group members are sparsely distributed in a wide scope.
- PIM-DM is applicable to small networks where group members are densely distributed.

Protocols and Standards

- RFC4601: Protocol Independent Multicast -Sparse Mode (PIM-SM)
- RFC5059: Bootstrap Router (BSR) Mechanism for Protocol Independent Multicast (PIM)
- RFC3962: Protocol Independent Multicast - Dense Mode protocol
- RFC4607: Source-Specific Multicast for IP

6.2 Applications

Application	Description
Enabling ASM for PIM-SM	The receiver receives any multicast source.
Enabling SSM for PIM-SM	The receiver receives only a specific multicast source.
PIM-SM Application in a Hot Backup Environment	The multicast PIM-SM protocol runs in a hot backup environment.

6.2.1 Enabling ASM for PIM-SM

Scenario

Provide multicast services within only one domain.

For example, in the following figure, the receiver receives any multicast source.

Figure 6-1

Remark	R 1 is connected directly to the multicast source.
s	R 2 serves as the rendezvous point (RP).
	R 3 is connected directly to Receiver A.
	R 4 is connected directly to Receiver B.

Deployment

- Run the Open Shortest Path First (OSPF) protocol to realize unicast routing.
- Run PIM-SM to realize multicast routing.
- Run the Internet Group Management Protocol (IGMP) in the network segment of the user host to manage group members.

6.2.2 Enabling SSM for PIM-SM

Scenario

Provide multicast services within only one domain.

For example, in the following figure, the receiver receives a specific multicast source.

Figure 6-2

Remark	R 1 is connected directly to the multicast source.
s	R 2 serves as the RP.
	R 2 is connected directly to Receiver A.
	R 2 is connected directly to Receiver B.

Deployment

- Run the OSPF protocol to realize unicast routing.
- Run PIM-SM to realize multicast routing.
- Run the source-specific multicast (SSM) of PIM-SM within the domain.
- Run IGMPv3 in the network segment of the user host to manage group members.

6.2.3 PIM-SM Application in a Hot Backup Environment

Scenario

In a hot backup environment, run PIM-SM. A device performs hot backup switching to ensure that traffic is not interrupted.

Figure 6-3

Remarks	R1 is connected to the video server, R2 is directly connected to the receiver, and R2 runs in hot backup mode. A Layer-3 multicast protocol runs on R1 and R2.
----------------	--

Deployment

Run OSPF on R1 and R2 to implement unicast routing.

Run PIM-SM on R1 and R2 to implement multicast routing.

Make R2 run in two-node cluster hot backup mode.

Remarks	R2 may perform hot backup switching in the hot backup environment. In this case, the keepalive time of PIM Join/Prune packets and C-RP notification interval need to be adjusted on R2. The multicast function relies on the unicast function currently, and the multicast function starts convergence after the unicast function convergence is complete. For example, the default graceful restart (GR) convergence time of the unicast function is 120 seconds. It is recommended that the query interval of PIM Hello packets be set to 60 seconds. The keepalive time of the neighbor in PIM Hello packets is 210 seconds. In this scenario, the query interval of PIM Hello packets need to be set with a reference to the GR convergence time of the unicast function and the value of 3.5 times the query interval of PIM Hello packets must be larger than the GR convergence time of the
----------------	--

unicast function. In addition, if the convergence time of the unicast function is long, the transmission interval of PIM Join/Prune packets also need to be adjusted, because the keepalive time of PIM Join/Prune packets is 3.5 times the transmission interval of PIM Join/Prune packets. The default keepalive time of PIM Join/Prune packets is 210 seconds. If R2 is configured as a dynamic RP, the interval for a candidate RP (C-RP) to transmit C-RP notifications also needs to be adjusted. The default transmission interval is 60 seconds and the keepalive time is 2.5 times the transmission interval of C-RP notifications. For example, if the convergence time of the unicast function is longer than 150 seconds, the transmission interval of C-RP notifications needs to be adjusted.

Changing the C-RP notification interval may cause PIM Join/Prune packet loss. R1 fails to generate forwarding entries and needs to wait for R2 to send PIM Join/Prune packets again. The waiting time is the PIM Join/Prune keepalive time.

6.3 Features

Basic Concepts

↘ PIM Router and PIM Interface

A router running PIM is called a PIM router. An interfaces running PIM is called a PIM interface.

Multicast packets are forwarded on PIM routers. The PIM interfaces where multicast packets are received are called upstream interfaces, and the PIM interfaces where multicast packets are sent are called downstream interfaces.

The network segments where upstream interfaces are located are called upstream network segments, and the network segments where downstream interfaces are located are called downstream network segments.

↘ PIM Network and PIM Domain

PIM routers are connected through PIM interfaces to form a PIM network.

On some PIM interfaces, borders can be set to divide a large PIM network into multiple PIM domains. The borders can reject the passage of specific multicast packets or limit the transmission of PIM packets.

↘ Multicast Distribution Tree, DR, and RP

Multicast packets are transmitted from one point to multiple points, forming a tree-shaped forwarding path. Such forwarding path is called the multicast distribution tree (MDT), which includes the following two types:

- RP Tree (RPT): It is rooted at an RP, and uses the designated router (DR) of the member groups connected to it as its leaves.
- Shortest path tree (SPT): It is rooted at a DR that is connected to the multicast source, and uses the RP or the DR of the member groups connected to it as its leaves.

Both the DR and RP are the functions of a PIM router.

- An RP collects the information of a multicast source or multicast member on the network.
- The DR connected to the multicast source advertises the multicast source information to the RP; the DR connected to multicast group members advertises the information of multicast group members to the RP.

↘ (*, G), (S, G)

- (*, G): Indicates the packets sent from any source to a group (G), the corresponding route entries, and the RPT.
- (S, G): Indicates the packets sent from the source (S) to a group (G), the corresponding routing entries, and the SPT.

📌 ASM, SSM

PIM-SM supports both any-source multicast (ASM) and SSM, and it is applicable to different multicast group address segments.

- ASM: In this model, a user is not allowed to select a multicast source. The user host joins a group, and receives the packets sent from all sources.
- SSM: In this model, a user can select a multicast source. The user host joins a group and specifies the source address. Then only the packets sent from this source address is received.

i Requirements for using an SSM model: Before selecting a multicast source, you need to learn the address of the multicast source using other network services.

Overview

Feature	Description
PIM-SM Neighbor	Establishes neighbor relationships between RIM routers to form a PIM network.
DR Election	In the network segment where group member hosts are located, PIM neighbors compete for the DR, and the one wins the election becomes the DR for connecting to the group members. In the network segment where the multicast source is located, PIM neighbors compete for the DR, and the one wins the election becomes the DR for connecting to the multicast source.
BSR Mechanism	On a PIM network, the BSR generates periodic candidate RPs and bootstrap packets of corresponding group addresses.
RP Mechanism	On a PIM network, through static RP configuration or dynamic RP election, the location of the RP can be learned by each PIM router.
Register Information of the Multicast Source	When the multicast source is detected on the network, the source DR sends a register packet to the RP, which obtains the source information and multicast packet.
Creating an RPT	When a group member is detected on the network, the DR connecting to the group members send packets toward the RP to form an RPT. If the multicast source already exists on the network, the packets arrived at the RP can be sent to the group members along the RPT.
Creating an SPT	When data packets arrive at the DR connecting to group members, the DR sends these packets toward the multicast source to form an SPT, and multicast packets are sent to group members along the SPT.
ASM and SSM	A PIM router can provide multicast services of both ASM model and SSM model at the same time. SSM model applies to the groups whose addresses are within the range of the SSM addresses. For other groups, use ASM model.

6.3.1 PIM-SM Neighbor

Neighbor relationships are established between PIM routers to form a PIM network. Neighbor relationships must be established between PIM routers before PIM control packets can be exchanged or multicast packets can be forwarded.

Working Principle

A PIM interface sends a Hello packet. For the IPv4 multicast packet whose Hello packet is encapsulated, the destination address is 224.0.0.13 (indicating all PIM routers in the same network segment), the source address is the IP address of the PIM interface, and the Time To Live (TTL) value is 1. For the IPv6 multicast packet whose Hello packet is encapsulated, the destination address is ff02::d.

A Hello packet is used to discover neighbors, coordinate protocol parameters, and maintain neighbor relationships.

Discovering Neighbors

PIM routers in the same network segment receive multicast packets from the destination address 224.0.0.13. In this way, the PIM routers obtain neighbor information and establish neighbor relationships.

When a PIM interface is enabled or detects a new neighbor, a triggered-hello-delay packet is used to generate a random time. Within the time, the interface sends Hello packets.

Coordinating Protocol Parameters

A Hello packet includes multiple protocol parameters, which are described as follows:

- DR_Priority: indicates the priority of a router interface for competing for the DR. A higher priority means a higher chance of winning.
- Holdtime: Indicates the time in which a neighbor is held in the reachable state
- LAN_Delay: Indicates the LAN delay for transmitting a Prune packet in a shared network segment.
- Override-Interval: Indicates the prune override time carried in a Hello packet.

When a PIM router receives a Prune packet from an upstream interface, it indicates that downstream interfaces exist in the shared network segment. If the PIM router still needs to receive multicast data, the PIM router must send a Prune Override packet to the upstream interface within the override interval.

$\text{LAN_Delay} + \text{Override Interval} = \text{PPT}$ (Prune-Pending Timer). After a PIM router receives a Prune packet from a downstream interface, the PIM router will not immediately perform pruning until PPT times out. Within the time of PPT, if the PIM router receives a Prune rejection packet from the downstream interface, the PIM router cancels pruning.

Maintaining Neighbor Relationships

A Hello packet is sent periodically between PIM routers. If a Hello packet is not received from a PIM neighbor within Holdtime, the neighbor is considered unreachable and is deleted from the neighbor list. Any change of PIM neighbors will cause change of the multicast topology in the network. If an upstream or downstream neighbor in an MDT is unreachable, multicast routes converge again and the MDT is reshaped.

Related Configuration

Enabling PIM-SM on an Interface

By default, PIM-SM is disabled on an interface.

Run **ip pim sparse-mode** to enable or disable PIM-SM on an interface.

PIM-SM must be enabled on an interface to involve the interface in the PIM protocol. If PIM-SM is not enabled for the interface of a DR, static RP, candidate RP (C-RP), or candidate BSR (C-BSR), corresponding roles of the PIM protocol cannot be run.

↘ Setting the Interval of Hello Packets on an Interface

By default, a Hello packet is sent every 30s.

Run **ip pim query-interval** *interval-seconds* to adjust the interval of Hello packets. The value ranges from 1 to 65,535.

A Hello packet is transmitted less frequently when the value of *interval-seconds* is greater.

6.3.2 DR Election

In the network segment where group member hosts are located, PIM neighbors compete for the DR, and the one wins the election becomes the DR for connecting to the group members.

In the network segment where the multicast source is located, PIM neighbors compete for the DR, and the one wins the election becomes the DR for connecting to the multicast source.

The DR sends Join/Prune packets toward the MDT, or sends the multicast source data to the MDT.

Working Principle

When creating a PIM neighbor, you can send a Hello packet to obtain the IP address and DR priority of the neighbor to elect a DR.

Two parameters play a key role in winning the DR election: the DR priority of an interface and the IP address of the interface.

↘ DR Priority of an Interface

During the DR election, the RIM router with the highest DR priority will be elected as the DR.

↘ Interface IP Address

During the DR election, if the priority of interfaces is the same, then interface IP addresses will be compared. The interface with the maximum IP address will be elected as the DR.

Related Configuration

↘ Enabling PIM-SM on an Interface

By default, PIM-SM is disabled on an interface.

Run **ip pim sparse-mode** to enable or disable PIM-SM on an interface.

PIM-SM must be enabled on an interface to involve the interface in the PIM protocol. If PIM-SM is not enabled for the interface of a DR, static RP, C-RP, or C-BSR, corresponding protocols cannot be run.

↘ Adjusting the DR Priority of an Interface

By default, the DR priority is 1.

Run **ip pim dr-priority** *priority-value* to adjust the DR priority of the interface. The value ranges from 0 to 4,294,967,294.

The DR priority is used in the DR election in the network segment directly connected the interface. A greater value indicates a higher priority.

6.3.3 BSR Mechanism

On a PIM network, the BSR generates periodic candidate RPs and bootstrap packets of corresponding group addresses. These bootstrap packets are sent hop by hop in the domain. All the routers on the entire network will receive these bootstrap packets, and record these candidate RPs and their corresponding group addresses.

Working Principle

One or multiple candidate BSRs are configured in a PIM-SM domain. You need to apply a certain algorithm to select the BSR from these candidate BSRs.

Related Configuration

Configuring Candidate BSRs

By default, candidate BSRs are not configured.

Run **ip pim bsr-candidate** *interface-type interface-number* [*hash-mask-length* [*priority-value*]] to configure or cancel the configuration of candidate BSRs.

Through bootstrap packet (BSM) learning and competition of candidate BSRs, a unique BSR is generated for the PIM-SM domain.

Configuring BSR Borders

By default, BSR borders are not configured.

Run **ip pim bsr-border** to configure or cancel the configuration of BSR borders.

After this command is configured, BSMs received by the interface will be discarded and will not be forwarded by this interface, preventing BSM flooding.

Filtering BSMs

By default, BSMs from the BSR are not filtered.

Run **ip pim accept-bsr list** { <1-99> | <1300-1999> | *WORD* } to configure whether to filter BSMs.

If this function is enabled, only legible BSMs are received by the interface; if this function is disabled, all the external BSMs will be received by the device running PIM-SM.

Configuring Legible C-RP Addresses and the Multicast Groups They Serve for a Candidate BSR

By default, Candidate-RP-Advertisement (C-RP-Adv) packets are not filtered by a candidate BSR.

Run **ip pim accept-crp list** { <100-199> | <2000-2699> | *WORD* } to configure whether to filter C-RP-Adv packets.

If this function is enabled, C-RP addresses and corresponding multicast groups are filtered by a candidate BSR. If this function is disabled, all external C-RP-Adv packets are received by a candidate BSR.

Allowing a C-BSR to Receive a C-RP-ADV Packet Whose Prefix-Count Is 0

By default, a candidate BSR cannot receive a C-RP-ADV packet whose prefix-count is 0.

Run **ip pim accept-crp-with-null-group** to configure whether to receive a C-RP-ADV packet whose prefix-count is 0.

If this function is enabled, a C-RP-ADV packet whose prefix-count is 0 can be received by a candidate BSR. If this function is disabled, a C-RP-ADV packet whose prefix-count is 0 cannot be received by a candidate BSR.

6.3.4 RP Mechanism

On a PIM network, through static RP configuration or dynamic RP election, the location of the RP can be learned by each PIM router. The RP as the root of the RPT, is the point where the RPT is rooted at and RPT data traffic is forwarded from.

Working Principle

All PIM routers in the same PIM domain must be mapped to the same RP as a specific multicast group address. On a PIM network, an RP can be configured as static or dynamic.

Static RP

In static RP configuration, RP addresses are configured directly on PIM routers and these addresses are learnt by the entire PIM network.

Dynamic RP

In a PIM-SM domain, there are candidate RPs that send unicast packets (including RP addresses and the multicast groups they serve) to the BSR, which generates periodic candidate RPs and bootstrap packets of corresponding group addresses. These bootstrap packets are sent hop by hop in the domain, and received and saved by PIM routers, which apply a hash function to map the group addresses to the candidate RP that can provide services. Then the RP corresponds to these multicast group addresses can be confirmed.

Related Configuration

Configuring Static RP Addresses

By default, no RP address is configured.

Run **ip pim rp-address** *rp-address* [*access-list*] to configure a static RP address for a PIM router.

To use static RP addresses, the static RP address of all routers in the PIM-SM domain must be the same, so that the PIM SM multicast routing remains consistent.

Configuring Candidate C-RP Addresses

By default, no C-RP address is configured.

Run **ip pim rp-candidate** *interface-type interface-number* [**priority** *priority-value*] [**interval** *interval-seconds*] [**group-list** *access-list*] to configure or cancel a PIM router as a candidate C-RP.

After a candidate RP is configured, it can send periodic C-RP-Adv packets to the BSR, and the information carried by these C-RP-Adv packets will be advertized to all PIM-SMs in the domain, ensuring the uniqueness of RP mapping.

Ignoring the RP Priority in RP-Set

By default, C-RP of the highest priority is configured.

Run **ip pim ignore-rp-set-priority** to select or deselect the RP priority when selecting the corresponding RP of a multicast group.

If you want to select an RP from multiples RPs that serve the same multicast group address, you can run this command to ignore the RP priority. If this command is not configured, RP priority will be considered when two RPs are compared.

6.3.5 Register Information of the Multicast Source

When the multicast source is detected on the network, the source DR sends a register packet to the RP, which obtains the source information and multicast packet.

Working Principle

When a source DR receives a multicast packet from the host directly connected to it, the source DR encapsulates the multicast packet into the register packet, and sends the unicast packet to RP to form an (S, G) entry.

If the RP has an outgoing interface for the forwarding entry, it encapsulates the data packet and forwards the packet to the outgoing interface.

If the RP does not have the forwarding entry of the present group, it generates the (S, G) entry and enables the timer. If the timer times out, the RP sends a Register-Stop packet to the DR to delete the entry. The source DR sends an inspection packet before timeout after it receives the Register-Stop packet.

If no Register-Stop packet is received by the DR, the DR on the timeout data source will encapsulate the multicast data in the register packet and send the unicast packet to the RP.

If a Register-Stop packet is received by the DR, time-delay will be performed once again, and an inspection packet will be sent before time delay.

Related Configuration

▾ Detecting the Reachability of a Register Packet

By default, the reachability of an RP is not detected.

Run **ip pim register-rp-reachability** to configure or cancel the detection of the reachability of an RP.

You can enable this function if you want to detect whether an RP is reachable for a register packet sent from a DR. After this function is enabled, the DR will detect the reachability of a register packet before it is sent to an RP, namely, the DR will check whether a route to the RP exists in the unicast routing entry and static multicast routing entry. If the route does not exist, the register packet will not be sent.

▾ Configuring an RP to Filter the Addresses of Register Packets

By default, all register packets are received an RP.

Run **ip pim accept-register { list access-list [route-map map-name] | route-map map-name [list access-list] }** to configure an RP to filter or cancel the filtering of the source addresses of received register packets.

You can run this command if you want to filter the source addresses of received register packets. If this function is not enabled, all register packets will be received by the RP. If this function is disabled, only the register packets whose source addresses and multicast group addresses included in access control lists (ACLs) are processed; otherwise, the packets will be filtered.

▾ Limiting the Speed for Sending a Register Packet

By default, the speed for sending a register packet is not limited.

Run **ip pim register-rate-limit rate** to limit or cancel the limitation of the speed for sending a register packet.

If the **no** form of this command is configured, the speed is not limited. This command takes effect for only the register packet of each (S, G) packet, but not all the register packets in the entire system.

↘ Calculating the Checksum of the Entire Register Packet Length

By default, the checksum of a register packet is calculated as stipulated by the protocol.

Run **ip pim register-checksum-wholepkt [group-list *access-list*]** to configure the checksum of the register packet length.

You can enable this function if you want to include the length of encapsulated multicast packets into the checksum of the register packet length. If this function is disabled, the checksum of a register packet is calculated as stipulated by the protocol.

↘ Configuring an RP to Forward Multicast Data Packets to Downstream Interfaces After Decapsulating Register Packets

By default, register packets are not decapsulated and multicast packet are not forwarded to interfaces.

Run **ip pim register-decapsulate-forward** to forward or cancel the forwarding of data packets to downstream interfaces.

You can run this command if you want to decapsulate a register packet and forward the multicast packet. If this function is disabled, the multicast packet will not be forwarded.

↘ Configuring the Source IP Address of a Register Packet

By default, the source IP address of a register packet is the same as the interface address of the DR connected to the multicast source.

Run **ip pim register-source { *local_address* | *Interface-type interface-number* }** to configure the source IP address.

You can run this command if you want to configure the source IP address of the register packet sent by a DR. If this function is disabled or the **no** form of this command is used, the source address of the register packet will be the same as the interface address of the DR connected to the multicast source. If you want to configure *local_address*, the configured address must be reachable for a unicast route. *Interface-type interface-number* can be a typical a loopback interface or an interface of other types. The interface address must have been advertised by a unicast route.

↘ Configuring the Suppression Time of a Register Packet

By default, the suppression time of a register packet is 60s.

Run **ip pim register-suppression *seconds*** to configure the suppression time.

If you run this command on a DR, you can change the suppression time of the register packets sent from the DR. If you run this command but does not run **ip pim rp-register-kat** on an RP, the keepalive period of the RP will be changed.

↘ Configuring the Inspection Time of a Null Register Packet

By default, the inspection time is 5s.

Run **ip pim probe-interval *interval-seconds*** to configure the inspection time.

In the time interval before the timeout of register packet suppression, the source DR can send a null register packet to an RP. This time interval is called the inspection time, which is 5s by default.

↘ Configuring the Time of a RP KAT

By default, the default value of a keepalive timer (KAT) is used. The default value is calculated as follows: Suppression time of a register packet x 3 + Inspection time of a null register packet.

Run **ip pim rp-register-kat** *seconds* to configure the KAT time.

You can run this command if you want to configure the keepalive time of (S, G) of a register packet sent from an RP.

6.3.6 Creating an RPT

When a group member is detected on the network, the DR connecting to the group members send packets toward the RP to form an RPT. If the multicast source already exists on the network, the packets arrived at the RP can be sent to the group members along the RPT.

Working Principle

To create an RPT, perform the following steps:

A receiver DR receives an IGMP (*, G) include report packet from the receiving end.

If the DR is not the RP of this group (G), the DR will send a (*, G) Join packet toward the RP. The router receiving this (*, G) Join packet will send the packet hop by hop until it is received by the RP, which means that the RP has joined the RPT.

When the data source host sends the multicast data to a group, the source data is encapsulated in the register packet, and sent from the source DR to the RP in unicast mode. Then the RP decapsulates the register packet, takes the data packets out, and forwards these packets to each group member along the RPT.

The RP sends the (S, G) Join packets along the data source to join the SPT of this source.

After the SPT between the RPs to the source DR is created, the data packets from the data source will be sent decapsulated to the RPs along the SPT.

When the first multicast data packet arrives at an RP along the SPT, the RP sends a Register-Stop packet to the source DR to stop sending a register packet. After the source DR receives the Register-Stop packet, it stops encapsulating a register packet and sends the packet along the SPT to the RP, which will forwards the packet to each group member.

Related Configuration

↘ **Configuring the Interval for Sending a Join/Prune Packet**

By default, the interval for sending a Join/Prune packet is 60s.

Run **ip pim jp-timer** *seconds* to configure the interval for sending a Join/Prune packet.

You can run this command to configure the interval for sending a Join/Prune packet. If not configured, the value will be a default 60s.

6.3.7 Creating an SPT

When data packets arrive at the DR connecting to group members, the DR sends these packets toward the multicast source to form an SPT, and multicast packets are sent to group members along the SPT. In this way, the burden on RP in the RPT is reduced, and the source DR will arrive at the receiver DR with less hops.

Working Principle

To create an SPT, perform the following steps:

The receiver DR sends (*, G) Join packets toward the source DR along the SPT, and (*, G) Join packets are then sent hop by hop until they are received by the source DR, forming an SPT.

Related Configuration

By default, SPT switchover is not enabled.

Run `ip pim spt-threshold [group-list access-list]` to configure whether to switch to an SPT.

If this function is enabled, upon the reception of the first (S, G) packet, a PIM Join packet is triggered, and an SPT is created. If **group-list** is specified, all the specified groups will be switched to the SPT. If the **no** form of this command is used and **group-list** is not specified, an RPT will not be switched to an SPT, and the DR will remain in the RPT and send a Prune packet toward the source DR; if the **no** form of this command is used and **group-list** is specified, and that the ACLs have been configured, it means that the association between **group-list** and the ACLs is canceled, and all the groups are allowed to switch from an RPT to an SPT.

6.3.8 ASM and SSM

A PIM router can provide multicast services of both ASM model and SSM model at the same time. SSM model applies to the groups whose addresses are within the range of the SSM addresses. For other groups, use ASM model. In an ASM model, only the multicast group (G) is specified for a multicast receiver, and the multicast source (S) is not specified. In an SSM model, both the multicast source (S) and multicast group (G) can be specified for a multicast receiver.

Working Principle

 To realize SSM in an IPv4 router, IGMPv3 needs to be applied for managing membership between the host and devices, and PIM-SM needs to be applied to connect to devices.

In an SSM model, as a multicast receiver has learnt the (S, G) of the multicast source through a certain channel (for example, by visiting the server or receiving an advertisement), when a multicast receiver needs to request a multicast service, the multicast receiver can send the IGMP (S, G) Join packet toward the router of last hop. For example, as shown in figure 6-4, the multicast receiver 1 sends the IGMP (S, G) Join packet to request the multicast service (S, G). After the router of last hop receives the IGMP (S, G) Join packet, it sends the PIM (S, G) Join packet to the multicast source hop by hop. As shown in figure 6-4, when R 1 receives the IGMP (S, G) Join packet sent from multicast Receiver 1, R 1 sends the PIM (S, G) Join packet to R 3, which then sends the packet to R 4, thereby forming an SPT connecting the multicast receiver and multicast source.

Figure 6-4 SSM Model

To create an SSM model, the following requirements need to be met:

- A multicast receiver needs to learn the (S, G) of the multicast source in advance, and an IGMP (S, G) Join packet needs to be sent if the receiver needs to request a multicast service.
- IGMPv3 must be run on the interface of the last hop router connecting to the multicast receiver. IGMPv1 and IGMPv2 does not support SSM.
- PIM-SM and SSM must be run on the devices connecting the multicast receiver and multicast source.

The default range of SSM groups is 232/8. You can run a command to change the value.

An SSM has the following features:

- A multicast receiver can learn the information of the multicast source through a certain channel (for example, by visiting the server or receiving an advertisement) in advance.
- An SSM model is a specific subnet of PIM-SM. It handles only the PIM (S, G) Join and PIM (S, G) Prune packets and discards the RPT-related packets, for example, PIM (*, G) Join/Prune packets, that are within the scope the SSM. If the SSM detects a register packet within the scope, it will respond immediately with a Register-Stop packet.
- If an RP is not required, the election and distribution of RP information are not performed. The MDTs in an SSM are all SPTs.

Related Configuration

ASM is enabled by default.

Run `ip pim ssm { default | range access-list }` to configure whether to switch to SSM.

In SSM, multicast packets can be received by the multicast source directly but not along the RP tree.

6.4 Configuration

Configuration	Description and Command
Configuring Basic PIM-SM	(Mandatory) It is used to configure the multicast service.

Configuration	Description and Command	
Functions	ip multicast-routing	Enables IPv4 multicast routing.
	ip pim sparse-mode	Enables PIM-SM.
	ip pim rp-address	Configures a static RP.
	ip pim rp-candidate	Configures a C-RP.
	ip pim bsr-candidate	Configures a C-BSR.
	ip pim ssm	Enables SSM.
Configuring BSR Parameters	 (Optional) It is used to configure a BSR.	
	ip pim bsr-border	Configures BSR borders.
	ip pim accept-bsr list { <1-99> <1300-1999> <i>WORD</i> }	Configures BSM packets limit on a PIM router.
	ip pim [accept-crp list <i>access-list</i>	Configures a C-BSR to inspect the address range of a C-PR.
Configuring RP and DR Parameters	 (Optional) It is used to configure the parameters of an RP or a DR.	
	ip pim gnore-rp-set-priority	Ignores the C-RP priority.
	ip pim register-rp-reachability	Enables the source DR to detect the RP reachability.
	ip pim accept-register list <i>access-list</i>	Configures the range of source register (S, G) addresses.
	ip pim register-rate-limit <i>rate</i>	Limits the speed for sending register packets.
	ip pim register-checksum-wholepkt [group-list <i>access-list</i>]	Calculates the checksum of the entire register packet.
	ip pim register-decapsulate-forward	Enables an RP to decapsulate a register packet and forwards the multicast packet to interfaces.
	ip pim register-source { <i>local_address</i> <i>Interface-type interface-number</i> }	Configures the source IP address of a register packet.
	ip pim register-suppression <i>seconds</i>	Configures the suppression time of a register packet.
	ip pim probe-interval <i>seconds</i>	Configures the inspection time of a null register packet.
ip pim rp-register-kat <i>seconds</i>	Configures the interval of KATs on an RP.	
Configuring the Interval for	 (Optional) It is used to specify the interval for sending a Join/Prune packet.	

Configuration	Description and Command	
Sending a Join/Prune Packet	<code>ip pim jp-timer seconds</code>	Configures the interval for sending a Join/Prune packet.
Configuring the Router of Last Hop to Switch from an RPT to SPT	 (Optional) It is used to switch from SPT to RPT.	
	<code>ip pim spt-threshold [group-list access-list]</code>	Enables SPT switchover.
Configuring the PIM-SM Sub VLAN Function	<code>ip pim dense-mode subvlan [all vid]</code>	Specifies, on an interface of a super VLAN, the sub VLAN to which packets are sent.

6.4.1 Configuring Basic PIM-SM Functions

Configuration Effect

- Create a PIM-SM network and provide data sources and user terminals on the network with the IPv4 multicast service.
- Any of ASM or SSM or both models can be configured.

Notes

- PIM-SM needs to use existing unicast routes on the network. Therefore, IPv4 unicast routes must be configured on the network.
- If the PIM network needs to support SSM multicast services, IGMPv3 or SSM mapping must be configured.

Configuration Steps

↳ Enabling IPv4 Multicast Routing

- Mandatory.
- If not specified, IPv4 multicast routing must be enabled on each router.

↳ Enabling PIM-SM

- Mandatory.
- If not specified, PIM-SM must be enabled on the following interfaces: interconnecting router interfaces, interfaces of static RPs, C-RPs, and C-BSRs, and the interfaces connecting to the multicast source and user hosts.

↳ Configuring an RP

- An RP must be configured if ASM multicast services need to be provided on a PIM network.
- An RP can be configured in three models: configuring only a static RP, configuring only a dynamic RP, and configuring both a static RP and dynamic RP. If both a static RP and dynamic RP are configured, the dynamic RP takes precedence over the static RP.
- Configuring a static RP: If not specified, a static RP should be configured on each router.
- Configuring a dynamic RP: If not specified, a C-RP and C-BSR should be configured on one or multiple routers.

↳ Enabling SSM

- SSM must be enabled if SSM multicast services need to be provided on a PIM network.

- If not specified, SSM must be enabled on every router.

↘ Configuring the PIM-SM Sub VLAN Function

- In most scenarios on the PIM network, the PIM SM protocol does not need to be enabled on interfaces of a super VLAN. In general, a super VLAN includes many sub VLANs. If the PIM SM protocol is enabled on the interfaces of the super VLAN, multicast packets will be replicated and sent to all sub VLANs. As a result, traffic generated easily exceeds the device processing capability, causing protocol flapping. In some scenarios that require the PIM SM protocol to be enabled on the interfaces of the super VLAN, the PIM-SM sub VLAN function may be configured, to send packets to a specified sub VLAN or all sub VLANs.
- This function is available only on the interfaces of the super VLAN.

Verification

Send multicast packets from the multicast source to the groups within the address rang of ASM and SSM, and join user hosts to these groups.

- Check whether the user hosts can successfully receive packets from each group.
- Check whether PIM-SM routing entries are created on routers correctly.

Related Commands

↘ Enabling IPv4 Multicast Routing

Command	ip multicast-routing
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Enabling PIM-SM

Command	ip pim sparse-mode
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	PIM interfaces must be at Layer-3, including: routing interfaces, aggregate ports(APs), switch virtual interfaces (SVIs), and loopback interfaces. For all PIM interfaces, IPv4 unicast routes should be reachable.

↘ Enabling the PIM-SM Sub VLAN Function

Command	ip pim dense-mode subvlan [all vid]
Parameter	all: sends packets to all sub VLANs.

Description	vid : sends packets to a specified sub VLAN.
Command Mode	Interface configuration mode
Usage Guide	The PIM interface must be an L3 interface, including routing interface, L3AP, SVI, loopback interface.

↘ Configuring a Static RP

Command	ip pim rp-address <i>rp-address</i> [<i>access_list</i>]
Parameter Description	<i>rp-address</i> : Indicates the address of an RP. <i>access_list</i> : Specifies the range of multicast group addresses served by a static RP using an ACL. By default, an RP services all groups.
Command Mode	Global configuration mode
Usage Guide	This command is used to locate a static RP. A static RP should be one with good routing performance. It is recommended that the address of the loopback interface be used as the static RP address. The static RP of all routers must be the same (including the RP address and the range of multicast group addresses it serves). It is recommended that the address of the loopback interface be used as the static RP address. The load can be shared if you configure multiple static RPs to serve different multicast group addresses. It is recommended that the address of the loopback interface be used as the static RP address.

↘ Configuring a C-RP

Command	ip pim rp-candidate <i>interface-type interface-number</i> [priority <i>priority-value</i>] [interval <i>seconds</i>] [group-list <i>access_list</i>]
Parameter Description	<i>interface-type interface-number</i> : Uses the address of this interface as the address of the C-RP. priority <i>priority-value</i> : Competes for the RP priority. A greater value indicates a higher priority. The value ranges from 0 to 255 (192 by default). interval <i>seconds</i> : Indicates the interval for sending a C-RP packet to a BSR. The value ranges from 1 to 16,383 (60 by default). group-list <i>access_list</i> : Specifies the range of multicast group addresses served by a C-RP using an ACL. By default, a C-RP services all multicast groups.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure a router as a C-RP. A C-RP should be one with good routing performance. A C-RP and C-BSR can be on the same router or different routers. It is recommended that the address of the loopback interface be used as the C-RP address. If multiple C-RPs serve the same group, redundancy can be realized. If multiple C-RPs serve the different groups, load can be shared.

↘ Configuring a C-BSR

Command	ip pim bsr-candidate <i>interface-type interface-number</i> [<i>hash-mask-length</i> [<i>priority-value</i>]]
Parameter Description	<i>interface-type interface-number</i> : Uses the address of this interface as the address of the C-BSR. <i>hash-mask-length</i> : Indicates the length of hash mask used to competing for the RP. The value ranges from 0 to 32 (10 by default). <i>priority-value</i> : Indicates the priority for competing for the BSR. A greater value indicates a higher priority. The value ranges from 0 to 255 (64 by default).
Command Mode	Global configuration mode
Usage Guide	This command is used to configure a router as a C-BSR. A C-BSR should be one with good routing performance. A C-RP and C-BSR can be on the same router or different routers. It is recommended that the address of the loopback interface be used as the C-BSR address. Configuring multiple C-BSRs can realize redundancy.

↘ Enabling SSM

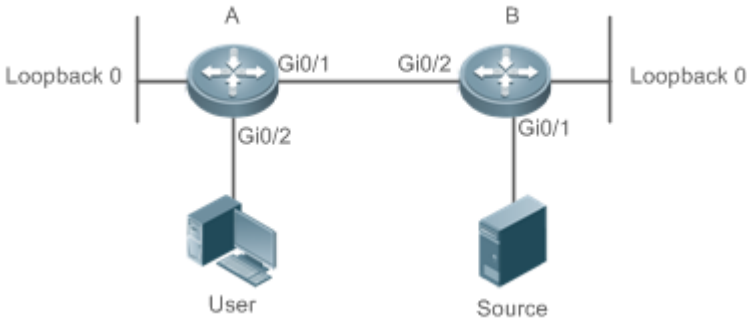

Command	ip pim ssm { default range <i>access_list</i> }
Parameter Description	default : Indicates the default range of SSM group addresses, which is 232.0.0.0/8. range <i>access_list</i> : Specifies the range of SSM group addresses using an ACL.
Command Mode	Global configuration mode
Usage Guide	The SSM group addresses configured on all routers must be the same.

↘ Displaying the PIM-SM Routing Entry

Command	show ip pim sparse-mode mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]]
Parameter Description	<i>group-or-source-address</i> : Indicates a multicast group address or source address (the two addresses cannot be multicast group addresses or source addresses at the same time).
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	Check whether sufficient routing entries are provided. Check the upstream and downstream interface lists and ensure that a correct SPT tree is created.

Configuration Example

↘ Enabling IPv4 Multicast Routing to Support ASM and SSM

<p>Scenario</p> <p>Figure 6-5</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure a IPv4 unicast routing protocol (such as OSPF) on a router, and the router is reachable for the unicast route of a loopback interface. (Omitted) ● Enable IPv4 multicast routing on all the routers. ● Enable PIM-SM on all the interconnected interfaces of the routers, Source, and Receiver. ● Configure C-RP and C-BSR on the loopback interfaces of Router A and Router B, and enable PIM-SM on the loopback interfaces. ● Enable SSM on all routers. ● Enable IGMPv3 on the router interfaces connecting to user terminals. (Omitted)
<p>A</p>	<pre>A# configure terminal A(config)# ip multicast-routing A(config)# ip pim ssm default A(config)# interface GigabitEthernet 0/1 A(config-if)# ip pim sparse-mode A(config-if)# exit A(config)# interface GigabitEthernet 0/2 A(config-if)# ip pim sparse-mode A(config-if)# exit A(config)# interface loopback 0 A(config-if)# ip pim sparse-mode A(config-if)# exit A(config)# ip pim rp-candidate loopback 0</pre>
<p>B</p>	<pre>B# configure terminal B(config)# ip multicast-routing B(config)# ip pim ssm default B(config)# interface GigabitEthernet 0/1 B(config-if)# ip pim sparse-mode B(config-if)# exit</pre>

	<pre> B(config)# interface GigabitEthernet 0/2 B(config-if)# ip pim sparse-mode B(config-if)# exit B(config)# interface loopback 0 B(config-if)# ip pim sparse-mode B(config-if)# exit B(config)# ip pim bsr-candidate loopback 0 </pre>
<p>Verification</p>	<p>Send packets from S (192.168.1.10) to G 1 (229.1.1.1) and G2 (232.1.1.1). Add the user to G 1 and G 2, and specify the source when the user joins G 2.</p> <ul style="list-style-type: none"> ● Check that multicast packets from S (192.168.1.10) to G 1 and G 2 are received by the user. ● Check the PIM-SM routing entries on Router A and Router B. Common Errors

- IPv4 unicast routing is incorrectly configured.
- IPv4 multicast routing is not enabled on a certain router.
- SSM is not enabled on a router or the SSM group address is different from that of the others'.
- PIM-SM is not enabled on an interface (for example, the interface is configured as a C-RP or C-BSR interface, or is used to connecting to the user host or used as an interface of the multicast source).
- IGMPv3 is not enabled on an interface connecting to the used host.
- RP is not configured on the network.
- A static RP is not configured on a router, or the configured static RP is different from that on other routers.
- C-RPs are configured on the network, but C-BSRs are not.
- Static RPs, C-RPs or C-BSRs are unreachable for unicast routes.

6.4.2 Configuring PIM-SM Neighbors

Configuration Effect

- Coordinate protocol parameters and adjust parameters in the Hello packet.
- A RIM router is used to discover neighbors, coordinate protocol parameters, and maintain neighbor relationships.
- Maintain neighbor relationships and filter the neighbors.

Notes

- Basic PIM-SM functions must be configured.

Configuration Steps

- Configure parameters on PIM router interfaces If not specified.

Verification

Configure the parameters of a Hello packet sent from an interface and run **debug ip pim sparse-mode packet** to display the parameters.

Enable neighbor filtering and run **show ip pim sparse-mode neighbor** to display neighbor information.

Related Commands

📄 **Configuring the Interval for Sending Hello Packets**

Command	ip pim query-interval <i>interval-seconds</i>
----------------	--

Parameter Description	Indicates the interval for sending Hello packets, Indicates the suppression time of a register packet in the unit of seconds. The value ranges from 1 to 65,535 (30 by default).
Command Mode	Interface configuration mode
Usage Guide	Every time when the interval for sending Hello packets is updated, the holdtime value is automatically updated as 3.5 times of the interval. If the result of the interval for sending Hello packets multiplied by 3.5 is greater than 65, 535, the holdtime value is forcibly updated as 18,725.

↘ Configuring the Prune Propagation Delay

Command	ip pim propagation-delay <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : The unit is ms. The value ranges from 1 to 32,767 (500 by default).
Command Mode	Interface configuration mode
Usage Guide	Once the prune propagation delay or prune override interval is changed, the Join/Prune packet override interval will be changed. As specified by the protocol, the Join/Prune packet override interval must be smaller than the holdtime of a Join/Prune packet; otherwise, short break-up of traffic may be caused. The administrator should maintain such configuration.

↘ Configuring the Prune Override Interval

Command	ip pim override-interval <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : The unit is ms. The value ranges from 1 to 65,535 (2,500 by default).
Command Mode	Interface configuration mode
Usage Guide	Once the prune propagation delay or prune override interval is changed, the Join/Prune packet override interval will be changed. As specified by the protocol, the Join/Prune packet override interval must be smaller than the holdtime of a Join/Prune packet; otherwise, short break-up of traffic may be caused. The administrator should maintain such configuration.

↘ Enabling Suppression Capability of an Interface for Sending Join Packets

Command	ip pim neighbor-tracking
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Once Join packets suppression of an interface is enabled, when the present router is to send a Join packet to the upstream neighbor, which has sent a Join packet to its own upstream neighbor, the present

	router will not send the Join packet; if Join packets suppression is disabled, the Join packet will be sent. When Join packets suppression from downstream receivers are disabled, upstream neighbors will learn how many downstream neighbors are there by counting the Join packets it received, which is called neighbor tracking.
--	---

↘ Configuring the Delay for Sending Hello Packets

Command	ip pim triggered-hello-delay <i>interval-seconds</i>
Parameter Description	<i>Seconds</i> : The unit is second. The value ranges from 1 to 5 (5 by default).
Command Mode	Interface configuration mode
Usage Guide	When a PIM interface is enabled or detects a new neighbor, a triggered-hello-delay packet is used to generate a random time. Within the time, the interface sends Hello packets.

↘ Configuring the DR Priority of a Hello Packet

Command	ip pim dr-priority <i>priority-value</i>
Parameter Description	<i>priority-value</i> : Indicates the priority. A greater value indicates a higher priority. The value ranges from 0 to 4,294,967,294 (1 by default).
Command Mode	Interface configuration mode
Usage Guide	A DR may be selected based on the following principles: If all the Hello packets sent from the routers on a local area network (LAN) are configured with priorities, when selecting a DR, the priorities will be compared, and the router with the highest priority will be selected as the DR. If the priority of all routers is the same, their IP addresses will be compared, and the router with the maximum IP address will be selected as the DR. If the priority of the Hello packets sent from a certain router is not configured, the IP addresses of the routers will be compared, and the router with the maximum IP address will be selected as the DR.

↘ Configuring Neighbor Filtering

Command	ip pim neighbor-filter <i>access_list</i>
Parameter Description	<i>access_list</i> : Configures the range of neighbor addresses using a standard IP ACL. The value can be set from 1 to 99 or a string.
Command Mode	Interface configuration mode
Usage Guide	Enabling neighbor filtering can enhance the security of the PIM network and limit the range of legible neighbor addresses. Once a neighbor is filtered out, PIM-SM will not establish peering with it or stop the peering with it.

↘ Displaying the Neighbor Information of an Interface

Command	show ip pim sparse-mode neighbor [detail]
Parameter	detail : Displays detailed information.

Description	
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	N/A

Configuration Example

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic PIM-SM functions. (Omitted) ● Configure the interval for sending Hello packets as 50s. ● Configure the prune propagation delay as 400 ms. ● Configure the prune override interval as 3,000 ms. ● Enable suppression capability of an interface for sending Join packets. ● Configure the delay for sending Hello packets as 3s. ● Configure the DR priority of a hello packet as 5.
	<pre>Ruijie# configure terminal Ruijie (config)#int gi 0/1 Ruijie (config-if-GigabitEthernet 0/1)#ip pim query-interval 50 Ruijie (config-if-GigabitEthernet 0/1)#ip pim propagation-delay 400 Ruijie (config-if-GigabitEthernet 0/1)#ip pim override-interval 3000 Ruijie (config-if-GigabitEthernet 0/1)#ip pim triggered-hello-delay 3 Ruijie (config-if-GigabitEthernet 0/1)#ip pim neighbor-tracking</pre>
Verification	Run debug ip pim sparse-mode packet to display the parameters of a Hello packet.
	<pre>Ruijie# debug ip pim sparse-mode packet 00:01:49:43: %7: VRF(0): Hello send to GigabitEthernet 0/1 00:01:49:43: %7: Send Hello packet 00:01:49:43: %7: Holdtime: 175 00:01:49:43: %7: T-bit: on 00:01:49:43: %7: Propagation delay: 400 00:01:49:43: %7: Override interval: 3000 00:01:49:43: %7: DR priority: 5 00:01:49:43: %7: Gen ID: 355154648 00:01:49:43: %7: RPF Vector capable</pre>
Configuration Steps	Configure neighbor filtering and set the allowed address range to 192.168.1.0 to 192.168.1.255.
	<pre>Ruijie# configure terminal</pre>

	<pre>Ruijie (config)#int gi 0/1 Ruijie (config-if-GigabitEthernet 0/1)# ip pim neighbor-filter 1 % access-list 1 not exist Ruijie(config)# access-list 1 permit 192.168.1.0 0.0.0.255 Ruijie(config)#</pre>												
Verification	Display neighbor information before neighbor filtering is configured.												
	<pre>Ruijie# show ip pim sparse-mode neighbor</pre> <table border="1"> <thead> <tr> <th>Neighbor Address</th> <th>Interface</th> <th>Uptime/Expires</th> <th>Ver</th> <th>DR</th> <th>Priority/Mode</th> </tr> </thead> <tbody> <tr> <td>192.168.36.89</td> <td>GigabitEthernet 0/1</td> <td>01:12:13/00:01:32</td> <td>v2</td> <td>1 / P</td> <td></td> </tr> </tbody> </table>	Neighbor Address	Interface	Uptime/Expires	Ver	DR	Priority/Mode	192.168.36.89	GigabitEthernet 0/1	01:12:13/00:01:32	v2	1 / P

	Display neighbor information after neighbor filtering is configured.												
	<pre>Ruijie# show ip pim sparse-mode neighbor</pre>												

Common Errors

- Basic PIM-SM functions are not configured or the configuration is not successful.

6.4.3 Configuring BSR Parameters

Configuration Effect

- Configure the address range of BSM packets.

Notes

- Basic PIM-SM functions must be configured.
- C-RPs and C-BSRs must be configured.
- Borders must be configured on the interfaces between domains.

Configuration Steps

▾ Configuring Borders

- Borders must be configured if there are multiple domains.
- Borders are configured on the interfaces separating two domains.

▾ Configuring BSM Packets Limit on a PIM Router

- Optional.
- If not specified, BSM packets limit can be configured on all PIM routers.

▾ Configuring a C-BSR to Inspect the Address Range of a C-PR

- Optional.
- If not specified, C-PR range inspection can be configured on all C-BSRs.

▾ Allowing a C-BSR to Receive a C-RP-ADV Packet Whose Prefix-Count Is 0

- Optional.
- If not specified, this function can be configured on all C-BSRs.

Verification

▾ Border Inspection

Enable basic PIM-SM functions. Configure two routers to be in different domains, configure Router B as the C-BSR, and Router A to receive BSM packets.

Configure the junction of Router A and Router B as the border so that Router A does not receive BSM packets.

▾ Configuring to Inspect BSM Packets Limit on a PIM Router

When basic PIM-SM functions are enabled, and Router B is set as the C-BSR, Router A can receive BSM packets. When the address range of C-BSRs are limited on Router A, BSM packets will not be received by Router A.

▾ Configuring a C-BSR to Inspect the Address Range of a C-PR

When basic PIM-SM functions are enabled, Router B is set as the C-BSR, and Router A as the C-RP, if the address range of the C-RPs is limited on C-BSR, Router B will not receive the packets sent from the C-RPs.

Related Commands

▾ Configuring BSR Borders

Command	ip pim bsr-border
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	To prevent BSM flooding, you can configure a BSR border on an interface, so that the BSM packets arriving at this interface will be discarded but not forwarded.

▾ Configuring BSM Packets Limit on a PIM Router

Command	ip pim accept-bsr list { <1-99> <1300-1999> WORD }
Parameter Description	list access-list: Configures the range of BSR addresses using a standard IP ACL. The value can be 1 to 99, 1,300 to 1,999, or a string.
Command Mode	Global configuration mode
Usage Guide	After this function is enabled, PIM-SM routers receive only the BSM packets sent from legible BSRs.

▾ Configuring a C-BSR to Inspect the Address Range of a C-PR

Command	ip pim accept-crp list access-list
Parameter Description	list access-list: Specifies the range of C-RP addresses and the multicast group addresses they serve using an extended IP ACL. The value can be 100 to 199, 2,000 to 2,699, or a string.

Command Mode	Global configuration mode
Usage Guide	This command should be configured on a C-BSR. When the C-BSR becomes a BSR, it can set the range of legible C-RP addresses and the range of multicast group addresses they serves.

↳ Displaying BSM Packets Information

Command	show ip pim sparse-mode bsr-router
Parameter Description	
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	N/A

↳ Displaying the Packets of All RPs and the Multicast Group Addresses They Serve

Command	show ip pim sparse-mode rp mapping
Parameter Description	
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	N/A

Configuration Example

↳ Configuring BSR Boarders

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic PIM-SM functions. (Omitted) ● On Router A, configure the address of the C-RP as 192.168.8.8. ● On Router B, configure the address of the C-RP as 192.168.5.5, and the address of the C-BSR as 192.168.6.6. ● Configure a BSR boarder on the junction of Router A and Router B.
	<pre>Ruijie# configure terminal Ruijie(config)# int GigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)# ip pim bsr-border Ruijie(config)# end</pre>
Verification	Before configuring the boarder, display the BSM information on Router A.
	<pre>Ruijie# show ip pim sparse-mode bsr-router PIMv2 Bootstrap information This system is the Bootstrap Router (BSR) BSR address: 192.168.6.6</pre>

<pre>Uptime: 01:14:25, BSR Priority: 64, Hash mask length: 10 Next bootstrap packet in 00:00:52 Role: Candidate BSR Priority: 64, Hash mask length: 10 State: Elected BSR Candidate RP: 192.168.8.8(Loopback 0) Advertisement interval 60 seconds Next Cand_RP_advertisement in 00:00:06</pre>
<p> Candidate RP: Indicates all the C-RPs configured on the existing router. It does not include the C-RPs configured on other routers.</p>
<p>After the boarder is configured, display the BSM information on Router A.</p>
<pre>Ruijie# show ip pim sparse-mode bsr-router</pre>

Configuring BSM Packets Limit on a PIM Router, Filtering BSM Source Addresses, and Configuring the Range of BSM Source Addresses to 192.168.1.1 to 192.168.1.255

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic PIM-SM functions. (Omitted) ● On Router A, configure the address of the C-RP as 192.168.8.8. ● On Router B, configure the address of the C-RP as 192.168.5.5, and the address of the C-BSR as 192.168.6.6. ● On Router A, configure the range of allowed BSM source addresses to 192.168.1.1 to 192.168.1.255.
Verification	<p>Before configuring BSM packets limit, display the BSM information on Router A.</p> <pre>Ruijie#show ip pim sparse-mode bsr-router PIMv2 Bootstrap information BSR address: 192.168.6.6 Uptime: 00:00:11, BSR Priority: 64, Hash mask length: 10 Expires: 00:01:59 Role: Non-candidate BSR Priority: 0, Hash mask length: 10 State: Accept Preferred Candidate RP: 192.168.8.8(Loopback 0)</pre>

	<pre>Advertisement interval 60 seconds Next Cand_RP_advertisement in 00:00:06</pre>

📌 Configuring a C-BSR to Inspect the Address Range of a C-PR, Filtering C-RP Addresses, and Configuring the Range of C-RP Addresses to 192.168.1.1 to 192.168.1.255

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic PIM-SM functions. (Omitted) ● On Router A, configure the address of the C-RP as 192.168.8.8. ● On Router B, configure the address of the C-RP as 192.168.5.5, and the address of the C-BSR as 192.168.6.6. ● On Router B, configure the range of allowed C-RP source addresses to 192.168.1.1 to 192.168.1.255.
	<pre>Ruijie# configure terminal Ruijie(config)# ip pim accept-crp list 100 % access-list 1 not exist Ruijie(config)# access-list 1 permit 192.168.1.0 0.0.0.255 Ruijie(config)#</pre>
Verification	Before configuring C-RP filtering, display the information of all RP groups on Router B.
	<pre>Ruijie#show ip pim sparse-mode rp mapping PIM Group-to-RP Mappings This system is the Bootstrap Router (v2) Group(s): 224.0.0.0/4 RP: 192.168.8.8(Not self) Info source: 192.168.8.8, via bootstrap, priority 192 Uptime: 00:15:16, expires: 00:02:18 RP: 192.168.5.5(Self) Info source: 192.168.6.6, via bootstrap, priority 192 Uptime: 18:52:30, expires: 00:02:00</pre>
	After C-RP filtering is configured, display the information of all RP groups on Router B.
	<pre>Ruijie#show ip pim sparse-mode rp mapping PIM Group-to-RP Mappings</pre>

<pre> This system is the Bootstrap Router (v2) Group(s): 224.0.0.0/4 RP: 192.168.5.5(Self) Info source: 192.168.6.6, via bootstrap, priority 192 Uptime: 21:38:20, expires: 00:02:10 </pre>
<p> After C-RP filtering is configured on a router, only the C-RP packets sent from other routers are filtered, and those sent from the present router are not filtered.</p>

Common Errors

- Basic PIM-SM functions are not configured or the configuration is not successful.
- C-BSRs are not configured.
- The BSR border is not configured on the interfaces of different domains.

6.4.4 Configuring RP and DR Parameters

Configuration Effect

- Ignore the C-RP priority and reselect an RP.
- Detect the reachability of an RP for the source DR.
- Configure the range of (S, G) addresses of source register packets, and allow the ASM to serve only the multicast packets within the range.
- Limit the speed of the source DR for sending register packets.
- Configure the checksum of the register packet length.
- Configure an RP to decapsulate register packets and forward the multicast packets to downstream interfaces.
- Configure the source IP address of a register packet.
- Configure the suppression time of a register packet.
- Configure the inspection time of a null register packet.
- Configure the (S, G) lifetime based on the register packet received by an RP.

Notes

- Basic PIM-SM functions must be configured.

Configuration Steps

↘ Ignoring the C-RP Priority and Reselecting an RP

- Optional.
- If not specified, the C-RP priority can be disabled on every router.

↘ Detecting the Reachability of an RP for the Source DR

- Optional.

- If not specified, this function can be enabled on the DR connected directly to the data source.

▾ **Configuring the Range of Source Register (S, G) Addresses**

- Optional.
- If not specified, source register address filtering can be enabled on all C-RPs or static RPs.

▾ **Limiting the Speed of the Source DR for Sending Register Packets**

- Optional.
- If not specified, this function can be enabled on the source DR.

▾ **Configuring the Checksum of the Register Packet Length**

- Optional.
- If not specified, this function can be enabled on all C-RPs or static RPs.

▾ **Configuring Whether to Forward the Multicast Packet After Decapsulating a Register Packet**

- Optional.
- If not specified, this function can be enabled on all C-RPs or static RPs.

▾ **Configuring the Source IP Address of a Register Packet**

- Optional.
- If not specified, the source IP address of a register packet can be configured on the DR connected directly to the data source.

▾ **Configuring the Suppression Time of a Register Packet**

- Optional.
- If not specified, the suppression time of a register packet can be configured on the DR connected directly to the data source.

▾ **Configuring the Inspection Time of a Null Register Packet**

- Optional.
- If not specified, the inspection time of a null register packet can be configured on the DR connected directly to the data source.

▾ **Configuring the (S, G) Lifetime Based on the Register Packet Received by an RP**

- Optional.
- If not specified, the (S, G) lifetime can be configured on all C-RPs or static RPs.

Verification

▾ **Ignoring the C-RP priority**

On Router A, configure the C-RP address as 192.168.8.8, and default priority as 192. On Router B, configure the C-RP address as 192.168.5.5, priority as 200, and C-BSR address as 192.168.6.6.

- Run **show ip pim sparse-mode rp** 233.3.3.3 to display the RPs of the present group.

↳ Enabling the Source DR to Detect RP Reachability

On Router A, configure the C-RP address as 192.168.8.8, and default priority as 192. On Router B, configure the C-RP address as 192.168.5.5, priority as 192, and C-BSR address as 192.168.6.6. Enable Router B to detect RP reachability.

- Run **show running-config** to check whether the preceding configurations take effect.

↳ Configuring the Range of Source Register (S, G) Addresses

On Router A, configure the C-RP address as 192.168.8.8, and default priority as 192. On Router B, configure the address of the C-BSR as 192.168.6.6. Configure the source address a 192.168.1.100 and the multicast group address as 233.3.3.3. On Router A, configure the range of allowed source multicast group addresses to 192.168.2.0 to 192.168.2.255.

- Run **show ip pim sparse-mode mroute** to display the (S, G) entry.

↳ Limiting the Speed of the Source DR for Sending Register Packets

Configure the speed of Router B for sending register packets, and run **show ip pim sparse-mode track** to display the number of packets that has been sent.

↳ Configuring the Checksum of the Register Packet Length

On Router A, configure to calculate the checksum of the entire register packet length but not just the packet header. Run **show running-config** to check the configuration.

↳ Forwarding an RP Register Packet After It Is Decapsulated

On Router A, configure to forward a register packet after it is decapsulated. Run **show running-config** to display the configuration.

↳ Configuring the Source IP Address of a Register Packet

Configure the source address of a register packet on Router B, and run **show running-config** to display the configuration.

↳ Configuring the Suppression Time of a Register Packet and the Inspection Time of a Null Register Packet

On Router B, configure the suppression time and inspection time of a register packet, and run **show ip pim sparse-mode track** to display the configuration.

↳ Configuring an RP to Receive Register Packets and the (S, G) Lifetime

On Router A, configuring an RP to receive register packets and the (S, G) lifetime, and run **show ip pim sparse-mode mroute** to display the maximum (S, G) lifetime.

Related Commands

↳ Ignoring the C-RP priority

Command	ip pim ignore-rp-set-priority
Parameter	N/A
Description	

Command Mode	Global configuration mode
Usage Guide	N/A

↳ Displaying the RP Corresponding to a Group

Command	show ip pim sparse-mode rp-hash <i>group-address</i>
Parameter Description	<i>group-address</i> : Indicates the parsed multicast group address.
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	N/A

↳ Enabling the Source DR to Detect RP Reachability

Command	ip pim register-rp-reachability
Parameter Description	
Command Mode	Global configuration mode
Usage Guide	After this function is enabled, the source DR will detect the RP reachability before sending a register packet. If the RP is unreachable, the packet will not be sent.

↳ Configuring the Range of Source Register (S, G) Addresses

Command	ip pim accept-register { list <i>access-list</i> [route-map <i>map-name</i>] route-map <i>map-name</i> [list <i>access-list</i>] }
Parameter Description	list <i>access-list</i> : Configures the range of (S, G) addresses using an extended IP ACL. The value can be 100 to 199, 2,000 to 2699, or a string. route-map <i>map-name</i> : Configures the range of (S, G) addresses using a route map.
Command Mode	Global configuration mode
Usage Guide	This command is run on a static RP or a C-RP to specify the source address and multicast group address of a register packet.

↳ Displaying a Multicast Routing Entry

Command	show ip pim sparse-mode mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]]
Parameter Description	<i>group-or-source-address</i> : Indicates a multicast group address or source address (the two addresses cannot be multicast group addresses or source addresses at the same time).
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	You can specify either a multicast group address or source address, or both a multicast group address

and source address; or you can specify neither a multicast group address nor source address. The two addresses cannot be multicast group addresses or source addresses at the same time.

↳ Limiting the Speed of the Source DR for Sending Register Packets

Command	ip pim register-rate-limit <i>rate</i>
Parameter Description	<i>Rate</i> : Indicates the maximum number of register packets that can be sent each second. The value ranges from 1 to 65,535.
Command Mode	Global configuration mode
Usage Guide	This command takes effect for only the register packet of each (S, G) packet, but not all the register packets in the entire system. Enabling this command can reduce the burden on the source DR and RPs. Only the packets within the speed limit can be sent.

↳ Displaying the Counters of PIM-SM Packets

Command	show ip pim sparse-mode track
Parameter Description	
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	The start time for counting PIM-SM packets is automatically enabled upon system startup. Run clear ip pim sparse-mode track to reset the start time and clear the PIM-SM packet counters.

↳ Calculating the Checksum of the Entire Register Packet Length

Command	ip pim register-checksum-wholepkt [group-list <i>access-list</i>]
Parameter Description	group-list <i>access-list</i> : Configures the multicast group addresses applicable to this configuration using an ACL. <i>access-list</i> : The value can be set to 1 to 99, and 1300 to 1999. It also supports the naming of the ACL.
Command Mode	Global configuration mode
Usage Guide	You can enable this function if you want to calculate the length of the entire PIM-SM packet, including that of the multicast packet encapsulated in the register packet, but not just the length of the PIM-SM packet header. If group-list <i>access-list</i> is specified, this configuration takes effect for all multicast group addresses.

↳ Enabling an RP to Decapsulate a Register Packet and Forward the Multicast Packet to Interfaces

Command	ip pim register-decapsulate-forward
Parameter Description	N/A
Command Mode	Global configuration mode

Usage Guide	<p>This command is configured on a static RP or a C-RP. It is used to decapsulate a register packet with multicast packet and forward the multicast packet to interfaces.</p> <p>If there are too many register packets to be decapsulated, the CPU will be greatly burdened. In this case, this function is recommended to be disabled.</p>
--------------------	--

↘ Configuring the Source IP Address of a Register Packet

Command	ip pim register-source { <i>local_address</i> <i>Interface-type interface-number</i> }
Parameter Description	<p><i>local_address</i>: Specifies the source IP address of a register packet.</p> <p><i>interface-type interface-number</i>: Specifies the IP address of this interface as the source IP address of the register packet.</p>
Command Mode	Global configuration mode
Usage Guide	<p>The specified address must be reachable. When an RP sends a Register-Stop packet, the PIM router corresponds to this address need to respond. Therefore, it is recommended that a loopback address (or other physical addresses) be used.</p> <p>This configuration does not require the enabling of PIM.</p>

↘ Configuring the Suppression Time of a Register Packet

Command	ip pim register-suppression <i>seconds</i>
Parameter Description	<i>Seconds</i> : Indicates the suppression time of a register packet in the unit of seconds. The value ranges from 1 to 65,535 (60 by default).
Command Mode	Global configuration mode
Usage Guide	If you configure this parameter on a DR, the suppression time of a register packet sent from the DR will be changed. If ip pim rp-register-kat is not configured and if you configure this parameter on an RP, the RP keepalive will be changed.

↘ Configuring the Inspection Time of a Null Register Packet

Command	ip pim probe-interval <i>seconds</i>
Parameter Description	<i>Seconds</i> : Indicates the inspection time of a null register packet in the unit of seconds. The value ranges from 1 to 65,535 (5 by default).
Command Mode	Global configuration mode
Usage Guide	<p>The inspection time of a null register packet indicates the period of time for sending a null register packet to an RP before the timeout of suppression time.</p> <p>The inspection time cannot exceed half of the suppression time; otherwise, the configuration will not take effect, and a warning message will be displayed. Meanwhile, the result of suppression time multiplied by 3 plus the inspection time cannot exceed 65,535, otherwise, a warning will be displayed.</p>

↘ Configuring the Interval of KATs on an RP

Command	ip pim rp-register-kat <i>seconds</i>
----------------	--

Parameter Description	<i>Seconds</i> : Indicates the interval of a KAT in the unit of second. The value ranges from 1 to 65,535 (210 by default).
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring the RPs of Corresponding Multicast Group Addresses When the C-RP Priority is Considered or Not Considered

Configuration Steps	<ul style="list-style-type: none"> Configure basic PIM-SM functions. (Omitted) On Router A, configure the address of the C-RP as 192.168.8.8. On Router B, configure the address of the C-RP as 192.168.5.5, priority as 200, and the address of the C-BSR as 192.168.6.6. Display the group corresponding to 233.3.3.3. Configure to ignore the C-RP priority on Router B.
	<pre>Ruijie# configure terminal Ruijie(config)# ip pim ignore-rp-set-priority</pre>
Verification	Display the information before you configure to ignore the C-RP priority.
	<pre>Ruijie# show ip pim sparse-mode rp-hash 233.3.3.3 RP: 192.168.8.8 Info source: 192.168.8.8, via bootstrap PIMv2 Hash Value 10(mask 255.192.0.0) RP 192.168.8.8, via bootstrap, priority 192, hash value 1084558102 RP 192.168.5.5, via bootstrap, priority 200, hash value 1094656709</pre>
	Display the information after you configure to ignore the C-RP priority.
	<pre>Ruijie# show ip pim sparse-mode rp-hash 233.3.3.3 RP: 192.168.5.5 Info source: 192.168.6.6, via bootstrap PIMv2 Hash Value 10(mask 255.192.0.0) RP 192.168.8.8, via bootstrap, priority 192, hash value 1084558102 RP 192.168.5.5, via bootstrap, priority 200, hash value 1094656709</pre>

Configuring to Inspect the Reachability of a Source RP

Configuration	<ul style="list-style-type: none"> Configure basic PIM-SM functions. (Omitted)
----------------------	---

n Steps	<ul style="list-style-type: none"> Configure to inspect the reachability of a source RP.
	<pre>Ruijie(config)# ip pim register-rp-reachability</pre>
Verification	Run show running-config to check whether the following information is displayed.
	<pre>Ruijie(config)#show running-config ip pim register-rp-reachability</pre>

📌 Configuring the Range of Source Register (S, G) Addresses

Configuration Steps	<ul style="list-style-type: none"> Configure basic PIM-SM functions. (Omitted) Configure source address filtering on Router A. The allowed address range is from 192.168.2.0 to 192.168.2.255.
	<pre>Ruijie#show ip pim sparse-mode mroute Ruijie(config)#ip pim accept-register list 101 % access-list 101 not exist Ruijie(config)#access-list 101 permit ip 192.168.2.0 0.0.0.255 any Ruijie#show ip pim sparse-mode mroute</pre>
Verification	Before enabling source address filtering, run show ip pim sparse-mode mroute to display the multicast entry, and check whether the (S, G) entry and (S, G, RPT) entry exist.
	<pre>Ruijie#show ip pim sparse-mode mroute IP Multicast Routing Table (*,*,RP) Entries: 0 (*,G) Entries: 1 (S,G) Entries: 1 (S,G,rpt) Entries: 1 FCR Entries: 0 REG Entries: 0 (192.168.1.100, 233.3.3.3) RPF nbr: 192.168.36.90 RPF idx: VLAN 1 SPT bit: 0 Upstream State: NOT JOINED kat expires in 187 seconds 00 01 02 03 04 05 06 07 08 09 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31</pre>

Limiting the Speed of the Source DR for Sending Register Packets

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic PIM-SM functions. (Omitted) ● Check the number of PIM-SM packets sent by Router B. ● Check the number of PIM-SM packets sent by Router B in 1s. ● Configure the speed of Router B for sending register packets. ● Check the number of PIM-SM packets sent by Router B in 1s.
	<pre>Ruijie (config)#ip pim register-rate-limit 1</pre>
Verification	<p>Display the number of PIM-SM packets sent by Router B before you configure the speed. The information should be displayed as follows:</p>
	<pre> Ruijie#show ip pim sparse-mode track PIM packet counters track Elapsed time since counters cleared: 04d01h01m received sent Valid PIM packets: 18754 29771 Hello: 11149 17842 Join-Prune: 0 3234 Register: 0 3211 Register-Stop: 3192 0 Assert: 0 0 BSM: 0 5484 C-RP-ADV: 4413 0 PIMDM-Graft: 0 PIMDM-Graft-Ack: 0 PIMDM-State-Refresh: 0 Unknown PIM Type: 0 </pre>

<pre> Errors: Malformed packets: 0 Bad checksums: 0 Send errors: 0 Packets received with unknown PIM version: 0 Ruijie# </pre>
<p>Display the number of PIM-SM packets sent by Router B in 1s before the speed is configured. The information should be displayed as follows:</p>
<pre> Ruijie #show ip pim sparse-mode track PIM packet counters track Elapsed time since counters cleared: 04d01h04ms received sent Valid PIM packets: 18765 29789 Hello: 11154 17852 Join-Prune: 0 3236 Register: 0 3214 Register-Stop: 3195 0 Assert: 0 0 BSM: 0 5487 C-RP-ADV: 4416 0 PIMDM-Graft: 0 PIMDM-Graft-Ack: 0 PIMDM-State-Refresh: 0 Unknown PIM Type: 0 Errors: Malformed packets: 0 Bad checksums: 0 Send errors: 0 Packets received with unknown PIM version: 0 Ruijie# </pre>
<p>Display the number of PIM-SM packets sent by Router B after the speed is configured. The information</p>

	should be displayed as follows:
	<pre>Ruijie#show ip pim sparse-mode track PIM packet counters track Elapsed time since counters cleared: 04d01h06m received sent Valid PIM packets: 18777 29808 Hello: 11159 17862 Join-Prune: 0 3239 Register: 0 3215 Register-Stop: 3196 0 Assert: 0 0 BSM: 0 5489 C-RP-ADV: 4419 0 PIMDM-Graft: 0 PIMDM-Graft-Ack: 0 PIMDM-State-Refresh: 0 Unknown PIM Type: 0 Errors: Malformed packets: 0 Bad checksums: 0 Send errors: 0 Packets received with unknown PIM version: 0 Ruijie#</pre>

📌 **Configuring the Checksum of the Register Packet Length**

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic PIM-SM functions. (Omitted) ● Calculate the checksum of the entire register packet length. ● Run show running-config to check whether the preceding configurations take effect.
	<pre>Ruijie(config)#ip pim register-checksum-wholepkt</pre>
Verification	Display the configurations on Router A, which should be as follows:
	<pre>Ruijie#show running-config</pre>

```

!
ip pim register-checksum-wholepkt
ip pim rp-candidate Loopback 0
!
. . . .
    
```

↳ **Enabling an RP to Decapsulate a Register Packet and Forward the Multicast Packet to Interfaces**

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic PIM-SM functions. (Omitted) ● Enable Router A to forward a register packet. ● Run show running-config to check whether the preceding configurations take effect.
	<pre>Ruijie(config)#ip pim register-decapsulate-forward</pre>
Verification	<p>Display the configurations on Router A, which should be as follows:</p>
	<pre> Ruijie#show running-config ! ! ip pim register-decapsulate-forward ip pim register-checksum-wholepkt ip pim rp-candidate Loopback 0 ! ! ! </pre>

↳ **Configuring the Source IP Address of a Register Packet**

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic PIM-SM functions. (Omitted) ● Configure the source address of Loop 2 as 192.168.2.2. ● Configure source address interface for the register packet of Router B as Loop 2. ● Run show running-config to check whether the preceding configurations take effect.
Verification	<p>Display the configurations on Router B, which should be as follows:</p>
	<pre> Ruijie#show running-config ! ! ! ip pim register-source Loopback 1 </pre>

```
ip pim bsr-candidate Loopback 0
!
!
!
!
```

📌 **Configuring the Suppression Time of a Register Packet and the Inspection Time of a Null Register Packet**

<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure basic PIM-SM functions. (Omitted) ● Configure the suppression time of a register packet on Router B to 20s. ● Configure the inspection time of a null register packet on Router B to 2s. ● Run show ip pim sparse-mode track to display number of register packets.
	<pre>Ruijie(config)#ip pim register-suppression 20 Ruijie(config)#ip pim probe-interval 2</pre>
<p>Verification</p>	<p>Display the number of register packets on Router B. The information should be displayed as follows:</p>
	<pre>Ruijie#show ip pim sparse-mode track PIM packet counters track Elapsed time since counters cleared: 04d23h15m received sent Valid PIM packets: 23788 43249 Hello: 13817 23178 Join-Prune: 0 4568 Register: 0 8684 Register-Stop: 4223 0 Assert: 0 0 BSM: 0 6819 C-RP-ADV: 5748 0 PIMDM-Graft: 0 PIMDM-Graft-Ack: 0 PIMDM-State-Refresh: 0 Unknown PIM Type: 0 Errors: Malformed packets: 0</pre>

```

Common Errors

- Basic PIM-SM functions are not configured or the configuration is not successful.
- The (S, G) of register packets is not configured on a C-RP or static RP, or the configuration is not successful.
- The ACL for limiting the (S, G) of register packets is not configured or the range of (S, G) in this ACL is not correctly configured.
- The range of (S, G) of register packets on each C-RP or static RP is not the same.

6.4.5 Configuring the Interval for Sending a Join/Prune Packet

Configuration Effect

- Change the interval for sending a Join/Prune packet to form an RPT or SPT.

Notes

- Basic PIM-SM functions must be configured.

Configuration Steps

- Configure the interval for sending a Join/Prune packet.

Verification

On Router B, configure the interval for sending a Join/Prune packet as 120s. Run **show ip pim sparse-mode mroute** to display the lifetime of the entry.

Related Commands

↳ Configuring the Interval for Sending a Join/Prune Packet

Command	ip pim jp-timer <i>seconds</i>
Parameter Description	<i>Seconds</i> : Indicates the interval for sending a Join/Prune packet. The unit is second. The value ranges from 1 to 65,535 (60 by default).
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

↳ Configuring the Interval for Sending a Join/Prune Packet

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic PIM-SM functions. (Omitted) ● Configure the interval for sending a Join/Prune packet.
	<pre>Ruijie(config)#ip pim jp-timer 120</pre>
Verification	Run show ip pim sparse-mode mroute to display the maximum timeout time of a Join/Prune packet.

6.4.6 Configuring the Router of Last Hop to Switch from an RPT to SPT

Configuration Effect

- Switch from an RPT to SPT

Notes

- Basic PIM-SM functions must be configured.

Configuration Steps

- Configure the router of last hop to switch from an RPT to SPT.

Verification

Configure basic PIM-SM functions first. Configure the source DR to send the data traffic (*, 233.3.3.3), and the receiving end to join group 233.3.3.3 forcibly to form an RPT. Configure the receiver DR to switch from the RPT to SPT forcibly. Run **show running-config** to display the result.

Related Commands

↳ Enabling SPT switchover

Command	ip pim spt-threshold [group-list access-list]
----------------	--

Parameter Description	group-list access-list. Specifies the range of multicast group addresses allowed for SPT switchover using an ACL. access-list: The supported value ranges from 1 to 99 or 1,300 to 1,999. Naming an ACL is also supported.
Command Mode	Global configuration mode
Usage Guide	If group-list access-list is not specified, all groups are allowed to perform SPT switchover.

Configuration Example

Configuring the Router of Last Hop to Switch from an RPT to SPT

Configuration Steps	<ul style="list-style-type: none"> Configure basic PIM-SM functions. (Omitted) Configure the source DR to send the data traffic of group 233.3.3.3. Configure the receiver DR to receive the data traffic of group 233.3.3.3. Configure the receiver DR of last hop to switch from an RPT to SPT.
	<pre>Ruijie(config)#ip pim spt-threshold</pre>
Verification	Run show running-config to display the configuration.
	<pre>! ! ip pim jp-timer 120 ip pim spt-threshold ip pim rp-candidate Loopback 0 ! ! !</pre>

6.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears multicast routing entries.	clear ip mroute { * <i>group-address</i> [<i>source-address</i>] }
Clears the counters of multicast routes.	clear ip mroute statistics { * <i>group-address</i> [<i>source-address</i>] }
Clears the information about dynamic RPs.	clear ip pim sparse-mode bsr rp-set *
Clears the counters of PIM-SM packets.	clear ip pim sparse-mode track

Displaying

Description	Command
Displays the details of BSR information.	show ip pim sparse-mode bsr-router
Displays the PIM-SM information of an interface.	show ip pim sparse-mode interface [<i>interface-type interface-number</i>] [detail]
Displays the local IGMP information about a PIM-SM interface.	show ip pim sparse-mode local-members [<i>interface-type interface-number</i>]
Displays the information about a PIM-SM multicast routing entry, and displays the RPF vector of a PIM-SM entry using proxy .	show ip pim sparse-mode mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]]
Displays the information about PIM-SM neighbors.	show ip pim sparse-mode neighbor [detail]
Displays the information about the next hop of PIM-SM obtained from the NSM.	show ip pim sparse-mode nexthop
Displays the information about the RP corresponding the multicast group address <i>group-address</i> .	show ip pim sparse-mode rp-hash <i>group-address</i>
Displays the information about all the RPs and the groups they serve.	show ip pim sparse-mode rp mapping
Displays the number of PIM-SM packets sent and received since the statistic start time.	show ip pim sparse-mode track

7 Configuring PIM-SMv6

7.1 Overview

Protocol Independent Multicast (PIM) is a multicast routing protocol.

PIM does not rely on a specific unicast routing protocol. It uses the unicast routing table established by any unicast routing protocol to complete the reverse path forwarding (RPF) check and establish multicast routes. PIM does not need to transmit and receive multicast route updates. Therefore, the overhead of PIM is much lower than that of other multicast routing protocols.

PIM defines two modes: dense mode and sparse mode. Protocol Independent Multicast Sparse Mode (PIM-SM) is applicable to various network environments.

 PIM-SM running on IPv6 is called PIM-SMv6.

Protocols and Standards

- RFC4601: Protocol Independent Multicast -Sparse Mode (PIM-SM)
- RFC5059: Bootstrap Router (BSR) Mechanism for Protocol Independent Multicast (PIM)
- RFC3962: Protocol Independent Multicast - Dense Mode protocol
- RFC4607: Source-Specific Multicast for IP

7.2 Applications

Application	Description
ASM Implementation by Using PIM-SMv6	A receiver receives packets from any multicast source.
SSM Implementation by Using PIM-SMv6	A receiver selects a multicast source.
Application Example of an Embedded RP	An embedded RP address is configured within the IPv6 multicast group address.
PIM-SMv6 Application in a Hot Backup Environment	The multicast PIM-SMv6 protocol runs in a hot backup environment.

7.2.1 ASM Implementation by Using PIM-SMv6

Scenario

The multicast service is provided only in one domain.

As shown in the following figure, receivers receive packets from any multicast source.

Figure 7-1

Remark	R1 is directly connected to the multicast source.
s	R2 is configured as a rendezvous point (RP). R3 is directly connected to Receiver A. R4 is directly connected to Receiver B.

Deployment

- Run the Open Shortest Path First for IPv6 (OSPFv6) protocol in the domain to implement unicast routing.
- Run the PIM-SMv6 protocol in the domain to implement multicast routing.
- Run the Internet Group Management Protocol version 6 (IGMPv6) protocol in a user host network segment to implement group member management.

7.2.2 SSM Implementation by Using PIM-SMv6

Scenario

The multicast service is provided only in one domain.

As shown in the following figure, receivers receive packets from a specific multicast source.

Figure 7-2

Remark	R1 is directly connected to the multicast source.
s	R2 is configured as an RP. R2 is directly connected to Receiver A. R2 is directly connected to Receiver B.

Deployment

- Run the OSPFv6 protocol in the domain to implement unicast routing.
- Run the PIM-SMv6 protocol in the domain to implement multicast routing.
- Enable the source-specific multicast (SSM) function of the PIM-SMv6 protocol to implement the SSM function.
- Run the Internet Group Management Protocol version 3 (IGMPv3) in a user host network segment to implement group member management.

7.2.3 Application Example of an Embedded RP

Scenario

The multicast service is provided only in one domain.

As shown in the following figure, an RP address is configured for R2 to make the router become an embedded RP.

Figure 7-3

Remark	R1 is directly connected to the multicast source.
s	R2 is configured as an RP.
	R2 is directly connected to Receiver A.
	R2 is directly connected to Receiver B.
	R2 is configured as an embedded RP.

Deployment

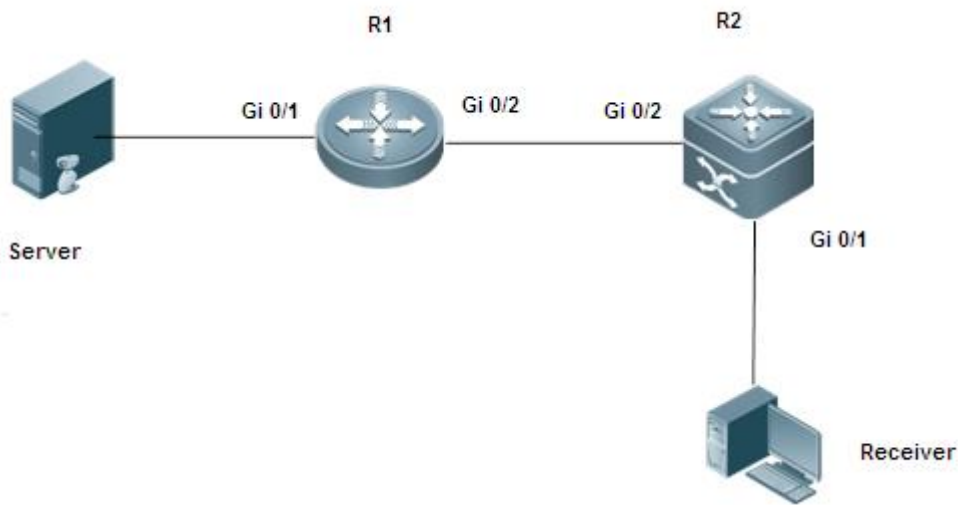

- Run the OSPFv6 protocol in the domain to implement unicast routing.
- Run the PIM-SMv6 protocol in the domain to implement multicast routing.
- Enable the SSM function of the PIM-SMv6 protocol to implement the SSM function.
- Run the IGMPv3 protocol in a user host network segment to implement group member management.
- Configure the RP address and embedded RP on R2.

7.2.4 PIM-SMv6 Application in a Hot Backup Environment

Scenario

In a hot backup environment, run PIM-SMv6. A device performs hot backup switching to ensure that traffic is not interrupted.

Figure 7-4

Remark s	R1 is connected to the video server, R2 is directly connected to the receiver, and R2 runs in hot backup mode. A Layer-3 multicast protocol runs on R1 and R2.
--------------------	---

Deployment

- Run OSPF on R1 and R2 to implement unicast routing.
- Run PIM-SMv6 on R1 and R2 to implement multicast routing.
- Make R2 run in two-node cluster hot backup mode.

Remark s	R2 may perform hot backup switching in the hot backup environment. In this case, the query interval of PIM Hello packets (the default value is 30 seconds) needs to be adjusted on R2 because the keepalive timer of the neighbor in PIM Hello packets of R1 may have expired (the default value is 3.5 times the query interval, that is, 105 seconds). The multicast function relies on the unicast function currently, and the multicast function starts convergence after the unicast function convergence is complete. For example, the default graceful restart (GR) convergence time of the unicast function is 120 seconds. It is recommended that the query interval of PIM Hello packets be set to 60 seconds. The keepalive time of the neighbor in PIM Hello packets is 210 seconds. In this scenario, the query interval of PIM Hello packets need to be set with a reference to the GR convergence time of the unicast function and the value of 3.5 times the query interval of PIM Hello packets must be larger than the GR convergence time of the unicast function. In addition, if the convergence time of the unicast function is long, the transmission interval of PIM Join/Prune packets also need to be adjusted, because the keepalive time of PIM Join/Prune packets is 3.5 times the transmission interval of PIM Join/Prune packets. The default keepalive time of PIM Join/Prune packets is 210 seconds. If R2 is configured as a dynamic RP, the interval for a candidate RP (C-RP) to transmit C-RP notifications also needs to be adjusted. The default transmission interval is 60 seconds and the keepalive time is 2.5 times the transmission interval of C-RP notifications. For example, if the convergence time of the unicast function is longer than 150 seconds, the transmission interval of C-RP notifications needs to be adjusted. In a hot backup environment, it is recommended that the query interval of PIM Hello packets be larger than the default value (30 seconds). Otherwise, the keepalive timer of the neighbor in PIM Hello packets of the peer end times out during hot backup switching.
--------------------	---

7.3 Features

Basic Concepts

↘ PIM Router and PIM Interface

Routers where the PIM protocol is enabled are called PIM routers. Interfaces where the PIM protocol is enabled are called PIM interfaces.

Multicast packets are forwarded by PIM routers. The PIM interfaces for receiving multicast packets are called upstream interfaces, and the PIM interfaces for transmitting multicast packets are called downstream interfaces.

Network segments where upstream interfaces are located are called upstream network segments. Network segments where downstream interfaces are located are called downstream network segments.

↘ PIM Network and PIM Domain

PIM routers are connected through PIM interfaces and form a PIM network.

On some PIM interfaces, borders are set to divide a large PIM network into multiple PIM domains. The borders may reject specific multicast packets or limit transmission of PIM messages.

↘ Multicast Distribution Tree, DR, RP

Multicast packets are transmitted from one point to multiple points. The forwarding path presents a tree structure. This forwarding path is called a multicast distribution tree (MDT). MDTs are classified into two types:

- Rendezvous point tree (RPT): Uses the rendezvous point (RP) as the root and designated routers (DRs) connected to group members as leaves.
- Shortest path tree (SPT): Use the DR connected to a multicast source as the root and the RPs or DRs connected to group members as leaves.

DRs and RPs are function roles of PIM routers.

- RPs collect information about multicast sources and group members in the network.
- The DR connected to a multicast source reports multicast source information to the RP and the DRs connected to group members report the group member information to the RP.

↘ (*,G), (S,G)

- (*,G): Indicates the packets transmitted from any source to Group G, routing entries corresponding to the packets, and forwarding path (RPT) corresponding to the packets.
- (S,G): Indicates the packets transmitted from Source S to Group G, routing entries corresponding to the packets, and forwarding path (SPT) corresponding to the packets.

↘ ASM, SSM

PIM-SM supports two multicast service models: any-source multicast (ASM) and source-specific multicast (SSM), which are applicable to different multicast address segments.

- ASM: In the ASM model, a user host cannot select a multicast source. The user host joins a multicast group and receives all packets sent from all sources to the multicast group.

- SSM: In the SSM model, a user host can select a multicast source. The user host specifies the source address when joining a multicast group, and then receives packets only from the specified source to the multicast group.
- i** SSM model requirement: Other network services must be used to enable a user host to know the position of a multicast source in advance so that the user host selects the multicast source.

Overview

Feature	Description
Establishment of PIM Neighbor Relationships	Neighbor relationships are established between PIM routers to form a PIM network.
DR Election	In the shared network segment connected to group members, DR election is conducted among PIM neighbors to elect the DR connected to group members. In the shared network segment connected to a multicast source, DR election is conducted among PIM neighbors to elect the DR connected to the multicast source.
RP Mechanism	In a PIM network, the RP is statically configured or dynamically elected so that each PIM router knows the position of the RP.
Registration Information About a Multicast Source	When a multicast source arises in a network, the DR connected to the multicast source transmits the Register packet to the RP so that the RP obtains information about the multicast source and multicast packets.
RPT Establishment	When a group member arises in a network, the DR connected to the group member transmits the Join packet in the RP direction to establish an RPT. If there is a multicast source in the network, the multicast packet transmitted to the RP can reach the group member along the RPT.
SPT Establishment	When a data packet reaches the DR connected to a group member, the DR connected to the group member transmits the Join packet in the multicast source direction to establish an SPT. Then, multicast packets are forwarded along the SPT.
ASM and SSM Models	PIM routers provide multicast services of the ASM model and SSM model. The SSM model is used for groups within the SSM address range, and the ASM model is used for other groups.

7.3.1 Establishment of PIM Neighbor Relationships

Neighbor relationships are established between PIM routers to form a PIM network. Neighbor relationships must be established between PIM routers before other PIM control messages are exchanged or multicast packets are forwarded.

Working Principle

A Hello message is sent by a PIM interface. For the multicast packet for encapsulating the Hello message, the destination address is ff02::d (indicating all PIM routers in the same network segment), the source address is the IP address of the PIM interface, and the time to live (TTL) value is 1.

Hello messages are used to discover neighbors, negotiate about protocol parameters, and maintain neighbor relationships.

📌 Discovering PIM Neighbors

PIM routers in the same network segment receive multicast packets with the destination address of ff02::d. In this way, the PIM routers obtain neighbor information and establish neighbor relationships.

When a PIM interface is enabled or detects a new neighbor, the Triggered-Hello-Delay message is used to generate a random time period. Within the time period, the interface sends Hello packets.

↘ Negotiating About Protocol Parameters

A Hello message contains multiple protocol parameters, which are described as follows:

- DR_Priority: Indicates the priority of each router interface for DR election. A higher priority means a higher possibility of being elected as the DR.
- Holdtime: Indicates the timeout time in which a neighbor is held in the reachable state.
- LAN_Delay: Indicates the delay for transmitting a Prune message in a shared network segment.
- Override-Interval: Indicates the prune override time carried in a Hello message.

When a PIM router receives a Prune message from an upstream interface, it indicates that other downstream interfaces exist in the shared network segment. If the PIM router still needs to receive multicast data, it must send a Prune Override message to the upstream interface within the time of **Override-Interval**.

$LAN_Delay + Override-Interval = PPT$ (Prune-Pending Timer). After a PIM router receives a Prune message from a downstream interface, it does not immediately perform pruning but waits for PPT timeout. After the PPT times out, the PIM router performs pruning. Within the time of PPT, if the PIM router receives a Prune Override message from the downstream interface, it cancels pruning.

↘ Maintaining Neighbor Relationships

A Hello message is sent periodically between PIM routers. If a Hello packet is not received from a PIM neighbor within Holdtime, the neighbor is considered unreachable and is deleted from the neighbor list. Any changes in PIM neighbors will cause multicast topology changes in the network. If an upstream neighbor or a downstream neighbor in an MDT is unreachable, multicast routing re-convergence is performed again and the MDT is migrated.

Related Configuration

↘ Enabling the PIM-SMv6 Function on an Interface

By default, the PIM-SMv6 function is disabled on an interface.

Run the **ipv6 pim sparse-mode** command to enable or disable the PIM-SMv6 function on an interface.

The PIM-SMv6 function must be enabled on an interface so that the interface participates in the operation of PIM protocols. If the PIM-SMv6 function is disabled on an interface that functions as a DR, static RP, candidate - rendezvous point (C-RP), or candidate – bootstrap router (C-BSR), the corresponding protocol role does not take effect.

↘ Adjusting the Transmission Interval of Hello Messages on an Interface

By default, Hello messages are transmitted at an interval of 30 seconds.

Run the **ipv6 pim query-interval** *seconds* command to adjust the transmission interval of Hello messages on an interface. The value ranges from 1 to 65,535.

A larger value of *interval-seconds* means a larger transmission interval of Hello messages and a smaller value of *interval-seconds* means a smaller transmission interval of Hello messages.

7.3.2 DR Election

In the shared network segment connected to group members, DR election is conducted among PIM neighbors to elect the DR connected to the group members.

In the shared network segment connected to a multicast source, DR election is conducted among PIM neighbors to elect the DR connected to the multicast source.

The DR transmits the Join/Prune message in the MDT root node direction for the directly connected group members, or transmits data of the directly connected multicast source to the MDT.

Working Principle

The neighbor IP address and DR priority are obtained from Hello packets of neighbors during establishment of PIM neighbor relationships, so as to elect the DR.

The key of DR election is the DR priorities and IP addresses of interfaces.

↳ Interface DR Priority

A higher interface DR priority means a higher probability that a PIM router is successfully elected as the DR during the DR election.

↳ Interface IP Address

If interfaces of PIM routers share the same DR priority during DR election, IP addresses of neighbors are compared. A larger IP address means a higher probability that a PIM router is successfully elected as the DR.

Related Configuration

↳ Setting IP Addresses of Interfaces

By default, no IP addresses are configured for interfaces.

Run the **ipv6 address** command to set an IP address for an interface.

When PIM routers share the same DR priority, the PIM router with a larger IP address is elected as the DR.

↳ Enabling the PIM-SMv6 Function on an Interface

By default, the PIM-SMv6 function is disabled on an interface.

Run the **ipv6 pim sparse-mode** command to enable or disable the PIM-SMv6 function on an interface.

The PIM-SMv6 function must be enabled on an interface so that the interface participates in the operation of PIM protocols. If the PIM-SMv6 function is disabled on an interface that functions as a DR, static RP, C-RP, or C-BSR, the corresponding protocol role does not take effect.

↳ Adjusting the DR Priority of an Interface

By default, the DR priority is 1.

Run the **ipv6 pim dr-priority** *priority-value* command to adjust the DR priority of an interface. The priority value ranges from 0 to 4,294,967,294.

The DR priority of an interface is used to elect the DR in the directly connected network segment of the interface. A larger priority value means a higher probability that a PIM router is elected as the DR.

7.3.3 BSR Mechanism

In a PIM network, the bootstrap router (BSR) periodically generates bootstrap messages (BSMs) including information about a series of C-RPs and relevant group addresses. BSMs are transmitted hop by hop in the entire domain. PIM routers throughout the network receive BSMs and record information about C-RPs and the relevant group addresses.

Working Principle

One or more C-BSRs are configured in the PIM-SMv6 domain and the BSR is elected from the candidate BSRs according to certain rules.

Related Configuration

Configuring a C-BSR

By default, no C-BSR is configured.

Run the **ipv6 pim bsr-candidate** *interface-type interface-number* [*hash-mask-length* [*priority-value*]] command to configure or cancel a C-BSR.

C-BSRs elect the globally unique BSR in the PIM-SM domain by means of BSM learning and election. The BSR transmits BSMs.

Configuring the BSR Border

By default, no BSR border is configured.

Run the **ipv6 pim bsr-border** command to configure or cancel the BSR border.

After this command is configured for an interface, the interface immediately discards the received BSMs and does not forward BSMs, thereby preventing BSM flooding. No BSR border is configured if this command is not configured.

Defining the Valid BSR Range

By default, the BSMs of BSRs are not filtered.

Run the **ipv6 pim accept-bsr list** *ipv6_access-list* command to define or cancel the BSR range.

After this command is configured, the valid BSR range is defined. If this command is not configured, the device with the PIM-SMv6 function enabled will receive all BSMs.

Configuring a C-BSR to Restrict the Address Range of Valid C-RPs and the Range of Multicast Groups Served by the C-RPs

A C-BSR receives notifications from all C-RPs.

Run the **ipv6 pim accept-crp list** *ipv6_access-list* command to configure whether to filter notifications from C-RPs.

After this command is configured, the C-BSR restricts the address range of valid C-RPs and the range of multicast groups served by the C-RPs. If this command is not configured, the C-BSR receives notifications from all C-RPs.

Configuring a C-BSR to Receive C-RP-ADV Packets with prefix-count of 0

By default, a C-BSR does not receive C-RP-ADV packets with prefix-count of 0.

Run the **ipv6 pim accept-crp-with-null-group** command to configure whether to receive C-RP-ADV packets with prefix-count of 0.

After this command is configured, the C-BSR can receive C-RP-ADV packets with prefix-count of 0. If this command is not configured, the C-BSR does not process C-RP-ADV packets with prefix-count of 0.

7.3.4 RP Mechanism

In a PIM network, the RP is statically configured or dynamically elected so that each PIM router knows the position of the RP. The RP serves as the root of the RPT. The RPT establishment and the forwarding of RPT data streams must use the RP as the forwarding point.

Working Principle

All PIM routers in a PIM domain must be able to be mapped to the same RP through a specific multicast group address. RPs are classified into static RPs and dynamic RPs in a PIM network.

Static RP

In static RP configuration, the RP address is directly configured on each PIM router so that all PIM routers in the PIM network know the RP address.

Dynamic RP

C-RPs are also configured in the PIM-SMv6 domain. These C-RPs transmit data packets that contain their addresses and information about multicast groups served by them to the BSR in unicast mode. The BSR periodically generates BSMs that contain information about a series of C-RPs and their group addresses. BSMs are transmitted hop by hop in the entire domain. Devices receive and store these BSMs. The DR at the receive end uses a hash algorithm to map a group address to the C-RP that can serve the group. Then, the RP corresponding to the group address can be determined.

Related Configuration

Setting a Static RP Address

By default, no RP address is configured.

Run the **ipv6 pim rp-address** *ipv6_rp-address* [*ipv6_access-list*] command to configure or cancel a static RP address for a PIM router.

An RP must be configured so as to implement ASM in a PIM-SMv6 network. You can configure a static RP or dynamic RP.

If a static RP is configured in a PIM-SMv6 network, the static RP configuration on all devices in the PIM-SMv6 domain must be consistent to prevent multicast route ambiguity in the PIM-SMv6 domain.

Configuring a C-RP Address

By default, no C-RP address is configured.

Run the **ipv6 pim rp-candidate** *interface-type interface-number* [**priority** *priority-value*] [**interval** *interval-seconds*] [**group-list** *ipv6_access-list*] command to configure or cancel a PIM router as a C-RP.

C-RPs periodically transmit C-RP notifications to the BSR. Information contained in these C-RP notifications is dispersed to all PIM-SMv6 devices in the domain, thereby ensuring the uniqueness of RP mapping.

Ignoring the RP Priority in RP Setting

By default, a C-RP with a higher priority is selected preferentially.

Run the **ipv6 pim ignore-rp-set-priority** command to specify or ignore the RP priority when selecting the RP for a group.

When one RP needs to be selected for a multicast address and multiple RPs can serve this multicast address, use this command if the RP priority needs to be ignored during the RP comparison. If this command is not configured, the RP priority will be considered during the RP comparison.

↳ Configuring the Static RP First

By default, a dynamic C-RP is adopted preferentially.

Run the **ipv6 pim static-rp-preferred** command to select the static RP first during RP selection.

After this command is configured, the static RP is adopted first. If this command is not configured, a C-RP is adopted first.

↳ Configuring the Embedded RP Function

By default, the embedded RP function is enabled for all IPv6 multicast group addresses where the RP address is embedded.

Run the **ipv6 pim rp embedded [group-list *ipv6_acl_name*]** command to enable the embedded RP function.

The embedded RP function is the peculiar RP discovery mechanism of IPv6 PIM. This mechanism uses the IPv6 multicast address where the RP address is embedded, to enable a multicast device to directly extract the RP address from the multicast address. By default, the embedded RP function is enabled for all IPv6 multicast group addresses where the RP address is embedded.

7.3.5 Registration Information About a Multicast Source

When a multicast source arises in a network, the DR connected to the multicast source transmits the Register packet to the RP so that the RP obtains information about the multicast source and multicast packets.

Working Principle

The DR at the data source end receives a multicast data packet from the directly connected host, and encapsulates the multicast data into a Register message. Then, it transmits the Register message to the RP in unicast mode. The RP generates the (S,G) entry.

If the forwarding entry contains an outgoing interface on the RP, the RP forwards the encapsulated data packet to the outgoing interface.

If the RP does not have the forwarding entry of the current group, it starts the (S,G) entry start timer. After the timer expires, the RP transmits the Register-Stop message to the DR and deletes the entry. After the DR at the data source end receives the Register-Stop message, the DR transmits the probing packet before the Register-Stop message timer expires.

If the DR does not receive the Register-Stop message, after the timer expires, the DR at the data source end encapsulates the multicast data into the Register message and transmits it to the RP in unicast mode.

If the DR receives the Register-Stop message, it re-starts the delay and re-transmits the probing packet before the delay expires.

Related Configuration

↳ Configuring Reachability Detection of RP Register Packets

By default, the RP reachability is not detected.

Run the **ipv6 pim register-rp-reachability** command to set or cancel the RP reachability detection.

If the RP reachability needs to be detected for the Register packet transmitted from the DR to the RP, you can configure this command. After this command is configured, the RP reachability is detected before the DR transmits the Register packet to the RP. That is, the DR queries the unicast routing table and static multicast routing table to check whether a route reachable to the RP exists. If no, the DR does not transmit the Register packet.

📄 Configuring the RP to Filter Register Packets

By default, the RP allows every received Register packet.

Run the **ipv6 pim accept-register { list ipv6_access-list [route-map map-name] | route-map map-name [list ipv6_access-list] }** command to enable or disable the RP to filter received Register packets.

To filter received Register packets on the RP, configure this command. If this command is not configured, the RP allows every received Register packet. If this command is configured, only Register packets whose source addresses and group addresses are allowed by the ACL are processed. Otherwise, the Register packets are filtered out.

📄 Configuring the Transmission Rate Limit for Register Packets

By default, the transmission rate of Register packets is not limited.

Run the **ipv6 pim register-rate-limit rate** command to configure whether to limit the transmission rate of Register packets.

If **no** is set in this command, the transmission rate is not limited. This command is used to configure the transmission rate of Register packets from the (S,G) multicast group address rather than the transmission rate of Register packets of the entire system.

📄 Configuring the Checksum Calculation of a Register Packet Based on the Entire Register Packet

By default, the checksum in a Register packet is calculated in default mode specified in the protocol.

Run the **ipv6 pim register-checksum-wholepkt [group-list ipv6_access-list]** command to set the packet length for checksum calculation.

If the entire PIM protocol packet including the encapsulated multicast data packet is used for checksum calculation of a Register packet, use this command. If this command is not configured, the checksum in a Register packet is calculated in default mode specified in the protocol.

📄 Configuring the Source Address of Register Packets

By default, the source address of Register packets uses the address of the DR interface connected to a multicast source.

Run the **ipv6 pim register-source { ipv6_local_address | interface-type interface-number }** command to configure the source address of Register packets.

To configure the source address of Register packets transmitted from the DR, use this command. If this command is not configured or **no** is set in this command, the source address of Register packets uses the address of the DR interface connected to a multicast source. If the address parameter of this command is used, the configured address must be a reachable unicast route. If the interface parameter of this command is used, this interface may be a loopback interface or an interface of other types and the interface address must be an advertised unicast route.

📄 Configuring the Suppression Time of Register Packets

The default suppression time of Register packets is 60 seconds.

Run the **ipv6 pim register-suppression seconds** command to configure the suppression time.

If this command is used to configure the suppression time of Register packets, configuring the value on the DR will change the suppression time of Register packets on the DR. If the **ipv6 pim rp-register-kat seconds** command is not configured, defining the value on the RP will change the keepalive time on the RP.

▾ Configuring the Probing Time of NULL Register Packets

The default probing time is 5 seconds.

Run the **ipv6 pim probe-interval interval-seconds** command to set the probing time.

The source DR transmits the NULL-Register packet to the RP within a certain interval prior to the timeout of the suppression time of the Register packet. This interval is the probing time. The default probing time is 5 seconds.

▾ Configuring the Time Value of the RP KAT Timer

By default, the KAT default value is used. KAT default value = Registration suppression time x 3 + Registration detection time.

Run the **ipv6 pim rp-register-kat seconds** command to set time of the KAT timer.

To configure the keepalive time of Register packets from the (S,G) multicast group address on the RP, use this command.

7.3.6 RPT Establishment

When a group member arises in a network, the DR connected to the group member transmits the Join packet in the RP direction to establish an RPT. If there is a multicast source in the network, the multicast packet transmitted to the RP can reach the group member along the RPT.

Working Principle

The RPT establishment process is as follows:

1. The DR at the receive end receives an MLD (*,G)Include report packet from a receiver.
2. If the DR at the receive end is not the RP of Group G, the DR at the receive end transmits one (*,G)join packet in the RP direction. The upstream device that receives the (*,G)join packet transmits the (*,G)join packet in the RP direction. The (*,G)join packet is transmitted hop by hop till the RP of Group G receives the (*,G)join packet, indicating that the DR at the receive end joins the RPT.
3. When the data source host transmits multicast data to a group, the source data is encapsulated into the Register message and is transmitted to the RP in unicast mode by the DR at the data source end. The RP decapsulates the Register message, retrieves the data packet, and then forwards it to each group member along the RPT.
4. The RP transmits the (S,G)join packet to the DR at the data source end to join the SPT of this data source.
5. After the SPT from the RP to the DR at the data source end is established, data packets from the data source are transmitted to the RP along the SPT without encapsulation.
6. When the first multicast data packet reaches the RP along the SPT, the RP transmits the Register-Stop message to the DR at the data source end to enable the DR to stop the encapsulation of Register packets. After the DR at the data source end receives the Register-Stop message, it does not encapsulate the Register packets but transmits the Register packets to the RP along the SPT of the data source. The RP forwards the Register packets to each group member along the RPT.

Related Configuration

Configuring the Transmission Interval of Join/Prune Packets

The default transmission interval of Join/Prune packets is 60 seconds.

Run the **ipv6 pim jp-timer** *seconds* command to set the transmission interval of Join/Prune packets.

To change the default transmission interval of Join/Prune packets, configure this command. If this command is not configured, the default transmission interval of Join/Prune packets is 60 seconds.

7.3.7 SPT Establishment

When a data packet reaches the DR connected to a group member, the DR connected to the group member transmits the Join packet in the multicast source direction to establish an SPT. Then, multicast packets are forwarded along the SPT, thereby relieving the load of the RP in the RPT and reducing the number of hops from the DR at the data source end to the receive end.

Working Principle

The SPT establishment process is as follows:

The DR at the receive end transmits the (*,G)join packet to the DR at the source end along the SPT. The (*,G)join packet is transmitted hop by hop till the DR at the source end receives the (*,G)join packet, forming an SPT.

Related Configuration

By default, SPT switching is disabled.

Run the **ipv6 pim spt-threshold** [**group-list** *ipv6_access-list*] command to configure whether to start SPT switching.

After this command is configured, when the DR receives the (S,G) packet from the first group member, one PIM Join message is generated and forwarded to the RP to establish a SPT tree. If **group-list** is defined, the defined group is switched from the RPT to the SPT. If **no** is set in this command and **group-list** is not defined, the switching from the RPT to the SPT is disabled and the device redirects to the RPT and transmits one Prune packet to the source. If **no** is set in this command, **group-list** is defined, and the defined ACL is a configured ACL, the ACL associated with **group-list** is cancelled and all groups are allowed to switch from the RPT to the SPT.

7.3.8 ASM and SSM Models

PIM-SM supports two multicast models: ASM and SSM. In the ASM model, a multicast data receiver specifies only to join a multicast group G but does not specify the multicast source S. In the SSM model, a multicast data receiver can specify both the multicast source S and multicast group G.

i When the SSM model is implemented over IPv6, MLDv2 needs to be used to manage the member relationship between hosts and devices and PIM-SMv6 needs to be used to connect devices.

In the SSM model, a multicast receiver learns about the multicast source (S,G) information by means of some channels (such as accessing the server or receiving advertisements) in advance. When the multicast receiver needs to order a multicast service, it directly transmits the MLD(S,G) Join packet to the last-hop device, for example, as shown in the following figure, Multicast Receiver 1 transmits the MLD(S,G) Join packet to order the multicast service (S,G). After receiving the MLD(S,G) Join packet from the multicast receiver, the last-hop device transmits the PIM(S,G) Join packet to the multicast source hop by hop, for example, as shown in the following figure, after receiving the MLD(S,G) Join packet

from Multicast Receiver 1, R1 transmits the PIM(S,G) Join packet to R3, which transmits the PIM (S,G) Join packet to R4. As a result, the SPT from the multicast receiver to the multicast source is established.

Figure 7-5

The following conditions need to be met for the implementation of the SSM model:

- A multicast receiver learns about the multicast source (S,G) information beforehand by means of some channels. The multicast receiver initiates the MLD(S,G) Join packet to the desired multicast service.
- MLDv2 must be enabled on the interface of the last-hop device connected to the multicast receiver. MLDv1 does not support SSM.
- PIM-SM and SSM must be enabled on the intermediate devices between the multicast receiver and the multicast source.

i After the SSM function is enabled, the default group range of SSM is FF3x::/32. You can run a command to change the group range of SSM.

The SSM model has the following features:

- In the SSM model, a multicast receiver can learn about the multicast source information in advance by means of some channels (for example, receiving advertisements or accessing a specified server).
- The SSM model is a specific subset of PIM-SM and processes only PIM(S,G) Join and PIM(S,G) Prune messages. It discards RPT-relevant messages within the SSM range, for example, PIM(*,G) Join/Prune messages. For Register packets within the SSM range, it immediately responds with the Register-Stop packet.
- In the SSM model, no RP is required and the election and distribution of RP messages are not required. The established MDT is the SPT in SSM.

7.4 Configuration

7.4.1 Configuring Basic Functions of PIM-SMv6

Configuration Effect

- Create a PIM network to provide the IPv6 multicast service for data sources and user terminals in the network.

- Both or either of the two multicast service models (ASM and SSM) can be supported.

Notes

- PIM-SMv6 needs to use the IPv6 unicast routing function.
- If the PIM network needs to support the multicast service of the SSM model, MLDv3 or SSM Mapping needs to be configured.

Configuration Steps

↳ Enabling the IPv6 Multicast Routing Function

- Mandatory.
- The IPv6 multicast routing function should be enabled on each router unless otherwise specified.

↳ Enabling the PIM-SMv6 Function

- Mandatory.
- The PIM-SMv6 function should be enabled on the following interfaces unless otherwise specified: router interconnection interfaces, interface that function as a static RP, C-RP, or C-BSR, interface for connecting to a multicast source, and interface for connecting to a user host.

↳ Configuring the PIM-SMv6 Sub VLAN Function

- In most scenarios on the PIM network, the PIM SMv6 protocol does not need to be enabled on interfaces of a super VLAN. In general, a super VLAN includes many sub VLANs. If the PIM SMv6 protocol is enabled on the interfaces of the super VLAN, multicast packets will be replicated and sent to all sub VLANs. As a result, traffic generated easily exceeds the device processing capability, causing protocol flapping. In some scenarios that require the PIM DM protocol to be enabled on the interfaces of the super VLAN, the PIM-SMv6 sub VLAN function may be configured, to send packets to a specified sub VLAN or all sub VLANs.
- This function is available only on the interfaces of the super VLAN.

↳ Configuring an RP

- If a PIM network needs to support the multicast service of the ASM model, an RP must be configured.
- There are three methods of configuring an RP: configuring only a static RP, configuring only a dynamic RP, and configuring both a static RP and a dynamic RP. If both a static RP and a dynamic RP are configured, the dynamic RP is preferred.
- Configuring a static RP: A static RP should be configured on each router unless otherwise specified.
- Configuring a dynamic RP: A C-RP or C-BSR should be configured on one or more routers unless otherwise specified.

↳ Enabling the SSM

- If a PIM network needs to support the multicast service of the SSM model, the SSM must be enabled.
- The SSM should be enabled on each router unless otherwise specified.

Verification

Make a multicast source in the network send packets to groups within the range of ASM and SSM and make a user host join the groups.

- Check whether the user host can successfully receive packets from each group.
- Check whether correct PIM-SMv6 routing entries are created on routers.

Related Commands

↳ Enabling the IPv6 Multicast Routing Function

Command	ipv6 multicast-routing
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

↳ Enabling the PIM-SMv6 Function

Command	ipv6 pim sparse-mode
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	<p>Before enabling the PIM-SMv6 function, enable the multicast routing forwarding function in global configuration mode. Otherwise, multicast data packets cannot be forwarded even if the PIM-SMv6 function is enabled.</p> <p>When the PIM-SMv6 function is enabled, MLD is automatically enabled on each interface without manual configuration.</p> <p>If the message "Failed to enable PIM-SMv6 on <interface name>, resource temporarily unavailable, please try again" is displayed during the configuration of this command, try to configure this command again.</p> <p>If the message "PIM-SMv6 Configure failed! VIF limit exceeded in NSM!!!" is displayed during the configuration of this command, the configured number of multicast interfaces reaches the upper limit of multicast interfaces that can be configured on the device. If the PIM-SMv6 function still needs to be enabled on an interface, delete some unnecessary PIM-SMv6 or PIM-DMv6 interfaces.</p> <p>If an interface is of the tunnel type, only the 6Over4 configuration tunnel, 6Over4 GRE tunnel, 6Over6 configuration tunnel, and 6Over6 GRE tunnel support the IPv6 multicast function. The multicast function can also be enabled on tunnel interfaces that do not support the multicast function but no prompts are displayed and multicast packets are neither received nor transmitted.</p> <p>Multicast tunnels can be established only on Ethernet ports. Embedded tunnels and QoS/ACL of multicast data are not supported.</p>

↳ Enabling the PIM-SMv6 Sub VLAN Function

Command	ip pim dense-mode subvlan [all vid]
Parameter Description	all: sends packets to all sub VLANs. vid: sends packets to a specified sub VLAN.
Command Mode	Interface configuration mode
Usage Guide	N/A

↳ Configuring a Static RP

Command	ipv6 pim rp-address <i>ipv6_rp-address</i> [<i>ipv6_access-list</i>]
Parameter Description	<i>ipv6_rp-address:</i> Indicates the IPv6 address of an RP. <i>ipv6_access_list:</i> References an IPv6 ACL to restrict the group address range served by the static RP. A named ACL is supported.
Command Mode	Global configuration mode
Usage Guide	Multicast static RPs can be configured. A static RP and a C-RP can coexist. Notes: <ol style="list-style-type: none"> 1. If both the BSR mechanism and RP static configuration are effective, the dynamic configuration is preferred. 2. A control list can be used to statically configure the address of an RP for multiple multicast groups (using the ACL) or all multicast groups (without using the ACL), but one static RP address cannot be used multiple times. 3. If multiple static RPs serve the same group, the static RP with a larger IPv6 address is used preferentially. 4. Only multicast groups with the addresses allowed by the ACL are effective. By default, all multicast groups are allowed. 5. After the configuration is complete, the static RP source address will be inserted into the group range-based static RP group tree structure. The multicast static group in each group range maintains the linked list structure of one static RP group. This linked list is arranged in descending order by IPv6 address. When an RP is selected for a group range, the RP with the largest IPv6 address will be selected. 6. When a static RP address is deleted, this address is deleted from all existing groups and an address is selected from the existing static RP tree structure as the RP address.

↳ Configuring a C-RP

Command	ipv6 pim rp-candidate <i>interface-type interface-number</i> [priority <i>priority-value</i>] [interval <i>interval-seconds</i>] [group-list <i>ipv6_access-list</i>]
Parameter Description	<i>interface-type interface-number:</i> Indicates an interface name. This interface address is used as the C-RP address. priority <i>priority-value:</i> Specifies the priority of the C-RP. The value ranges from 0 to 255 and the default value is 192 .

	<p>interval seconds: Indicates the interval for transmitting C-RP messages to the BSR, with the unit of seconds. The value ranges from 1 to 16,383 and the default value is 60.</p> <p>group-list ipv6_access-list: References an IPv6 ACL to restrict the group address range served by the C-RP. A named ACL is supported.</p>
Command Mode	Global configuration mode
Usage Guide	<p>In the PIM-SMv6 protocol, the RPT created by the multicast routing uses an RP as the root node. After the BSR is elected, all C-RPs periodically transmit C-RP messages to the BSR in unicast mode and then the BSR disperses the messages in the entire PIM domain.</p> <p>To specify an interface as the C-RP of a specific group range, contain the ACL option in this command. Note that the calculation of the group range is based only on the permitted access control entries (ACEs) and denied ACEs are not involved in the calculation.</p> <p>If group-list ipv6_access-list is not carried in the command, all groups are served.</p>

📌 Configuring a C-BSR

Command	ipv6 pim bsr-candidate <i>interface-type interface-number</i> [<i>hash-mask-length</i> [<i>priority-value</i>]]
Parameter Description	<p><i>interface-type interface-number:</i> Indicates an interface name. This interface address is used as the C-BSR address.</p> <p><i>hash-mask-length:</i> Indicates the hash mask length. The value ranges from 0 to 128 and the default value is 126.</p> <p><i>priority-value:</i> Indicates the priority. The value ranges from 0 to 255 and the default value is 64.</p>
Command Mode	Global configuration mode
Usage Guide	<p>A unique BSR must exist in a PIM-SMv6 domain. The BSR collects and advertises RP information. The unique well-known BSR is elected from multiple C-BSRs by means of BSMs. All C-BSRs consider that they are the BSR before knowing the BSR information. They periodically transmit BSMs that contain the BSR address and priority in the PIM-SMv6 domain.</p> <p>This command can be used to enable a device to transmit one BSM to all PIM neighbors by using the allocated BSR address. Each neighbor compares the original BSR address with the address in the received BSM. If the IPv6 address in the received BSM is equal to or larger than its BSR address, the neighbor stores this address as the BSR address and forwards the BSM. Otherwise, the neighbor discards the BSM.</p> <p>The current device deems that it is the BSR till it receives a BSM from another C-BSR and learns that the C-BSR has a higher priority (or the same priority but a larger IPv6 address).</p>

📌 Enabling the SSM

Command	ipv6 pim ssm { default / range <i>ipv6_access-list</i> }
Parameter Description	<p>default: The default group address range of SSM is FF3x::/32.</p> <p>range <i>ipv6_access-list:</i> References an IPv6 ACL to restrict the SSM group address range. A named ACL is supported.</p>
Command Mode	Global configuration mode

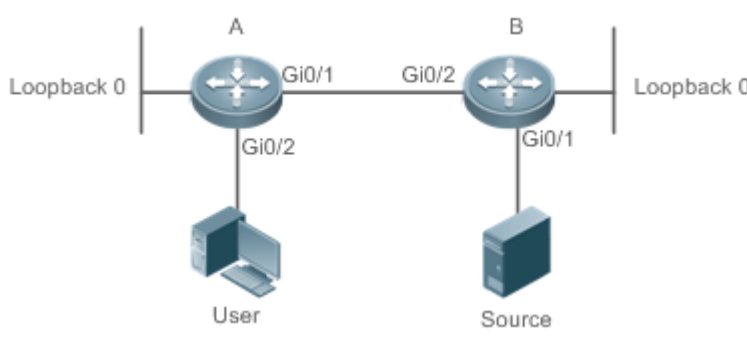

Mode	
Usage Guide	To apply SSM in a PIM-SMv6 network, you must configure this command.

📄 **Displaying the PIM-SM Routing Table**

Command	show ipv6 pim sparse-mode mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]]
Parameter Description	<i>group-or-source-address</i> : Indicates the group address or source address. The two addresses cannot be group addresses or source addresses at the same time.
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	A group address, a source address, or both group address and source address can be specified each time. You can also not specify a specific group address or source address but you cannot specify two group addresses or two source addresses at the same time.

Configuration Example

📄 **Creating the IPv6 Multicast Service on an IPv6 Network to Support ASM and SSM**

<p>Scenario Figure 7-6</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure an IPv6 unicast routing protocol (such as OSPFv6) on the routers and ensure that the unicast routes of the loopback interfaces are reachable. (Omitted) ● Enable the IPv6 multicast routing function on all routers. ● Enable the PIM-SMv6 function on device interconnection interfaces, interface for connecting to the user host, and interface for connecting to the multicast source. ● Configure a C-RP and a C-BSR on the loopback interfaces of Router A and Router B. Enable the PIM-SMv6 function on the loopback interfaces. ● Enable SSM on all routers. ● Enable MLDv3 on the router interface for connecting to the user host. (Omitted)
<p>A</p>	<pre>switch(config)#ipv6 multicast-routing switch(config)#ipv6 pim ssm default switch(config)#int gi 0/2 switch(config-if-GigabitEthernet 0/2)#ipv6 add 2000::2/64</pre>

	<pre> switch(config-if-GigabitEthernet 0/2)#ipv6 pim sparse-mode switch(config-if-GigabitEthernet 0/2)#exit switch(config)#int gi 0/1 switch(config-if-GigabitEthernet 0/1)#ipv6 add 1000::1/64 switch(config-if-GigabitEthernet 0/1)#ipv6 pim sparse-mode switch(config-if-GigabitEthernet 0/1)#exit switch(config)#int Loopback 0 switch(config-if-Loopback 0)#ipv6 add 3000::5/64 switch(config-if-Loopback 0)#ipv6 pim sparse-mode switch(config-if-Loopback 0)#exit switch(config)#ipv6 pim rp-candidate Loopback 0 </pre>
B	<pre> ruijie(config)#ipv6 multicast-routing ruijie(config)#ipv6 pim ssm default ruijie(config)#int gi 0/2 ruijie(config-if-GigabitEthernet 0/2)#ipv6 add 2000::1/64 ruijie(config-if-GigabitEthernet 0/2)#ipv6 pim sparse-mode ruijie(config-if-GigabitEthernet 0/2)#exit ruijie(config)#int gi 0/1 ruijie(config-if-GigabitEthernet 0/1)#ipv6 add 1100::1/64 ruijie(config-if-GigabitEthernet 0/1)#ipv6 pim sparse-mode ruijie(config-if-GigabitEthernet 0/1)#exit ruijie(config)#int Loopback 0 ruijie(config-if-Loopback 0)#ipv6 add 5000::5/64 ruijie(config-if-Loopback 0)#ipv6 pim sparse-mode ruijie(config-if-Loopback 0)#exit ruijie(config)#ipv6 pim bsr-candidate Loopback 0 </pre>
Verification	<p>Make Source(2000::2/64) send packets to G1(ff16::1) and make User join G1.</p> <ul style="list-style-type: none"> ● Check the multicast packets received by the User. The User should be able to receive multicast packets from G1. ● Check PIM-SMv6 routing tables on Router A and Router B. Entries should exist on the PIM-SMv6 routing tables.
A	<pre> switch(config)# show ipv6 pim sparse-mode mroute IPv6 Multicast Routing Table </pre>

Common Errors

- IPv6 unicast routing is incorrectly configured.
- IPv6 multicast routing is not enabled on a router.
- SSM is not enabled on a router or the SSM group address range of the router is different from that of other routers.
- PIM-SMv6 is not enabled on an interface (for example, interface that is specified as a C-RP or C-BSR, or interface that functions as the gateway of a user host or multicast source).
- MLDv3 is not enabled on an interface connected to a user host.
- No RP is configured in the network.
- No static RP is configured on a router or the configured static RP is different from that on other routers.
- A C-RP is configured but no C-BSR is configured in the network.
- The unicast route to the static RP, C-RP, or C-BSR is unreachable.

7.4.2 Configuring PIM Neighbor Parameters

Configuration Effect

- Negotiate about protocol parameters and adjust parameters in a Hello packet.

- PIM routers discover neighbors, negotiate about protocol parameters, and maintain neighbor relationships.
- Protect neighbor relationships to restrict neighbors.

Notes

- The basic functions of PIM-SMv6 must be configured.

Configuration Steps

- Set parameters on each PIM router interface unless otherwise specified.

Verification

Set parameters in a Hello packet on an interface and run the **debug ipv6 pim sparse-mode packet** command to check parameters in the Hello packet.

Set neighbor filtering and run the **show ipv6 pim sparse-mode neighbor** command to check the neighbor relationship.

Related Commands

↳ Configuring the Transmission Interval of Hello Messages

Command	ipv6 pim query-interval <i>seconds</i>
Parameter Description	Indicates the transmission interval of Hello packets. The unit is seconds. The value ranges from 1 to 65,535 and the default value is 30 .
Command Mode	Interface configuration mode
Usage Guide	Each time the transmission interval of Hello messages is updated, the Holdtime of Hello messages is accordingly updated according to the following rule: The Holdtime of Hello messages is updated to 3.5 times transmission interval of Hello messages. If the transmission interval of Hello messages multiplied by 3.5 is larger than 65,535, the transmission interval of Hello messages is forcibly updated to 18,725.

↳ Configuring the Propagation Delay for Hello Messages

Command	ipv6 pim propagation-delay <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : The unit is milliseconds. The value ranges from 1 to 32,767 and the default value is 500 .
Command Mode	Interface configuration mode
Usage Guide	Changing the propagation delay or prune override delay will affect J/P-override-interval. According to the protocol, J/P-override-interval must be smaller than the Holdtime of Join-Prune packets. Otherwise, short flow interruption will be incurred. This must be maintained and guaranteed by network administrators.

↳ Configuring the Prune Override Interval for Hello Messages

Command	ipv6 pim override-interval <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : The unit is milliseconds. The value ranges from 1 to 65,535 and the default value is 2500 .

Command Mode	Interface configuration mode
Usage Guide	Changing the propagation delay or prune override delay will affect J/P-override-interval. According to the protocol, J/P-override-interval must be smaller than the Holdtime of Join-Prune packets. Otherwise, short flow interruption will be incurred.

↳ Configuring the Interface Joining Suppression Capability for Hello Messages

Command	ipv6 pim neighbor-tracking
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	When the joining suppression capability of an interface is enabled and the local router needs to transmit a Join packet to an upstream neighbor, the Join packet of the local router is suppressed and is not transmitted if the local router receives a Join packet from a neighbor to the upstream router. If the joining suppression capability of the interface is disabled, the local router transmits the Join packet. When the joining suppression capability of a downstream receiver is disabled, the upstream neighbor can accurately know the number of receivers connected to the downstream neighbor through the received Join packet, thereby implementing neighbor tracking.

↳ Configuring the Delay of Sending Out Hello Messages

Command	ipv6 pim triggered-hello-delay <i>seconds</i>
Parameter Description	<i>Seconds</i> : The unit is seconds. The value ranges from 1 to 5 and the default value is 5 .
Command Mode	Interface configuration mode
Usage Guide	When an interface is enabled or detects a new neighbor, the Triggered-Hello-Delay message is used to generate a random time period. Within the time period, the interface sends Hello packets.

↳ Configuring the DR Priority for Hello Messages

Command	ipv6 pim dr-priority <i>priority-value</i>
Parameter Description	<i>priority-value</i> : Indicates the priority. A larger value means a higher priority. The value ranges from 0 to 4,294,967,294 and the default value is 1 .
Command Mode	Interface configuration mode
Usage Guide	The process of selecting a DR is as follows: The priority parameter is set for Hello packets of devices in the same LAN. The priority is compared for the selection of a DR. The device with a higher priority is the DR. If multiple devices share the same priority, the device with a larger IP address is the DR. When the priority parameter is not set for Hello packets of a device in a LAN, the device with a larger IP address is elected as the DR in the LAN.

Configuring Neighbor filtering

Command	ipv6 pim neighbor-filter <i>ipv6_access-list</i>
Parameter Description	<i>ipv6_access-list</i> : References an IPv6 ACL to restrict the neighbor address range.
Command Mode	Interface configuration mode
Usage Guide	This command can be used to filter neighbors to strengthen the security of the PIM network and restrict the address range of legitimate neighbors. If a neighbor is rejected by an ACL, PIM-SMv6 will not establish a peering relationship with this neighbor or suspend the peering relationship with this neighbor.

Displaying Neighbor Information About an Interface

Command	show ipv6 pim sparse-mode neighbor [detail]
Parameter Description	detail : Displays details.
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	N/A

Configuration Example

Configuration Steps	<ul style="list-style-type: none"> Configure basic functions of PIM-SMv6. (Omitted) Set the transmission interval of Hello packets of PIM-SMv6 to 50 seconds. Set the propagation delay of Hello packets of PIM-SMv6 to 400 milliseconds. Set the prune override interval of Hello packets of PIM-SMv6 to 3,000 milliseconds. Configure the interface joining suppression capability for Hello messages of PIM-SMv6. Set the delay of sending out Hello messages of PIM-SMv6 to 3 seconds. Set the DR priority of Hello messages of PIM-SMv6 to 5.
	<pre> switch # configure terminal switch (config)#int gi 0/1 switch (config-if-GigabitEthernet 0/1)#ipv6 pim query-interval 50 switch (config-if-GigabitEthernet 0/1)#ipv6 pim propagation-delay 400 switch (config-if-GigabitEthernet 0/1)#ipv6 pim override-interval 3000 switch (config-if-GigabitEthernet 0/1)#ipv6 pim triggered-hello-delay 3 switch (config-if-GigabitEthernet 0/1)# ipv6 pim dr-priority 5 </pre>
Verification	Run the debug ipv6 pim sparse-mode packet command to check parameters in a Hello packet.

	<pre>switch # debug ipv6 pim sparse-mode packet *Jan 2 02:37:55: %7: Hello send to GigabitEthernet 0/2 *Jan 2 02:37:55: %7: Send Hello message *Jan 2 02:37:55: %7: Holdtime: 175 *Jan 2 02:37:55: %7: T-bit: off *Jan 2 02:37:55: %7: Propagation delay: 400 *Jan 2 02:37:55: %7: Override interval: 3000 *Jan 2 02:37:55: %7: DR priority: 5 *Jan 2 02:37:55: %7: Gen ID: 99572792 *Jan 2 02:37:55: %7: Secondary Addresses: *Jan 2 02:37:55: %7: 2000::2</pre>
<p>Configuration Steps</p>	<p>Configure neighbor filtering on an interface to receive neighbor packets with the address of (8000::1/64).</p>
	<pre>switch(config-if-GigabitEthernet 0/2)#ipv6 pim neighbor-filter acl % access-list acl not exist switch(config-if-GigabitEthernet 0/2)#exit switch(config)#ipv6 access-list acl switch(config-ipv6-acl)#permit ipv6 8000::1/64 any</pre>
<p>Verification</p>	<p>Before neighbor filtering is configured, display the neighbor information.</p>
	<pre>switch#show ipv6 pim sparse-mode neighbor Neighbor Address Interface Uptime/Expires DR Pri/Mode fe80::21a:a9ff:fe3a:6355 GigabitEthernet 0/2 00:32:29/00:01:16 1 /</pre>
<p>Verification</p>	<p>After neighbor filtering is configured, the neighbor information is blank.</p>
	<pre>switch#show ipv6 pim sparse-mode neighbor</pre>

Common Errors

- The basic functions of PIM-SMv6 are not configured or fail to be configured.

7.4.3 Configuring BSR Parameters

Configuration Effect

- Restrict the range of BSMs.

Notes

- The basic functions of PIM-SMv6 must be configured.
- A C-RP and a C-BSR must be configured.
- The border must be configured on the interface between domains.

Configuration Steps

↳ Configuring the Border

- The border must be configured if there are multiple domains.
- Configure the border the interface between two domains.

↳ Configuring a PIM Router to Restrict BSMs

- Optional.
- This configuration can be performed on a PIM router unless otherwise specified.

↳ Configuring a C-BSR to Restrict the C-PR Range

- Optional.
- This configuration can be performed on all C-BSRs unless otherwise specified.

↳ Configuring a C-BSR to Receive C-RP-ADV Packets with prefix-count of 0

- Optional.
- This configuration can be performed on all C-BSRs unless otherwise specified.

Verification

↳ Verifying the Border

Enable the basic functions of PIM-SMv6, set two routers in different domains, and set Router B as a C-BSR. Router A can normally receive BSMs.

Set the common border between Router A and Router B as a border interface. Router A cannot receive BSMs.

↳ Verifying a PIM Router to Restrict BSMs

Enable the basic functions of PIM-SMv6 and set Router B as a C-BSR. Router A can normally receive BSMs. Restrict the C-BSR range on Router A. Router A cannot receive BSMs.

↳ Verifying a C-BSR to Restrict the C-PR Range

Enable the basic functions of PIM-SMv6, set Router B as a C-BSR, set Router A as a C-RP, and restrict the C-RP range on the C-BSR. Router B cannot receive packets from the C-RP.

Related Commands

↳ Configuring the BSR Border

Command	ipv6 pim bsr-border
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	The BSR border can be configured on an interface to restrict flooding of BSMs. When this interface receives BSMs, it immediately discards them and BSMs are not forwarded by this interface.

↳ Configuring a PIM Router to Restrict BSMs

Command	ipv6 pim accept-bsr list <i>ipv6_access-list</i>
Parameter Description	list <i>ipv6_access-list</i> . References an IPv6 ACL to restrict the BSR address range. A named ACL is supported.
Command Mode	Global configuration mode
Usage Guide	N/A

↳ Configuring a C-BSR to Restrict the C-PR Range

Command	ipv6 pim accept-crp list <i>ipv6_access-list</i>
Parameter Description	list <i>ipv6_access-list</i> . References an IPv6 ACL to restrict the address range of the C-RP and the group address range served by the C-RP. A named ACL is supported.
Command Mode	Global configuration mode
Usage Guide	Configure this command on a C-BSR. When this C-BSR is elected as the BSR, it can restrict the address range of the valid C-RP and the multicast group range served by the C-RP.

↳ Displaying BSMs

Command	show ipv6 pim sparse-mode bsr-router
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	N/A

↳ Displaying All RPs Configured on the Local Device and the Multicast Groups Served by the RPs

Command	show ipv6 pim sparse-mode rp mapping
Parameter Description	N/A

Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	N/A

Configuration Example

Configuring the BSR Border

Configuration Steps	<ul style="list-style-type: none"> Configure basic functions of PIM-SMv6. (Omitted) Configure the BSR border on the juncture interface between Router B and Router A.
	<pre>Ruijie(config-if-GigabitEthernet 0/2)#ipv6 pim bsr-border</pre>
Verification	Before the BSR border is configured, the BSM information of Router A is displayed as follows:
	<pre>switch#show ipv6 pim sparse-mode bsr-router PIMv2 Bootstrap information BSR address: 5000::5 Uptime: 00:05:42, BSR Priority: 64, Hash mask length: 126 Expires: 00:01:28 Role: Non-candidate BSR Priority: 0, Hash mask length: 126 State: Accept Preferred Candidate RP: 3000::5(Loopback 0) Advertisement interval 60 seconds Next Cand_RP_advertisement in 00:00:24 switch#</pre>
	 Candidate RP: Indicates all C-RPs configured on the local router, excluding other routers.
	After the BSR border is configured, the BSM information of Router A is displayed as follows:
	<pre>switch#show ipv6 pim sparse-mode bsr-router Candidate RP: 3000::5(Loopback 0) Advertisement interval 60 seconds Next Cand_RP_advertisement in 00:00:53</pre>

Configuring a PIM Router to Restrict the Source Address Range of BSMs to (8000::5/64)

Configuration Steps	<ul style="list-style-type: none"> Configure basic functions of PIM-SMv6. (Omitted) Configure PIM Router A to restrict BSMs. The restricted source address range is (8000::5/64).
----------------------------	---

	<pre>switch(config)#ipv6 access-list acl switch(config-ipv6-acl)#permit ipv6 8000::5/64 any switch(config-ipv6-acl)#exit switch(config)#ipv6 pim accept-crp list acl</pre>
Verification	<p>Before the BSM restriction is configured, the BSM information of Router A is displayed as follows:</p>
	<pre>switch#show ipv6 pim sparse-mode bsr-router PIMv2 Bootstrap information BSR address: 5000::5 Uptime: 00:05:42, BSR Priority: 64, Hash mask length: 126 Expires: 00:01:28 Role: Non-candidate BSR Priority: 0, Hash mask length: 126 State: Accept Preferred Candidate RP: 3000::5(Loopback 0) Advertisement interval 60 seconds Next Cand_RP_advertisement in 00:00:24 switch#</pre>
	<p>After the BSM restriction is configured, the BSM information of Router A is displayed as follows:</p>
	<pre>switch#show ipv6 pim sparse-mode bsr-router Candidate RP: 3000::5(Loopback 0) Advertisement interval 60 seconds Next Cand_RP_advertisement in 00:00:34</pre>

📌 Configuring a C-BSR to Restrict the Source Address Range of C-PR Packets to (9000::5/64)

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic functions of PIM-SMv6. (Omitted) ● Configure Router B to restrict C-RP packets. The restricted source address range is (9000::5/64).
	<pre>Ruijie(config)#ipv6 access-list acl Ruijie(config-ipv6-acl)#permit ipv6 9000::5/64 any Ruijie(config-ipv6-acl)#exit Ruijie(config)#ipv6 pim accept-crp list acl</pre>
Verification	<p>Before C-RP packet filtering is configured, information about all RP groups on Router B is displayed as follows:</p>

	<pre>Ruijie#show ipv6 pim sparse-mode rp mapping PIM Group-to-RP Mappings This system is the Bootstrap Router (v2) Group(s): ff00::/8 RP: 3000::5(Not self) Info source: 3000::5, via bootstrap, priority 192 Uptime: 00:02:26, expires: 00:02:08 Ruijie#</pre>
	<p>After C-RP packet filtering is configured, information about all RP groups on Router B is displayed as follows:</p>
	<pre>Ruijie#show ipv6 pim sparse-mode rp mapping PIM Group-to-RP Mappings This system is the Bootstrap Router (v2)</pre>

📌 **Configuring the Static RP First**

<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure basic functions of PIM-SMv6. (Omitted) ● Set the address of Interface Loopback0 of Router A to 3000::5. (Omitted) ● Set the address of Interface Loopback1 of Router A to 4000::5. (Omitted) ● Set the static address of Router A to 3300::5. (Omitted) ● Set the static address of Router B to 3300::5. ● Configure the static RP first on Router A.
	<pre>switch(config)#ipv6 pim rp-address 3300::5 switch(config)#ipv6 pim static-rp-preferred</pre>
<p>Verification</p>	<p>Before static RP first is configured, display information about the RP corresponding to FF16::1.</p>
	<pre>switch#show ipv6 pim sparse-mode rp ff16::1 RP: 4000::5 Info source: 5000::5, via bootstrap PIMv2 Hash Value 126 RP 4000::5, via bootstrap, priority 56, hash value 892666309 RP 3000::5, via bootstrap, priority 200, hash value 1161101765 RP 3300::5, static (hash value 204800453 not used)</pre>
<p>Verification</p>	<p>After static RP first is configured, display information about the RP corresponding to FF16::1.</p>

```
switch(config)#show ipv6 pim sparse-mode rp ff16::1
RP: 3300::5 (Static)

PIMv2 STATIC RP PREFERRED
PIMv2 Hash Value 126
RP 4000::5, via bootstrap, priority 56, hash value 892666309
RP 3000::5, via bootstrap, priority 200, hash value 1161101765
RP 3300::5, static (hash value 204800453 not used)

switch(config)#
```

Common Errors

- The basic functions of PIM-SMv6 are not configured or fail to be configured.
- No C-BSR is configured.
- The BSR border is not configured on an interface between different domains.

7.4.4 Configuring RP and DR Parameters

Configuration Effect

- Configure the ignorance of the C-RP priority for the RP reselection.
- Configure the DR at the data source end to detect the RP reachability.
- Restrict the (S,G) multicast group address of the data source so that the ASM model provides the multicast service only for multicast packets within the allowable range.
- Configure the rate limit for the DR at the data source end to transmit Register packets.
- Configure the checksum length of Register packets.
- Configure the source address of Register packets.
- Configure the suppression time of Register packets.
- Configure the probing time of NULL packets.
- Configure the TTL of Register packets received by the RP from the (S,G) multicast group address.
- Configure the static RP first.

Notes

- The basic functions of PIM-SMv6 must be configured.

Configuration Steps

📌 Configuring the Ignorance of the C-RP Priority for the RP Reselection

- Optional.

- The ignorance of the C-RP priority can be enabled on each router unless otherwise specified.
- ↳ **Configuring the DR at the Data Source End to Detect the RP Reachability**
- Optional.
- The reachability detection can be enabled on the DR that is directly connected to the data source unless otherwise specified.
- ↳ **Restricting the (S,G) Address Range of Register Packets at the Data Source End**
- Optional.
- The (S,G) address range of Register packets at the data source end can be restricted on all routers that function as C-RPs or static RPs unless otherwise specified.
- ↳ **Restricting the Rate for the DR at the Data Source End to Transmit Register Packets**
- Optional.
- The transmission rate limit of Register packets can be enabled on the DR that is directly connected to the data source unless otherwise specified.
- ↳ **Configuring the Checksum Length of Register Packets**
- Optional.
- The checksum length of Register packets can be configured on all C-RPs or static RPs unless otherwise specified.
- ↳ **Configuring the Source Address of Register Packets**
- Optional.
- The source address of Register packets can be configured on the DR that is directly connected to the data source unless otherwise specified.
- ↳ **Configuring the Suppression Time of Register Packets**
- Optional.
- The suppression time of Register packets can be configured on the DR that is directly connected to the data source unless otherwise specified.
- ↳ **Configuring the Probing Time of NULL Packets**
- Optional.
- The probing time of NULL packets can be configured on the DR that is directly connected to the data source unless otherwise specified.
- ↳ **Configuring the TTL of Register Packets Received by the RP from the (S,G) Multicast Group Address**
- Optional.
- The TTL of Register packets from the (S,G) multicast group address can be configured on all routers that function as C-RPs or static RPs unless otherwise specified.
- ↳ **Configuring the Static RP First**

- Optional.
- The static RP first can be configured on all routers unless otherwise specified.

Verification

↘ Verifying the Ignorance of the C-RP Priority

Set the address to 3000::5 and priority to 200 for Interface Loopback0 on Router A. Set the address to 4000: : 5 and priority to 56 for Interface Loopback1 on Router A. Set the C-BSR address to 5000: : 5 on Router B.

- Run the **show ipv6 pim sparse-mode rp ff16::2** command to display information about the RP that serves the current group.

↘ Verifying the DR at the Data Source End to Detect the RP Reachability

Set the address to 3000::5 and priority to 200 for Interface Loopback0 on Router A. Set the address to 4000: : 5 and priority to 56 for Interface Loopback1 on Router A. Set the C-BSR address to 5000: : 5 on Router B. Configure the RP reachability detection on Router B.

- Run the **show running-config** command to check whether the RP reachability detection is configured.

↘ Verifying the Restriction of the (S,G) Address Range of Register Packets at the Data Source End

Set the address to 3000::5 and priority to 200 for Interface Loopback0 on Router A. Set the address to 4000: : 5 and priority to 56 for Interface Loopback1 on Router A. Set the C-BSR address to 5000: : 5 on Router B. The address of the multicast group is FF16::2. Set Router A to receive packets only from the multicast source with the source address of (1300::1/64).

- Run the **show ip pim sparse-mode mroute** command to display the (S,G) entries.

↘ Verifying the Rate Limit for the DR at the Data Source End to Transmit Register Packets

- Set the rate of transmitting Register packets for Router B and then run the **show ip pim sparse-mode track** command to check the number of transmitted Register packets for confirmation.

↘ Verifying the Checksum Length of Register Packets

- Set Router A to check a Register packet based on the entire packet rather than based only on the packet header and Register packet header. Run the **show running-config** command to check the configuration.

↘ Verifying the Source Address of Register Packets

- Configure the source address of Register packets on Router B and run the **show running-config** command to check the configuration on Router A.

↘ Verifying the Suppression Time and Probing Time of Register Packets

- Configure the suppression time and probing time of Register packets on Router B and run the **show running-config** command to check the configuration.

↘ Verifying the TTL of Register Packets Received by the RP from the (S,G) Multicast Group Address

- Configure the TTL of Register packets from the (S,G) multicast group address on Router A and run the **show ip pim sparse-mode mroute** command to display the maximum (S,G) TTL.

↘ Verifying the Static RP First

- Configure a static RP and a C-RP on Router A, configure the static RP first, and then run the **show ipv6 pim sparse-mode rp ff16::2** command to display information about the current RP.

Related Commands

↳ Ignoring the C-RP Priority

Command	ipv6 pim ignore-rp-set-priority
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

↳ Displaying Information About the RP That Serves a Group

Command	show ipv6 pim sparse-mode rp-hash <i>group-address</i>
Parameter Description	<i>group-address</i> : Indicates the parsed group address.
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	N/A

↳ Configuring the DR Directly Connected to the Data Source to Detect RP Reachability

Command	ipv6 pim register-rp-reachability
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After this command is configured, the RP reachability is detected before Register packets are transmitted. If the RP is reachable, Register packets are transmitted. If the RP is unreachable, Register packets are not transmitted.

↳ Restricting the (S,G) Address Range of Register Packets at the Data Source End

Command	ipv6 pim accept-register { list <i>ipv6_access-list</i> [route-map <i>map-name</i>] route-map <i>map-name</i> [list <i>ipv6_access-list</i>] }
Parameter Description	list <i>ipv6_access-list</i> : References an IP extended ACL to restrict the (S,G) address range. The value range is 100-199, 2000-2699, and Word. route-map <i>map-name</i> : Uses a route map to restrict the (S,G) address range.
Command Mode	Global configuration mode
Usage Guide	After this command is configured, when receiving a Register packet from an unauthorized source, the RP immediately returns the Register-Stop packet.

▾ Displaying Multicast Routing Entries

Command	show ipv6 pim sparse-mode mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]]
Parameter Description	<i>group-or-source-address</i> : Indicates the group address or source address. The two addresses cannot be group addresses or source addresses at the same time.
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	A group address, a source address, or both addresses can be specified each time. You can also not specify a specific group address or source address but you cannot specify two group addresses or two source addresses at the same time.

▾ Configuring the Rate Limit for the DR to Transmit Register Packets

Command	ipv6 pim register-rate-limit <i>rate</i>
Parameter Description	<i>Rate</i> : Indicates the number of Register packets that are allowed to be transmitted per second. The value ranges from 1 to 65,535.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the transmission rate of Register packets from the (S,G) multicast group address rather than the Register packets of the entire system. After this command is configured, the load of the source DR and RP will be relieved and Register packets whose rate does not exceed the limit will be transmitted.

▾ Displaying the Statistics on PIM Packets

Command	show ipv6 pim sparse-mode track
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	When the system is started, the statistics start time point is first set. Each time clear ip pim sparse-mode track is called, the statistics start time point is set again and the PIM packet counter is cleared.

▾ Configuring the Checksum Calculation of a Register Packet Based on the Entire Packet

Command	ipv6 pim register-checksum-wholepkt [group-list <i>ipv6_access-list</i>]
Parameter Description	group-list <i>access-list</i> : Uses an ACL to restrict the group addresses that use this configuration. <i>access-list</i> : Supports digits <1,99> and <1300,1999>. A named ACL is supported.
Command Mode	Global configuration mode
Usage Guide	The device calculates the checksum of a Register packet based on the entire PIM protocol packet including the encapsulated multicast data packet, rather than the PIM header of the Register packet. If group-list <i>ipv6_access-list</i> is not carried in this command, all group addresses apply this configuration.

Configuring the Source Address of Register Packets

Command	ipv6 pim register-source { <i>ipv6_local_address</i> <i>interface-type interface-number</i> }
Parameter Description	<i>local_address</i> : Specifies an IPv6 address as the source address of Register packets. <i>interface-type interface-number</i> : Specifies the IPv6 address of an interface as the source address of Register packets.
Command Mode	Global configuration mode
Usage Guide	The configured address must be reachable. When the RP receives a Register packet, it transmits the Register-Stop packet with the source IPv6 address of the Register packet as the destination address. PIM-SMv6 does not need to be enabled on associated interfaces.

Configuring the Suppression Time of Register Packets

Command	ipv6 pim register-suppression <i>seconds</i>
Parameter Description	<i>Seconds</i> : Indicates the suppression time of Register packets. The unit is seconds. The value ranges from 1 to 65,535 and the default value is 60 .
Command Mode	Global configuration mode
Usage Guide	Configuring this value on the DR will change the suppression time of Register packets defined on the DR. If the ipv6 pim rp-register-kat command is not configured, configuring this value on the RP will change the keepalive time of the RP.

Configuring the Probing Time of Register Packets

Command	ipv6 pim probe-interval <i>seconds</i>
Parameter Description	<i>Seconds</i> : Indicates the probing time of Register packets. The unit is seconds. The value ranges from 1 to 65,535 and the default value is 5 .
Command Mode	Global configuration mode
Usage Guide	Probing time of Register packets is the interval for the source DR to transmit the NULL-Register packet to the RP prior to the timeout of the suppression time of Register packets. The probing time of Register packets cannot be larger than half of the suppression time of Register packets. Otherwise, the configuration fails and a warning is displayed. In addition, the suppression time of Register packets multiplied by three plus the probing time of Register packets cannot be larger than 65,535. Otherwise, a warning will be displayed.

Configuring the KAT Interval on the RP

Command	ipv6 pim rp-register-kat <i>seconds</i>
Parameter Description	<i>Seconds</i> : Indicates the time of the KAT timer. The unit is seconds. The value ranges from 1 to 65,535 and the default value is 210 .
Command Mode	Global configuration mode

Usage Guide	N/A
--------------------	-----

↘ **Configuring the Static RP First**

Command	ipv6 pim static-rp-preferred
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After this command is configured, the priority of the static RP is higher than that of the RP elected by using the BSR mechanism.

Configuration Example

↘ **Configuring Whether the C-RP Priority Is Considered for the Group-to-RP Mapping**

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic functions of PIM-SMv6. (Omitted) ● Set the address to 3000::5 and priority to 200 for Interface Loopback0 on Router A. (Omitted) ● Set the address to 4000::5 and priority to 56 for Interface Loopback1 on Router A. (Omitted) ● Set the C-BSR address to 5000::5 on Router B. (Omitted) ● Display the group corresponding to FF16::1. ● Configure the ignorance of C-RP priority on Router B.
	<pre>switch#configure terminal Ruijie(config)# ipv6 pim ignore-rp-set-priority</pre>
Verification	Before the ignorance of the C-RP priority is configured, the following information is displayed:
	<pre>switch(config)#show ipv6 pim sparse-mode rp FF16::1 RP: 4000::5 Info source: 5000::5, via bootstrap PIMv2 Hash Value 126 RP 4000::5, via bootstrap, priority 56, hash value 892666309 RP 3000::5, via bootstrap, priority 200, hash value 1161101765</pre>
	After the ignorance of the C-RP priority is configured, the following information is displayed:
	<pre>switch(config)#show ipv6 pim sparse-mode rp FF16::1 RP: 3000::5 Info source: 5000::5, via bootstrap</pre>

↘ **Configuring the Reachability Detection of the RP Directly Connected to the Data Source**

<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure basic functions of PIM-SMv6. (Omitted) ● Configure the reachability detection of the RP directly connected to the data source.
	<pre>Ruijie(config)#ipv6 pim register-rp-reachability</pre>
<p>Verification</p>	<p>Run the show running-config command to check the configuration. The following information is displayed:</p>
	<pre>Ruijie(config)#show running-config ! ! ! ipv6 pim register-rp-reachability ipv6 pim bsr-candidate Loopback 0 ! !</pre>

📌 **Restricting the (S,G) Address Range of Register Packets at the Data Source End**

<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure basic functions of PIM-SMv6. (Omitted) ● Set Router A to filter packets by source address and receive packets only from the source address (1300::1/64).
	<pre>switch(config)#ipv6 pim accept-register list acl % access-list 101 not exist switch(config)#ipv6 access-list acl switch(config-ipv6-acl)#permit ipv6 1300::1/64 any switch(config-ipv6-acl)#exit</pre>
<p>Verification</p>	<p>Before the (S,G) address range of Register packets at the data source end is restricted, run the show ipv6 pim sparse-mode mroute command to display multicast entries. The (S,G) entry and (S,G,RPT) entry exist.</p>
	<pre>switch#show ipv6 pim sparse-mode mroute IPv6 Multicast Routing Table (*,*,RP) Entries: 0 (*,G) Entries: 1 (S,G) Entries: 1 (S,G,rpt) Entries: 1 FCR Entries: 0 REG Entries: 0</pre>

Restricting the Rate for the DR at the Data Source End to Transmit Register Packets

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic functions of PIM-SMv6. (Omitted) ● Check the number of PIM packets transmitted by Router B. ● Check the number of PIM packets transmitted by Router B one second later. ● Set the rate for Router B to transmit Register packets. ● Check the number of PIM packets transmitted by Router B one second later.
	<pre>Ruijie(config)#ipv6 pim register-rate-limit 1</pre>
Verification	<p>Before the rate limit is configured, check the number of PIM packets transmitted by the DR. The following information is displayed:</p>
	<pre> Ruijie#show ipv6 pim sparse-mode track PIMv6 packet counters track Elapsed time since counters cleared: 17:14:54 received sent Valid PIMv6 packets: 5064 7727 Hello: 1329 4057 Join-Prune: 863 0 Register: 0 2636 Register-Stop: 975 0 Assert: 0 0 BSM: 0 1034 C-RP-ADV: 1897 0 </pre>

<pre> PIMDM-Graft: 0 PIMDM-Graft-Ack: 0 PIMDM-State-Refresh: 0 Unknown PIM Type: 0 Errors: Malformed packets: 0 Bad checksums: 0 Send errors: 5 Packets received with unknown PIM version: 0 </pre>
<p>Before the rate limit is configured, check the number of PIM packets transmitted by the DR one second later. The following information is displayed:</p>
<pre> Ruijie#show ipv6 pim sparse-mode track PIMv6 packet counters track Elapsed time since counters cleared: 17:14:55 received sent Valid PIMv6 packets: 5064 7727 Hello: 1335 4063 Join-Prune: 866 0 Register: 0 2639 Register-Stop: 978 0 Assert: 0 0 BSM: 0 1035 C-RP-ADV: 1897 0 PIMDM-Graft: 0 PIMDM-Graft-Ack: 0 PIMDM-State-Refresh: 0 Unknown PIM Type: 0 Errors: Malformed packets: 0 Bad checksums: 0 Send errors: 5 </pre>

	Packets received with unknown PIM version: 0
	After the rate limit is configured, check the number of PIM packets transmitted by the DR. The following information is displayed:
	<pre> Ruijie#show ipv6 pim sparse-mode track PIMv6 packet counters track Elapsed time since counters cleared: 17:14:56 received sent Valid PIMv6 packets: 5064 7727 Hello: 1341 4069 Join-Prune: 869 0 Register: 0 2640 Register-Stop: 979 0 Assert: 0 0 BSM: 0 1036 C-RP-ADV: 1897 0 PIMDM-Graft: 0 PIMDM-Graft-Ack: 0 PIMDM-State-Refresh: 0 Unknown PIM Type: 0 Errors: Malformed packets: 0 Bad checksums: 0 Send errors: 5 Packets received with unknown PIM version: 0 </pre>

Configuring the Checksum Length of Register Packets

Configuration Steps	<ul style="list-style-type: none"> Configure basic functions of PIM-SMv6. (Omitted) Configure the checksum calculation of a Register packet based on the entire packet on Router A. Run the show running-config command to check the configuration.
	<pre> switch(config)#ipv6 pim register-checksum-wholepkt switch(config)#show running-config </pre>
Verification	Check the configuration on Router A. The configuration is displayed as follows:

```

!
!
ipv6 pim register-checksum-wholepkt
ipv6 pim rp-candidate Loopback 0 priority 200
ipv6 pim rp-candidate Loopback 1 priority 56
ipv6 pim ssm default
!
!
    
```

📌 **Configuring the Source Address of Register Packets**

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic functions of PIM-SMv6. (Omitted) ● Set the source address of Interface Loopback1 to 5500::5/64 on Router B. (Omitted) ● Set the source address of Register packets to the address of Interface Loopback2 on Router B. (Omitted) ● Run the show running-config command to check the configuration.
	<pre>Ruijie(config)#ipv6 pim register-source Loopback 1</pre>
Verification	Check the configuration on Router B.
	<pre> ! ! ipv6 pim register-source Loopback 1 ipv6 pim register-rate-limit 1 ipv6 pim bsr-candidate Loopback 0 ! ! </pre>

📌 **Configuring the Suppression Time and Probing Time of Register Packets**

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic functions of PIM-SMv6. (Omitted) ● Set the suppression time to 20 seconds on Router B. ● Set the probing time to 2 seconds on Router B. ● Run the show running-config command to check the configuration.
	<pre> Ruijie(config)#ipv6 pim register-suppression 20 Ruijie(config)#ipv6 pim probe-interval 2 Ruijie(config)# show ip pim sparse-mode track </pre>
Verification	Check the configuration on Router B.
	<pre>!</pre>

```

ipv6 pim register-source Loopback 1
ipv6 pim register-rate-limit 1
ipv6 pim register-suppression 20
ipv6 pim probe-interval 2
ipv6 pim bsr-candidate Loopback 0
!
!
    
```

Configuring the TTL of Register Packets Received by the RP from the (S,G) Multicast Group Address

<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure basic functions of PIM-SMv6. (Omitted) ● Set the TTL of Register packets received by Router A from the (S,G) multicast group address to 60 seconds. ● Run the show ip pim sparse-mode mroute command to check the number of Register packets.
	<pre>Ruijie(config)#ip pim rp-register-kat 60</pre>
<p>Verification</p>	<p>After the TTL is configured, check the TTL of Register packets from the (S,G) multicast group address on Router A. The TTL is not larger than 60 seconds.</p>
	<pre> switch(config)#show ipv6 pim sparse-mode mroute IPv6 Multicast Routing Table (*,*,RP) Entries: 0 (*,G) Entries: 0 (S,G) Entries: 1 (S,G,rpt) Entries: 1 FCR Entries: 0 REG Entries: 0 (1100::2, ff16::1) RPF nbr: fe80::21a:a9ff:fe3a:6355 RPF idx: GigabitEthernet 0/2 SPT bit: 0 Upstream State: NOT JOINED kat expires in 60 seconds 00 01 02 03 04 05 06 07 08 09 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 Local </pre>

Common Errors

- The basic functions of PIM-SMv6 are not configured or fail to be configured.
- The (S,G) address range of Register packets at the data source end is not restricted or fails to be configured on a C-RP or static RP.
- When the (S,G) address range of Register packets at the data source end is restricted, the referenced ACL is not configured or the source/group address range allowed by the ACL is configured incorrectly.
- The source/group address ranges allowed by C-RPs or static RPs are inconsistent.

7.4.5 Configuring the Transmission Interval of Join/Prune Packets

Configuration Effect

- Change the transmission interval of Join/Prune packets to form an RPT or SPT.

Notes

- The basic functions of PIM-SMv6 must be configured.

Configuration Steps

- Configure the transmission interval of Join/Prune packets.

Verification

Set the transmission interval of Join/Prune packets to 120 seconds on Router B. Run the **show ipv6 pim sparse-mode mroute** command to check the entry TTL.

Related Commands

▾ Configuring the Transmission Interval of Join/Prune Packets

Command	ipv6 pim jp-timer <i>seconds</i>
Parameter Description	<i>Seconds</i> : Indicates the transmission interval of Join/Prune packets. The unit is seconds. The value ranges from 1 to 65,535 and the default value is 60 .
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

▾ Configuring the Transmission Interval of Join/Prune Packets on a Router

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic functions of PIM-SMv6. (Omitted) ● Configure the transmission interval of Join/Prune packets on a router.
	<pre>Ruijie(config)#ip pim jp-timer 120</pre>
Verification	Run the show ipv6 pim sparse-mode mroute command to check the entry. The transmission time of Join/Prune packets is not larger than 120.
	<pre>switch(config)#show ipv6 pim sparse-mode mroute IPv6 Multicast Routing Table (*,*,RP) Entries: 0 (*,G) Entries: 1 (S,G) Entries: 1 (S,G,rpt) Entries: 1 FCR Entries: 0 REG Entries: 0</pre>

7.4.6 Configuring the Last-Hop Device to Switch from the RPT to the SPT

Configuration Effect

- Switch the last-hop device from the RPT to the SPT.

Notes

- The basic functions of PIM-SMv6 must be configured.

Configuration Steps

- Configure the last-hop device to switch from the RPT to the SPT.

Verification

Configure basic functions of PIM-SMv6, make the DR at the data source end transmit data streams to Group FF16::1, and make the receiver forcibly join the Group FF16::1 to form a RPT. The DR at the receive end forcibly performs the switching from the RPT to SPT. Check the configuration on the RP.

Related Commands

↳ **Enabling the SPT Switching Function**

Command	ipv6 pim spt-threshold [group-list <i>ipv6_access-list</i>]
Parameter Description	group-list <i>ipv6_access-list</i> : References an IPv6 ACL to restrict the group address range that allows SPT switching. <i>ipv6_access-list</i> : A named ACL is supported.
Command Mode	Global configuration mode
Usage Guide	If group-list <i>ipv6_access-list</i> parameter is not carried in this command, all multicast groups are allowed to conduct SPT switching. If no is set in this command, group-list is carried, and the carried ACL is a configured ACL, the restriction of the ACL associated with group-list is cancelled and all groups are allowed to switch from the RPT to the SPT.

Configuration Example

↳ **Configuring the Last-Hop Device to Switch from the RPT to the SPT**

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic functions of PIM-SMv6. (Omitted) ● Make the DR at the data source end transmit code streams to Group FF16::1. ● Make the DR at the receive end receive code streams from Group FF16::1. ● Configure the last-hop device to switch from the RPT to the SPT on the DR at the receive end.

	<pre>switch(config)#ipv6 pim spt-threshold</pre>
Verification	Run the show running-config command to check the configuration.
	<pre>switch(config)#show running-config ! ! ip pim jp-timer 120 ip pim spt-threshold ip pim rp-candidate Loopback 0 ! !</pre>

7.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears information about the dynamic RP.	clear ipv6 pim sparse-mode bsr rp-set *
Sets the packet statistics start time again and clears the PIMv6 packet counter.	clear ipv6 pim sparse-mode track

Displaying

Description	Command
Displays details about the BSR.	show ipv6 pim sparse-mode bsr-router
Displays the PIM-SM information about an interface.	show ipv6 pim sparse-mode interface [<i>interface-type interface-number</i>] [detail]
Displays the local MLD information about a PIM-SMv6 interface.	show ipv6 pim sparse-mode local-members [<i>interface-type interface-number</i>]
Displays the PIM-SMv6 routing information.	show ipv6 pim sparse-mode mroute [<i>group-or-source-address</i>] [<i>group-or-source-address</i>]
Displays the PIM-SMv6 neighbor information.	show ipv6 pim sparse-mode neighbor [detail]
Displays next hop-relevant information, including the next-hop interface ID, address, and metric.	show ipv6 pim sparse-mode nexthop

Displays all RPs configured on the local device and the groups served by the RPs.	show ipv6 pim sparse-mode rp mapping
Displays information about the RP that serves the group address.	show ipv6 pim sparse-mode rp-hash <i>ipv6-group-address</i>
Displays the number of PIM packets transmitted and received from the statistics start time to the current time.	show ipv6 pim sparse-mode track

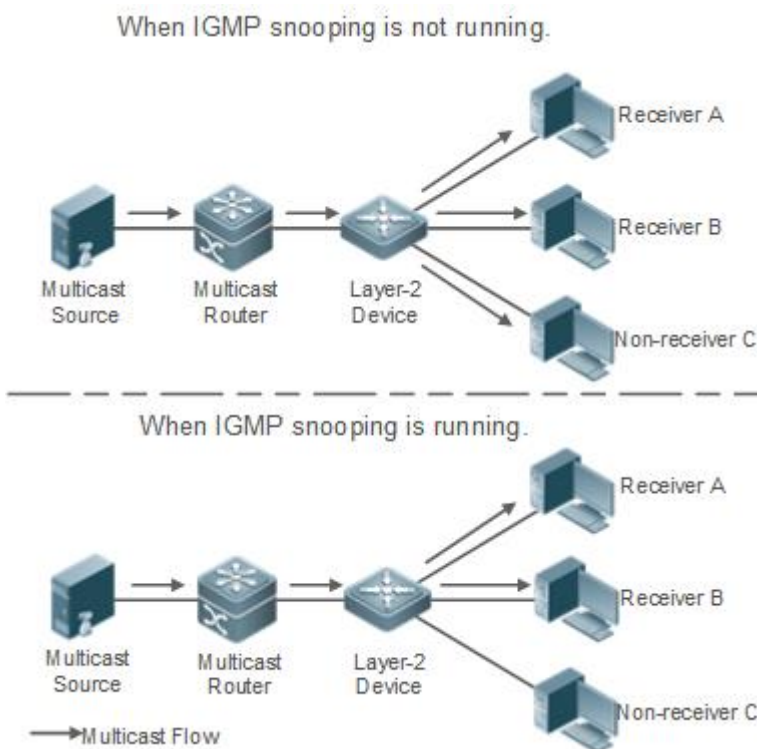

8 Configuring IGMP Snooping

8.1 Overview

Internet Group Management Protocol (IGMP) snooping is a mechanism of listening to IP multicast. It is used to manage and control the forwarding of IP multicast traffic within VLANs, realizing Layer-2 multicasting.

As shown in the following figure, when a Layer-2 device is not running IGMP snooping, IP multicast packets are broadcasted within the VLAN; when the Layer-2 device is running IGMP snooping, IP multicast packets are transmitted only to profile members.

Figure 8-1 Networking Topology of IP Multicast Forwarding within the VLAN Before and After IGMP Snooping Is Run on the Layer-2 Device

Protocols and Standards

- RFC4541: Considerations for Internet Group Management Protocol (IGMP) and Multicast Listener Discovery (MLD) Snooping Switches

8.2 Applications

Application	Description
Layer-2 Multicast Control	Enables precise forwarding of Layer-2 multicast packets to avoid flooding at this

	layer.
Shared Multicast Services (Multicast VLAN)	Multiple users can share the multicast traffic of the same VLAN.
Premium Channels and Preview	Controls the range of multicast addresses that allow user demanding and allows preview for profiles who are inhibited from demanding.

8.2.1 Layer-2 Multicast Control

Scenario

As shown in the following figure, multicast packets are transmitted to users through a Layer-2 switch. When Layer-2 multicast control is not performed, namely, when IGMP snooping is not implemented, multicast packets are flooded to all the users including those who are not expected to receive these packets. After IGMP snooping is implemented, the multicast packets from an IP multicast profile will no longer be broadcast within the VLAN but transmitted to designated receivers.

Figure 8-2 Networking Topology of Implementing Layer-2 Multicast Control (Multicast VLAN)

Deployment

- Configure basic IGMP snooping functions.

8.2.2 Shared Multicast Services (Multicast VLAN)

Scenario

In Shared VLAN Group Learning (SVGL) mode or IVGL-SVGL mode (IVGL: Independent VLAN Group Learning), a device running IGMP snooping can provide shared multicast services (or multicast VLAN services) to the VLAN users. Typically, this function is used to provide the same video-on-demand (VOD) services to multiple VLAN users.

The following figure shows the operation of a Layer-2 multicast device in SVGL mode of IGMP snooping. The multicast router sends a multicast packet to VLAN 1, and the Layer-2 multicast device automatically transfers the packet to VLAN 1, VLAN 2, and VLAN 3. In this way, the multicast services of VLAN 1 are shared by VLAN 2 and VLAN 3.

Figure 8-3 Networking Topology of Shared Multicast Services (Multicast VLAN)

i If the Layer-2 multicast device operates in IVGL mode, the router must send a packet to each VLAN, which wastes bandwidth and burdens the Layer-2 multicast device.

Deployment

- Configure basic IGMP snooping functions (in SVGL mode or IVGL-SVG mode).

8.2.3 Premium Channels and Preview

Scenario

In VOD application, by limiting the range of the multicast addresses that a user host can access, unpaid users will not be able to watch the premium channels. Thereafter, the preview service is offered to unpaid users before they decide whether to pay for it.

The users can preview a premium channel for a certain period of time (for example 1 minute) after demanding it.

Deployment

- Configure basic IGMP snooping functions (in any working mode).
- Configure the range of multicast addresses that a user can access.
- Enable the preview function for VOD profiles that are denied access.

8.3 Features

Basic Concepts

↳ Multicast Router Ports and Member Ports

i IGMP snooping is VLAN-based. The ports involved refer to the member ports within the VLAN.

The device running IGMP snooping identifies the ports within the VLAN as a multicast router port or member port so as to manage and control the forwarding of IP multicast traffic within the VLAN. As shown in the following figure, when IGMP snooping is run on a Layer-2 device, multicast traffic enters the multicast router port and exits from the member ports.

Figure 8-4 Networking Topology of Two IGMP Snooping Ports

- Multicast router port: The location of the multicast source is directed by the port on the Layer-2 multicast device which is connected to the multicast router (Layer-3 multicast device): By listening to IGMP packets, the Layer-2 multicast device can automatically detect the multicast router port and maintain the port dynamically. It also allows users to configure a static router port.
- Member port: The port is on a Layer-2 multicast device and is connected to member hosts. It directs the profile members. It is also called the Listener Port. By listening to IGMP packets, the Layer-2 multicast device can automatically detect the member port and maintain the port dynamically. It also allows users to configure a static member port.

Overview

Feature	Description
Listening to IGMP Packets	Discovers and identifies the router port and member port to establish and maintain the IGMP snooping forwarding entries. :
IGMP Snooping Working Modes	Provides independent or shared multicast services to the user VLAN.
Multicast Security Control	Controls the multicast service scope and load to prevent illegal multicast traffic.
Profile	Defines the range of multicast addresses that permit or deny user requests for reference of other functions.
Handling QinQ	Sets the forwarding mode of multicast packets on the QinQ interface.

[IGMP Querier](#)

On a network without a Layer-3 multicast device, the Layer-2 multicast device acts as an IGMP querier.

8.3.1 Listening to IGMP Packets

A device running IGMP snooping analyzes IGMP packets received, and finds and identifies the router port and member port using these packets, thereby creating and maintaining an IGMP snooping entry.

Working Principle

A device running IGMP snooping can identify and handle the following types of IGMP packets:

Query Packets

- An IGMP querier periodically sends General Query packets. When the IGMP querier receives Leave packets, it sends Group-Specific Query packets.

When the device running IGMP snooping receives the Query packets, it performs the following operations within the VLAN:

- Forward the IGMP Query packets to all the ports (except the receiving port of these packets).
- If the receiving port is a dynamic router port, reset the aging timer. If the timer expires, the port will no longer be used as the dynamic router port.
- If the receiving port is not a dynamic router port, use it as a dynamic router port and enable the aging timer. If the timer expires, the port will no longer be used as the dynamic router port.
- For general queries, reset the aging timer for all the dynamic member ports. If the timer expires, the port will no longer be used as the dynamic member port for the general group. By default, the maximum response time carried by the IGMP query packets is used as the timeout time of the aging timer. If **ip igmp snooping query-max-response-time** is run, the time displayed is used as the timeout time of the aging timer.
- For designated query packets, reset the aging timer for all the dynamic member ports of the designated profile. If the timer expires, the port will no longer be used as the dynamic member port of the designated profile. By default, the maximum response time carried by the IGMP query packets is used as the timeout time of the aging timer. If **ip igmp snooping query-max-response-time** is run, the time displayed is used as the timeout time of the aging timer.
- If dynamic router port learning is disabled, IGMP snooping will not learn the dynamic router port.

Report Packets

- When a member host receives a query, it responds to the query with a Report packet. If a host requests to join a profile, it will also send a report.
- By default, IGMP Snooping is capable of processing IGMPv1 and IGMPv2 packets. For IGMPv3 Report packets, it processes profile information but does not process carried source information. IGMP Snooping v3 can be configured to process all information in IGMPv1, IGMPv2, and IGMPv3 packets.

When the device running IGMP snooping receives the Report packets, it performs the following operations within the VLAN:

- Forward the Report packets from all the router ports. After the **ip igmp snooping suppression enable** command is run in one IGMP query cycle, only the first report received by each profile will be forwarded.

- If the port on which Report packets are received is a dynamic member port, reset the aging timer. If the timer expires, the port will no longer be used as the dynamic member port of the designated profile.
- If the port on which Report packets are received is not a dynamic member port, use it as a dynamic member port and enable the aging timer. If the timer expires, the port will no longer be used as the dynamic member port of the designated profile.

↳ Leave Packets

i If a host requests to leave a profile, it will send a Leave packet.

When the device running IGMP snooping receives the Leave packets, it performs the following operations within the VLAN:

- Forward the leave packets from all the router ports.
- If the port on which leave packets are received is a dynamic member port and the Leave function is enabled, the port will be immediately deleted from the IGMP snooping forwarding entry of the designated profile and will no longer be used as the dynamic member port.
- If the port on which the leave packets are received is a dynamic member port and the Leave function is disabled, the port state should be maintained.

Related Configuration

↳ Configuring a Static Router Port

Run the **ip igmp snooping vlan mrouter interface** command to configure a static router port.

↳ Configuring a Static Member Port

Run the **ip igmp snooping vlan static interface** command to configure a static member port.

↳ Enabling Report Suppression

Report suppression is disabled by default.

Run the **ip igmp snooping suppression enable** command to enable report suppression.

After report suppression is enabled, in one IGMP query cycle, only the first Report packet received by each profile will be forwarded. The source media access control (MAC) address of the forwarded report will be changed to the MAC address of the device.

↳ Enabling Immediate Leave

Immediate leave is disabled by default.

Run the **ip igmp snooping fast-leave enable** command to enable immediate leave.

↳ Enabling Dynamic Router Port Learning

Dynamic router port learning is enabled by default.

Run the **no ip igmp snooping mrouter learn pim-dvmrp** command to disable dynamic router port learning.

Run the **no ip igmp snooping vlan vid mrouter learn pim-dvmrp** command to disable dynamic router port learning for designated VLANs.

↘ **Configuring the Aging Time of a Dynamic Router Port**

The default aging time is 300s.

When a dynamic router port receives a query packet, the aging timer of the port is enabled or reset; if the aging time is not configured, the maximum response time carried by the query packet is used as the aging time.

Run **ip igmp snooping dyn-mr-aging-time** to configure the aging time of the dynamic router port.

↘ **Configuring the Aging Time of a Dynamic Member Port**

The default aging time is 260s.

When a dynamic member port receives a query packet, the aging timer of the port is enabled or reset, and the aging time is the maximum response time carried by the query packet.

When a dynamic member port receives a Report packet, the aging timer of the port is enabled or reset, and the aging time is the maximum response time of the dynamic member port.

Run **ip igmp snooping host-aging-time** to configure the aging time of the dynamic member port.

↘ **Configuring the Maximum Response Time of a Query Packet**

The maximum response time of a query packet is not configured by default and the maximum response time carries by the query packet is used.

Run **ip igmp snooping query-max-response-time** to configure the maximum response time of a query packet.

↘ **Configuring the IGMP Snooping Version**

The default version is IGMP Snooping v2, which processes only IGMPv1 and IGMPv2 packets. It conducts simple processing on IGMPv3 packets and does not process source information carried in packets.

Run the **ip igmp snooping version 3** command to configure IGMP Snooping v3 to process all information in IGMPv3 packets.

Run the **no ip igmp snooping version** command to restore IGMP Snooping v2.

8.3.2 IGMP Snooping Working Modes

Working Principle

↘ **IVGL**

In IVGL mode, a device running IGMP snooping can provide independent multicast services to each user VLAN.

Independent multicast services indicate that multicast traffic can be forwarded only within the VLAN it belongs to, and a user host can subscribe to the multicast traffic within the VLAN that the host belongs to.

↘ **SVGL**

In SVGL mode, a device running IGMP snooping can provide shared multicast services to the user VLAN.

Shared multicast services can be provided only on shared VLANs and sub VLANs and SVGL multicast addresses are used. In a shared VLAN, the multicast traffic within the range of SVGL multicast addresses is forwarded to a sub VLAN, and the user hosts within the sub VLAN subscribe to such multicast traffic from the shared VLAN.

- In a shared VLAN and sub VLAN, shared multicast services will be provided to the multicast traffic within the range of SVGL multicast addresses. Other multicast traffic will be discarded.
- Other VLANs (except shared VLANs and sub VLANs) apply to independent multicast services.

 When the user VLAN is set to a shared VLAN or sub VLAN, shared multicast services are provided; when a user VLAN is set to other VLANs, independent multicast services are provided.

IVGL-SVGL

IVGL-SVGL mode is also called the hybrid mode. In this mode, a device running IGMP snooping can provide both shared and independent multicast services to the user VLAN.

- In a shared VLAN and sub VLAN, multicast services will be provided to the multicast traffic within an SVGL profile. For other multicast traffic, independent multicast services will be provided.
- Other VLANs (except shared VLANs and sub VLANs) apply to independent multicast services.

 When a user VLAN is configured as a shared VLAN or sub VLAN, both public multicast services and independent multicast services are available. When a user VLAN is configured as a VLAN other than shared VLAN and sub VLAN, only the independent multicast services are available.

Related Configuration

Enabling IGMP Snooping and Selecting a Working Mode

IGMP snooping is disabled by default.

Run the **ip igmp snooping ivgl** command to enable IGMP snooping in IVGL mode.

Run the **ip igmp snooping svgl** command to enable IGMP snooping in SVGL mode.

Run the **ip igmp snooping ivgl-svgl** command to enable IGMP snooping in IVGL-SVGL mode.

A working mode must be designated when enabling IGMP snooping, namely, one of the preceding working modes must be selected.

Configuring Shared VLAN

The shared VLAN is VLAN 1 by default.

Run the **ip igmp snooping svgl vlan** command to designate a VLAN as the shared VLAN.

In SVGL mode and IVGL-SVGL mode, only one VLAN can be configured as the shared VLAN.

Configuring Sub VLAN

By default, a sub VLAN is any VLAN except the shared VLAN.

Run the **ip igmp snooping svgl subvlan** command to designate a VLAN as the sub VLAN.

In SVGL mode and IVGL-SVGL mode, the number of sub VLANs is not limited.

Configuring an SVGL Profile

No default setting.

Run the **ip igmp snooping svgl profile *profile_num*** command to configure the address range of an SVGL profile.

 In SVGL mode and IVGL-SVGL mode, the SVGL profile range must be configured; otherwise, shared multicast services cannot be provided.

8.3.3 IGMP Security Control

A device running IGMP snooping can control the multicast service scope and load, and effectively prevents illegal multicast traffic.

Working Principle

Configuring the Profile Filtering for User Demanding

By configuring the profile list that a user can access, you can customize the multicast service scope to guarantee the interest of operators and prevent illegal multicast traffic.

To enable this function, you should use a profile to define the range of multicast addresses that a user is allowed to access.

- When the profile is applied on a VLAN, you can define the multicast addresses that a user is allowed to access within the VLAN.
- When the profile is applied on an interface, you can define the multicast addresses that a user is allowed to access under the port.

Multicast Preview

If the service provider wants to allow the users to preview some multicast video traffic that denies the users' access, and stop the multicast video traffic after the preview duration is reached, the user-based multicast preview function should be provided.

The multicast preview function is used together with multicast permission control. For example, in the application of videos, the administrator controls some premium channels by running the **ip igmp profile** command on a port or VLAN. In this way, unsubscribed users will not be able to watch these channels on demand. If users want to preview the channels before they decide whether to pay for watching or not, the multicast preview function can be enabled, allowing the premium channels to be previewed by unpaid users for a certain period of time (for example 1 minute).

Controlling the Maximum Number of Profiles Allowed for Concurrent Request

If there is too much multicast traffic requested at the same time, the device will be severely burdened. Configuring the maximum number of profiles allowed for concurrent request can guarantee the bandwidth.

- You can limit the number of profiles allowed for concurrent request globally.
- You can also limit the number of profiles allowed for concurrent request on a port.

Controlling the Entry of Multicast Traffic

By running the **ip igmp snooping source-check port** command to enable source port inspection, you can restrict the entry of multicast traffic to prevent illegal traffic.

- When source port inspection is enabled, only the multicast traffic entered from the router port is considered as legal; the traffic from other ports is considered as illegal and will be discarded.
- When source port inspection is disabled, the traffic entered from any port is considered as legal.

Configuring the Source IP Inspection for Multicast Traffic

By enabling source IP inspection, you can restrict the IP address of multicast traffic to prevent illegal traffic.

Source IP inspection includes the inspection of the source IP addresses of specific profiles and of default profiles.

- Inspection of the source IP addresses of default profiles (also called source-check default-server): Specifies the source IP addresses for all the multicast profiles within all VLANs. Only the multicast traffic whose source IP address is the same as the set one is considered as legal.
- Inspection of the source IP addresses of specific profiles (also called limit-ipmc): Specifies the source IP addresses for specific multicast profiles within specific VLANs. Among the multicast traffic received from the specific multicast profiles within the VLANs, only the one with the same source IP address as the set one is considered as legal and will be forwarded by the multicast device; other traffic will be discarded.

Related Configuration

↳ Configuring the Profile Filtering

By default, profiles are not filtered and allow user access.

To filter multicast profiles, run the **ip igmp snooping filter** command in interface configuration mode or global configuration mode.

↳ Enabling Preview

Preview is not enabled by default.

Run the **ip igmp snooping preview** command to enable preview and restrict the range of the profiles permitted for multicast preview.

Run the **ip igmp snooping preview interval** to set the multicast preview duration.

↳ Configuring the Maximum Number of Profiles Allowed for Concurrent Request on a Port

By default, the number of profiles allowed for concurrent request is not limited.

Run the **ip igmp snooping max-groups** command to configure the maximum number of profiles allowed for concurrent request.

↳ Configuring the Maximum Number of Multicast Profiles Allowed Globally

By default, the maximum number of multicast profiles allowed globally is 65,536.

Run the **ip igmp snooping l2-entry-limit** command to configure the maximum number of multicast profiles allowed globally.

↳ Enabling Source Port Inspection

By default, source port inspection is not configured.

Run the **ip igmp snooping source-check port** command to enable source port inspection.

↳ Enabling Source IP Inspection

By default, source IP inspection is disabled.

- Run the **ip igmp snooping source-check default-server address** command to enable source IP inspection and specify the default source IP address (applicable to any profile of any VLAN).
- (Optional) Run the **ip igmp snooping limit-ipmc vlan vid address group-address server source-address** command to specify a specific source IP address for a specific profile of specific VLAN (applicable to a specific profile of specific VLAN).

First, you must enable source IP inspection to specify default source address, and then a specific source address can be specified for a specific profile of specific VLAN. If a source address is specified for a specific profile of specific VLAN, the multicast traffic of the specific profile will perform inspection for the source address specified by this command. Other multicast traffic will perform inspection for default source addresses.

8.3.4 IGMP Profile

A multicast profile is used to define the range of multicast addresses that permit or deny user demanding request for reference of other functions.

Working Principle

The profile is used to define the range of multicast addresses.

When SVGL mode is enabled, an SVGL profile is used to define the range of SVGL multicast addresses.

When the multicast filter is configured on an interface, a profile is used to define the range of multicast addresses that permit or deny user request under the interface.

When a VLAN filter is configured, a profile is used to define the range of multicast addresses that permit or deny user request under within the VLAN.

When the preview function is enabled, a profile is used to define the range of multicast address allowed for preview.

Related Configuration

↳ Configuring a Profile

Default configuration:

- Create a profile, which is **deny** by default.

Configuration steps:

- Run the **ip igmp profile** *profile-number* command to create a profile.
- Run the **range** *low-address high-address* command to define the range of multicast addresses. Multiple address ranges are configured for each profile.
- (Optional) Run the **permit** or **deny** command to permit or deny user request (**deny** by default). Only one **permit** or **deny** command can be configured for each profile.

8.3.5 IGMP QinQ

Working Principle

On a device with IGMP snooping enabled and dot1q-tunnel (QinQ) port configured, IGMP snooping will handle the IGMP packets received by the QinQ port using the following two approaches:

- Approach 1: Create a multicast entry on the VLAN where IGMP packets are located. The forwarding of IGMP packets on the VLAN where these packets are located is called transparent transmission. For example, presume that IGMP snooping is enabled for a device, Port A is designated as the QinQ port, the default VLAN of this port is VLAN 1, and it allows the passage of VLAN 1 and VLAN 10 packets. When a multicast Query packet is sent by VLAN 10 to Port A, IGMP snooping establishes a multicast entry for VLAN 10 and forwards the multicast Query packet to the router port of VLAN 10.

- Approach 2: Create a multicast entry on the default VLAN of the QinQ port. Encapsulate the multicast packet with the VLAN tag of the default VLAN where the QinQ port is located and forward the packet within the default VLAN. For example, presume that IGMP snooping is enabled for a device, Port A is designated as the QinQ port, the default VLAN of this port is VLAN 1, and it allows the passage of VLAN 1 and VLAN 10 packets. When a multicast Query packet is sent by VLAN 10 to Port A, IGMP snooping establishes a multicast entry for VLAN 1, encapsulates the multicast query packet with the tag of VLAN 1, and forward the packet to VLAN 1 router port.

Related Configuration

↳ Configuring QinQ

By default, IGMP snooping works in the mode specified in Approach 2.

Run the **ip igmp snooping tunnel** command to implement Approach 1.

8.3.6 IGMP Querier

On a network with a Layer-3 multicast device, the Layer-3 multicast device acts as an IGMP querier. In this case, a Layer-2 device needs only to listen to IGMP packets to establish and maintain the forwarding entry, realizing Layer-2 multicast.

On a network without a Layer-3 multicast device, the Layer-2 multicast device must be configured with the IGMP querier function so that the device can listen to IGMP packets. In this case, a Layer-2 device needs to act as an IGMP querier as well as listen to IGMP packets to establish and maintain the forwarding entry to realize Layer-2 multicast.

Working Principle

A Layer-2 device acts as an IGMP querier to periodically send IGMP Query packets, listen to and maintain the IGMP Report packets replied by a user, and create a Layer-2 multicast forwarding entry. You can adjust relevant parameters of the Query packets sent by the IGMP querier through configuration.

When the device receives a Protocol-Independent Multicast (PIM) or Distance Vector Multicast Routing Protocol (DVMRP) packet, it considers that a multicast router, which will act as an IGMP querier, exists on the network and disables the querier function. In this way, IGMP routing will not be affected.

When the device receives the IGMP Query packets from other devices, it will compete with other devices for the IGMP querier.

↳ Enabling the Querier Function

You can enable the querier for a specific VLAN or all VLANs.

Only when the global querier function is enabled can the queriers for specific VLANs take effect.

↳ Specifying the IGMP Version for a Querier

The version of IGMP used for sending Query packets can be configured as IGMPv1, IGMPv2, or IGMPv3.

↳ Configuring the Source IP Address of a Querier

You can configure the source IP address of a query packet sent by the querier based on VLANs.

When the source IP address of the querier is not configured, the querier will not take effect.

↳ Configuring the Query Interval of a Querier

You can configure the intervals for sending global Query packets based on different queriers on different VLANs.

✚ Configuring the Maximum Response Time of a Query Packet

You can configure the maximum response time carried by a Query packet that is sent by a querier. As IGMPv1 does not support the carrying of maximum response time by a Query packet, this configuration does not take effect when the querier is running IGMPv1. You can configure different maximum response time for queriers on different VLANs.

✚ Configuring the Aging Time of a Querier

When other IGMP queriers exist on a network, the existing device will compete with other queriers. If the existing device fails to be elected and is in the non-querier state, the aging timer of a querier will be enabled. After the timer expires, other queriers on the network are considered as expired and the existing device will be resumed as the querier.

Related Configuration

✚ Enabling the Querier Function

By default, the querier function of a device is disabled.

Run the **ip igmp snooping querier** command to enable the global querier function.

Run the **ip igmp snooping vlan *num* querier** command to enable the querier function for specific VLANs.

✚ Specifying the IGMP Version for a Querier

By default, a querier runs IGMPv2.

Run the **ip igmp snooping querier version** command to configure the global querier version.

Run the **ip igmp snooping vlan querier version** command to specify the querier version for specific VLANs.

✚ Configuring the Source IP Address of a Querier

By default, the source IP address of a querier is 0.

Run the **ip igmp snooping querier address** command to enable global source IP addresses of queriers.

Run the **ip igmp snooping vlan querier address** command to specify the source IP addresses of the queriers on specific VLANs.

✚ Configuring the Query Interval of a Querier

By default, the query interval of a querier is 60s.

Run the **ip igmp snooping querier query-interval** command to enable the global query interval of queriers.

Run **ip igmp snooping vlan querier query-interval** to specify the global query interval of the queriers on specific VLANs.

✚ Configuring the Maximum Response Time of a Query Packet

By default, the maximum response time of a query packet is 10s.

Run the **ip igmp snooping querier max-response-time** command to configure the maximum response time of the query packets sent by global queriers.

Run the **ip igmp snooping vlan querier max-response-time** command to specify the maximum response time of the query packets sent by the queriers on specific VLANs.

Configuring the Aging Time of a Querier

By default, the aging time of a querier is 125s.

Run the **ip igmp snooping querier max-response-time** command to configure the aging time of global queriers.

Run the **ip igmp snooping vlan querier max-response-time** command to configure the aging time of queriers on specific VLANs.

8.4 Configuration

Configuration	Description and Command	
Configuring Basic IGMP Snooping Functions (IVGL Mode)	 Any of IVGL mode, SVGL mode, and IVGL-SVGL mode must be selected. It is used to enable IGMP snooping in IVGL mode.	
	ip igmp snooping ivgl	Enables global IGMP snooping in IVGL mode.
	no ip igmp snooping vlan num	Disables IGMP snooping for a VLAN.
Configuring Basic IGMP Snooping Functions (SVGL Mode)	 Any of IVGL mode, SVGL mode, and IVGL-SVGL mode must be selected. It is used to enable IGMP snooping in SVGL mode.	
	ip igmp snooping svgl	Enables global IGMP snooping in IVGL mode.
	no ip igmp snooping vlan num	Disables IGMP snooping for a VLAN.
	ip igmp snooping svgl profile profile_num	Configures the SVGL profile.
	ip igmp snooping svgl vlan	Specifies the SVGL shared VLAN.
Configuring Basic IGMP Snooping Functions (IVGL-SVGL Mode)	 Any of IVGL mode, SVGL mode, and IVGL-SVGL mode must be selected. It is used to enable IGMP snooping in IVGL-SVGL mode.	
	ip igmp snooping ivgl-svgl	Enables global IGMP snooping in IVGL-SVGL mode.
	no ip igmp snooping vlan num	Disables IGMP snooping for a VLAN.
	ip igmp snooping svgl profile profile_num	Configures the SVGL profile.
	ip igmp snooping svgl vlan	Specifies the SVGL shared VLAN.
Configuring the Packet Processing	 (Optional) It is used to adjust relevant configurations for processing protocol packets.	
	ip igmp snooping vlan vlan-id mrouter interface interface-id	Configures a static router port.
	p igmp snooping vlan vid static group-address interface interface-type interface-number	Configures a static member port.

	ip igmp snooping vlan <i>vlan-id</i> mrouter learn pim-dvmrp	Enables dynamic router port learning.
	ip igmp snooping dyn-mr-aging-time <i>time</i>	Configures the aging time of a dynamic router port.
	ip igmp snooping host-aging-time <i>time</i>	Configures the aging time of a dynamic member port.
	ip igmp snooping fast-leave enable	Enables the immediate-leave function for a dynamic member port.
	ip igmp snooping query-max-response-time <i>time</i>	Configures the maximum response time of an IGMP query packet.
	ip igmp snooping suppression enable	Enables IGMP Report packet suppression.
	ip igmp snooping version <i>number</i>	Configures IGMP Snooping version.
Configuring IGMP Security Control	 (Optional) It used to guarantee the security when a user requests a multicast profile.	
	ip igmp snooping filter <i>profile-number</i>	Configures the profile filtering for user access.
	ip igmp snooping vlan <i>num</i> filter <i>profile-number</i>	Configures the per-VLAN profile filtering for user access.
	ip igmp snooping l2-entry-limit <i>number</i>	Configures the maximum number of profiles globally for user access.
	ip igmp snooping max-groups <i>number</i>	Configures the maximum number of dynamic profiles for user access.
	ip igmp snooping source-check port	Enables source IP inspection, which ensures the multicast traffic from the router port is legal.
	ip igmp snooping source-check default-server <i>address</i>	Enables source IP inspection. The multicast traffic whose source IP address matches the specified source IP address is considered as legal traffic.
	ip igmp snooping limit-ipmc vlan <i>vid</i> address <i>group-address</i> server <i>source-address</i>	Specifies a VLAN. In the multicast traffic of multicast addresses, the one whose source IP address matches the specified source IP address is considered as legal traffic.
	ip igmp snooping preview <i>profile-number</i>	Enables the preview function for a specified profile.
	ip igmp snooping preview interval <i>num</i>	Configures the preview duration.
Configuring an IGMP Profile	 (Optional) It is used to define the range of multicast addresses that permits or denies the access of a user host.	

	ip igmp profile <i>profile-number</i>	Creates a profile.
	range <i>low-address high_address</i>	Configures the profile range.
	permit	Permits the access of a user host.
	deny	Denies the access of a user host.
Configuring IGMP QinQ	 (Optional) It is used to configure QinQ interface to forward multicast packets using the VLAN identifier (VID) carried by packets.	
	ip igmp snooping tunnel	Configures QinQ to transmit IGMP packets transparently.
Configuring an IGMP Querier	 (Optional) It is used to enable IGMP querier function on a network without a Layer-3 multicast device.	
	ip igmp snooping querier	Enables global querier function.
	ip igmp snooping vlan <i>num</i> querier	Enables the querier for a VLAN.
	ip igmp snooping querier version <i>num</i>	Specifies the IGMP version for queriers globally.
	ip igmp snooping vlan <i>num</i> querier version <i>num</i>	Specifies the IGMP version for a querier of a VLAN.
	ip igmp snooping querier address a.b.c.d	Configures the source IP address of queriers globally.
	ip igmp snooping vlan <i>num</i> querier address a.b.c.d	Configures the source IP address for a querier of a VLAN.
	ip igmp snooping querier query-interval <i>num</i>	Configures the query interval of queriers globally.
	ip igmp snooping vlan <i>num</i> querier query-interval <i>num</i>	Configures the query interval for a querier of a VLAN.
	ip igmp snooping querier max-response-time <i>num</i>	Configures the maximum response time for query packets globally.
	ip igmp snooping vlan <i>num</i> querier max-response-time <i>num</i>	Configures the maximum response time of query packets for a VLAN.
	ip igmp snooping querier timer expiry <i>num</i>	Configures the aging timer for queriers globally.
ip igmp snooping vlan <i>num</i> querier timer expiry <i>num</i>	Configures the aging timer for a querier of a VLAN.	

8.4.1 Configuring Basic IGMP Snooping Functions (IVGL Mode)

Configuration Effect

- Enable IGMP snooping to realize Layer-2 multicast.
- Provide independent multicast services to each VLAN.

Notes

- IP multicast cannot be realized in SVGL mode. If IP multicast must be used, select the IVGL mode.

Configuration Steps

↳ Enabling Global IGMP Snooping in IVGL Mode

Mandatory.

After IGMP snooping is enabled globally, this function will be enabled for all VLANs.

If not specified, it is advised to run global IGMP snooping on all the devices connected user hosts.

↳ Disabling IGMP Snooping for a VLAN

(Optional) You can use this function if you wish to disable IGMP snooping on specified VLANs.

Only when global IGMP snooping is enabled can it be disabled on specified VLANs.

In IVGL mode, each VLAN can enjoy independent multicast services. Disabling any VLAN multicast services will not interfere in the services provided to the others.

Verification

- Run the **show ip igmp snooping gda-table** command to display the IGMP snooping forwarding table and verify that the member ports include only those connecting member hosts.
- Run the **show ip igmp snooping** command to display the basic IGMP snooping information and verify that IGMP snooping is working in IVGL mode.

Related Commands

↳ Enabling Global IGMP Snooping in IVGL Mode

Command	ip igmp snooping ivgl
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After this command is executed, IGMP snooping will be run on all VLANs. By default, IGMP snooping is disabled.

↳ Disabling IGMP Snooping for a VLAN

Command	no ip igmp snooping vlan <i>num</i>
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Only when global IGMP snooping is enabled can it be disabled on specified VLANs.

In IVGL mode, you can disable IGMP snooping on any VLAN.

▾ **Displaying the IGMP Snooping Entry**

Command	show ip igmp snooping gda-table
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	This command is used to verify that the ports include only those connecting member hosts.

▾ **Displaying the IGMP Snooping Working Mode**

Command	show ip igmp snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If a device is running in IVGL mode, the following information is displayed: <pre>IGMP Snooping running mode: IVGL</pre>

Configuration Example

▾ **Providing Layer-2 Multicast Services for the Subnet Hosts**

<p>Scenario Figure 8-5</p>	
	<p>A is the multicast router and is connected directly to the multicast source. B is the Layer-2 device and is connected directly to the user host. Receiver 1, Receiver 2, and Receiver 3 belong to VLAN 1.</p>
Configuration Steps	<ul style="list-style-type: none"> ● Configure the IP address and VLAN. ● Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1)

	<p>and VLAN 1).</p> <ul style="list-style-type: none"> ● Enable IGMP snooping on B and select IVGL mode.
A	<pre>A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode A(config-if-GigabitEthernet 0/1)# exit A(config)# interface vlan 1 A(config-if-VLAN 1)# ip pim sparse-mode A(config-if-VLAN 1)# exit</pre>
B	<pre>B# configure terminal B(config)# ip igmp snooping ivgl</pre>
Verification	<p>Send packets from the source (10.1.1.1) to G (229.1.1.1) to add Receiver 1 to G.</p> <ul style="list-style-type: none"> ● Confirm that the packets (10.1.1.1 and 229.1.1.1) are received by Receiver 1. ● Display the IGMP snooping forwarding entry on B and ensure that the port (10.1.1.1, 229.1.1.1, 1) includes only Fa0/2. ● Check whether the IGMP snooping working mode is IVGL.
B	<pre>B# show ip igmp snooping gda-table Multicast Switching Cache Table D: DYNAMIC S: STATIC M: MROUTE (*, 224.1.1.1, 1): VLAN(1) 2 OPORTS: FastEthernet 0/1 (M) FastEthernet 0/2 (D)</pre> <pre>B# show ip igmp snooping IGMP Snooping running mode: IVGL IGMP Snooping L2-entry-limit: 65536 Source port check: Disable Source ip check: Disable IGMP Fast-Leave: Disable IGMP Report suppress: Disable IGMP Global Querier: Disable</pre>

```

IGMP Preview: Disable
IGMP Tunnel: Disable
IGMP Preview group aging time : 60(Seconds)

Dynamic Host Aging Time : 260(Seconds)

vlan 1
-----

IGMP Snooping state: Enable
Multicast router learning mode: pim-dvmrp
IGMP Fast-Leave: Disabled
IGMP VLAN querier: Disable
IGMP VLAN Mode: STATIC

```

Common Errors

- The working mode of IGMP snooping is improper.

8.4.2 Configuring Basic IGMP Snooping Functions (SVGL Mode)

Configuration Effect

- Enable IGMP snooping and select SVGL mode to realize Layer-2 multicast.
- Share the VLAN multicast services.

Configuration Steps

▾ Enabling Global IGMP Snooping in SVGL Mode

Mandatory.

Enable global IGMP snooping in SVGL mode.

Configure the range of associated SVGL profiles.

▾ Specifying the SVGL Shared VLAN

(Optional) By default, VLAN 1 is used as the shared VLAN. You can adjust this configuration for other options.

▾ Specifying the SVGL Sub VLAN

(Optional) By default, all the VLANs are used as the sub VLANs of SVGL and can share the multicast services of the shared VLAN. You can adjust this configuration for other options.

Verification

- Run the **show ip igmp snooping** command to display the basic IGMP snooping information and verify that IGMP snooping is working in SVGL mode.

- Run the **show ip igmp snooping gda-table** command to check whether inter-VLAN multicast entries are properly formed.

Related Commands

↳ Enabling Global IGMP Snooping in SVGL Mode

Command	ip igmp snooping svgl
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	By default, IGMP snooping is disabled. After the SVGL mode is selected, the range of profiles within SVGL multicast addresses needs to be associated.

↳ Configuring the SVGL profile

Command	ip igmp snooping svgl profile <i>profile_num</i>
Parameter Description	<i>profile_num</i> : Configures SVGL to associate a profile.
Command Mode	Global configuration mode
Usage Guide	By default, no profile is associated with SVGL.

↳ Specifying the SVGL Shared VLAN

Command	ip igmp snooping svgl vlan <i>vid</i>
Parameter Description	<i>vid</i> : Indicates a VLAN.
Command Mode	Interface configuration mode
Usage Guide	By default, VLAN 1 is used as the shared VLAN.

↳ Specifying the SVGL Sub VLAN

Command	ip igmp snooping svgl subvlan <i>vid-range</i>
Parameter Description	<i>vid-range</i> : Indicates VLAN ID or the range of VLAN IDs.
Command Mode	Interface configuration mode
Usage Guide	By default, all the VLANs except the shared VLAN are used as sub VLANs.

↳ Displaying the IGMP Snooping Working Mode

Command	show ip igmp snooping
----------------	------------------------------

Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If a device is running in SVGL mode, the following information is displayed: <div style="background-color: #f0f0f0; padding: 5px; border: 1px solid #ccc;"> IGMP Snooping running mode: SVGL </div>

Configuration Example

Enabling SVGL on the Access Device

<p>Scenario Figure 8-6</p>	
	<p>A is the multicast router and is connected directly to the multicast source. B is the Layer-2 device and is connected directly to the user host. Receiver 1 is connected to VLAN 2, Receiver 2 is connected to VLAN 3, and Receiver 3 is connected to VLAN 4.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure the IP address and VLAN. (Omitted) ● Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1 and VLAN 1). ● Enable IGMP snooping on B and select SVGL mode. ● Configure the range of associated SVGL multicast addresses on B.
<p>A</p>	<pre> A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode A(config-if-GigabitEthernet 0/1)# exit A(config)# interface vlan 1 A(config-if-VLAN 1)# ip pim sparse-mode A(config-if-VLAN 1)# exit </pre>

B	<pre> B# configure terminal B(config)#ip igmp profile 1 B(config-profile)#permit B(config-profile)#range 224.1.1.1 238.1.1.1 B(config-profile)#exit B(config)#ip igmp snooping svgl B(config)#ip igmp snooping svgl profile 1 </pre>
Verification	<p>Send packets from the source (10.1.1.1) to G (229.1.1.1) and add Receiver 1, Receiver 2 and Receiver 3 to G.</p> <ul style="list-style-type: none"> ● Confirm that the packets (10.1.1.1 and 224.1.1.1) are received by Receiver 1, Receiver 2, and Receiver 3. ● Display the IGMP snooping forwarding entry on B and ensure that the ports (*, 224.1.1.1, 1) include Gi0/2, Gi0/3, and Gi0/4. ● Check whether the IGMP snooping working mode is SVGL.
B	<pre> B# show ip igmp snooping gda-table Multicast Switching Cache Table D: DYNAMIC S: STATIC M: MROUTE (*, 224.1.1.1, 1): VLAN(2) 1 OPORTS: GigabitEthernet 0/2(D) VLAN(3) 1 OPORTS: GigabitEthernet 0/3(D) VLAN(4) 1 OPORTS: GigabitEthernet 0/4(D) B# show ip igmp snooping IGMP Snooping running mode: SVGL IGMP Snooping L2-entry-limit: 65536 SVGL vlan: 1 SVGL profile number: 1 Source port check: Disable Source ip check: Disable IGMP Fast-Leave: Disable </pre>

```

IGMP Globle Querier: Disable
IGMP Preview: Disable
IGMP Tunnel: Disable
IGMP Preview group aging time : 60(Seconds)
Dynamic Mroute Aging Time : 300(Seconds)
Dynamic Host Aging Time : 260(Seconds)
```

Common Errors

- The SVGL profile is not configured.
- The sent multicast traffic is not within the SVGL profile.

8.4.3 Configuring Basic IGMP Snooping Functions (IVGL-SVGL Mode)

Configuration Effect

- Enable IGMP snooping and select IVGL-SVGL mode to realize Layer-2 multicast.
- The SVGL profiles can share the multicast services.
- The non-SVGL profiles run in IVGL mode.

Configuration Steps

↳ Enabling Global IGMP Snooping in IVGL-SVGL Mode

Mandatory.

Enable global IGMP snooping in IVGL-SVGL mode.

Configure the range of associated SVGL profiles.

↳ Specifying the SVGL Shared VLAN

(Optional) By default, VLAN 1 is used as the shared VLAN. You can adjust this configuration for other options.

↳ Specifying the SVGL Sub VLAN

(Optional) By default, all the VLANs are used as the sub VLANs of SVGL and can share the multicast services of the shared VLAN. You can adjust this configuration for other options.

Verification

- Run the **show ip igmp snooping** command to display the basic IGMP snooping information and verify that IGMP snooping is working in IVGL-SVGL mode.
- Run the **show ip igmp snooping gda-table** command to check whether inter-VLAN multicast entries are properly formed for the SVGL profiles.
- Run the **show ip igmp snooping gda-table** command to check whether intra-VLAN multicast entries are properly formed for the SVGL profiles.

Related Commands

↳ Enabling Global IGMP Snooping in IVGL-SVGL Mode

Command	ip igmp snooping ivgl-svgl
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	By default, IGMP snooping is disabled. After the IVGL-SVGL mode is selected, the SVGL profiles needs to be associated.

↳ Configuring the SVGL Profile

Command	ip igmp snooping svgl profile <i>profile_num</i>
Parameter Description	<i>profile_num</i> : Configures SVGL to associate a profile.
Command Mode	Global configuration mode
Usage Guide	By default, no profile is associated with SVGL.

↳ Specifying the SVGL Shared VLAN

Command	ip igmp snooping svgl vlan <i>vid</i>
Parameter Description	<i>vid</i> : Indicates a VLAN.
Command Mode	Interface configuration mode
Usage Guide	By default, VLAN 1 is used as the shared VLAN.

↳ Specifying the SVGL Sub VLAN

Command	ip igmp snooping svgl subvlan <i>vid-range</i>
Parameter Description	<i>vid-range</i> : Indicates VLAN ID or the range of VLAN IDs.
Command Mode	Interface configuration mode
Usage Guide	By default, all the VLANs except the shared VLAN are used as sub VLANs.

↳ Displaying the IGMP Snooping Working Mode

Command	show ip igmp snooping
Parameter Description	N/A
Command	Privileged EXEC mode, global configuration mode, or interface configuration mode

Common Errors

- The SVGL profile is not configured.
- The sent multicast traffic is not within the SVGL profile.
- The IVGL multicast traffic cannot be forwarded within the SVGL profile.

8.4.4 Configuring the Packet Processing

Configuration Effect

- Configure specified ports as the static router ports to receive the multicast traffic from all profiles.
- Configure specified ports as the static member ports to receive the multicast traffic from specified profiles

- Enable Report packets suppression to forward only the first Report packet from a specified VLAN or profile to the router port within a query interval, and the following Report packets will not be forwarded to the router port, thereby reducing the quantity of packets on the network.
- Configure the immediate-leave function to delete a port from the entry of member ports when a leave packet is received by the port.
- Disable dynamic router port learning to disable the learning of any router port.
- Based on network load and configuration of a multicast device, you can adjust the aging time of a router port and member port as well as the maximum response time of a query packet.

Notes

- Only when basic IGMP snooping is configured can relevant configurations take effect.

Configuration Steps

▾ Configuring a Static Router Port

- Optional.
- You can perform this configuration if you want to specify a static port to receive all the multicast traffic within the VLAN.

▾ Configuring a Static Member Port

- Optional.
- You can perform this configuration if you want to specify a static port to receive specific multicast traffic within the VLAN.

▾ Enabling Report Packet Suppression

- Optional.
- When there are numerous receivers to receive the packets from the same multicast profile, you can enable Report packets suppression to suppress the number of Report packets to be sent.

▾ Enabling the Immediate-Leave Function

- Optional.
- When there is only one receiver on a port, you can enable Leave to speed up the convergence of protocol upon leave.

▾ Disabling Dynamic Router Port Learning

- Optional.
- This function is used when multicast traffic needs to be forwarded only within the Layer-2 topology but not to a Layer-3 router.

▾ Configuring the Aging Time of a Dynamic Router Port

- Optional.
- You can configure the aging time based on network load.

▾ Configuring the Aging Time of a Dynamic Member Port

- Optional.
- You can configure the aging time based on the interval for sending IGMP query packets by the connected multicast router. Typically, the aging time is calculated as follows: Interval for sending IGMP query packets x 2 + Maximum response time of IGMP packets

▾ Configuring the Maximum Response Time of a Query Packet

- Optional.
- You can configure the aging time based on network load.

Verification

- Run the **show ip igmp snooping mrouter** command to check whether the configured static router port has an "S" in the displayed configuration information.
- Run the **show ip igmp snooping gda** command to check whether the configured static member port is marked with an S.
- Run the **show ip igmp snooping** command to check whether Report packets suppression, immediate leave, router port learning, router port aging time, member port aging time, and the maximum response time of the Query packet take effect.

Related Commands

▾ Configuring a Static Router Port

Command	ip igmp snooping vlan <i>vid</i> mrouter interface <i>interface-type interface-number</i>
Parameter Description	<i>vid</i> : Indicates a VLAN. The value ranges from 1 to 4,094. <i>interface-type interface-number</i> : Indicates an interface name.
Command Mode	Global configuration mode
Usage Guide	In SVGL mode, if a sub VLAN is not configured, only the configurations for the static router port within the shared VLAN can take effect, and the others can be configured but cannot take effect. If a sub VLAN is configured, only the configurations for the static router port within the shared VLAN or a non-sub VLAN can take effect, and the others can be configured but cannot take effect. In IVGL-SVGL mode, if a sub VLAN is not configured, the configurations for the static router ports within all the VLANs can take effect; if a sub VLAN is configured, only the configurations for the static router port within the shared VLAN or a non-sub VLAN can take effect, and the others can be configured but cannot take effect. In IVGL mode, the configurations for the static router ports within all the VLANs can take effect.

▾ Configuring a Static Member Port

Command	ip igmp snooping vlan <i>vid</i> static <i>group-address</i> interface <i>interface-type interface-number</i>
Parameter Description	<i>vid</i> : Indicates a VLAN. The value ranges from 1 to 4,094. <i>group-address</i> : Indicates a profile address.

	<i>interface-type interface-number</i> : Indicates an interface name.
Command Mode	Global configuration mode
Usage Guide	By default, no static member port is configured.

↳ Enabling Report Packet Suppression

Command	ip igmp snooping suppression enable
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	<p>When Report packets suppression is enabled, only the first Report packet from a specified VLAN or profile is forwarded to the router port within a Query interval, and the following Report packets will not be forwarded to the router port, thereby reducing the quantity of packets on the network.</p> <p>Only the IGMPv1 and IGMPv2 Report packets can be suppressed, and the IGMPv3 Report packets cannot be suppressed.</p>

↳ Enabling the Immediate-Leave Function

Command	ip igmp snooping fast-leave enable
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	<p>When this function is enabled, a port will be deleted from the entry of the member port when the port receives a leave packet. After that, the packets will no longer be forwarded to this port when it receives the query packets of specified profiles. Leave packets include the IGMPv2 Leave packets as well as the IGMPv3 Report packets that include types but carry no source address.</p> <p>The immediate-leave function applies only to the scenario where only one host is connected to a device port. It is used to conserve bandwidth and resources.</p>

↳ Enabling Dynamic Router Port Learning

Command	ip igmp snooping [vlan <i>vid</i>] mrouter learn pim-dvmrp
Parameter Description	vlan <i>vid</i> : Specifies a VLAN. This configuration applies to all VLANs by default.
Command Mode	Global configuration mode
Usage Guide	A router port is the port that is connected directly to a multicast device running IGMP snooping and a multicast neighbor device running multicast routing protocol. By default, dynamic router port learning is enabled and the device automatically listens to IGMP Query packets, DVMRP packets, and PIM Hello packets.

▾ Configuring the Aging Time of a Dynamic Router Port

Command	ip igmp snooping dyn-mr-aging-time <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the aging time of a dynamic router port in the unit of seconds. The value ranges from 1 to 3,600.
Command Mode	Global configuration mode
Usage Guide	<p>If a dynamic router port does not receive an IGMP general query packet or a PIM Hello packet before the aging timer expires, the device will delete this port from the router port entry.</p> <p>When dynamic router port learning is enabled, you can run this command to adjust the aging time of the dynamic router port. If the aging time is too short, the multicast device may frequently add or delete a router port.</p>

▾ Configuring the Aging Time of a Dynamic Member Port

Command	ip igmp snooping host-aging-time <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the aging time.
Command Mode	Global configuration mode
Usage Guide	<p>The aging time of a dynamic member port indicates the time when a device port receives the IGMP join packet sent from host for subscribing to an IP multicast profile.</p> <p>When the IGMP join packet is received, the aging time of the dynamic member port will be reset. The value of the timer time is host-aging-time. If the timer expires, the multicast device deems that no user host for receiving the multicast packet exists under the port, and will delete the port from the entry of IGMP snooping member port. After the aging time is configured, the aging time of following received IGMP join packets will be host-aging-time. This configuration takes effect after the next IGMP join packet is received, and the timer of the port in use will not be refreshed.</p>

▾ Configuring the Maximum Response Time of a Query Packet

Command	ip igmp snooping query-max-response-time <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the maximum response time.
Command Mode	Global configuration mode
Usage Guide	<p>When an IGMP general Query packet is received, the multicast device will reset the aging time of all the dynamic member ports, which is query-max-response-time. If the timer expires, the multicast device deems that no user host for receiving the multicast packet exists under the port, and will delete the port from the entry of IGMP snooping member port.</p> <p>When an IGMP profile-specific Query packet is received, the multicast device will reset the aging time of all the dynamic member ports of the specific profile, which is query-max-response-time. If the timer expires, the multicast device deems that no user host for receiving the multicast packet exists under the port, and will delete the port from the entry of IGMP snooping member port.</p>

	This configuration takes effect after the next Query packet is received, and the timer in use will not be refreshed. The timer of an IGMPv3 profile-specific Query packet is not refreshed.
--	---

▾ Displaying Router Ports

Command	show ip igmp snooping mroute
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	<p>If the router port is successfully configured, an "S" will be displayed in the port information.</p> <pre>Ruijie(config)#show ip igmp snooping mrouter Multicast Switching Mroute Port D: DYNAMIC S: STATIC (*, *, 1): VLAN(1) 1 MROUTES: GigabitEthernet 0/1(S)</pre>

▾ Displaying the Information of Dynamic Router Port Learning

Command	show ip igmp snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	<p>Run the show ip igmp snooping command to display the aging time and learning status of the dynamic router port.</p> <pre>Dynamic Mroute Aging Time : 300(Seconds) Multicast router learning mode: pim-dvmrp</pre>

▾ Displaying the Information of a Member Port

Command	show ip igmp snooping gda-table
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If the member port is successfully configured, an "S" will be displayed in the port information.

```
Ruijie(config)#show ip igmp snooping gda-table
Multicast Switching Cache Table

D: DYNAMIC

S: STATIC

M: MROUTE

(*, 224.1.1.1, 1):

VLAN(1) 1 OPORTS:

GigabitEthernet 0/1(S)
```

📄 **Displaying Other Parameters**

Command	show ip igmp snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	Run the show ip igmp snooping command to display the aging time of the router port, aging time of the dynamic member port, response time of the query packet, and Report packets suppression, and immediate leave. <pre>IGMP Fast-Leave: Enable IGMP Report suppress: Enable Query Max Response Time: 20(Seconds) Dynamic Mroute Aging Time : 300(Seconds) Dynamic Host Aging Time : 260(Seconds)</pre>

Configuration Example

📄 **Configuring a Static Router Port and Static Member Port**

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic IGMP snooping functions. ● Configure a static router port and static member port.
	<pre>Ruijie# configure terminal Ruijie(config)# ip igmp snooping vlan 1 mrouter interface GigabitEthernet 0/0 Ruijie(config)# ip igmp snooping vlan 1 static 224.1.1.1 interface GigabitEthernet 0/0 Ruijie(config)# end</pre>
Verification	Run the show ip igmp snooping mrouter and show ip igmp snooping gda-table commands to check whether the configuration takes effect.
	<pre>Ruijie#show ip igmp snooping mrouter</pre>

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic IGMP snooping functions. ● Configure a static router port and static member port.

Verification	Run the show ip igmp snooping mrouter and show ip igmp snooping gda-table commands to check whether the configuration takes effect.
	<pre>Multicast Switching Mroute Port D: DYNAMIC S: STATIC (*, *, 1): VLAN(1) 1 MROUTES: GigabitEthernet 0/0(S) Ruijie#show ip igmp snooping gda-table Multicast Switching Cache Table D: DYNAMIC S: STATIC M: MROUTE (*, 224.1.1.1, 1): VLAN(1) 1 OPORTS: GigabitEthernet 0/0(SM)</pre>

➤ Enabling Report Packet Suppression

Scenario
Figure 8-8

A is the multicast router and is connected directly to multicast Source 1.
 B is a Layer-2 device and is connected directly to the user host and multicast Source 2.
 Receiver 1, Receiver 2, and Receiver 3 are connected to VLAN 1.

Configuration Steps

- Configure the IP address and VLAN. (Omitted)
- Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1 and VLAN 1).
- Enable IGMP snooping on B and select IVGL mode.
- Enable Report packets suppression on B.

A

```
A# configure terminal
A(config)# ip multicast-routing
A(config)# interface GigabitEthernet 0/1
A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode
A(config-if-GigabitEthernet 0/1)# exit
A(config)# interface vlan 1
A(config-if-VLAN 1)# ip pim sparse-mode
A(config-if-VLAN 1)# exit
```

B

```
B# configure terminal
B(config)# ip igmp snooping ivgl
B(config)# ip igmp snooping suppression enable
```

Verification

Check whether Receiver 1 and Receiver 2 are added to profile 239.1.1.1, and only the IGMP Report packets of profile 239.1.1.1 are forwarded from interface Gi0/1 of B.

B

```
B# show ip igmp snooping
IGMP Snooping running mode: IVGL
```

	<pre> IGMP Snooping L2-entry-limit: 65536 Source port check: Disable Source ip check: Disable IGMP Fast-Leave: Disable IGMP Report suppress: Enable IGMP Globle Querier: Disable IGMP Preview: Disable IGMP Tunnel: Disable IGMP Snooping version: 2IGMP Preview group aging time : 60(Seconds) Dynamic Mroute Aging Time : 300(Seconds) Dynamic Host Aging Time : 260(Seconds) </pre>
--	--

↘ Configuring Other Parameters

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic IGMP snooping functions. ● Enable Immediate-leave function. ● Disable router port learning. ● Configure the aging time of a router port. ● Configuring the aging time of a member port. ● Configure the response time of a Query packet.
	<pre> Ruijie# configure terminal Ruijie(config)# ip igmp snooping fast-leave enable Ruijie(config)# no ip igmp snooping mrouter learn pim-dvmrp Ruijie(config)#ip igmp snooping dyn-mr-aging-time 200 Ruijie(config)#ip igmp snooping host-aging-time 100 Ruijie(config)#ip igmp snooping query-max-response-time 60 Ruijie(config)# end </pre>
Verification	Run the show ip igmp snooping command to check whether the configuration is successful.
	<pre> Ruijie#show ip igmp snooping IGMP Snooping running mode: IVGL IGMP Snooping L2-entry-limit: 65536 Source port check: Disable Source ip check: Disable IGMP Fast-Leave: Enable IGMP Report suppress: Enable IGMP Globle Querier: Disable </pre>

```
IGMP Preview: Disable
IGMP Tunnel: Disable
IGMP Snooping version: 2Query Max Response Time: 60(Seconds)
IGMP Preview group aging time : 60(Seconds)
Dynamic Mroute Aging Time : 200(Seconds)
Dynamic Host Aging Time : 100(Seconds)
```

Common Errors

- Basic IGMP snooping functions are not configured or the configuration is not successful.

8.4.5 Configuring IGMP Security Control

Configuration Effect

- Configure the range of multicast addresses that a user can access.
- Configure to allow a user from an unauthorized profile to preview a multicast channel.
- Configure the number of multicast addresses that a user can access.
- Configure to limit a user to receive only the multicast traffic from a router port to prevent illegal multicast traffic sent by the end user.
- Configure to limit a user to receive only the multicast traffic from designated source IP addresses to prevent illegal multicast traffic.

Notes

- Basic IGMP snooping functions must be configured.

Configuration Steps

▾ Configuring the Profile Filtering

- Optional.
- If you want to limit the profile packets to be received by a port, you can configure the profile filtering on the port.
- If you want to limit the multicast packets to be received by a VLAN, you can configure the per-VLAN profile filtering.

▾ Enabling Multicast Preview

- Optional.
- You can enable multicast preview for a user from an unauthorized profile.

▾ Configuring the Maximum Number of Profiles

- Optional.
- If you want to limit the number of multicast profiles that a port is allowed to receive, you can configure the maximum number of multicast profiles allowed for this port.

- If you want to limit the number of multicast profiles that global ports are allowed to receive, you can configure the maximum number of multicast profiles allowed for these ports.

↳ Configuring Source Port Inspection

- Optional.
- You can perform this configuration if you want to allow a port to receive only the multicast traffic from the router port.

↳ Configuring Source IP Inspection

- Optional.
- You can perform this configuration to specify the source IP address for all the multicast profiles of all VLANs. Only the multicast traffic whose source IP address is the same as the set one is considered as legal.
- You can also specify the source IP addresses for specific multicast profiles within specific VLANs. Among the multicast traffic received from the specific multicast profiles within the VLANs, only the one with the same source IP address as the set one is considered as legal and will be forwarded by the multicast device; other traffic will be discarded.

Verification

- Run the **show ip igmp snooping interfaces** command to display the profile filtering and the maximum number of multicast profiles for a port.
- Run the **show ip igmp snooping vlan** command to display the per-VLAN profile filtering.
- Run the **show ip igmp snooping** command to check whether the maximum number of global multicast profiles, preview function, source port inspection, and source IP address inspection take effect.

Related Commands

↳ Configuring the Profile Filtering

Command	ip igmp snooping filter <i>profile-number</i>
Parameter Description	<i>profile-number</i> : Indicates a profile number.
Command Mode	Interface configuration mode
Usage Guide	N/A

↳ Configuring the Per-VLAN Profile Filtering

Command	ip igmp snooping vlan <i>vid filter profile-number</i>
Parameter Description	<i>vid</i> : Indicates a VLAN. The value ranges from 1 to 4,094. <i>profile-number</i> : Indicates a profile number.
Command Mode	Global configuration mode
Usage Guide	N/A

↳ Configuring the Maximum Number of Profiles on a Port

Command	ip igmp snooping max-groups <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of multicast profiles.
Command Mode	Interface configuration mode
Usage Guide	This value indicates only the number of dynamic multicast profiles, and the number of static profiles is not included. The counter of multicast profiles is based on the VLAN that the port belongs to. For example, if a port belongs to three VLANs, and all three of them receive a request packet from multicast profile 224.1.1.1 simultaneously, then the counter of multicast profiles will be 3 but not 1.

↘ Configuring the Maximum Number of Global Profiles

Command	ip igmp snooping l2-entry-limit <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of multicast profiles.
Command Mode	Global configuration mode
Usage Guide	This value includes the number of both dynamic profiles as well as static profiles.

↘ Configuring Source Port Inspection

Command	ip igmp snooping source-check port
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After source port inspection is enabled, the multicast traffic received by a device will be discarded if no router port is detected in the network environment.

↘ Configuring Source IP Inspection

Command	ip igmp snooping source-check default-server <i>source-address</i>
Parameter Description	<i>source-address</i> : Indicates the source IP address.
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Enabling Source IP Inspection for a Specific Profile

Command	ip igmp snooping limit-ipmc vlan <i>vid</i> address <i>group-address</i> server <i>source-address</i>
Parameter Description	<i>vid</i> vlan id <i>group-address</i> : Indicates a profile address. <i>source-address</i> : Indicates the source IP address.

Command Mode	Global configuration mode
Usage Guide	N/A

↳ Enabling Preview

Command	ip igmp snooping preview <i>profile-number</i>
Parameter Description	<i>profile number</i> : Indicates the range of multicast addresses allowed for preview. The value ranges from 1 to 1,024.
Command Mode	Global configuration mode
Usage Guide	N/A

↳ Configuring the Preview Duration

Command	ip igmp snooping preview interval <i>num</i>
Parameter Description	<i>num</i> : Specifies the preview duration which ranges from 1s to 300s (60s by default).
Command Mode	Global configuration mode
Usage Guide	This configuration allows unauthorized users to receive multicast traffic within the preview duration. After the duration is met, the preview will be stopped; the preview can be resumed in 300s.

↳ Displaying the Per-Port Profile Filtering

Command	show ip igmp snooping interface									
Parameter Description	N/A									
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode									
Usage Guide	<p>If the function is configured, the profile will be displayed, for example:</p> <pre>Ruijie#show ip igmp snooping interfaces gigabitEthernet 0/1</pre> <table border="1"> <thead> <tr> <th>Interface</th> <th>Filter profile number</th> <th>max-group</th> </tr> <tr> <th>-----</th> <th>-----</th> <th>-----</th> </tr> </thead> <tbody> <tr> <td>GigabitEthernet 0/1</td> <td>1</td> <td></td> </tr> </tbody> </table>	Interface	Filter profile number	max-group	-----	-----	-----	GigabitEthernet 0/1	1	
Interface	Filter profile number	max-group								
-----	-----	-----								
GigabitEthernet 0/1	1									

↳ Displaying the Per-VLAN Profile Filtering

Command	show ip igmp snooping vlan
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode

Usage Guide	If the function is configured, the profile will be displayed, for example: <pre>IGMP VLAN filter: 1</pre>
--------------------	--

↳ **Displaying the Maximum Number of Interface Profiles**

Command	show ip igmp snooping interface						
Parameter Description	N/A						
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode						
Usage Guide	If the maximum number of multicast addresses for a port is configured, the value will be displayed, for example: <pre>Ruijie#show ip igmp snooping interfaces gigabitEthernet 0/1</pre> <table border="1"> <thead> <tr> <th>Interface</th> <th>Filter profile number</th> <th>max-group</th> </tr> </thead> <tbody> <tr> <td>GigabitEthernet 0/1</td> <td>1</td> <td>200</td> </tr> </tbody> </table>	Interface	Filter profile number	max-group	GigabitEthernet 0/1	1	200
Interface	Filter profile number	max-group					
GigabitEthernet 0/1	1	200					

↳ **Displaying the Maximum Number of Global Profiles**

Command	show ip igmp snooping vlan
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If the function is configured, the profile will be displayed, for example: <pre>IGMP Snooping L2-entry-limit: 65536</pre>

↳ **Displaying the Information of Source Port Inspection**

Command	show ip igmp snooping vlan
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If source port inspection is enabled, the following information will be displayed: <pre>Source port check: Enable</pre>

↳ **Displaying the Information of Source IP Inspection**

Command	show ip igmp snooping vlan
Parameter Description	N/A

Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If source IP address inspection is enabled, the following information will be displayed: <pre>Source ip check: Enable</pre>

📄 **Displaying the Information of the Preview Function**

Command	show ip igmp snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If the range of multicast addresses for a port is configured, preview will be enabled, for example: <pre>IGMP Preview: Enable</pre> <pre>IGMP Preview group aging time : 60(Seconds)</pre>

Configuration Example

📄 **Configuring the Profile Filtering and the Maximum Number of Demanded Profiles**

<p>Scenario Figure 8-9</p>	
<p>A is the multicast router and is connected directly to multicast Source 1. B is a Layer-2 device and is connected directly to the user host and multicast Source 2. Receiver 1, Receiver 2, and Receiver 3 are connected to VLAN 1. By configuring VLAN 1, you can configure to allow the users within VLAN 1 to receive only the profiles whose addresses range from 225.1.1.1 to 225.1.255.255. You can configure Receiver 1 to receive only the profiles whose addresses range from 225.1.1.1 to 225.1.1.255, Receiver 2 to receive only the profiles whose addresses range from 225.1.2.1 to 255.1.2.255, and Receiver 3 to receive only the profiles whose addresses range from 225.1.3.1 to 225.1.3.255.</p>	

	At most 10 profiles can be added to a port and at most 100 profiles can be added globally.
Configuration Steps	<ul style="list-style-type: none"> ● Configure the IP address and VLAN. (Omitted) ● Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1 and VLAN 1). ● Enable IGMP snooping on B and select IVGL mode. ● Configure the range and maximum number of multicast addresses on B.
A	<pre>A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode A(config-if-GigabitEthernet 0/1)# exit A(config)# interface vlan 1 A(config-if-VLAN 1)# ip pim sparse-mode A(config-if-VLAN 1)# exit</pre>

➤ **Configuring Source Port Inspection**

<p>Scenario Figure 8-10</p>	
	<p>A is the multicast router and is connected directly to multicast Source 1. B is a Layer-2 device and is connected directly to the user host and multicast Source 2. Receiver 1, Receiver 2, and Receiver 3 are connected to VLAN 1. Source 1 sends the multicast address traffic from profile 224.1.1.1, and Source 2 sends the multicast address traffic from profile 225.1.1.1. Receiver 1 can request profiles 224.1.1.1 and 225.1.1.1 respectively. Source port inspection is enabled.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure the IP address and VLAN. ● Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1 and VLAN 1). ● Enable IGMP snooping on B and select IVGL mode. ● Enable source port inspection on B.
<p>A</p>	<pre>A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode A(config-if-GigabitEthernet 0/1)# exit A(config)# interface vlan 1 A(config-if-VLAN 1)# ip pim sparse-mode A(config-if-VLAN 1)# exit</pre>
<p>B</p>	<pre>B# configure terminal B(config)# ip igmp snooping ivgl B(config)# ip igmp snooping source-check port</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● Run the show ip igmp snooping mroute command to check whether Gi0/1 is learned as a router

	<p>port.</p> <ul style="list-style-type: none"> Check whether Receiver 1 can request the multicast traffic of profile 224.1.1 and cannot request that of profile 225.1.1.1.
<p>B</p>	<pre> Multicast Switching Mroute Port D: DYNAMIC S: STATIC (*, *, 1): VLAN(1) 1 MROUTES: GigabitEthernet 0/1(S) B#show ip igmp snooping IGMP Snooping L2-entry-limit: 100 Source port check: Enable Source ip check: Disable </pre>

📌 **Configuring Source IP Inspection**

<p>Scenario Figure 8-11</p>	
	<p>A is the multicast router and is connected directly to multicast Source 1.</p> <p>B is a Layer-2 device and is connected directly to the user host and multicast Source 2.</p> <p>Receiver 1, Receiver 2, and Receiver 3 are connected to VLAN 1.</p> <p>Source 1 sends the multicast address traffic from profiles 10.1.1.1 and 224.1.1.1, Source 2 sends the multicast address traffic from profiles 192.168.1.3 and 225.1.1.1, and Source 3 sends the multicast address traffic from profiles 192.168.1.3 and 226.1.1.1.</p> <p>Receiver 1 can request profiles 224.1.1.1, 225.1.1.1, and 226.1.1.1 respectively.</p> <p>The default IP address for source IP inspection is 10.1.1.1.</p> <p>Configure limit-ipmc and the multicast traffic of profile 225.1.1.1, and set the legal source address as 192.168.1.3.</p>

Configuration Steps	<ul style="list-style-type: none"> ● Configure the IP address and VLAN. ● Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1 and VLAN 1). ● Enable IGMP snooping on B and select IVGL mode. ● Enable source port inspection on B.
A	<pre>A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode A(config-if-GigabitEthernet 0/1)# exit A(config)# interface vlan 1 A(config-if-VLAN 1)# ip pim sparse-mode A(config-if-VLAN 1)# exit</pre>
B	<pre>B# configure terminal B(config)# ip igmp snooping ivgl B(config)# ip igmp snooping source-check default-server 10.1.1.1 B(config)# ip igmp snooping limit-ipmc vlan 1 address 225.1.1.1 server 192.168.1.3</pre>
Verification	<ul style="list-style-type: none"> ● Run the show ip igmp snooping command to check whether source IP inspection is enabled. ● Check whether Receiver 1 can request the multicast traffic of profile 224.1.1 and 225.1.1.1 and cannot request that of profile 226.1.1.1.
B	<pre>B#show ip igmp snooping IGMP Snooping running mode: IVGL IGMP Snooping L2-entry-limit: 65536 Source port check: Disable Source ip check: Enable IGMP Fast-Leave: Disable IGMP Report suppress: Disable IGMP Globle Querier: Disable IGMP Preview: Disable IGMP Tunnel: Disable IGMP Preview group aging time : 60(Seconds) Dynamic Mroute Aging Time : 300(Seconds) Dynamic Host Aging Time : 260(Seconds)</pre>

Common Errors

- Basic IGMP snooping functions are not configured or the configuration is not successful.

- The multicast router port is not learned, leading to failure to receive the multicast traffic.
- The IP address for source IP inspection is inconsistent with the multicast IP address, leading to failure to receive the multicast traffic.

8.4.6 Configuring an IGMP Profile

Configuration Effect

- Create an IGMP filtering profile.

Configuration Steps

↳ Creating a Profile

- (Optional) Create an IGMP filtering profile.

↳ Configuring the Profile Range

- (Optional) Configure the range of multicast profile addresses.

↳ Configuring the Profile Filtering

- (Optional) Configure the filtering mode of profile to **permit** or **deny**.

Verification

- Run the **show running-config** command to check whether the preceding configurations take effect.

Related Commands

↳ Creating a Profile

Command	ip igmp profile <i>profile-number</i>
Parameter Description	<i>profile-number</i> : Indicates the number of a profile.
Command Mode	Global configuration mode
Usage Guide	

↳ Configuring the Profile Range

Command	range <i>low-ip-address</i> [<i>high-ip-address</i>]
Parameter Description	<i>low-ip-address</i> : Specifies the start address. <i>low-ip-address</i> : Specifies the end address. Only one address is configured by default.
Command Mode	Profile configuration mode
Usage Guide	You can configure multiple addresses. If the IP addresses of different ranges are consecutive, the addresses will be combined.

↳ Configuring the Profile Filtering

Command	deny
Parameter Description	N/A
Command Mode	Profile configuration mode
Usage Guide	If the filtering mode of profile is set to deny while the range of multicast profiles is not specified, no profile is to be denied, which means to permit all profiles.

↘ Configuring the Profile Filtering

Command	permit
Parameter Description	N/A
Command Mode	Profile configuration mode
Usage Guide	If the filtering mode of profile is set to permit while the range of multicast profiles is not specified, no profile is to be permitted, which means to deny all profiles.

Configuration Example

↘ Creating a Filtering Profile

Configuration Steps	<ul style="list-style-type: none"> ● Create a filtering profile.
	<pre>B(config)#ip igmp profile 1 B(config-profile)#permit B(config-profile)#range B(config-profile)#range 224.1.1.1 235.1.1.1 B(config-profile)#</pre>
Verification	Run the show running-config command to check whether the configuration is successful.
	<pre>ip igmp profile 1 permit range 224.1.1.1 235.1.1.1 !</pre>

Common Errors

- Basic IGMP snooping functions are not configured or the configuration is not successful.
- The mode of profile is set to **permit** while the range of multicast profiles is not specified, leading to the denial of all profiles.

8.4.7 Configuring IGMP QinQ

Configuration Effect

- Create a multicast entry on the VLAN where IGMP packets are located. Forward IGMP packets on the VLAN where these packets are located, realizing transparent transmission.

Notes

- Basic IGMP snooping functions must be configured.

Configuration Steps

▾ Configuring QinQ Transparent Transmission

- If the QinQ interface needs to forward multicast packets on the VLANs where the VIDs of the packets specify, enable QinQ to realize transparent transmission.

Verification

- Run the **show ip igmp snooping** command to check whether the configuration takes effect.

Related Commands

▾ Configuring QinQ Transparent Transmission

Command	ip igmp snooping tunnel
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Enable QinQ to realize transparent transmission of IGMP packets.

▾ Displaying QinQ Configuration

Command	show ip igmp snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If QinQ is enabled, the following content is displayed. <pre>IGMP Tunnel: Enable</pre>

Configuration Example

▾ Configuring QinQ Transparent Transmission

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic IGMP snooping functions. ● Configure QinQ transparent transmission.
----------------------------	--

	<pre>Ruijie# configure terminal Ruijie(config)# ip igmp snooping tunnel Ruijie(config)# Ruijie(config)# end</pre>
Verification	Run the show ip igmp snooping command to check whether the configuration is successful.
	IGMP Tunnel: Enable

Common Errors

- Basic IGMP snooping functions are not configured or the configuration is not successful.

8.4.8 Configuring an IGMP Querier

Configuration Effect

- Configure the device as an IGMP querier, which will send IGMP Query packets periodically and collect user demanding information.

Notes

- Basic IGMP snooping functions must be configured.

Configuration Steps

▾ Enabling the Querier Function

- (Optional) Enable IGMP querier function globally or for a specified VLAN.
- (Optional) Disable the IGMP querier function for a specified VLAN.

▾ Configuring the Source IP Address of a Querier

- (Optional) You can configure the source IP address of a Query packet sent by the querier based on VLANs.
- After a querier is enabled, a source IP address must be specified for the querier; otherwise, the configuration will not take effect.

▾ Configuring the Maximum Response Time of a Query Packet

- (Optional) Adjust the maximum response time carried by an IGMP Query packet. As IGMPv1 does not support the carrying of maximum response time by a Query packet, this configuration does not take effect when the querier is running IGMPv1.

▾ Configuring the Query Interval of a Querier

- (Optional) Adjust the interval of the IGMP querier for sending query packets.

▾ Configuring the Aging Timer of a Querier

- (Optional) Configure the aging timer of other IGMP queriers on the network.

▾ Specifying the IGMP Version for a Querier

- (Optional) Specify the IGMP version for a querier (IGMPv2 by default).

Verification

- Run the **show ip igmp snooping querier detail** command to check whether the configuration takes effect.

Related Commands

↳ Enabling the IGMP Querier Function

Command	ip igmp snooping [vlan <i>vid</i>] querier
Parameter Description	vlan <i>vid</i> : Specifies a VLAN. This configuration applies to all VLANs by default.
Command Mode	Global configuration mode
Usage Guide	IGMP querier for a specified VLAN will take effect only after global IGMP querier is enabled. If global IGMP querier is disabled, IGMP querier for all the VLANs will be disabled.

↳ Configuring the Source IP Address of a Querier

Command	ip igmp snooping [vlan <i>vid</i>] querier address <i>a.b.c.d</i>
Parameter Description	vlan <i>vid</i> : Specifies a VLAN. This configuration applies to all VLANs by default. <i>a.b.c.d</i> : Indicates the source IP address.
Command Mode	Global configuration mode
Usage Guide	After a querier is enabled, a source IP address must be specified for the querier; otherwise, the configuration will not take effect. If the source IP address is specified by a VLAN, the address will be used preferentially.

↳ Configuring the Maximum Response Time of a Querier

Command	ip igmp snooping [vlan <i>vid</i>] querier max-response-time <i>seconds</i>
Parameter Description	vlan <i>vid</i> : Specifies a VLAN. This configuration applies to all VLANs by default. <i>seconds</i> : Indicates the maximum response time. in the unit of seconds. The value ranges from 1 to 25.
Command Mode	Global configuration mode
Usage Guide	If the query interval is specified by a VLAN, the value will be used preferentially.

↳ Configuring the Query Interval of a Querier

Command	ip igmp snooping [vlan <i>vid</i>] querier address <i>a.b.c.d</i>
Parameter Description	vlan <i>vid</i> : Specifies a VLAN. This configuration applies to all VLANs by default. <i>seconds</i> : Indicates the query interval in the unit of seconds. The value ranges from 1 to 18,000.
Command Mode	Global configuration mode
Usage Guide	If the query interval is specified by a VLAN, the value will be used preferentially.

↳ **Configuring the Aging Timer of a Querier**

Command	ip igmp snooping [vlan vid] querier timer expiry seconds
Parameter Description	vlan vid: Specifies a VLAN. This configuration applies to all VLANs by default. seconds: Indicates the timeout time in the unit of seconds. The value ranges from 60 to 300.
Command Mode	Global configuration mode
Usage Guide	A device may fail to be elected as the querier even when its querier function is enabled. If a device that fails to be elected does not receive the Query packet sent by the querier in the aging time, the querier in use is considered as expired, and a new round of election will be raised. If the aging time is specified by a VLAN, the value will be used preferentially.

↳ **Specifying the IGMP Version for a Querier**

Command	ip igmp snooping [vlan vid] querier version 1
Parameter Description	vlan vid: Specifies a VLAN. This configuration applies to all VLANs by default.
Command Mode	Global configuration mode
Usage Guide	A querier can be run in IGMPv1 and IGMPv2 (IGMPv2 by default). You can also run a command to configure the version to IGMPv1. If the IGMP version for a querier is specified by a VLAN, the version will be used preferentially.

↳ **Displaying the IGMP Querier Configuration**

Command	show ip igmp snooping querier detail
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If QinQ is enabled, the following content is displayed. <pre>Ruijie(config)#show ip igmp snooping querier detail Vlan IP Address IGMP Version Port ----- Global IGMP switch querier status ----- admin state : Enable admin version : 2 source IP address : 1.1.1.1</pre>

```

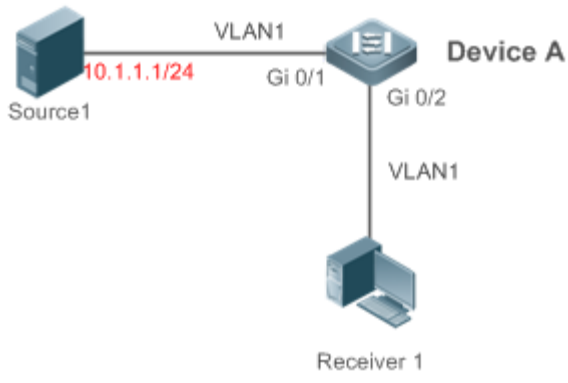

query-interval (sec)          : 60
max-response-time (sec)      : 10
querier-timeout (sec)        : 125

Vlan 1:  IGMP switch querier status
-----

admin state                   : Disable
admin version                 : 2

```

Configuration Example

Enabling the IGMP Querier Function

<p>Scenario Figure 8-12</p>	
	<p>In the scenario without Layer-3 multicast equipment, the multicast traffic can be forwarded only on the Layer-2 network. A acts as a Layer-2 device to connect to the multicast source and receiver.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable global IGMP snooping on A in IVGL mode. ● Enable IGMP querier for VLAN 1 on A.
<p>A</p>	<pre> A(config)#ip igmp snooping ivgl A(config)#ip igmp snooping querier A(config)#ip igmp snooping querier address 10.1.1.1 A(config)#ip igmp snooping vlan 1 querier </pre>

Verification	Run the show ip igmp snooping querier command to check whether the querier of VLAN 1 takes effect.
A	<pre> A(config)#show ip igmp snooping querier Vlan IP Address IGMP Version Port ----- 1 10.1.1.1 2 switch A(config)#show ip igmp snooping querier vlan 1 Vlan 1: IGMP switch querier status ----- elected querier is 10.1.1.1 (this switch querier) ----- admin state : Enable admin version : 2 source IP address : 10.1.1.1 query-interval (sec) : 60 max-response-time (sec) : 10 querier-timeout (sec) : 125 operational state : Querier operational version : 2 </pre>

Common Errors

- The source IP address is not configured for the querier and the querier does not take effect.

8.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears the statistics on IGMP snooping.	clear ip igmp snooping statistics
Clears the dynamic router ports and member ports.	clear ip igmp snooping gda-table

Displaying

Description	Command
Displays basic IGMP snooping configurations.	show ip igmp snooping [<i>vlan vlan-id</i>]
Displays the statistics on IGMP snooping.	show ip igmp snooping statistics [<i>vlan vlan-id</i>]
Displays the router ports.	show ip igmp snooping mrouter
Displays the IGMP snooping entries.	show ip igmp snooping gda-table
Displays the profile.	show ip igmp profile [<i>profile-number</i>]
Displays the IGMP snooping configurations on an interface.	show ip igmp snooping interface <i>interface-name</i>
Displays the IGMP querier.	show ip igmp snooping querier [<i>detail</i>]
Displays user information.	show ip igmp snooping user-info

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs all IGMP Snooping functions.	debug igmp-snp
Debugs the IGMP snooping events.	debug igmp-snp event
Debugs the IGMP snooping packets.	debug igmp-snp packet
Debugs the communications between IGMP snooping and MSF.	debug igmp-snp msf
Debugs the IGMP snooping alarms.	debug igmp-snp warning

9 Configuring MLD Snooping

9.1 Overview

Multicast Listener Discovery (MLD) Snooping is used to control and manage the forwarding behaviors of IPv6 multicast packets at Layer 2.

The device running MLD Snooping analyzes MLD packets received by a port to create a mapping between the port and the MAC multicast address and forwards IPv6 multicast data at Layer 2 based on the mapping. When MLD Snooping is disabled, IPv6 multicast data packets are broadcasted at Layer 2. When MLD Snooping is enabled, multicast data packets of a known IPv6 multicast group are forwarded to a specified receiver at Layer 2 instead of being broadcasted at Layer 2.

Protocols and Standards

RFC4541: Considerations for Internet Group Management Protocol (IGMP) and Multicast Listener Discovery (MLD) Snooping Switches

9.1.1 Two Types of MLD Snooping Ports

As shown in Figure 9-1, the Layer-3 multicast device is connected to the multicast source. MLD Snooping is enabled on the access device. Host A and Host B are receivers (that is, members of the IPv6 multicast group).

Figure 9-1 Two Types of MLD Snooping Ports

- Multicast router port: Indicates the port on the access device for connecting to the Layer-3 multicast device, for example, Port Eth0/1 of the access device.
- Member port: Is short for IPv6 multicast group member port, also called listener port, and indicates the port on the access device for connecting to an IPv6 multicast group member, for example, Port Eth0/2 and Port Eth0/3 on the access device.

9.1.2 Work Mode of MLD Snooping

- **DISABLE mode:** MLD Snooping does not take effect in this mode. That is, the Layer-2 multicast device does not "snoop" MLD packets between the host and the router, and multicast streams are broadcasted within VLANs.
- **Independent VLAN Group Learn (IVGL) mode:** In this mode, multicast streams between VLANs are mutually independent. A host can request only the multicast router port in the same VLAN as the host to receive multicast packets, and can forward the received multicast data packets of any VLAN only to the member port and multicast router port in the same VLAN as the host.
- **Shared VLAN Group Learn (SVGL) mode:** In this mode, hosts of VLANs share the same multicast stream. A host in one VLAN can request multicast streams of another VLAN. When a shared VLAN is specified, only the multicast data streams of this VLAN can be forwarded to hosts of other VLANs. Multicast data streams of a shared VLAN, can be forwarded to the member ports of this multicast address, even though some member ports do not belong to the shared VLAN. In SVGL mode, MLD profiles must be used to allocate a batch of multicast address ranges to SVGL. Within the multicast address ranges, member ports in the multicast forwarding entries support trans-VLAN packet forwarding. By default, all the group ranges are not within the SVGL application ranges, and all the multicast packets are discarded.
- **IVGL-SVGL mode:** In this mode, IVGL and SVGL coexist. You can use MLD profiles to allocate a batch of multicast address ranges to SVGL. Within the multicast address ranges, member ports in the multicast forwarding entries support trans-VLAN packet forwarding. Member ports in the multicast forward entries corresponding to other multicast address ranges must belong to the same VLAN.

9.1.3 Working Principle of MLD Snooping

The device running MLD Snooping processes different MLD packets as follows:

MLD QUERY

The Layer-3 multicast device regularly sends an MLD General Query packet to all hosts and routers (with the address of FF02::1) in the local network segment, to query the IPv6 multicast group members in this network segment. When receiving the MLD General Query packet, the device running MLD Snooping forwards the packet all ports in the VLAN except the one receiving the packet, and processes the port receiving the packet as follows:

- If the port is already in the router multicast port list, its aging timer is reset.
- If the port is not contained in the router multicast port list, the port is added to the router multicast port list and its aging timer is started.
- Each time the Layer-2 multicast device receives an MLD General Query packet, it starts the aging timer for each member port, and updates the timer time to the configured maximum response time of MLD query packet. When the aging timer time of a port is reduced to 0, it is deemed that no member receives multicast streams through this port, and therefore, the Layer-2 multicast device deletes the port from the MLD Snooping forwarding table.
- Each time the Layer 2 multicast device receives a MLD Group-Specific Query packet, it starts the aging timer for each member port in the specific group, and updates the timer time to the configured maximum response time of MLD query packet. When the aging timer time of a port is reduced to 0, it is deemed that no member receives multicast streams through this port, and therefore, the Layer-2 multicast device deletes the port from the MLD Snooping forwarding table.

- When the Layer-2 multicast device receives a MLD Group-Specific Query packet, it no longer updates the preceding two types of timers.

MLD REPORT

In either of the following cases, the host sends an MLD Membership Report packet to the MLD querier.

- After receiving an MLD query (General Query or Group-Specific Query) packet, an IPv6 multicast group member host responds with an MLD Membership Report packet.
- If a host needs to join an IPv6 multicast group, it actively sends an MLD Membership Report packet to MLD querier to request to join this IPv6 multicast group.

When receiving an MLD Membership Report packet, the device running MLD Snooping forwards it to all multicast router ports in the VLAN, retrieves, from the packet, the address of the IPv6 multicast group that the host needs to join, and processes the port receiving the packet as follows:

- If there is no forwarding entry corresponding to the IPv6 multicast group, the forwarding entry is created, the port is added to the egress port list as a dynamic member port, and its aging timer is started.
- If there is a forwarding entry corresponding to the IPv6 multicast group but the port is not contained in the egress port list, the port is added to the egress port list as a dynamic member port, and its aging timer is started.
- If there is a forwarding entry corresponding to the IPv6 multicast group and dynamic member port is contained in the egress port list, its aging timer is reset.

MLD LEAVE

When a host leaves an IPv6 multicast group, it sends an MLD Leave packet (with the address of FF02::2) to notify the multicast router that it has left the IPv6 multicast group. When receiving an MLD Leave packet from a member port, the device running MLD Snooping directly forwards it to the multicast router port. If the fast leave function is enabled, the device directly deletes the port from the forwarding port list of the relevant multicast group.

9.1.4 Source Port Check

The source port check function of MLD Snooping improves the network security.

This function strictly limits the ingress ports of MLD multicast streams. When this function is disabled, multicast streams from any port are valid and the Layer-2 multicast device forwards them to registered member ports according to the forwarding list of MLD Snooping. When this function is enabled, multicast streams only from the multicast router ports are valid and the Layer-2 multicast device forwards them to registered ports. Multicast data streams from non-multicast router ports are invalid and discarded.

9.2 Applications

Application	Description
MLD Snooping SVGL Trans-VLAN Multicast On demand	MLD Snooping works in SVGL mode
Source Port Filtering	Multicast streams only from multicast router ports are received.

9.2.1 MLD Snooping SVGL Trans-VLAN Multicast On demand

Scenario

As shown in Figure 9-2, Host A of VLAN 3 and Host B of VLAN 4 order a video. The video streams are in VLAN 2.

- Enable the SVGL mode on the access device and set a shared VLAN 2.

Figure 9-2

Remark	VLAN 2 is a shared VLAN.
s	VLAN 3 and VLAN 4 are the VLANs through which the video on-demand service is output.

Deployment

- Enable the Layer-3 multicast protocol on the Layer-3 multicast device.
- Enable the SVGL mode on the Layer-2 device.

9.2.2 Source Port Filtering

Scenario

As shown in Figure 9-3, when the source port check function is configured, video streams can be received only from the source multicast router port. Multicast video streams from other ports are invalid and discarded. Note that when the source port check function is configured, there shall be at least one multicast router port. Otherwise, packet filtering is not performed on the multicast router port even though the source port filtering is enabled. When the source port check function is not configured, multicast video streams from all ports are received by default.

- Enable the IVGL mode on the access device.

Figure 9-3

Remark	Port Eth0/1 is a multicast router port and Port Eth0/2 is a non-multicast router port.
s	Video servers send same multicast video streams. Hosts A and B can receive multicast streams only from Video Server A.

Deployment

- Enable the source port check function and configure a static multicast router port.
- Enable the IVGL mode on the Layer-2 device.

9.3 Features

Basic Concepts

Multicast Router Port and Member Port

Multicast router ports are classified into dynamic multicast router ports and static multicast router ports. If MLD Snooping is enabled, when the dynamic multicast router port learning function is enabled on a port, after receiving an MLD Query or PIMv6-Hello packet, the port learns the dynamic multicast router port and starts the aging timer of the dynamic multicast router port. A static multicast router port can be added by configuring the **ipv6 mld snooping vlan mrouter** command.

Member ports are classified into dynamic member ports and static member ports. If MLD Snooping is enabled, after receiving an MLD Report packet, a port learns the dynamic member router port and starts the aging timer of the dynamic member port. A static member port can be added by configuring the **ipv6 mld snooping vlan static interface** command.

Fast Leave and Packet Suppression

When the fast leave function is enabled, a port is directly deleted after receiving an MLD Leave packet. The fast leave function is applicable only to scenarios in which only one user is connected to a port, and helps save the bandwidth. When multiple users are connected to a port, if the fast leave function is enabled, other users wanting to receive packets fail to receive any packets.

When the packet suppression function is enabled, only the first MLD Report packet is forwarded within one query period.

Overview

Feature	Description
Globally Enabling MLD Snooping	Globally enables MLD Snooping and configures the work mode.
VLAN-based MLD Snooping	Enables or disables MLD Snooping for a single VLAN when MLD Snooping is globally enabled.
Aging Time of Multicast Router Ports	Adjusts the aging time of dynamic multicast router ports. The default aging time is 300s.
Dynamic Multicast Router Port Learning	After receiving an MLD query packet or a PIMv6 Hello packet, the port is learnt as a dynamic multicast router port.
Fast Leave of Multicast Group Member Ports	A member port can be quickly deleted, instead of being aged and deleted after the query interval of a Group-Specific Query expires.
MLD Report Packet Suppression	Only the first Report packet is processed within one query period, reducing the work load of the module.
Source Port Check	Multicast streams received only from a multicast router port can be forwarded. Packets received from non-multicast router ports cannot be forwarded.
Port-based Specific Multicast Group Filtering	Only multicast group packets that meet the filter conditions can be received.
Maximum Number of Multicast Groups Supported by a Port	Limits the maximum number of multicast groups that a port can join.

9.3.1 Globally Enabling MLD Snooping

Globally enable MLD Snooping and configure the work mode. Multicast forwarding entries can be learnt and multicast streams are forwarded to a specified port.

Working Principle

Enable MLD Snooping. When an MLD Report packet with the time to live (TTL) of 1 is received, a multicast forwarding entry is created and the forwarding egress is this port.

↳ Learning a Dynamic Member Port

After a valid MLD Report packet is received, a dynamic member port is learnt and a forwarding entry is generated. The forwarding egress of this entry is the member port.

↳ Coordinating Parameters

Configure the MLD Report packet suppression function.

[Related Configuration](#)

Configure the MLD Report packet suppression function so that only the first Report is processed within one query period, thereby reducing the number of packets in the network.

9.3.2 VLAN-based MLD Snooping

Enable or disable MLD Snooping for a single VLAN. By default, if MLD Snooping is globally enabled, the MLD Snooping function of each VLAN is enabled.

[Related Configuration](#)

Globally configure MLD Snooping. Then configure MLD Snooping for a single VLAN.

9.3.3 Aging Time of Multicast Router Ports

Multicast router ports are classified into dynamic multicast router ports and static multicast router ports. By default, the aging time of a dynamic multicast router port is 300s. Static multicast router ports are not aged.

[Related Configuration](#)

Ability of learning from dynamic multicast router port learning function

9.3.4 Dynamic Multicast Router Port Learning

By default, all ports support the dynamic multicast router port learning function.

[Working Principle](#)

When a port supports the dynamic multicast router port learning function, after receiving an MLD query packet or a PIMv6 Hello packet, the port is learnt as a dynamic multicast router port.

[Related Configuration](#)

Configure a port as a static multicast router port.

9.3.5 Aging Time of Dynamic Member Ports

Member ports are classified into dynamic member ports and static member ports. By default, the aging time of a dynamic member port is 260s. Static member ports are not aged.

9.3.6 Fast Leave of Multicast Group Member Ports

By default, the fast leave function of multicast group member ports are disabled. If the fast leave function is enabled, the port is directly deleted after receiving a done packet.

9.3.7 MLD Report Packet Suppression

By default, the MLD report packet suppression function is disabled. If the function is enabled, only the first Report packet is processed within one query interval, thereby reducing the number of packets in the network.

9.3.8 Source Port Check

The source port check function is disabled by default.

Working Principle

When the source port check function is enabled, packets only from multicast router ports are valid and packets from non-multicast router ports are invalid.

Related Configuration

Configure a port as a static multicast router port.

9.3.9 Port-based Specific Multicast Group Filtering

Under certain circumstances, you may use the port filtering function to control a port to forward multicast packets only of a certain range.

9.3.10 Maximum Number of Multicast Groups Supported by a Port

The maximum number of multicast groups that a port is allowed to join can control the maximum number of multicast groups supported by the port.

9.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of MLD Snooping	ipv6 mld snooping	Enables MLD Snooping and specifies the work mode.
	ipv6 mld snooping vlan <i>vlan-id</i> mrouter interface <i>interface-id</i>	Configures the static multicast router port.
	ipv6 mld snooping vlan <i>vlan-id</i> static ip-addr interface <i>interface-id</i>	Configures a static member port.
	ipv6 mld profile <i>profile-num</i>	Configures a profile.
	ipv6 mld snooping source-check port	Configures source port check.
	ipv6 mld snooping filter <i>profile-num</i>	Configures multicast group filtering for a port.
	ipv6 mld snooping max-groups <i>num</i>	Configures the maximum number of multicast groups that a port can join.

9.4.1 Configuring Basic Functions of MLD Snooping

Configuration Effect

- Enable MLD Snooping and configure the work mode.

Notes

- Enable MLD Snooping and set the work mode to SVGL. The MLD Snooping SVGL mode cannot coexist with IPv4 or IPv6 Layer-3 multicasting.
- When the work mode is SVGL or IVGL-SVGL, a profile must be associated to specify the multicast group range in which the SVGL mode applies.

Configuration Steps

↳ Enabling IPv6 MLD Snooping

- Mandatory.

Verification

Run the **show ipv6 mld snooping** command to check whether MLD Snooping is enabled.

- Check whether the device can create correct multicast forwarding entries.

Related Commands

↳ Enabling IPv6 MLD Snooping

Command	ipv6 mld snooping <i>mode</i>
Parameter Description	mode: Specifies the work mode.
Command Mode	Global configuration mode
Usage Guide	N/A

↳ Configuring a Profile

Command	ipv6 mld profile <i>profile-num</i>
Parameter Description	<i>profile-num:</i> Indicates the profile number.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure a profile and enter the profile configuration mode.

↳ Configuring a Static Multicast Router Port

Command	ipv6 mld snooping vlan <i>vlan-id</i> mrouter interface <i>interface-id</i>
Parameter Description	vlan-id: Indicates the VLAN ID. interface-id: Indicates interface changes.
Command Mode	Global configuration mode
Usage Guide	N/A

↳ Configuring a Static Member Port

Command	ipv6 mld snooping vlan <i>vlan-id</i> static <i>ip-addr</i> interface <i>interface-id</i>
Parameter Description	<i>vlan-id</i>: Indicates the VLAN ID. <i>ip-addr</i>: Indicates the group address. <i>interface-id</i>: Indicates interface changes.
Command Mode	Global configuration mode
Usage Guide	N/A

↳ Configuring Source Port Check

Command	ipv6 mld snooping source-check port
Parameter Description	
Command Mode	Global configuration mode
Usage Guide	-

↳ Configuring Port-based Multicast Group Filtering

Command	ipv6 mld snooping filter <i>profile-num</i>
Parameter Description	<i>profile-num</i>: Indicates the profile number.
Command Mode	Interface configuration port
Usage Guide	N/A

↳ Configuring the Maximum Number of Multicast Groups Supported by a Port

Command	ipv6 mld snooping max-groups <i>num</i>
Parameter Description	<i>num</i>: Indicates the number of groups.
Command Mode	Interface configuration port
Usage Guide	N/A

↳ Configuring Report Packet Suppression

Command	ipv6 mld snooping suppression enable
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	When the Report packet suppression function is enabled, only the first Report packet of a specific VLAN and group is forwarded to a multicast router port within one query interval. The subsequent Report

	packets are forwarded to the multicast router port, so as to reduce the number of packets in the network. This function can only suppress the Report packets of MLDv1. It is invalid on the Report packets of MLDv2.
--	--

↳ Configuring Port Fast Leave

Command	ipv6 mld snooping fast-leave enable
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	<p>When the port fast leave function is enabled, after receiving a Leave packet, the port is directly deleted from the member ports in the corresponding forwarding entries. Later, when receiving a relevant Group-Specific Query packet, the device does not forward the packet to this port. The Leaver packet includes the Leave packet of MLDv1, include type of MLDv2, and Report packet containing no source address.</p> <p>This function is applicable only to scenarios in which only one user is connected to a port, and helps save bandwidth and resources.</p>

↳ Configuring Dynamic Multicast Router Port Learning

Command	ipv6 mld snooping [vlan <i>vid</i>] mrouter learn
Parameter Description	vlan-id: Specifies a VLAN ID. This function is applicable to all VLANs by default.
Command Mode	Global configuration mode
Usage Guide	A multicast router port is a port that directly connects an MLD Snooping-enabled multicast device to a neighbor multicast device in which a multicast routing protocol is enabled. By default, when the dynamic multicast router port learning function is enabled, the device automatically listens to the MLD Query/PIM Hello packet and dynamically identifies a multicast router port.

↳ Configuring Aging Time of Dynamic Multicast Router Ports

Command	ipv6 mld snooping dyn-mr-aging-time <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the aging time of dynamic multicast router ports. The unit is second and the value ranges from 1 to 3,600.
Command Mode	Global configuration mode
Usage Guide	<p>If a dynamic multicast router port does not receive an MLD General Query packet or a PIM Hello packet before the timeout of its aging time, the device deletes the port from the multicast router port list.</p> <p>When the dynamic multicast router learning function is enabled, you can use this command to adjust the aging time of dynamic multicast router ports. If the aging time is too short, a multicast router port may be added and deleted frequently.</p>

↳ Configuring Aging Time of Dynamic Member Ports

Command	ipv6 mld snooping host-aging-time <i>seconds</i>
Parameter Description	seconds: Indicates the aging time.
Command Mode	Global configuration mode
Usage Guide	<p>The aging time of a dynamic member port refers to the aging time set when a dynamic member port of a device receives from the host an MLD packet of joining a certain IPv6 multicast group.</p> <p>After receiving an MLD Join packet from a dynamic member port, the device resets the aging timer of the dynamic member port and sets the timer time to host-aging-time. If the timer times out, it is deemed that no user host receives multicast packets through this port, and then the multicast device deletes the port from the MLD Snooping member port list. After this command is configured, the aging timer value of dynamic member ports when MLD Join packets are received subsequently is host-aging-time. The aging time takes effect immediately after configuration and the timers of started member ports are updated.</p>

↳ Configuring Response Time of Query Packets

Command	ipv6 mld snooping query-max-response-time <i>seconds</i>
Parameter Description	seconds: Indicates the response time.
Command Mode	Global configuration mode
Usage Guide	<p>After receiving an MLD General Query packet from a port, the multicast device resets the aging timers of all dynamic member ports and sets the timer time to query-max-response-time. If the timer times out, it is deemed that no user host receives multicast packets through the port, and then the multicast device deletes the port from the MLD Snooping member port list.</p> <p>After receiving an MLD Group-Specific Query packet from a port, the multicast device resets the aging timers of all dynamic member ports in the specific group and sets the timer time to query-max-response-time. If the timer times out, it is deemed that no user host receives multicast packets through the port, and then the multicast device deletes the port from the MLD Snooping member port list.</p> <p>The configuration takes effect when the a query packet is received next time, and the configuration of currently started timers are not updated. For Group-Specific Query packets of MLDv2, timers are not updated.</p>

↳ Checking Multicast Router Ports

Command	show ipv6 mld snooping mroute
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, interface configuration mode
Usage Guide	<p>If a multicast router port is successfully configured, the mark "S" is shown in the interface information displayed. For example:</p> <pre>Ruijie(config)#show ipv6 mld snooping mrouter</pre>

	<pre> Multicast Switching Mroute Port D: DYNAMIC S: STATIC (*, *, 1): VLAN(1) 1 MROUTES: GigabitEthernet 0/1(S) </pre>
--	---

↳ Checking Dynamic Multicast Router Port Learning

Command	show ipv6 mld snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, interface configuration mode
Usage Guide	<p>Run the show ip igmp snooping command to check the aging time and learning status of dynamic multicast router ports.</p> <pre> Dynamic Mroute Aging Time : 300(Seconds) Multicast router learning mode: Enable </pre>

↳ Checking Member Ports

Command	show ipv6 mld snooping gda-table
Parameter Description	-
Command Mode	Privileged EXEC mode, global configuration mode, interface configuration mode
Usage Guide	<p>If a member port is successfully configured, the mark "S" is shown in the interface information displayed. For example:</p> <pre> Ruijie(config)#show ipv6 mld snooping gda-table Multicast Switching Cache Table D: DYNAMIC S: STATIC M: MROUTE (*, FF15::100, 1): VLAN(1) 2 OPORTS: GigabitEthernet 3/7(S) </pre>

↳ Checking Other Parameters

Command	show ipv6 mld snooping
----------------	-------------------------------

Parameter Description	-
Command Mode	Privileged EXEC mode, global configuration mode, interface configuration mode
Usage Guide	<p>Run the show ipv6 mld snooping command to check the aging time of multicast router ports, aging time of dynamic member ports, response time of query packet, and Report packet suppression, and fast leave parameters.</p> <pre> MLD-snooping mode: IVGL Source port check: Disable MLD Fast-Leave: Disable MLD Report suppress: Disable Query Max Response Time: 10 (Seconds) Dynamic Mroute Aging Time: 300(Seconds) Dynamic Host Aging Time: 260(Seconds) </pre>

9.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears MLD Snooping multicast forwarding entries.	clear ipv6 mld snooping gda-table
Clears MLD Snooping statistics.	clear ipv6 mld snooping statistics

Displaying

Description	Command
Displays the current MLD Snooping mode.	show ipv6 mld snooping
Displays MLD Snooping forwarding entries.	show ipv6 mld snooping gda-table
Displays MLD Snooping statistics.	show ipv6 mld snooping statistics
Displays MLD Snooping multicast router ports.	show ipv6 mld snooping mrouter
Displays MLD Snooping interface information, interface filtering profiles and maximum number of groups that a port can join.	show ipv6 mld snooping interfaces <i>interface-type interface-name</i>

Displays multicast information about a single VLAN, on which MLD Snooping is configured.	show ipv6 mld snooping vlan <i>vid</i>
Displays an MLD Profile.	show ipv6 mld profile <i>profile-number</i>

MPLS Configuration

1. Configuring MPLS
2. Configuring MPLS-L2VPN
3. Configuring BGP/MPLS IP VPN
4. Configuring MPLS GR
5. Configuring MPLS BFD

1 Configuring MPLS

i The routers and router icons described in this chapter refer to general routers as well as Layer-3 switches running routing protocols.

1.1 Overview

Multiprotocol Label Switching (MPLS) supports multiple network layer protocols, for example, Internet Protocol (IP), IP version 6 (Ipv6), and Internetwork Packet Exchange (IPX). It is compatible with multiple link layer technologies, for example, asynchronous transfer mode (ATM), frame relay, Ethernet, and Point to Point Protocol (PPP). Labels are attached to packets, and packets are forwarded based on labels. MPLS uses connectionless control plane and connection-oriented data plane, which adds connection-oriented attributes to connectionless IP networks. MPLS was originally intended to make routers forward data faster. With the development of hardware technologies and network processors, this advantage has faded. However, as MPLS integrates the Layer-2 switching technology with Layer-3 routing technology, it outperforms other technologies in solving problems of virtual private networks (VPNs) and traffic engineering (TE). MPLS VPNs get increasingly popular among carriers in regard to enterprise interconnection and new services, becoming an important means by which carriers provide value-added services on IP networks. MPLS TE also has become an important means of managing network traffic, reducing congestion, and ensuring the QoS of IP networks. Therefore, MPLS is attracting more and more attention and increasingly applied to VPNs and TE.

Protocols and Standards

RFC3032: MPLS Label Stack Encoding

RFC3036: LDP Specification

RFC4182: Removing a Restriction on the use of MPLS Explicit NULL

RFC 5283: LDP Extension for Inter-Area Label Switched Paths (LSPs)

1.2 Applications

Application	Description
Providing the MPLS VPN Service	The geographically different branches of a private network are connected through label switched paths (LSPs) to form a unified network.

1.2.1 Providing the MPLS VPN Service

Scenario

MPLS Layer-3 VPN and MPLS Layer-2 VPN can be implemented through Multiprotocol Label Switching (MPLS).

Figure 1-1 shows the application scenario of MPLS Layer-3 VPN.

Figure 1-1 Application scenario of MPLS Layer-3 VPN

Deployment

- Public tunnels are established in a backbone network through the Label Distribution Protocol (LDP).
- Multiple VPN routing and forwarding (VRF) tables are created to maintain VPN routing information.
- Multiprotocol Extensions for BGP (MP-BGP) and Border Gateway Protocol (BGP) extended attributes are configured to transmit VPN routing information and carry VPN attributes and labels.

1.3 Features

Basic Concepts

➤ MPLS Node

An MPLS node can identify the MPLS signaling protocol (control protocol), run one or more Layer-3 routing protocols (including static routing protocols), and forwards packets based on MPLS labels. Generally, an MPLS node is capable of forwarding original Layer-3 packets (for example, IP packets).

➤ Forwarding Equivalence Class (FEC)

FEC refers to the packets forwarded equivalently, for example, packets sharing the same destination address or prefix. Packets can be classified in different ways in different application scenarios. In an IP unicast routing scenario, packets can be classified by address prefix; that is, a route corresponds to an FEC. Packets of the same FEC will be processed equivalently on an MPLS network.

➤ Label

A label is a short identifier of a fixed length that takes effect locally. Labels are transmitted only between two adjacent label switching routers (LSRs) and thereby are valid only between the LSRs. One label categorizes one FEC. When arriving at the MPLS network ingress, packets will be classified into different FECs based on rules. Labels are encapsulated in packets, and the packets are forwarded based on labels on the MPLS network.

➤ LSR

As the core of an MPLS network, LSRs switch and distribute labels. As described in RFC3031, an LSR is also an MPLS node capable of forwarding original Layer-3 packets (for example, IP packets or IPv6 packets), which means LSRs are capable of forwarding IP packets on IP networks.

↘ Label Switching Edge Router (LER)

On the MPLS network edge, an LER classifies data flows entering the network into different FECs and requests labels. When data flows exit the network, the LER pops the labels to restore original packets. Therefore, an LER classifies data flows, maps labels, and removes labels.

↘ LSP

Data flows of an FEC are given definite labels on different nodes. Labels are switched on all nodes during data forwarding. Data flows pass through an LSP, which is a collection of LSRs. An LSP can be considered as a tunnel that passes through the core MPLS network.

↘ Next Hop Label Forwarding Entry (NHLFE)

An NHLFE is used to forward the data on the next hop of MPLS packets. An NHLFE includes the following content:

- The next hop of packets.
- Link layer encapsulation used to forward packets.
- Coding mode used to forward packet label stacks.
- Operations on packet label stacks.

↘ Incoming Label Map (ILM)

An ILM table is a label forwarding table. It maps each incoming label to a series of NHLFEs (multiple NHLFEs indicate multiple paths). ILM is used when an LSR forwards labeled MPLS packets.

↘ FEC-to-NHLFE (FTN)

Different from ILM, FTN maps each FEC to a series of NHLFEs (multiple NHLFEs indicate multiple paths). FTN is used when an LER receives unlabeled packets. The LER encapsulates labels into the packets and then forwards them.

↘ LDP Peers

The LDP instances on two label switching routers (LSRs) that exchange label binding messages are called LDP peers.

↘ LDP Sessions

An LDP session is established through the Transmission Control Protocol (TCP) between two LDP peers to exchange label binding messages.

Overview

Feature	Description
MPLS Labels and Forwarding	This section describes the principles of labeling and label forwarding.

Static MPLS LSP	This section describes the process of establishing a static LSP through MPLS.

LDP LSP	This section describes the process of establishing an LSP through LDP.
Inter-Domain LDP LSP	This section describes the inter-domain LDP LSP feature.

1.3.1 MPLS Labels and Forwarding

Working Principle

Label Structure

Figure 1-2 Coding structure of MPLS labels

As shown in the figure, a label contains four domains. The following describes the domains.

- Label domain

The label domain stores label values and contains 20 bits. A label value is the index value of the label forwarding table. The Internet Engineering Task Force (IETF) specifies 0 to 15 as retained label values and predefines them.

Retained label value	Definition
0	It indicates IPv4 explicit null labels. According to RFC3032, Labels 0 must appear on the stack bottom; routers pop the labels and then forward packets based on IP addresses. According to RFC4182, routers pop Labels 0 and then forward packets based on what follows the labels: if labels follow, routers forward packets based on labels; if IPv4 packets follow, routers forward them based on IP addresses.
1	It indicates router alert labels, which must not appear on the stack bottom. Packets with router alert labels must be processed by the local software module and forwarded based on the labels following router alert labels. However, before the packets are forwarded, router alert labels must be pushed into the stack again, which is similar to the Router Alert option of an IP packet. After this option is selected, the LSR will check the MPLS packets every hop.
2	It indicates IPv6 explicit null labels. According to RFC3032, Labels 2 must appear on the stack bottom; routers pop the labels and then forward packets based on IP addresses. According to RFC4182, routers pop Labels 2 and then forward packets based on what follows the labels: if labels follow, routers forward packets based on labels; if IPv6 packets follow, routers forward them based on IP addresses.
3	It indicates implicit null labels, which can be distributed through the label distribution protocol but never appear in the label stack of MPLS packets. When an LSR switches labels of MPLS packets, Labels 3 on the stack top will be popped rather than replaced. These labels will be used for "penultimate-hop popping (PHP)".

Retained label value	Definition
4 to 15	They will be retained by the IETF for future use.

- Exp domain

The Exp domain stores MPLS QoS information and contains three bits.

- S flag

It is a flag on the stack bottom and contains one bit. If there are multiple labels, the S flag of labels on the stack bottom will be set to 0 and others 1.

- Time To Live (TTL)

The TTL contains 8 bits, similar to that of IP packet headers. It can be copied from the TTL domain of IP packet headers (or IPv6 hop limit) when IP packets are labeled for the first time. The TTL value of outer (top) labels is decreased by 1 when labels are switched. The MPLS packets running on an ATM link are coded in a different way because they don't have a TTL domain. For more details, see RFC3032.

↘ Label Stack

One MPLS packet may have multiple labels, which constitute a label stack. Labels close to the link layer header are called stack-top labels, and labels close to the IP header are called stack-bottom labels. LSRs always switch labels based on stack-top labels. Each label contains 32 bits. The label stack allows one MPLS packet to have multi-layer labels, which allows MPLS to support the layered network system as well as LSP tunnels.

↘ Operations on Labels

The following describes the basic operations on labels by an MPLS node:

- Push (adding labels)

On the ingress LER, the node inserts labels between link layer header and network layer header; or transit LSRs add labels to the top of the label stack.

- Pop (popping labels)

On the egress LER, the node removes all labels to restore packets to IP packets; or transit LSRs remove stack-top labels to reduce label stack layers.

- Swap (switching labels)

The node replaces stack-top labels based on the ILM table during packet forwarding.

↘ Label Distribution Protocol

As a new network system, MPLS has its signaling protocol or "routing protocol". In the MPLS system, two LSRs must reach an agreement upon the meanings of labels attached to the data transmitted between them through LDP. An LSR notifies label binding to the other through LDP. MPLS has more than one LDP. MPLS uses independent distribution protocols, for example, LDP defined by IETF in RFC3036, and extends existing protocols through piggybacking to support label distribution, for example, MP-BGP and Resource Reservation Protocol (RSVP). In a simple topology, you can manually assign labels to LSRs and establish static LSPs. You can choose label distribution protocols based on scenarios.

➤ **MPLS Network**

Figure 1-3

An MPLS network consists of two basic elements: LSR and LER. As the core of an MPLS network, LSRs run the MPLS signaling protocol LDP and forward labeled packets. When packets enter the MPLS network, LERs classify them into different FECs, label them, encapsulate them into MPLS packets, and forward them. When packets exit the network, LERs remove the labels to restore original packets. On an MPLS network, labeled packets will be forwarded through the LSP established through LDP.

The MPLS system consists of forwarding unit (data plane) and control unit (control plane). The forwarding unit searches the label forwarding information base and then forwards packets. The control unit creates a label forwarding information base between connected MPLS device nodes and maintains the base. Each MPLS node must run one or more routing protocols (including static routing protocols) to exchange routing information with other nodes. From the perspective of the control plane, each MPLS node is an IP router. Similar to traditional IP routers, MPLS nodes use unicast routing protocols (including static routing protocols) to establish and maintain routing tables. However, traditional routers use routing tables to establish forwarding tables, while MPLS nodes use routing tables to exchange label binding messages with adjacent nodes for destination subnets. A protocol used to exchange label binding messages is called LDP.

➤ **MPLS Forwarding**

Figure 1-4 Process of forwarding penultimate-hop popping MPLS packets

The following uses the example of traditional IP routing to describe MPLS forwarding.

- All LSRs (including LERs) use traditional routing protocols, for example, Open Shortest Path First (OSPF) and Intermediate System to Intermediate System (IS-IS), to establish IP routing tables.
- LSPs are established through LDP based on IP routing tables.

- The ingress LER receives an IP packet, analyzes the IP packet header and maps it into an FEC, attaches L1 to the packet, and forwards the labeled packet to the next-hop LSR through the LSP.
- The LSR receives the labeled packet and finds the LSP based on the label on the stack top, replaces the label, and forwards the packet to the next-hop LSR through the LSP.
- Transit LSRs repeat the previous step.
- The penultimate-hop LSR receives the labeled packet and checks the label forwarding table. If the outgoing label is an implicit null label (3), the LSR pops the label and forwards the original IP packet to the LSR of the last hop. If the label is an explicit null label, the LSR replaces the outermost label with a Label 0 and forwards the packet to the LSR of the last hop.
- If the penultimate-hop LSR pops the label, the egress LER of the last hop will receive an original IP packet and forward the packet based on the IP routing table. If the penultimate-hop LSR does not pop off the label because it is an explicit null label, the last-hop label edge router (LER) will receive the packet with the label value of 0 and pop off the label before forwarding the packet through a lookup into the IP routing table.

▾ MPLS TTL Mode

After MPLS encapsulation and decapsulation, IP (or MPLS) packets can be processed in two TTL modes.

- TTL replication mode: It is a default mode. When Push operation is performed, the TTL of the pushed label is copied from the TTL domain of the existing IP or MPLS packet header to the TTL domain of the pushed label. When Pop operation is performed, the inner IP or MPLS packet TTL is copied back from the TTL domain of outer labels. When TTL replication is enabled, if the inner header TTL is smaller than the outer header TTL, the inner header TTL will not be copied or changed.
- TTL non-replication mode: The TTL will not be copied. **When Push operation is performed, the TTL of the pushed label is set to 255. When Pop operation is performed, the inner IP or MPLS packet TTL will not change.**

In TTL replication mode, LSRs that pass through the MPLS domain can be tracked by using Tracert on the Customer Edge (CE). In TTL non-replication mode, LSPs will be processed as one hop.

Related Configuration

▾ Enabling MPLS Forwarding Globally

- By default, MPLS forwarding is disabled globally.
- Run the **mpls ip** command in global configuration mode to enable devices to support MPLS forwarding. After MPLS forwarding is enabled, the devices implement label switching preferentially; when label switching fails, the devices switch to IP forwarding.

▾ Enabling Label Forwarding on an Interface

- By default, label forwarding is disabled on interfaces.
- Run the **label-switching** command to enable MPLS forwarding on the specified interface. When you enable label forwarding on an interface, adjust the interface's maximum transmission unit (MTU) based on the service type; otherwise, the transmission of large packets may be affected.

↘ Configuring the MPLS MTU of an Interface

- The MPLS MTU determines whether an MPLS packet needs to be fragmented before being sent. The length defined by the MPLS MTU includes the total length of the MPLS encapsulation layer and encapsulated layer (such as IP).
- By default, the MPLS MTU of an interface is the same as its MTU.
- Run the **mpls mtu** command to configure the MPLS MTU of an interface.

↘ Configuring MPLS Packet Fragmentation

- You can configure the processing mode for MPLS packets whose sizes exceed the MPLS MTU.
- By default, IP fragmentation is implemented. The IP packet fragments are encapsulated with the original label and forwarded along the LSP associated with this label.
- Run the **mpls ip fragment** command to configure MPLS packet fragmentation.

↘ Configuring the ICMP Error Packet Processing Mode

- Configure the processing mode for ICMP error packets that are generated during MPLS packet forwarding. ICMP error packets include those generated when MPLS time to live (TTL) times out.
- By default, ICMP error packets are forwarded along the LSP associated with the label stack.
- Run the **mpls ip icmp-error pop labels** command to configure packet processing based on the label quantity. If the number of labels on the stack is smaller than or equal to the specified label quantity, the ICMP error packet will be forwarded through a lookup into the IP routing table that contains the forwarding equivalence class (FEC) of the topmost label. If the number of labels on the stack is greater than the specified label quantity, the ICMP error packet will be forwarded along the LSP associated with the label stack.

↘ Configuring MPLS TTL Replication

- By default, TTL replication is applied to the packets that the local device sends and forwards.
- Run the **mpls ip ttl propagate { public | vpn }** command to control TTL replication on the local device when sending and forwarding packets.

1.3.2 Static MPLS LSP

You can enable MPLS forwarding through static configuration without LDP.

-
- i** As LDP is not required for static configuration, IPv4 routes are not required. Even if no IPv4 route is available, static LSPs will take effect if the physical network is accessible.
-

Working Principle

↘ Configuring Static FTN on the Ingress LSR

At the LSP ingress, you need to establish FTN entries for FECs; that is, you need to bind FECs with labels.

↘ Configuring Static ILM on Transit LSRs

On transit LSRs, you need to configure ILM forwarding entries to map incoming labels to outgoing labels.

↳ [Configuring Static ILM on the Penultimate-hop LSR](#)

As PHP will be enabled on the penultimate hop, ILM entries on the penultimate hop must be different from those on transit LSRs; that is, the outgoing label of ILM on the penultimate-hop LSR must be an implicit null label (3).

 For information on PHP, see related materials.

[Related Configuration](#)

↳ [Configuring Static FTN on the Ingress LSR](#)

- In global configuration mode, run the **mpls static ftn** command to configure static FTN.
- The ingress LSR must be configured with FEC to NHLFE (FTN) to forward IP traffic to an LSP.
- If you configure FTN with the outgoing label value of 3, you must configure IP routes with the same prefix to make FTN effective.

↳ [Configuring Static ILM on Transit LSRs](#)

- In global configuration mode, run the **mpls static ilm in-label** command to configure static ILM.
- Transit LSRs must be configured with incoming label map (ILM) to forward MPLS packets.
- It is recommended that the outgoing label value of 3 be configured on the penultimate-hop LSR so that the egress LSR can directly receive IP packets; otherwise, you need to configure ILM on the egress LSR.

1.3.3 LDP and Session

LDP is mainly used to exchange label binding messages between IP unicast routes and Martini Layer-2 VPN.

 This section describes how to establish LSPs on unicast routes. For details about Martini Layer-2 VPN configuration and application, see the "Configuring Layer-2 VPN" section.

LDP peer discovery and LDP session establishment are the prerequisites of LSP establishment.

[Working Principle](#)

↳ [LDP Router ID](#)

An LDP Router ID uniquely identifies an LSR in a domain. It is in the IPv4 address format. By default, the LDP Router ID is the same as the Router ID (LSR ID) and must be globally unique.

↳ [LDP Peer Discovery and Maintenance](#)

LDP periodically sends User Datagram Protocol (UDP) Hello packets to advertise its state and listens to Hello packets to discover LDP peers.

If LDP discovers an LDP peer but has not received a Hello packet from this peer for a period of time, LDP determines that the LDP peer is invalid. This period is called the Hello packet keep-alive period.

↳ LDP Session Establishment and Maintenance

When LDP receives a Hello packet from an LDP peer, it uses the transport address advertised by the Hello packet to set up a TCP connection and initializes message exchange through the connection to negotiate LDP session parameters, in order to establish an LDP session.

After the LDP session is established, the two LDP peers periodically send keepalive packets to monitor the TCP connection. If a peer has not received a keepalive packet from the other peer for a period of time, it determines that the TCP connection is invalid and closes the LDP session. This period is called the keepalive packet keep-alive period.

Related Configuration

↳ Enabling LDP Globally

- By default, LDP is disabled globally.
- Run the **mpls router ldp** [*vrf-name*] command in global configuration mode to enable LDP for a VRF instance and enter LDP configuration mode.

↳ Enabling LDP on an Interface

- By default, LDP is disabled on interfaces.
- Run the **mpls ip** command in interface configuration mode to enable LDP on an interface.

↳ Configuring an LDP Router ID

- By default, the LDP Router ID is the same as the Router ID.
- Run the **ldp router-id** command to modify the LDP Router ID.

↳ Configuring a Transport Address

By default, the transport address used by an LDP session is the same as the LDP Router ID.

Run the **transport-address** command to specify the primary address of an interface or an IP address as the transport address used by the LDP session on the interface.

You can configure the transport address in either of the following modes:

- Run the **mpls ldp transport-address** command in interface configuration mode.
- Run the **transport-address** command in LDP configuration mode to globally configure the transport address used by all LDP sessions.

↳ Configuring the Hello Packet Interval

- The default Hello packet interval used by the basic LDP discovery mechanism is 5s.
- You can change the Hello packet interval in the range from 1s to 65,535s in interface configuration mode.

↳ Configuring the Hello Packet Keep-Alive Period

- By default, the default Hello packet keep-alive period used by the basic LDP discovery mechanism is 15s.

- You can change the Hello packet keep-alive period in the range from 1s to 65,535s in interface configuration mode. If it is set to 65,535s, the keep-alive period is infinitely long.

▾ Configuring the Keepalive Packet Keep-Alive Period

- By default, the keep-alive period of keepalive packets sent through an interface is 45s.
- You can change the keep-alive period in the range from 15s to 65,535s. The keepalive packet interval is one-third of its keep-alive period.

▾ Configuring the Maximum PDU Size

- LDP entities exchange messages as protocol data units (PDUs). By default, the maximum PDU size is 4,096. You can change it in the range from 256 to 4,096.

▾ Configuring LDP MD5 Authentication

- You can configure MD5 authentication of TCP connections to improve LDP session security.
- By default, LDP MD5 authentication is not configured.
- Run the **neighbor ip-address password [0 | 7] pwd-string** command to configure MD5 authentication of the TCP connection with the specified address.

1.3.4 LDP Session Protection

Faulty links will seriously affect network convergence and aggregation because the Hello adjacency between associated interfaces for LDP sessions will be disconnected when links fail and thereby LDP sessions will be closed. When links recover from failures, LSRs need to establish LDP sessions and exchange label binding messages again, which reduces the efficiency of LDP convergence.

LDP session protection can protect LDP sessions between two directly connected LSRs and LDP over TE sessions, and accelerate LDP convergence in case of link failures, especially when failures last for only a short time.

Working Principle

After LDP sessions between two LSRs are protected, a target Hello adjacency will be established between the LSRs. When the link between them fails, if alternative paths exist, the target Hello adjacency will be maintained. When the link fails, the link Hello adjacency will be disconnected, but the target Hello adjacency will maintain LDP sessions. When the link recovers from failures, LSRs do not need to establish LDP sessions again, which improves the efficiency of LDP convergence.

Figure 1-5 LDP session protection

As shown in the figure, R1, R2, and R3 are interconnected with each other at the link layer with OSPF enabled. LDP is enabled between R1 and R2. A link Hello adjacency will be established between R1 and R2 so that LDP sessions will be established. To protect LDP sessions between R1 and R2, you can enable LDP session protection on R1 and R2. In this way, a target Hello adjacency will be established between R1 and R2.

When the link between R1 and R2 fails, the link Hello adjacency will be disconnected. However, the target Hello adjacency will be maintained because of another path R1-R3-R2. Therefore, LDP sessions will not be closed.

When the link recovers from failures, R1 and R2 do not need to establish LDP sessions or exchange label binding messages again.

Related Configuration

Configuring LDP Session Protection

- By default, LDP instance session protection is disabled.
- Run the **session protection** command to enable or disable LDP session protection.
- You can enable LDP session protection on the two LSRs engaged in an LDP session. If only one LSR supports LDP session protection, you can configure this function on this LSR and run the **discovery targeted-hello accept** command on the other LSR to receive and reply to target Hello packets (or run the **neighbor ip-address** command to specify the remote peer).

1.3.5 LDP LSP

The LDP LSPs described in this section are the LSPs that LDP establishes on IP unicast routes.

Working Principle

Process of Establishing an LSP

Establishing an LSP means binding FECs with labels and notifying the operation to the adjacent LSR. This process is implemented through LDP based on RFC3036.

After LDP sessions are established, two LSRs can exchange label messages to bind labels and establish LSPs for FECs.

Labels can be distributed in Downstream on Demand (DOD) mode and Downstream Unsolicited (DU) mode. In DOD mode, an LSR replies to a label binding message only when receiving a label request from the adjacent LSR. In DU mode, an LSR distributes labels to the adjacent LSR without receiving requests.

Labels can be controlled in independent mode and ordered mode. In independent mode, each LSR can notify its adjacent LSR of label-FEC binding. In independent DOD mode, an LSR can immediately reply to label mapping requests from an upstream LSR rather than wait for label mapping messages from the next hop. In independent DU mode, an LSR can notify label mapping whenever it is ready to switch labels for an FEC.

In ordered mode, an LSR distributes upstream the label bound with an FEC only when it receives the label mapping message from the next hop or when it is the egress for the FEC; otherwise, the LSR must wait for the label mapping message from a downstream LSR. In ordered DU mode, an LSR notifies label mapping to an upstream LSR only when it is the egress for an FEC or when it receives the label from a downstream LSR. If downstream LDP session labels are distributed in DOD mode, the LSR will send downstream the label request from an upstream LSR.

If a label mapping message is not from the next hop of an FEC or if the message does not match any FEC, the message can be processed based on the label retention mode.

In liberal label retention mode, FEC label binding learned from the neighbor is retained; in conservative label retention mode, FEC label binding learned from the neighbor is not retained.

In conservative label retention mode, there are only a few labels to be used and maintained; however, when routes change, label values need to be obtained again, which increases the response time. In liberal label retention mode, LSRs respond to route changes quickly; however, unnecessary labels need to be distributed and maintained.

↳ LSP Loop Control

A loop detection mechanism is required. Two methods are available to prevent a loop: maximum hop count and path vector.

Maximum hop count: The number of LSRs is included in a label binding message. It is increased by 1 when an LSR passes. When the number exceeds the specified maximum, it indicates that a loop occurs, and LSP establishment will be stopped.

Path vector: The LSR ID is recorded in the vector list of a label binding message when an LSR passes. When receiving a label binding message, an LSR checks whether its ID is recorded in the vector list. If the ID is not recorded, the LSR will add it to the list. If the ID is recorded, it indicates that a loop occurs, and LSP establishment will be stopped.

↳ Policy-Based Label Distribution Control

By default, LDP distributes labels to all valid Interior Gateway Protocol (IGP) routes, except BGP routes. In special cases, you may want to distribute labels only to specified routes or LDP peers to reduce labels and LSPs used, in order to alleviate device and network burden. To do this, you can configure label distribution policies to achieve either or both of the following effects:

- Distribute Label Mapping messages with corresponding FECs only to specified IP routes.
- Distribute Label Mapping messages only to specified LDP peers.

↳ Policy-Based Label Reception Control

By default, LDP receives all Label Mapping messages over LDP sessions in DU mode and DOD mode. If an LDP session is in DOD mode, LDP sends the peer Label Request messages with FECs indicating the peer as the next hop. You can configure reception policies to achieve the following effects:

- Only receive the Label Mapping messages with FECs mapped to the specified IP route from the specified peer.
- Only send the Label Request messages with the specified FEC to the specified LDP peer.
- Do not receive Label Mapping messages from the specified peer.
- Do not send Label Request messages to the specified peer.

Related Configuration

▾ Configuring the Label Distribution Control Mode

- By default, label distribution is controlled in independent mode.
- Run the **lsp-control-mode** command to configure the LDP label distribution control mode.

▾ Configuring the Label Distribution Mode

- By default, labels are distributed in DU mode.
- Run the **mpls ldp distribution-mode** command in interface configuration mode to configure the LDP label distribution mode on an interface.

▾ Configuring the Label Retention Mode

- By default, labels are retained in liberal mode.
- Run the **label-retention-mode** command to configure the label retention mode.

▾ Configuring Loop Detection

- By default, loop detection is disabled.
- Run the **loop-detection** command to configure loop detection.

▾ Configuring the Maximum Number of Hops

- Run the **mpls ldp max-hop-count** command in interface configuration mode to configure the maximum number of hops in loop detection. The value ranges from 1 to 255. The default value is 254.
- After loop detection is enabled, loop occurs if the number of hops traversed by an LDP message exceeds the threshold.

▾ Configuring the Maximum Number of LSRs in the Path Vector List

- Run the **mpls ldp max-path-vector** command to configure the maximum number of LSRs in the path vector list used for loop detection. After loop detection is enabled, loop occurs if an LSR detects that its LSR ID is contained in the path vector list or the number of LSR IDs in the path vector list exceeds the threshold. The default value is 254.
- Run the **mpls ldp max-path-vector** command in interface configuration mode to configure the maximum number of LSRs in the path vector list.

↘ Configuring the Label Release Message Propagation Mode

- When an FEC is invalid, LDP will send a label release message from upstream to downstream to revoke the label bound to the FEC. The label release message propagation mode determines whether each receiving LDP entity on an LSP propagates the label release message to the downstream.
- By default, the receiving LDP entity does not propagate the label release message to the downstream.
- Run the **propagate-release** command to configure the label release message propagation mode.

↘ Configuring Label Distribution Policies

- Run the **advertise-labels for host-routes** command to distribute labels only to the host routes with a 32-bit mask in VRF tables. By default, labels are distributed to host routes with various mask lengths.
- Run the **advertise-labels for bgp-routes** [**acl** *acl-name*] command to distribute labels to BGP routes. By default, LDP does not distribute labels to BGP routes.
- Run the **advertise-labels for default-route** command to distribute labels to default routes. By default, LDP distributes implicit null labels with the value of 3 to default routes.
- Run the **advertise-labels for acl** *prefix-access-list* [**to** *peer-access-list*] command to distribute labels only to FECs and LDP peers that meet access control list (ACL) rules.

↘ Configuring Label Reception Policies

- Run the **neighbor** *ip-address* **labels accept** *acl-name* command to configure label reception policies. By default, LDP receives label binding messages over all sessions.

↘ Configuring Explicit Null Label Distribution

- By default, LDP distributes implicit null labels to FECs with local devices as the egress (for example, direct routes).
- Run the **explicit-null** command to distribute explicit null labels to all direct routes or direct routes that meet specified ACL rules.

1.3.6 Inter-Domain LDP LSP

When an autonomous system (AS) is divided into multiple IGP areas, to downsize the routing table and improve the efficiency, you need to configure host route aggregation on area border routers (ABRs). You can establish an LSP across multiple IGP areas for the route through the inter-area LDP LSP technology.

Such LSP is established by extending the longest route match.

Working Principle

↘ Inter-area LSP

An inter-area LSP crosses multiple IGP areas of an AS.

↘ ABR

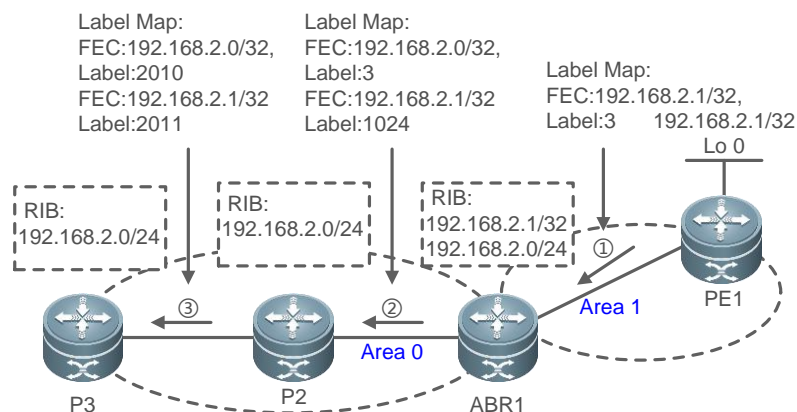

For OSPF, an ABR is a node connecting backbone areas to other areas; for IS-IS, an ABR is a node between Level 1 and Level 2.

i When an AS is divided into multiple IGP areas and host routes are aggregated on ABRs, you can enable the inter-area LDP LSP function to establish an LSP across multiple IGP areas for the host routes.

When the inter-area LDP LSP function is disabled, LDP forwards labels only to accurately matched routes and distributes label mapping messages to all LDP neighbors. When the function is enabled, if there is a route with the longest mask that is matched to the FEC in a label mapping message and the neighbor sending the label mapping message corresponds to the next hop of the route, LDP will add forwarding entries and distributes label mapping messages to LDP neighbors (based on FECs in received label mapping messages rather than FECs matched to the route with the longest mask in the routing table).

The following figure shows the process of establishing an inter-area LDP LSP.

Figure 1-6

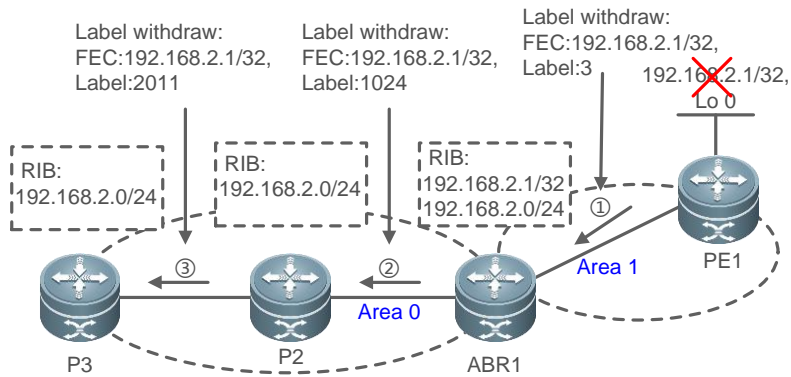

Based on the figure, the following describes the process of establishing an inter-area LDP LSP.

- On ABR1, aggregated routes are notified to backbone areas. Both aggregated route (192.168.2.0/24) and host route (192.168.2.1/32) are available in the routing table of ABR1.
- PE1 sends ABR1 a label mapping message of the FEC 192.168.2.1/32.
- ABR1 sends P2 label mapping messages of FECs 192.168.2.0/24 and 192.168.2.1/32, respectively.
- Only the aggregated route 192.168.2.0/24 is available in the routing table of P2. P2 sends P3 the label mapping message of the FEC 192.168.2.0/24. As there is a route with the longest mask (192.168.2.0/24) that is matched to the FEC 192.168.2.1/32 and ABR1 corresponds to the next hop of the route, P2 also sends P3 the label mapping message of the FEC 192.168.2.1/32.
- P3 repeats the actions of P2.
- An inter-area LSP across P3, P2, ABR1, and PE1 (192.168.2.1/32) is established between Area 0 and Area 1.

This process is similar to the process in ordered DU mode (as only aggregate routes are available upstream, the inter-area LDP LSP technology is inapplicable to the DOD mode). The LSP established in this way is the shortest IGP path.

If the MPLS forwarding entries added based on the longest match principle need to be deleted because of label cancellation messages from a downstream device or deletion of the matched route with the longest mask, the label cancellation messages need to be sent upstream (whether label distribution is controlled in ordered or independent mode). The following figure shows the process of canceling an inter-area LSP.

Figure 1-7

If the matched route with the longest mask changes (a better route is available or the route is deleted), the routing platform will notify LDP to update or delete the MPLS forwarding entries added based on the longest match principle to improve the accuracy of LSPs.

Related Configuration

Configuring the Inter-Domain LDP LSP Feature

- By default, the inter-area LDP LSP function is disabled.
- Run the **inter-area-lsp** command to enable or disable the inter-domain LDP LSP feature.
- The inter-domain LDP LSP feature only takes effect for aggregated host routes. If a longest match ACL rule is configured for aggregated non-host routes, this rule will be invalid.

1.4 Product Information

✔ On the S8600E, the MPLS MTU of an interface cannot exceed the actual packet size allowed by the interface. The MTU configuration is invalid on switches that forward MPLS packets through application-specific integrated circuits (ASICs). Packets are forwarded through an interface based on its MTU. Any packet exceeding the MTU size will be discarded instead of fragmented. You can run the **mtu** command in interface configuration mode to adjust the MTU. Fragmentation is only supported during process forwarding and router forwarding. You should adjust the MTU to minimize fragmentation, in order to avoid reduced performance.

✔ After the TTL replication feature is enabled on the S8600E, TTL replication is always performed regardless of whether the inner header TTL is smaller than the outer header TTL.

- ✓ The **mpls ip** command (in global configuration mode) is used to control software forwarding instead of chip forwarding on switches.

1.5 Configuration

Configuration	Description and Command	
Configuring MPLS Forwarding	 (Mandatory) It is used to enable MPLS.	
	mpls ip	Enables MPLS forwarding globally.
	label-switching	Enables MPLS forwarding on an interface.
	 (Optional) It is used to configure MPLS forwarding parameters.	
	mpls mtu	Configures the MPLS MTU of an interface.
	mpls ip fragment	Configures MPLS packet fragmentation.
	mpls ip icmp-error pop	Configures the processing mode for ICMP error packets that are generated during MPLS packet forwarding.
Configuring a Static MPLS LSP	 (Mandatory) It is used to enable MPLS.	
	mpls static ftn out-label nexthop	Configures static FTN.
	mpls static ilm in-label forward-action swap-label nexthop fec	Configures static ILM.
	 (Mandatory) It is used to establish an LDP session.	
Configuring an LDP Session	mpls router ldp	Enables LDP.
	mpls ip	Enables LDP on an interface.
	neighbor	Creates a remote LDP peer.
	discovery targeted-hello accept	Configures the reception of target LDP Hello packets.
	 (Optional) It is used to configure LDP session parameters.	
	ldp router-id interface loopback	Configures an LDP Router ID.
	mpls ldp transport-address	Configures the transport address used by the local LDP session on an interface.
	transport-address	Configures the transport address used by the local LDP session in global configuration mode.
mpls ldp hello-interval	Configures the Hello packet interval on every interface.	

Configuration	Description and Command	
	discovery targeted-hello	Configures the Hello packet interval or keep-alive period used by the extended LDP discovery mechanism.
	mpls ldp hello-holdtime	Configures the Hello packet keep-alive period on every interface.
	mpls ldp keepalive-holdtime	Configures the keepalive packet keep-alive period on an interface.
	targeted-session holdtime	Configures the keepalive packet keep-alive period used by the remote LDP session.
	mpls ldp max-pdu	Configures the maximum length of every LDP message.
	neighbor <i>ip-address</i> password	Enables LDP MD5 authentication.
	route wait label-mapping <i>seconds</i>	Configures the waiting time for label mapping during route updating.
Configuring LDP Session Protection	 (Mandatory) It is used to enable LDP session protection.	
	session protection	Configures LDP session protection.
Configuring an LDP LSP	 (Optional) It is used to establish an LDP LSP.	
	loop-detection	Enables loop detection.
	mpls ldp max-hop-count	Configures the maximum number of hops in loop detection on an interface.
	mpls ldp max-path-vector	Configures the maximum number of LSRs in the path vector list used for loop detection on an interface.
	propagate-release	Enables label release message propagation.
	lsp-control-mode	Configures the LDP control mode globally.
	mpls ldp distribution-mode	Configures the LDP label distribution mode on every interface.
	label-retention-mode	Configures the label retention mode.
	advertise-labels	Configures label distribution policies for FECs mapped to IP routes.
	neighbor <i>ip-address</i> labels accept <i>acl-name</i>	Configures LSRs to filter Label Mapping messages sent by specified LDP peers based on specified ACL rules.
explicit-null	Configures distribution of explicit null labels to all direct routes or direct routes that meet specified ACL rules, or configures distribution of explicit null labels to neighbors that meet specified ACL rules and implicit null labels to other neighbors.	

Configuration	Description and Command	
Configuring the Inter-Domain LDP LSP Feature	 (Mandatory) It is used to enable the inter-domain LDP LSP feature.	
	inter-area-lsp	Configures the inter-domain LDP LSP feature.

1.5.1 Configuring MPLS Forwarding

Configuration Effect

- Enable MPLS forwarding on all LSRs and corresponding interfaces traversed by an LSP. The device forwards packet labels first rather than IP packets. When label forwarding fails, the device forwards IP packets.

Notes

- Enable MPLS forwarding in global configuration mode and interface configuration mode.

Configuration

↘ Enabling MPLS Forwarding Globally

- (Mandatory) Perform this configuration in global configuration mode.
- (Mandatory) Perform this configuration in global configuration mode on every LSR traversed by an LSP, unless otherwise specified.

↘ Enabling MPLS Forwarding on an Interface

- (Mandatory) Perform this configuration in interface configuration mode.
- (Mandatory) Perform this configuration in interface configuration mode on every interface traversed by an LSP, unless otherwise specified.

↘ Configuring the MPLS MTU of an Interface

- (Optional) Perform this configuration in interface configuration mode.
- This configuration is required only in special cases.

↘ Configuring MPLS Packet Fragmentation

- (Optional) Perform this configuration in global configuration mode.
- Perform this configuration on every LSR traversed by an LSP, unless otherwise specified. If MPLS packet fragmentation is not enabled, LSRs cannot forward large packets that exceed the MTU size. By default, MPLS packet fragmentation is enabled.

↘ Configuring the ICMP Error Packet Processing Mode

- (Optional) Perform this configuration in global configuration mode.
- This configuration is required only in special cases.

↘ Configuring MPLS TTL Replication

- (Optional) Perform this configuration in global configuration mode.
- Disable MPLS TTL replication on every LSR traversed by an LSP if you want to hide the MPLS network topology.

Verification

Run the **show mpls summary** command to display the list of interfaces enabled with MPLS forwarding.

Run the **show run** command to check whether the configuration takes effect.

Related Commands

↘ Enabling MPLS Forwarding Globally

Command	mpls ip
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Enabling MPLS Forwarding on an Interface

Command	label-switching
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	MPLS interface commands can be run only on Layer-3 interfaces. Therefore, non-Layer-3 interfaces need to be converted into Layer-3 interfaces.

↘ Configuring the MPLS MTU of an Interface

Command	mpls mtu bytes
Parameter Description	bytes: Indicates the length of an MPLS packet, which ranges from 64 to 1,500 bytes by default.
Command Mode	Interface configuration mode
Usage Guide	<ol style="list-style-type: none"> 1. The MPLS MTU must not exceed the size of transmitted packets. You can run the mpls mtu command to adjust the MTU in interface configuration mode. 2. After encapsulating MPLS packets, devices that support MPLS packet fragmentation will fragment the packets whose length exceeds the MPLS MTU based on the MPLS MTU. Devices that do not support MPLS packet fragmentation will discard the packets whose length exceeds the MPLS MTU.

↘ Fragmenting MPLS Packets

Command	mpls ip fragment
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	<ol style="list-style-type: none"> 1. This command is valid for IP packets only. 2. On devices that support MPLS packet fragmentation, you can use the no form of this command to disable MPLS packet fragmentation. On devices that do not support MPLS packet fragmentation, this command is invalid.

📌 Processing ICMP Error Packet

Command	mpls ip icmp-error pop labels
Parameter	<i>labels</i> : Indicates the number of labels of packets to be processed.
Description	
Command Mode	Global configuration mode
Usage Guide	You can run this command to have packets processed based on the number of labels. If the number of labels exceeds the configured value, the device will forward the packets through the LSP of the label stack. If the number of labels is below or equal to the configured value, the device will forward the ICMP error packets based on the IP routing table of the FEC corresponding to stack-top labels.

📌 Configuring MPLS TTL Replication

Command	mpls ip ttl propagate public
Parameter	public : Enables or disables TTL replication for sent packets.
Description	vpn : Enables or disables TTL replication for forwarded packets.
Command Mode	Global configuration mode
Usage Guide	When TTL replication is enabled, if the inner header TTL is smaller than the outer header TTL, the inner header TTL will not be copied or changed.

Configuration Example

📌 Configuring MPLS Forwarding

Scenario Figure 1-8	
Configuration Steps	<ul style="list-style-type: none"> ● Configure MPLS forwarding on the ingress LSR. ● Configure MPLS forwarding on transit LSRs.

	<ul style="list-style-type: none"> ● Configure MPLS forwarding on the penultimate-hop LSR.
LER-A	<pre>Ruijie(config)# mpls ip Ruijie(config)# interface gigabitEthernet 2/2 Ruijie(config-if-GigabitEthernet 2/2)# label-switching Ruijie(config-if-GigabitEthernet 2/2)# end</pre>
LSR-B	<pre>Ruijie(config)# mpls ip Ruijie(config)# interface gigabitEthernet 2/1 Ruijie(config-if-GigabitEthernet 2/1)# label-switching Ruijie(config-if-GigabitEthernet 2/1)# exit Ruijie(config)# interface gigabitEthernet 2/2 Ruijie(config-if-GigabitEthernet 2/2)# label-switching Ruijie(config-if-GigabitEthernet 2/2)# exit Ruijie(config)# end</pre>
LER-C	<pre>Ruijie(config)# interface gigabitEthernet 2/1 Ruijie(config-if-GigabitEthernet 2/1)# label-switching Ruijie(config-if-GigabitEthernet 2/1)# end</pre>
Verification	Check whether MPLS forwarding is enabled in interface configuration mode on all routers.
LER-A	<pre>A# show mpls summary Minimum label configured: 16 Maximum label configured: 1048575 Per label-space information: Label-space 0 is using minimum label: 16 and maximum label: 1048575 Label-Switching Interface: Interface Label space Gi2/2 0 Total number of mpls interface is 1</pre>
LSR-B	<pre>B# show mpls summary Minimum label configured: 16 Maximum label configured: 1048575</pre>

	<pre> Per label-space information: Label-space 0 is using minimum label: 16 and maximum label: 1048575 Label-Switching Interface: Interface Label space ----- - Gi2/1 0 Gi2/2 0 Total number of mpls interface is 2 </pre>
LER-C	<pre> C# show mpls summary Minimum label configured: 16 Maximum label configured: 1048575 Per label-space information: Label-space 0 is using minimum label: 16 and maximum label: 1048575 Label-Switching Interface: Interface Label space ----- - Gi2/1 0 Total number of mpls interface is 1 </pre>

Common Errors

- MPLS forwarding is not enabled globally.
- LDP is not enabled in interface configuration mode.

1.5.2 Configuring a Static MPLS LSP

Configuration Effect

Establish a static LSP

Notes

- Enable MPLS forwarding in global configuration mode and interface configuration mode.
- When you configure static TFN with the label value of 3, configure IP routes with the same next hop for forwarding.

Configuration

📌 Configuring MPLS Forwarding on All LSRs

- Perform this configuration according to section 1.5.1.

➤ **Configuring Static FTN on the Ingress LSR**

- (Mandatory) Perform this configuration in global configuration mode.

➤ **Configuring Static ILM on Transit LSRs**

- (Mandatory) Perform this configuration in global configuration mode.

Verification

Run the **show mpls forwarding-table** command to display MPLS entries.

Related Commands

➤ **Configuring Static FTN on the Ingress LSR**

Command	mpls static ftn <i>ip-address/mask</i> out-label <i>label</i> nexthop <i>interface nexthop-ip</i>
Parameter Description	<i>ip-address/mask</i> : Indicates the address of an FEC, namely the destination address. out-label <i>label</i> : Indicates the outgoing label of the FEC. The value ranges from 16 to 1048575, or is 3. nexthop <i>interface-name nexthop-ip</i> : Indicates the next hop of the FEC, including the next-hop outgoing interface and IP address.
Command Mode	Global configuration mode
Usage Guide	You can run this command to add an FTN entry to the global FTN table. Upon receipt of an IP packet, the device on which MPLS is enabled finds the next hop based on the destination address of the IP packet by following the longest match principle, and then forwards the label of the IP packet. This command is valid for FTN entries whose destination address and mask are 0 only when the default route is available in the IP routing forwarding table.

➤ **Configuring Static ILM on Transit LSRs**

Command	mpls static ilm in-label <i>in_label</i> forward-action swap-label <i>swap_label</i> nexthop <i>interface nexthop-ip</i> fec <i>ip-address/mask</i>
Parameter Description	<i>in_label</i> : Indicates the incoming label of an ILM entry. The value ranges from 16 to 1025. forward-action : Specifies the forwarding action of the ILM entry. <i>label</i> : Specifies the value of the outgoing label when swap-label action is performed. The value ranges from 16 to 1048575, or is 0 or 3. <i>vrf-name</i> : Specifies the VPN for the ILM entry (namely VRF) when pop-l3vpn-nexthop action is performed. <i>interface-name</i> : Specifies the egress when pop-l2vc-destport action is performed. nexthop <i>interface-name nexthop-ip</i> : Specifies the next hop, including the next-hop egress and IP address. fec : Indicates the FEC for which the ILM entry is created. <i>ip-address/mask</i> : Specifies a destination network based on the FEC format of global or Layer-3 VPN application. <i>vc_id</i> : Specifies a virtual circuit (VC) instance based on the FEC format of Layer-2 VPN application. <i>The</i>

	<p>value ranges from 1 to 2147483647.</p> <p><i>vc-peer-addr</i>: Indicates the address of a VC peer.</p>
Command Mode	Global configuration mode
Usage Guide	You can run this command to add an ILM entry to the ILM table. Upon receipt of an IP packet, the device on which MPLS is enabled finds the next hop based on the IP packet label value by following the longest match principle, and then forwards the label.

Configuration Example

Configuring a Static MPLS LSP Network

<p>Scenario</p> <p>Figure 1-9</p>

Common Errors

- MPLS forwarding is not enabled globally.
- MPLS forwarding is not enabled in interface configuration mode.

1.5.3 Configuring an LDP Session

Configuration Effect

- Establish an LDP session between two LSRs to exchange label binding messages.

Notes

- A reachable IP route to the transport address used by the peer to establish an LDP session must exist.

Configuration

▾ Configuring IP Routes

- (Mandatory) Configure static routes in global configuration mode or configure routes through OSPF or other IGP protocols.
- For details, see the *Configuring IP Routes*.

▾ Configuring LDP

- (Mandatory) Perform this configuration on the two LSRs engaged in an LDP session.

▾ Configuring an LDP Router ID

- (Optional) Perform this configuration in config-mpls-router configuration mode.
- It is recommended that an LDP Router ID be configured on each of the two LSRs engaged in an LDP session to ensure stable and reliable LDP.

 You must configure the LDP Router ID in actual application; otherwise, if the Router ID is changed during protocol restart, some functions (such as LDP MD5 authentication using the Router ID) may fail.

▾ Configuring the LDP Capability on an Interface or Configuring the Remote Peer

- Enable the LDP capability in interface configuration mode if a local LDP session needs to be established.
- Configure the remote peer in config-mpls-router configuration mode if a remote LDP session needs to be established.

▾ Configuring a Transport Address

- (Optional) If no transport address is configured, the LDP Router ID is used as the transport address.
- Configure a global transport address in config-mpls-router configuration mode if a local LDP session needs to be established. If a neighbor requires a specified transport address, configure this address on the interface connected to the neighbor.
- This configuration is not required if a remote LDP session needs to be established.

↘ **Configuring the Hello Packet Interval**

- This configuration is required only in special cases.
- Perform this configuration in interface configuration mode if a local LDP session needs to be established.
- Perform this configuration in config-mpls-router configuration mode if a remote LDP session needs to be established.

↘ **Configuring the Hello Packet Keep-Alive Period**

- This configuration is required only in special cases.
- Perform this configuration in interface configuration mode if a local LDP session needs to be established.
- Perform this configuration in config-mpls-router configuration mode if a remote LDP session needs to be established.

↘ **Configuring the Keepalive Packet Keep-Alive Period**

- This configuration is required only in special cases.
- Perform this configuration in interface configuration mode if a local LDP session needs to be established.
- Perform this configuration in config-mpls-router configuration mode if a remote LDP session needs to be established.

↘ **Configuring the Maximum PDU Size**

- This configuration is required only in special cases.
- Perform this configuration in interface configuration mode.

↘ **Configuring LDP MD5 Authentication**

- You can configure LDP MD5 authentication on the two LSRs engaged in an LDP session to improve session security.
- (Optional) Perform this configuration in config-mpls-router configuration mode.

↘ **Configuring the Waiting Time for Label Mapping During Route Updating**

- This configuration is required only in special cases.
- (Optional) It is performed in global configuration mode.

Verification

- Run the **show mpls ldp discovery** command to display the LDP peer discovery state.
- Run the **show mpls ldp neighbor** command to display the LDP session state.
- Run the **show mpls ldp bindings** command to display the LDP label binding state.

- Run the **show run** command to check whether the configuration takes effect.

Related Commands

↳ Enabling LDP Globally

Command	mpls router ldp [<i>vrf-name</i>]
Parameter	<i>vrf-name</i> : Enables or disables LDP of a specified VRF instance.
Description	
Command Mode	Global configuration mode
Usage Guide	The number of LDP instances is limited by the number of VRF instances. Each VRF instance can enable one LDP instance. By default, LDP instances of global VRF instances are enabled (or disabled).

↳ Configuring an LDP Router ID

Command	ldp router-id { <i>ip-address</i> interface <i>interface-name</i> [force] }
Parameter	<i>ip-address</i> : Specifies a static IP address as the LDP router ID. The ID takes effect immediately.
Description	<i>interface-name</i> [force]: Specifies the primary address of a specified interface as the LDP router ID. If force is specified, the ID must be forced to take effect immediately.
Configuration Mode	config-mpls-router mode
Usage Guide	Configures an LDP router ID.

↳ Enabling LDP on an Interface

Command	mpls ip
Parameter	N/A
Description	
Configuration Mode	Interface configuration mode
Usage Guide	Enables LDP on an interface.

↳ Configuring a Remote LDP Peer

Command	neighbor <i>ip-address</i>
Parameter	<i>ip-address</i> : Indicates the ID of the peer LSR.
Description	
Configuration Mode	config-mpls-router mode
Usage Guide	Creates a remote LDP peer.

↳ Receiving Target Hello Packets Through LDP

Command	discovery targeted-hello accept [from <i>acl-name</i>]
----------------	--

Parameter Description	<i>acl-name</i> : Indicates the name of ACL rules. Only the target Hello packets from neighbors specified by ACL rules can be received.
Configuration Mode	config-mpls-router mode
Usage Guide	When remote peers of two devices are established, you can configure a neighbor at one end and enable this function at the other end. To delete a remote peer, you only need to delete the neighbor configuration.

📌 Configuring a Transport Address

Command	mpls ldp transport-address { interface <i>ip-address</i> }
Parameter Description	interface : An LDP session uses the primary address of an interface. <i>ip-address</i> : An LDP session uses the specified IP address.
Configuration Mode	Interface configuration mode
Usage Guide	This command is valid for local LDP sessions established by the basic LDP discovery mechanism and invalid for remote LDP sessions established by the extended LDP discovery mechanism. It is valid for new local LDP sessions and invalid for existing local LDP sessions.

Command	transport-address { interface <i>ip-address</i> <i>interface-name</i> }
Parameter Description	interface : A local LDP session uses the primary IP address of an interface as a transport address. <i>ip-address</i> : All local LDP sessions use a specified IP address as the transport address. <i>interface-name</i> : All local LDP sessions use the primary IP address of a specified interface as the transport address.
Configuration Mode	config-mpls-router mode
Usage Guide	This command is valid for local LDP sessions established by the basic LDP discovery mechanism and invalid for remote LDP sessions established by the extended LDP discovery mechanism. Remote LDP sessions always use the LDP LSR ID as the transport address. If transport addresses are configured in both global and interface configuration modes, the transport address configured in interface configuration mode is preferred.

📌 Configuring the Hello Packet Interval

Command	mpls ldp hello-interval <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the Hello packet interval, which ranges from 1 to 65,535 seconds.
Configuration Mode	Interface configuration mode
Usage Guide	Configures the LDP link Hello packet interval.

Command	discovery targeted-hello <i>interval seconds</i>
----------------	---

Parameter Description	<i>seconds</i> : Indicates the Hello packet interval, which ranges from 1 to 65,535 seconds.
Configuration Mode	config-mpls-router mode
Usage Guide	Configures the LDP target Hello packet interval.

↘ Configuring the Hello Packet Keep-Alive Period

Command	mpls ldp hello-holdtime <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the Hello packet keep-alive period, which ranges from 1 to 65,535 seconds. 65,535 seconds indicate that a timeout will never occur.
Configuration Mode	Interface configuration mode
Usage Guide	Configures the link Hello packet keep-alive period.

Command	discovery targeted-hello <i>holdtime seconds</i>
Parameter Description	Indicates the target Hello packet keep-alive period, which ranges from 1 to 65,535 seconds. 65,535 seconds indicate infinite hold time.
Configuration Mode	config-mpls-router mode
Usage Guide	Configures the target Hello packet keep-alive period.

↘ Configuring the Keepalive Packet Keep-Alive Period

Command	mpls ldp keepalive-holdtime <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the keep-alive packet keep-alive period, which ranges from 15 to 65,535 seconds.
Configuration Mode	Interface configuration mode
Usage Guide	Configures the keep-alive packet keep-alive period for local LDP sessions in interface configuration mode.

Command	targeted-session holdtime <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the keep-alive packet keep-alive period, which ranges from 15 to 65,535 seconds.
Configuration Mode	config-mpls-router mode
Usage Guide	The default keep-alive packet keep-alive period is used for restoration of local LDP sessions.

↘ Configuring the Maximum PDU Size

Command	mpls ldp max-pdu <i>max-pdu</i>
Parameter	<i>max-pdu</i> : Indicates the maximum PDU length for message exchange, which ranges from 256 to 4,096

Description	bytes.
Configuration Mode	Interface configuration mode
Usage Guide	Configures the maximum PDU length.

↘ **Configuring LDP MD5 Authentication**

Command	neighbor <i>ip-address</i> password [0 7] <i>pwd-string</i>
Parameter Description	<i>ip-address</i> : Indicates the transport address of the peer LSR. [0 7]: (Optional) 0 indicates a plaintext key; 7 indicates a cyphertext key. By default, a plaintext key is entered. <i>pwd-string</i> : Indicates a password string, which is case-sensitive. A plaintext password string contains 1 to 25 characters, while a cyphertext password string contains 1 to 52 characters.
Configuration Mode	config-mpls-router mode
Usage Guide	Configures MD5 authentication of TCP connections to the peer LSR.

↘ **Configuring the Waiting Time for Label Mapping**

Command	route wait label-mapping <i>seconds</i>
Parameter Description	<i>seconds</i> : Configures the waiting time for label mapping during route updating.
Configuration Mode	Global configuration mode
Usage Guide	During IP route updating, an LSP corresponding to the new next hop perhaps is not yet established. However, LDP will delete the LSP corresponding to the old next hop so that the traffic will be interrupted until a new LSP is established. To solve this problem, you can run this command to have LDP delay deleting the old LSP until a new LSP is established. During this period, once a new LSP is established, the traffic will be switched to the new LSP. If a new LSP is not established within this period, the LDP will delete the old LSP.

Configuration Example

↘ **Establishing a Local LDP Session**

Scenario Figure 1-10	
Configuration Steps	<ul style="list-style-type: none"> ● Configure an IPv4 unicast routing protocol (such as OSPF) on each router and check that a unicast route is reachable to its loopback interface. ● Enable LDP globally. ● Configure an LDP Router ID.

	<ul style="list-style-type: none">● Enable LDP on an interface.

Verification	<p>Check whether an LDP session is established between LER A and LER C.</p>
LER-A	<pre>A# show mpls ldp neighbor Default VRF: Peer LDP Ident: 192.168.0.3:0; Local LDP Ident: 192.168.0.1:0 TCP connection: 192.168.0.3.1102 - 192.168.0.1.646 State: OPERATIONAL; Msgs sent/rcv: 7/8; UNSOLICITED</pre>

	<pre> Up time: 00:00:55 Graceful Restart enabled; Peer reconnect time (msecs): 300000 LDP discovery sources: Targeted Hello 192.168.0.1 -> 192.168.0.3, active, passive; Addresses bound to peer LDP Ident: 192.168.2.2 192.168.0.3 </pre>
LER-C	<pre> C# show mpls ldp neighbor Default VRF: Peer LDP Ident: 192.168.0.1:0; Local LDP Ident: 192.168.0.3:0 TCP connection: 192.168.0.1.646 - 192.168.0.3.1102 State: OPERATIONAL; Msgs sent/rcv: 7/8; UNSOLICITED Up time: 00:00:09 Graceful Restart enabled; Peer reconnect time (msecs): 300000 LDP discovery sources: Targeted Hello 192.168.0.3 -> 192.168.0.1, active, passive; Addresses bound to peer LDP Ident: 192.168.1.1 192.168.0.1 </pre>

Common Errors

- IPv4 unicast routing is incorrectly configured.
- LDP is not enabled globally.
- LDP is not enabled interface configuration mode (or a remote peer is not configured).

1.5.4 Configuring LDP Session Protection

Configuration Effect

Protect LDP sessions between two directly connected LSRs.

Notes

You can enable LDP session protection on the two LSRs engaged in an LDP session. If only one LSR supports LDP session protection, configure LDP session protection on this LSR and run the **discovery targeted-hello accept** command on the other LSR to enable it to receive and reply to target Hello packets (or run the **neighbor ip-address** command to specify the remote peer).

Configuration

▾ Configuring an LDP Session

- (Mandatory) Perform this configuration according to section 1.5.3.

▾ Configuring LDP Session Protection

- (Mandatory) Perform this configuration in config-mpls-router configuration mode.
- Enable LDP session protection on the two LSRs engaged in an LDP session (see "Notes"), unless otherwise specified.

Verification

- Run the **show mpls ldp parameters** command to check whether LDP session protection is enabled.
- Run the **show mpls ldp neighbor** command to check whether LDP session protection takes effect.

Related Commands

▾ Configuring LDP Session Protection

Command	session protection [for acl <i>acl_name</i>] [duration { <i>infinite</i> <i>seconds</i> }]
Parameter Description	<p>for acl <i>acl_name</i>: Configures ACL rules. Only the LDP sessions of LDP neighbors whose LSR IDs meet ACL rules are protected.</p> <p>duration: Configures the duration of session protection. When links fail and cause a Hello adjacency without associated interfaces, session protection will be enabled, and a target Hello adjacency will maintain LDP sessions.</p> <p>infinite: The target Hello adjacency will maintain LDP sessions infinitely.</p> <p>seconds: Indicates the duration of session protection, which ranges from 30 to 2,147,483 seconds.</p>
Configuration Mode	config-mpls-router mode
Usage Guide	Enables LDP protection.

Configuration Example

▾ Enabling LDP Session Protection Between LSRs

<p>Scenario Figure 1-12</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● On all nodes, configure the interface IP address, configure OSPF, and enable LDP. ● Enable LDP session protection.

1.5.5 Configuring an LDP LSP

Configuration Effect

Establish an LSP on IP unicast routes through LDP.

Notes

- LDP needs to use unicast routes existing in the network; therefore, IP unicast routes must be configured.

Configuration

↳ **Configuring MPLS Forwarding**

- (Mandatory) Configure MPLS forwarding according to the section "Configuring Basic PIM-SM Functions 1".

↳ **Configuring LDP Sessions**

- (Mandatory) Configure LDP sessions according to the section "Configuring LDP Sessions 1".

↳ **Configuring Loop Detection**

- (Optional) Perform this configuration in config-mpls-router configuration mode.
- If IP routes are statically configured instead of being generated by IGP, you are advised to enable loop detection on every LSR traversed by the LSP to avoid loop caused by misconfiguration.

↳ **Configuring the Maximum Number of Hops**

- Perform this configuration in interface configuration mode.
- This configuration is required only in special cases.

↳ **Configuring the Maximum Number of LSRs in the Path Vector List**

- Perform this configuration in interface configuration mode.
- This configuration is required only in special cases.

↳ **Configuring the Label Release Message Propagation Mode**

- Perform this configuration in config-mpls-router configuration mode.
- This configuration is required only in special cases.

↘ Configuring the LDP Label Distribution Control Mode

- Perform this configuration in config-mpls-router configuration mode.
- This configuration is required only in special cases.

↘ Configuring the LDP Label Distribution Mode

- Perform this configuration in interface configuration mode.
- This configuration is required only in special cases.

↘ Configuring the LDP Label Retention Mode

- Perform this configuration in config-mpls-router configuration mode.
- This configuration is required only in special cases.

↘ Configuring Label Distribution Policies

- (Optional) Perform this configuration in config-mpls-router configuration mode.

i By default, LDP distributes labels only to IGP routes but not to BGP routes. To distribute labels to BGP routes, run the **advertise-labels for bgp-routes** command.

i By default, LDP distributes implicit null labels with the value of 3 to default routes; therefore, an LSP is not established on default routes.

↘ Configuring Label Reception Policies

- Perform this configuration in config-mpls-router configuration mode.
- This configuration is required only in special cases.

↘ Configuring Explicit Null Label Distribution Policies

- Perform this configuration in config-mpls-router configuration mode.
- This configuration is required only in special cases.

i Explicit null label distribution policies can be configured only for global LDP instances but not for VRF instances.

Verification

- Run the **show mpls ldp discovery** command to display the LDP peer discovery state.
- Run the **show mpls ldp neighbor** command to display the LDP session state.
- Run the **show mpls ldp bindings** command to display the LDP label binding state.
- Run the **show mpls forwarding-table** command to display the LSP entry state.

Related Commands

↘ Configuring Loop Detection

Command	loop-detection
Parameter	N/A
Description	
Configuration Mode	config-mpls-router mode
Usage Guide	Enables loop detection.

↘ Configuring the Maximum Hop Count

Command	mpls ldp max-hop-count <i>number</i>
Parameter	<i>number</i> : Indicates the maximum hop count allowed for loop detection. The value ranges from 1 to 255.
Description	
Configuration Mode	Interface configuration mode
Usage Guide	Configures the maximum hop count for loop detection.

↘ Configuring the Maximum Number of LSRs in the Path Vector List

Command	mpls ldp max-path-vector <i>number</i>
Parameter	<i>number</i> : Indicates the maximum number of LSRs in the path vector list. The value ranges from 0 to 255.
Description	
Configuration Mode	Interface configuration mode
Usage Guide	Configures the maximum number of LSRs in the path vector list.

↘ Propagating Label Release Messages

Command	propagate-release
Parameter	N/A
Description	
Configuration Mode	config-mpls-router mode
Usage Guide	Propagates label release messages downstream.

↘ Configuring the LDP Label Distribution Control Mode

Command	lsp-control-mode { independent orderd }
Parameter	independent : Indicates the independent control mode.
Description	ordered : Indicates the ordered control mode.
Configuration Mode	The independent control mode is used.
Usage Guide	Configures the label distribution control mode.

↘ Configuring the LDP Label Distribution Mode

Command	<code>mpls ldp distribution-mode { du dod }</code>
Parameter	dod: Indicates the DOD distribution mode.
Description	du: Indicates the DU distribution mode.
Configuration Mode	Interface configuration mode
Usage Guide	Configures the label distribution mode.

↘ Configuring the LDP Label Retention Mode

Command	<code>label-retention-mode { liberal conservation }</code>
Parameter	liberal: Indicates the liberal label retention mode.
Description	conservative: Indicates the conservative label retention mode.
Configuration Mode	config-mpls-router mode
Usage Guide	Configures the label retention mode.

↘ Configuring Label Distribution Policies

Command	<code>advertise-labels [for host-routes for bgp-routes [acl <i>acl_name</i>] for default-route for acl <i>prefix-access-list</i> [to <i>peer-access-list</i>]</code>
Parameter	for host-routes: Distributes labels to host routes (with a 32-bit mask) only.
Description	for bgp-routes [acl <i>acl_name</i>]: Distributes labels to BGP routes. You can use the acl keyword to have labels distributed to eligible BGP routes only. for default-route: Distributes labels whose value is not 3 to default routes. for acl <i>prefix-access-list</i>: Specifies the route prefix. to <i>peer-access-list</i>: Specifies the neighbors to which label binding messages should be sent.
Configuration Mode	config-mpls-router mode
Usage Guide	Configures label distribution policies for FECs mapped to IP routes. You can use the no form of this command to recover the default.

↘ Configuring Label Reception Policies

Command	<code>neighbor <i>ip-address</i> labels accept <i>acl-name</i></code>
Parameter	<i>ip-address:</i> Indicates the ID of the peer LSR.
Description	<i>acl-name:</i> Specifies the name of ACL rules.
Configuration Mode	config-mpls-router mode
Usage Guide	Configures label reception policies.

↘ Configuring Explicit Null Label Distribution Policies

Command	<code>explicit-null [for <i>prefix_acl</i>] [to <i>peer_acl</i>]</code>
Parameter	for <i>prefix_acl</i>: Specifies the address prefix of the direct route for replacing implicit null labels with explicit null

Description	labels. to peer-acl: Specifies the LDP peer for replacing implicit null labels with explicit null labels.
Configuration Mode	config-mpls-router mode
Usage Guide	Distributes explicit null labels to all direct routes or to routes meeting ACL rules.

Configuration Example

Establishing an LDP LSP

<p>Scenario Figure 1-13</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable MPLS forwarding globally. ● Enable LDP globally. ● Enable LDP on an interface. ● Configure an LDP Router ID. ● Enable label forwarding on an interface. ● Configure an IPv4 unicast routing protocol (such as OSPF) on each router and check that a unicast route is reachable to its loopback interface.
<p>LER-A</p>	<pre>Ruijie(config)# mpls ip Ruijie(config)# mpls router ldp Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force Ruijie (config-mpls-router)# exit Ruijie(config)# interface gigabitEthernet 2/2 Ruijie(config-if-GigabitEthernet 2/2)# mpls ip Ruijie(config-if-GigabitEthernet 2/2)# label-switching Ruijie(config-if-GigabitEthernet 2/2)# exit Ruijie (config)# router ospf 10 Ruijie (config-router)# network 192.168.100.0 0.0.0.255 area 0 Ruijie (config-router)# network 192.168.0.1 0.0.0.0 area 0 Ruijie (config-router)# network 192.168.1.0 0.0.0.255 area 0 Ruijie(config-router)# end</pre>

Common Errors

- IPv4 unicast routing is incorrectly configured.
- MPLS forwarding is not enabled globally.
- LDP is not enabled globally.
- LDP is not enabled on an interface.
- Label forwarding is not enabled on an interface.

1.5.6 Configuring the Inter-Domain LDP LSP Feature

Configuration Effect

When an AS is divided into multiple IGP areas and host routes are aggregated on ABRs, establish an LSP across multiple IGP areas for the host routes.

Notes

- The inter-domain LDP LSP feature takes effect only when the free label retention mode is configured.
- The inter-domain LDP LSP feature is not applicable in DOD label distribution mode.

Configuration Steps

▾ Configuring IGP

- (Mandatory) Perform this configuration according to the *Configuring OSPF* or *Configuring IS-IS*.

▾ Enabling Area Border Routers (ABRs) to Aggregate Host Routes

- (Mandatory) Perform this configuration according to the *Configuring OSPF* or *Configuring IS-IS*.

▾ Configuring MPLS Forwarding

- (Mandatory) Configure MPLS forwarding according to the section "Configuring Basic PIM-SM Functions 1".

▾ Configuring LDP Sessions

- (Mandatory) Configure LDP sessions according to the section "Configuring LDP Sessions 1".

▾ Configuring the Inter-Domain LDP LSP Feature

- (Mandatory) Perform this configuration in config-mpls-router configuration mode.
- After route aggregation, enable the inter-domain LDP LSP feature on every LSR traversed by the corresponding LSP.

Verification

- Display configurations of LDP instances to check whether the inter-area LDP LSP function is enabled.
- Check whether an MPLS entry is added to the route compliant with the longest match rule on every router.

Related Commands

Command	inter-area-lsp [for acl <i>acl_name</i>]
Parameter	for acl <i>acl_name</i> : Configures ACL rules and establishes inter-area LSPs for the aggregated host routes (with a 32-bit mask) that meet ACL rules only.
Description	(with a 32-bit mask) that meet ACL rules only.
Configuration Mode	config-mpls-router mode
Usage Guide	Enables the inter-area LDP LSP function on all devices between PEs.

Configuration Example

📌 **Establishing an LSP (Across Different Areas) Between PE1 and PE2, and Enabling the Inter-area LDP LSP Function (OSPF Network)**

<p>Scenario Figure 1-14</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● On all nodes, configure the interface IP address, configure OSPF, and enable LDP. ● On PEs, configure VPN routing instances and MP-IBGP neighbors, and propagate VPN routing information. ● Announce aggregated routes on ABRs. ● Enable the inter-area LDP LSP function on all nodes.
<p>PE1</p>	<pre> Ruijie(config)# interface Loopback 0 Ruijie(config-if-Loopback 0)# ip address 8.8.8.8 255.255.255.255 Ruijie(config-if-Loopback 0)# exit Ruijie(config)# mpls ip Ruijie(config)# mpls router ldp Ruijie(config-mpls-router)# ldp router-id interface Loopback 0 force Ruijie(config-mpls-router)# exit Ruijie(config)# interface gigabitEthernet 1/2 Ruijie(config-if-GigabitEthernet 1/2)# ip address 1.1.1.2 255.255.255.0 Ruijie(config-if-GigabitEthernet 1/2)# mpls ip Ruijie(config-if-GigabitEthernet 1/2)# label-switching Ruijie(config-if-GigabitEthernet 1/2)# exit Ruijie(config)# router ospf 1 </pre>

1.6 Monitoring and Maintenance

Clearing

 Running the **clear** commands may lose vital information and thereby interrupt services.

Description	Command
Resets existing LDP sessions.	clear mpls ldp neighbor [all vrf <i>vrf-name</i>] [* <i>ip-address</i>]

Displaying

Description	Command
Displays basic MPLS information.	show mpls summary

Description	Command
Displays the MPLS forwarding table.	show mpls forwarding-table [detail] show mpls forwarding-table { <i>ip-address/mask</i> <i>ipv6-address/mask</i> } [detail] show mpls forwarding-table label <i>label</i> [detail] show mpls forwarding-table interface <i>interface-name</i> [detail] show mpls forwarding-table next-hop { <i>ip-address</i> <i>ipv6-address</i> } [detail] show mpls forwarding-table { <i>ftn</i> <i>ilm</i> } [<i>ip</i> <i>ipv6</i> <i>vc</i>] [detail] show mpls forwarding-table { <i>vrf vrf-name</i> <i>global</i> } [<i>ftn</i> <i>ilm</i>] [<i>ip</i> <i>ipv6</i>] [detail] show mpls forwarding-table summary
Displays usage of the MPLS label pool.	show mpls label-pool
Detects LSP connectivity.	ping mpls ipv4 <i>ip-address/mask</i> [repeat <i>repeat</i>] [ttl <i>time-to-live</i>] [timeout <i>timeout</i>] [size <i>size</i>] [interval <i>mseconds</i>] [source <i>ip-address</i>] [destination <i>ip-address</i>] [force-explicit-null] [pad <i>pattern</i>] [reply mode { <i>ipv4</i> <i>router-alert</i> }] [dsmap] [flags fec] [verbose]
Detects LSR nodes that LSPs pass through.	traceroute mpls ipv4 <i>ip-address/mask</i> [timeout <i>timeout</i>] [ttl <i>tll</i>] [source <i>ip-address</i>] [destination <i>ip-address</i>] [force-explicit-null] [reply mode { <i>ipv4</i> <i>router-alert</i> }] [flags fec] [verbose]
Displays FEC-label binding.	show mpls ldp bindings [all <i>vrf vrf-name</i>] [<i>ip-address/mask</i> <i>label label</i>] [remote local]
Displays discovered LDP neighbors.	show mpls ldp discovery [all <i>vrf vrf-name</i>] [detail]
Displays LDP interfaces.	show mpls ldp interface [all <i>vrf vrf-name</i> <i>interface-name</i>]
Displays LDP neighbors.	show mpls ldp neighbor [all <i>vrf vrf-name</i>] [<i>ip-address</i>] [detail]
Displays LDP attributes.	show mpls ldp parameters [all <i>vrf vrf-name</i>]
Displays MPLS express forwarding.	show mpls ref ftn-ipv4 [global <i>vrf vrf_name</i>] [<i>ip_address / mask</i> [detail]] show mpls ref ftn-ipv6 [global <i>vrf vrf_name</i>] [<i>ipv6_address / mask</i> [detail]] show mpls ref ilm [in-label <i>label</i> [detail]] summary] show mpls ref nhlfe [[<i>nhlfe_id</i> [detail]]] summary] show mpls ref summary
Displays the routing information base (RIB).	show mpls rib [all <i>vrf vrf-name</i>] [ipv6]

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs LDP session messages.	debug mpls ldp message
Debugs LDP label binding.	debug mpls ldp binding
Debugs internal processing of MPLS entries.	debug mpls
Debugs MPLS messages.	debug mpls msg [send recv]

Debugs the MPLS express forwarding control plane.	debug mpls ref control
Debugs MPLS express forwarding.	debug mpls ref packet
Debugs events during execution of the ping mpls or traceroute mpls command.	debug mpls lspv event
Debugs packets during execution of the ping mpls or traceroute mpls command.	debug mpls lspv packet
Debugs packet encapsulation TLV during execution of the ping mpls or traceroute mpls command.	debug mpls lspv tlv
Debugs errors during execution of the ping mpls or traceroute mpls command.	debug mpls lspv error

2 Configuring MPLS-L2VPN

2.1 Overview

Similar to MPLS/BGP L3VPN, L2VPN uses a public network to expand a private network. MPLS-based L2VPN transmits users' Layer-2 data (for example, ATM cell, Frame Relay frame, and Ethernet frame) transparently on an MPLS network. To users, the MPLS network is a Layer-2 switching network which can be used to establish a Layer-2 connection between different sites.

L2VPN is superior to L3VPN as follows:

- It supports multiple link-layer protocols and multiple network-layer protocols such as IP, IPv6, IPX, and SNA. It uses the same MPLS network to provide Layer-2 VPN services based on different media, including ATM, Frame Relay, VLAN, Ethernet, PPP, and HDLC.
- VPN routing information at the client end does not need to be saved at PEs, greatly reducing PE usage and workload of PEs and the whole SP (carrier) network, so that the carrier can support more VPNs and users.
- Users can control distribution of VPN routes and PEs do not manage VPN routes, ensuring the reliability and privacy of user routes, and reducing the carrier management workload.

Currently, MPLS L2VPN provides the following two services:

- Virtual Private Wire Service (VPWS)

It creates a pseudo wire, also called virtual circuit, on an IP/MPLS network to simulate Layer-2 point-to-point connection services, including Ethernet, PPP, HDLC, AAL5 frame, ATM cell, Frame Relay, and SONET/SDH. VPWS is like a physical line in the carrier network that is provided for the user.

- Virtual Private LAN Service (VPLS)

It simulates LAN services on an IP/MPLS network to connect to Ethernet through WAN interfaces. The user's Layer-2 devices are connected crossing the IP/ MPLS core network, as being connected to a virtual switch.

2.2 Applications

Application	Description
Providing Layer-2 VPN Accesses	Provides Layer-2 VPN services, and links branches of a private network in different regions to form a Layer-2 network through VPN.

2.2.1 Providing Layer-2 VPN Accesses

Scenario

L2VPN is provided through MPLS.

An L2VPN scenario is shown in the figure below.

Figure 2-1 L2VPN scenario

Deployment

- Use the Label Distribution Protocol (LDP) in a backbone network to establish a public tunnel.
- Bind an interface to the PW.

2.3 Features

Basic Concepts

Figure 2-2

Custom Edge (CE)

User device directly connected to the service provider.

Provider Edge Router (PE)

An edge device on the service provider network, which is connected to a CE and used for VPN accesses. It forwards packets from a private network to a public tunnel and then to a private network.

In a layered VPLS network, PEs fall into two types: U-PE and N-PE.

- User Facing Provider Edge (U-PE)

PE that is close to the user in a layered VPLS network and provided to the user for VPN accesses.

- Network Facing Provider Edge (N-PE)

PE at the edge of the core area of a layered VPLS network, which is used for transparent transmission of VPLS between core networks.

↳ Attachment Circuits (ACs)

In L2VPN (VPWS/VPLS) of any mode, CEs shall be connected to PEs through a physical line or a virtual line. Such type of physical line or virtual line is called AC. An AC can be an Ethernet line, a VLAN, or an MPLS LSP. All user packets on ACs shall be forwarded intact to peer CEs.

↳ Pseudo Wire (PW)

A PW is established and maintained through signaling protocols between PEs. An AC transmits a frame from a CE to a PE, and PW transmits a frame from a PE to another PE.

In a layered VPLS network, PWs fall into two types: Hub PW and Spoke PW.

- Hub PW

PW created between two N-PEs.

- Spoke PW

PW between a U-PE and a N-PE, or PWs used to connect to a PE in a basic VPLS network.

↳ Forwarder

In L2VPN, a PE forwards the frame received from an AC to a corresponding PW, and the PE forwards the frame received from a PW to a corresponding AC. The forward decision process is called a Forwarder.

In VPWS, a Forwarder establishes mapping between ACs and PWs.

In VPLS, a Forwarder is also called Virtual Switch Instance (VSI) or Virtual Forwarding Instance (VFI); that is, the VPLS forwarding table. It maps ACs of VPLS users to PWs through VFI.

↳ Tunnel

PW traffic between PEs is transmitted through a tunnel. One tunnel can carry multiple PWs. Tunnels in this document refer to the MPLS LSP tunnels.

↳ Encapsulation

L2VPN load is transmitted through PWs. PWE3 defines encapsulation formats and transmission technologies for Layer-2 packets to be transmitted through PWs. RFC4448 defines two encapsulation modes for PWs in the Ethernet: Raw and Tag. In Raw mode, PDU is transmitted through a PW without the service distinguisher; in Tag mode, PDU is transmitted through a PW with the service distinguisher. For a simulation service on the Ethernet, the service distinguisher is usually a VLAN tag. Refer to RFC4618 for details about PPP/HDLC encapsulation and transmission methods.

↳ PW Signaling

PW signaling protocol is used to create and maintain PWs. There are two types of PW signaling: LDP and BGP.

1. Operating Principles of Using LDP to Create PWs

To create a PW, two types of LDP sessions need to be established: LDP sessions based on the discovery mechanism and LDP sessions based on the extended discovery mechanism. The former are used to establish LSPs on a public network, and the latter are used to transmit PW label mapping messages. PW establishment and removal are introduced briefly below:

- Target Hello packets are transmitted between PEs using the remote LDP session discovery mechanism to establish LDP sessions.
- When the AC at one PE is UP, the PE allocates a label for the corresponding PW.
- The PE encodes the label value and corresponding PW ID to FEC TLV, and sends the label mapping message to the peer PE through a remote LDP session.
- Upon receiving the label mapping message, the peer PE decodes the PW ID and label value and checks whether the related interface parameters (such as MTU) and PW Type are consistent.
- After two ends of the session exchange the label values and check the validity of PW IDs and interface parameters, the PW is established.
- One PE sends a label cancelling message to the peer PE to remove the PW.

The following conditions must be met before a PW can be established using LDP sessions:

- MTU parameters and PW types of devices at two ends of PW must be consistent.
- PW IDs (VC IDs) of devices at two ends of PW must be consistent.

2. Operating Principles of Using BGP to Create PWs

In BGP mode, static connection between CEs is not required. Instead, the whole carrier network is divided into different VPNs, and CEs are globally numbered inside a VPN site. Similar to BGP/MPLS L3VPN, BGP/MPLS L2VPN also uses VPN Target to identify CEs inside the same VPN site. The process that VPN Target detects a VPN site is called automatic discovery. The BGP signaling protocol consists of two stages: automatic discovery, and establishment of a bidirectional PW between PEs based on results of automatic discovery.

The concept of label block is introduced when a PW is established based on the BGP signaling protocol. Label block is used to allocate labels for multiple connections at a time. A user can specify a site range for a local CE to indicate how many remote CEs the local CE can establish connections to. The system allocates one label block for the CE each time, and the label block size is equal to the site range. In such a way, the user is allowed to allocate additional labels for a VPN, which may result in waste of label resources in the short term but can reduce configuration workload during VPN expansion.

When using BGP signaling to establish PWs, you can make use of characteristics of the BGP protocol (such as characteristics of the route reflector) to reduce all interconnections of BGP sessions, which helps expand the scale.

↘ **Martini Method and Kompella Method**

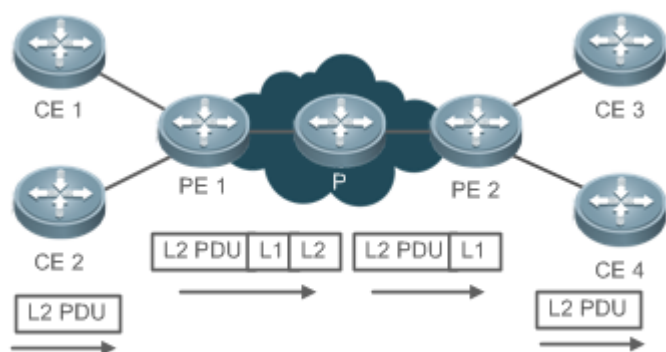

No formal MPLS L2VPN standards are available yet. Provider-provisioned Virtual Private Network (PPVPN) workgroup of Internet Engineering Task Force (IETF) has developed multiple framework drafts, including the Martini draft (draft-martini-l2circuit-trans-mpls) and Kompella draft (draft-kompella-ppvnp-l2vpn).

- In the Martini draft, a point-to-point link is established to realize MPLS L2VPN. LDP is used as the signaling protocol to transmit the VC labels, which is called Martini MPLS L2VPN.
- In the Kompella draft, MPLS L2VPN is established in an end-to-end mode (CE-to-CE) on the MPLS network. Currently, it uses BGP as the signaling protocol to release Layer-2 reachable messages and VC labels, which is called Kompella MPLS L2VPN.

Basic Forwarding Procedures

L2VPN uses two-layer label stacks for transmission in a backbone network. The external-layer label is used to forward packets as labels in the backbone network, while the inner-layer VC label is used to identify specific VC instances on a PE, and the PE determines to which CE the packet should be forwarded based on the inner-layer VC label value. The forwarding procedures are shown in the figure below:

Figure 2-3

After receiving a Layer-2 packet from CE2, PE1 finds the PW forwarding entries based on the AC's associated PW. The entries show that the next hop is PE2 and the PW label is L1. PE1 finds the public LSP tunnel based on the next hop (PE2), encapsulates an MPLS header to the Layer-2 packet, adds the inner-layer label L1 and external-layer label L2, and sends the packet to P. P forwards the packet on MPLS based on the labels, and sends the external-layer label of the P displayed at the second last hop to PE2. After receiving the packet, PE2 finds the entries of PW ID based on the PW label L1, displays the inner-layer label based on the egress AC, and then sends the Layer-2 packet directly to the target CE4.

Feature

Feature	Description
VPWS	Introduces operating principles of VPWS.
VPLS	Introduces operating principles of VPLS.

2.3.1 VPWS

VPWS is an end-to-end Layer-2 service carrying technology, and a point-to-point L2VPN. It provides MPLS L2VPNs to allow a carrier to provide L2VPN services based on different media on the same MPLS network, including ATM, Frame Relay,

VLAN, Ethernet, and PPP. Besides, the MPLS network still can provide traditional services such as IP and MPLS L3VPN. In brief, MPLS L2VPN transmits the user's Layer-2 data on the MPLS network transparently.

- VPWS signaling protocol

VPWS can be divided into Martini VPWS and Kompella VPWS according to the signaling protocol. Martini VPWS uses LDP as the signaling protocol while Kompella VPWS uses BGP as the signaling protocol.

- VPWS heterogeneous media interconnection

If CE links at two ends of the same L2VPN are of different types, the L2VPN heterogeneous media interconnection is applied. As suggested by draft-kompella-ppvnp-l2vpn, when an L2VPN connection is established, ip-interworking is used as the encapsulation type of the L2VPN interface of a PE, and Layer-3 data (that is, IP packets) are transmitted on the MPLS network transparently.

2.3.1.1 Basic Martini VPWS

Working Principle

↘ PW Label

- After receiving a packet, a PE must judge from which PW the packet is received and associate the packet with the PW. A PE checks the MPLS label used as the demultiplexer to identify the PW. The MPLS label is called a PW label.
- In Martini mode, PW labels are distributed through the extended LDP. When forwarding the packet, a PE adds the PW label. If the backbone network tunnel is MPLS LSP, the PE adds the tunnel label as the top label of the label stack. When the MPLS packet passes through the IP/MPLS network, the inner-layer PW label is invisible to the P device in the network until it reaches the egress PE (the other end of the PW). The egress PE identifies the PW label and associates the label to the PW.

↘ Extended LDP Sessions

- LDP sessions should be established between PEs before PEs can send the PW label mapping message for negotiation. Ordinary LDP sessions are only applicable to two PEs directly connected to each other, and thus cannot be established when two PEs in the network are not directly connected. The LDP extension discovery mechanism is used to extend the ordinary LDP sessions. In such a mechanism, two PEs not directly connected specify each other as its LDP target neighbor to establish an extended LDP session, as shown in Figure 2-4.

Figure 2-4

Specify each other as its LDP target neighbor to establish an extended LDP session

↳ **Extended LDP**

- In VPWS, the extended LDP is used to establish PWs, and distribute and manage PW labels. LDP needs to provide a method describing the association relationship between a PW label and a certain PW instance so as to associate them. IETF defines an FEC structure describing the routing message in RFC3036, and an extended FEC element describing PW in RFC4447. The components are described as follows:

Figure 2-5

Pseudowire ID FEC (1 Octet) [=128]	C	Pseudowire Type (15 Bits)	Pseudowire Info Length (1 Octet)
Group ID (4 Octets)			
Pseudowire ID (4 Octets)			
Interface Parameters (Variable Length)			

- PW ID FEC: It indicates a PW ID FEC when the value is 128.
- Control word bit: It indicates whether the packet transmitted on a PW has a control word; If yes, the value is 1; otherwise, the value is 0.
- PW Type: The value range and meaning are described below:

Figure 2-6

PW Type	Description
0x0001	Frame Relay data-link connection identifier (DLCI)
0x0002	ATM AAL5 service data unit (SDU) virtual channel connection (VCC)
0x0003	ATM Transparent Cell
0x0004	Ethernet Tagged Mode (Ethernet Vlan)
0x0005	Ethernet
0x0006	High-Level Data Link Control (HDLC)
0x0007	PPP

- VPWS of Ruijie switch supports Ethernet VLAN and Ethernet, and Ruijie router supports Ethernet VLAN, Ethernet, HDLC, PPP, and heterogeneous media interconnection.

Group ID: It is a 32-bit integer which is used to identify a group of PWs sharing some attributes, for example, the index numbers of interfaces connected to the CE. LDP uses the Group ID to perform label withdraw and label release for PW labels in batches. The Group IDs at the two ends of a PW can be different.

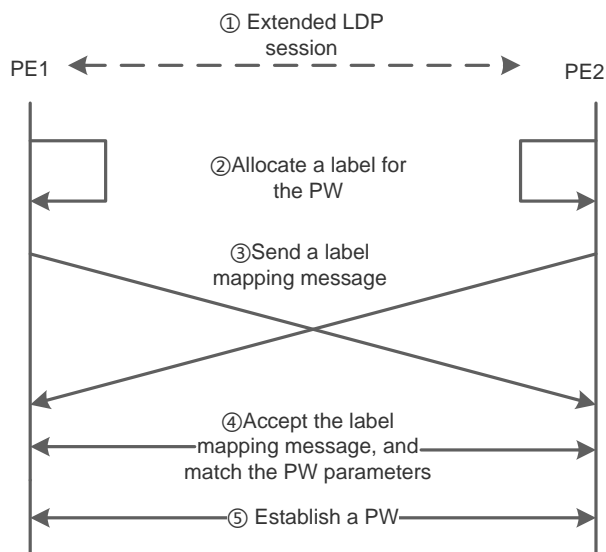

PW ID: It is a 32-bit non-zero identifier used to distinguish different PWs. To connect two ACs with one PW, you need to set the same PW ID and PW type for the two ends of the PW.

Interface parameters: They provide AC information, including MTU and interface description.

Process of Establishing a PW

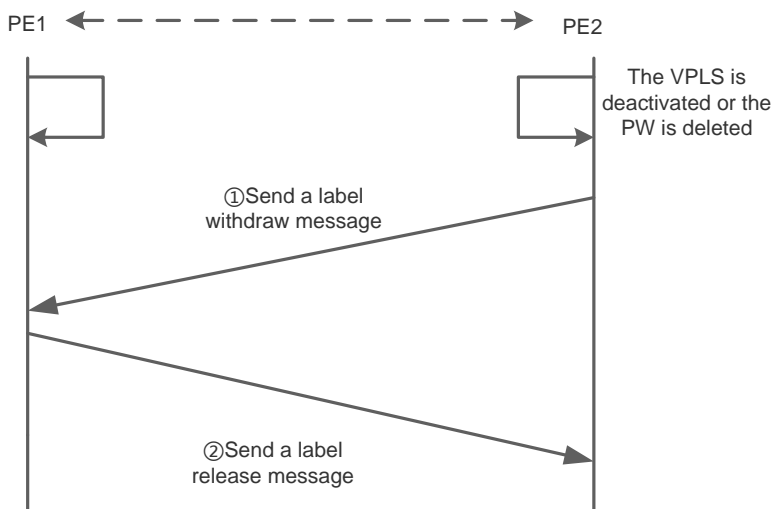

- Two types of LDP sessions are required to establish a PW: LDP sessions established based on the basic discovery mechanism and LDP sessions established based on the extended discovery mechanism. The former are used to establish LSPs on a public network, and the latter are used to transmit PW's labels. The process of establishing a PW is as follows:

Figure 2-7

- Target Hello packets are transmitted between PEs using the extended LDP session discovery mechanism to establish LDP sessions.
- When the AC at one PE is UP, the PE allocates a label for the corresponding PW and binds the PW label to the PW ID.
- The PE encodes the label value and corresponding PW ID to FEC TLV, and sends the label mapping message to the peer PE through the targeted LDP session.
- The peer PE receives the label mapping message, decodes the PW ID and label value, checks whether there is a local PW ID matching the PW ID. If yes, the peer PE checks whether the interface parameters (such as MTU) and PW type are matched.
- After two ends of the session exchange the label values and PW IDs and interface parameters are valid, a PW is established.
- If the AC between the PE and the CE goes down or the PW is removed, the PE sends a PW label withdraw message to the peer PE. Upon receiving the label withdraw message, the peer PE releases the corresponding PW label, disconnects the PW, and sends a label release message to the other PE. As shown in the figure below, PE2 sends a label withdraw message to PE1, and PE1 sends a label release message to PE2 after receiving the label withdraw message.

Figure 2-8

Related Configuration

📌 Configuring a Public Tunnel

- LSP tunnels must be established on a public network to carry VCs. To run MPLS on a backbone network, the LDP must be run simultaneously on P and PE to establish a public tunnel. A label distribution protocol should be configured for corresponding devices, and the MPLS forwarding function must be enabled for each interface.

📌 Configuring a Remote LDP Peer

- LSP tunnels must be established on a public network to carry VCs. To run MPLS on a backbone network, the LDP must be run simultaneously on P and PE to establish a public tunnel. A label distribution protocol should be configured for corresponding devices, and the MPLS forwarding function must be enabled for each interface.

▾ Configuring VPWS Access

- Configure the VPWS access mode.
- Only Ethernet-based VPWS can be provided for a switch. Based on whether the packet contains a VLAN Tag, the following access modes are provided:

1. Access interface

Access through VLAN access interface is applicable to user packets that are not encapsulated by 802.1Q; that is, the packets contain no VLAN Tag.

2. Trunk interface

Access through a VLAN trunk interface is applicable when multiple VPWSs are transmitted on the same access link. A PE distinguishes to which VPWS a packet belongs based on the packet's VLAN Tag, and then provides a combo access interface.

3. 802.1Q tunnel interface

Access through a VLAN tunnel interface is applicable when the user service packet transmitted on the AC already contains a private VLAN Tag when the user accesses a VPWS. In such a mode, the PE forwards intact all packets received from the interface, and VLAN member ports connecting the PE to the CE need to work in tunnel mode.

- Users can access VPWSs provided by a router in multiple ways as required. The VPWSs depend on the link protocol of interfaces connecting the PE and the CE. Currently, the point-to-point L2VPN services are supported.

1. Ethernet interface

In such a scenario, the interface connecting the PE to the CE encapsulates the Ethernet link protocol and provides VPWSs, the CE accesses the PE through an Ethernet link, and the PE transmits Ethernet frames transparently. Such a mode is applicable no matter whether the packet contains a private VLAN Tag when the user accesses a VPWS. In such a mode, the PE forwards intact all packets received from the interface.

2.3.1.2 Inter-AS Martini VPWS

Working Principle

Martini VPWS has two Inter-AS solutions:

- Inter-AS Option A: It can be easily realized. This solution is applied when the number of Inter-AS L2VPNs on an ASBR is low.

In such a mode, ASBRs of two Autonomous Systems (ASs) are directly connected, and ASBRs serve as PEs of each AS. Two ASBRs take each other as their CEs. As shown in the figure above, ASBR2-AS2 of AS2 is a CE for ASBR1-AS1 of AS1, and vice versa.

Option A has an advantage of easy realization, because no special Inter-AS configurations are required for two PEs serving as ASBRs, and no IP addresses are needed for interfaces between ASBRs. The disadvantage is that, a link should be allocated for ASBRs between two ASs when each Inter-AS L2VPN or PW is established. The link is either a logical or physical link. Pressure on ASBRs increases when there are a great many Inter-AS PWs, which limits the scale expansion.

The configuration method of this mode is similar to that of basic VPWS above, and thus is omitted here.

- Inter-AS Option C: No VC needs to be created and maintained on an ASBR. This solution is applicable when each AS contains a great many Inter-AS L2VPNs, to avoid the ASBR scale expansion bottleneck.

An ASBR releases the label IPv4 routes to PEs inside its own AS through MP-IBGP and notifies the label IPv4 routes reaching PEs inside its own AS to the ASBR peer of the peer AS, so as to connect the two AS tunnels and establish an LSP tunnel between the ingress PE and egress PE. Next, it establishes Inter-AS LDP remote session connection between PEs of different ASs and switches PW information.

In this solution, the ASBR neither needs to maintain Inter-AS L2VPN information nor needs to allocate a physical or logical interface for the Inter-AS L2VPNs, but has to provide an MPLS channel. L2VPN information is exchanged directly between PEs, reducing pressure on ASBR and facilitating scale expansion.

Related Configuration

For details about the configuration, see [Basic VPWS](#). The configuration method of Option C is described below:

↘ **Configuring MPLS Signaling**

Enable MPLS and LDP for PEs and Ps in each AS as well as for ASBR interfaces connecting to Ps or PEs inside the AS, so as to establish a basic MPLS network.

↘ **Configuring a PE**

Configure PEs inside an AS to establish an IBGP session between PEs and the ASBR inside the AS, and exchange the IPv4 routes carrying the labels.

↘ **Configuring an ASBR**

Configure an ASBR to establish an IBGP session between the ASBR and PEs inside the same AS and establish an EBGP session with the ASBR inside another AS. Enable IPv4 routes carrying the labels for the two sessions. Configure a PE address on the ASBR which must be transmitted to another ASBR.

↘ **Configuring a Remote LDP Session**

Establish Inter-AS remote LDP sessions between PEs inside each AS.

↘ **Configuring VPWS Access**

Configure the VPWS access mode.

2.3.1.3 Basic Kompella VPWS

Working Principle

↘ BGP Session

- In the Kompella solution, BGP sessions need to be established between PEs and L2VPN VPWS address family needs to be enabled. BGP plays two roles in this solution:

Automatic discovery: It uses BGP to automatically discover PEs belonging to the same VPN, which greatly reduces the configuration workload of L2VPN.

Signaling: It uses BGP to distribute and recycle labels. When allocating its label block, a PE needs to notify PEs of the VPWS to complete the following two events:

2. Use the UPDATE packet to notify its label block information and VPWS site identifier to other PEs.
3. The CE connected to the PE uses a corresponding label to send data.

↘ Process of Establishing a PW

- If the L2VPN VPWS address family is enabled, the BGP Update message contains RT, RD, VE ID, VE block deviation, VE block size, and label base number. RT indicates the L2VPN instances. The other five parameters indicate the information reachable at the network layer, which are used to establish or remove a PW.

Related Configuration

↘ Configuring a Public Tunnel

- LSP tunnels must be established on a public network to carry VCs. To run MPLS on a backbone network, the LDP must be run simultaneously on P and PE to establish a public tunnel. Distribution protocols should be configured for corresponding MPLS devices, and the MPLS-based forwarding function must be enabled for each interface.

↘ Configuring an L2VPN Address Family

- Kompella VPWS uses MP-BGP4 as the signaling protocol to transmit Layer-2 messages and VC labels and realize point-to-point VPNs. Besides, it can also use MP-BGP4 as an automatic discovery protocol to connect to remote CEs.

↘ Configuring a Kompella VPWS Instance

- Run the **I2 vfi** command to create a Kompella VPWS instance, or enter the Kompella VPWS configuration mode. Run the **no I2 vfi** command to delete a VFI instance. Specify a locally unique name and VPN ID for the VFI instance you create, and enable automatic discovery for the VFI instance. The VFI name must map to the VPN ID.

↘ Configuring VPWS Access

- Configure the VPWS access mode.
 - Only Ethernet-based VPWS can be provided for a switch. Based on whether the packet contains a VLAN Tag, the following access modes are provided:
1. Access interface

Access through VLAN access interface is applicable to user packets that are not encapsulated by 802.1Q; that is, the packets contain no VLAN Tag.

2. Trunk interface

Access through a VLAN trunk interface is applicable when multiple VPWSs are transmitted on the same access link. A PE distinguishes to which VPWS a packet belongs based on the packet's VLAN Tag, and then provides a combo access interface.

3. 802.1Q tunnel interface

Access through a VLAN tunnel interface is applicable when the user service packet transmitted on the AC already contains a private VLAN Tag when the user accesses a VPWS. In such a mode, the PE forwards intact all packets received from the interface, and VLAN member ports connecting the PE to the CE need to work in tunnel mode.

2.3.1.4 Inter-AS Kompella VPWS

Working Principle

Multiple sites of one VPN may be connected to multiple service providers using different ASs or to multiple ASs of one service provider. Such an application that one VPN crosses multiple ASs is called Inter-AS VPN. Kompella VPWS has two Inter-AS solutions:

- Inter-AS Option A: It can be easily realized. This solution is applied when the number of Inter-AS L2VPNs on an ASBR is low.
- Inter-AS Option C: No VC needs to be created and maintained on an ASBR. This solution is applicable when each AS contains a great many Inter-AS L2VPNs, to avoid the ASBR scale expansion bottleneck.

Inter-AS Option A

Figure 2-9 Option A: Inter-AS VPWS

In such a mode, ASBRs of two ASs are directly connected, and ASBRs serve as PEs of each AS. Two ASBRs take each other as their CEs. As shown in the figure above, ASBR2-AS2 of AS2 is a CE for ASBR1-AS1 of AS1, and vice versa.

Option A has an advantage of easy realization, because no special Inter-AS configurations are required for two PEs serving as ASBRs, and no IP addresses are needed for interfaces between ASBRs. The disadvantage is that, a link should be

allocated for ASBRs between two ASs when each Inter-AS L2VPN or PW is established. The link is either a logical or physical link. Pressure on ASBRs increases when there are a great many Inter-AS PWs, which limits the scale expansion.

Inter-AS Option C

Figure 2-10 Option C: Inter-AS VPWS

In Option C in the figure above, an Inter-AS PW is established between PEs on two ASs to exchange PW labels, so as to realize an Inter-AS L2VPN. The working principle is as follows:

An ASBR releases the label IPv4 routes to PEs inside its own AS through MP-IBGP and notifies the label IPv4 routes reaching PEs inside its own AS to the ASBR peer of the peer AS, so as to connect the two AS tunnels and establish an LSP tunnel between the ingress PE and egress PE. Next, it establishes Inter-AS LDP remote session connection between PEs of different ASs and switches PW information.

In this solution, ASBR either needs to maintain Inter-AS L2VPN information nor needs to allocate a physical or logical interface for the Inter-AS L2VPNs. L2VPN information is exchanged directly between PEs, reducing pressure on ASBR and facilitating scale expansion.

Related Configuration

The configuration method of this mode is similar to that of basic VPWS above. Configurations of Option C are described below:

➤ **Configuring MPLS Signaling**

- Enable MPLS and LDP for PEs and Ps in each AS as well as for ASBR interfaces connecting to P devices or PEs inside the AS, so as to establish a basic MPLS network.

➤ **Configuring a PE**

- Configure PEs inside an AS to establish an IBGP session between PEs and the ASBR inside the AS and exchange the IPv4 routes carrying the labels.

➤ **Configuring an ASBR**

- Configure ASBR to establish an IBGP session between ASBR and PEs inside the same AS and establish an EBGP session with ASBR inside another AS. Enable IPv4 routes carrying the labels for the two sessions. Configure a PE address on the ASBR which must be transmitted to another ASBR.

▾ **Configuring an L2VPN Address Family**

- Configure the L2VPN address family of PEs in each AS. For details, refer to Configuring the L2VPN Address Family in Basic Kompella VPWS.

▾ **Configuring a Kompella VPWS Instance**

- Configure the L2VPN address family of PEs in each AS.

▾ **Configuring VPWS Access**

- Refer to Configuring VPWS Access in Basic Kompella VPWS.

2.3.2 VPLS

VPLS is a technology that provides virtual private Ethernet in an IP/MPLS network. It can be used to establish network-wide PWs among multiple PEs to forward encapsulated Layer-2 Ethernet frames among PEs through the MPLS network, so as to establish a point-to-multipoint Ethernet VPN. VPLS VPN is like a virtual switch to which users' Layer-2 devices are connected crossing the IP/MPLS core network.

Compared with VPWS, VPLS can provide point-to-multipoint solutions. Compared with L3VPN, VPLS has advantages of L2VPN and provides better network extension and maintenance.

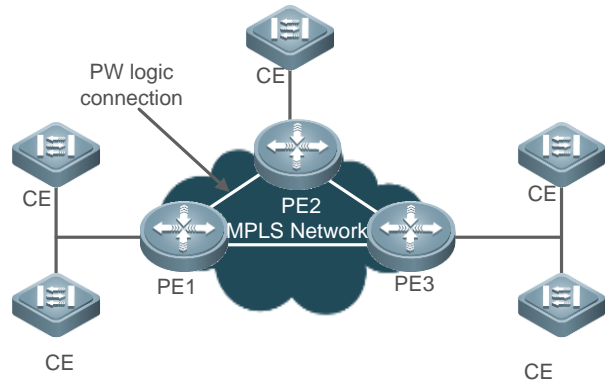

Terms are explained as follows:

- PW: Pseudo Wire
- VPLS: Virtual Private LAN Service
- H-VPLS: Hierarchical VPLS
- MTU: Multi-Tenant Unit. It indicates a carrier's enterprise users in office buildings and business districts.
- MTU is a small aggregated PE used to access enterprise customers and aggregate users using VPLS to the PE through a virtual circuit.
- Spoke Connection: It indicates the links between U-PE and N-PE in H-VPLS, and can use a PW or QinQ.
- Spoke PW: It indicates the Spoke Connection between N-PE and U-PE when a PW is used, or a PW from CE to PE when the user uses a PW for access.

Working Principle

▾ **Basic VPLS**

Figure 2-11

In the figure above, VPLS establishes a PW logical connection between each two PEs and connects each CE to PEs for which VPLS is enabled. The VPLS devices form a point-to-multipoint service for CEs. It seems that the CEs are connected to the same Layer-2 switch.

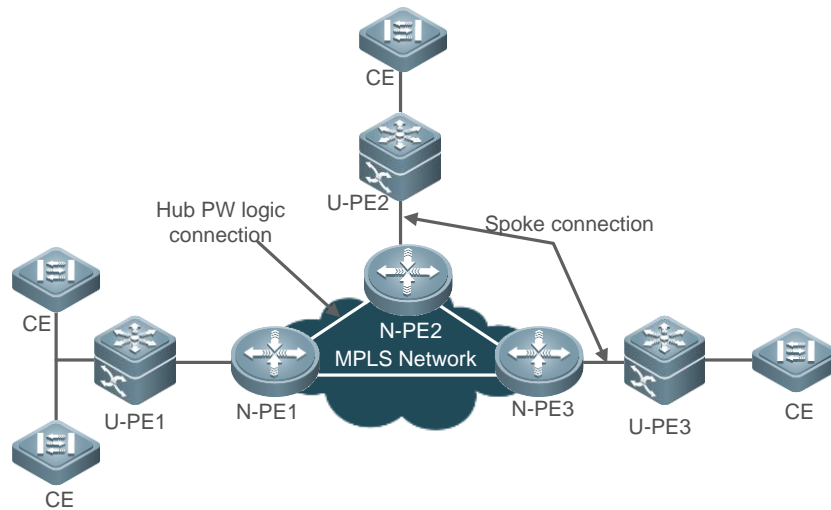

The VPLS model in the dual-IGP instance graph has the following defects:

- To prevent loops, split horizon is applied when packets are forwarded through PWs between PEs; that is, packets received from Hub PW are not forwarded to another Hub PW. Therefore, a PW needs to be established between each two PEs, resulting in large system costs. Therefore, this model is not applicable for large networks.
- The forwarded broadcast and multicast packets need to be duplicated on each PW, resulting in a low efficiency.

H-VPLS is introduced to solve these problems.

↳ **H-VPLS**

Figure 2-12 H-VPLS model

H-VPLS grades a VPLS network into multiple hierarchies, and establishes Hub PWs between each two N-PEs only on core networks, so as to make up for defects of an ordinary VPLS network. Spoke Connection between U-PE and N-PE can be established through PW or QinQ Tunnel. U-PE may not support VPLS, but can support VPWS or QinQ Tunnel.

H-VPLS can reduce load on VPLS core devices, overhead of signaling protocols, and duplication of packets, greatly increasing scalability of the VPLS network.

Ruijie's H-VPLS supports Martini H-VPLS and Kompella H-VPLS currently. In Martini H-VPLS, LDP signaling is used to create VPLS instances between N-PEs, and LDP signaling or QinQ Tunnel is used for access between U-PE and N-PE.

▾ VPWS Signaling Protocol

VPLS is divided into Martini VPLS and Kompella VPLS according to the signaling protocol used. As defined in RFC4762 and RFC4761, the former is based on LDP signaling, and the latter is based on BGP signaling. In Kompella VPLS, you can make use of characteristics of the BGP protocol (such as characteristics of the route reflector) to reduce all interconnections of BGP sessions, which helps to expand the scale. Martini VPLS is applicable for small-scale deployment in a simple environment.

▾ VPLS Inter-AS

Both Martini VPLS and Kompella VPLS can realize the Inter-AS structure in Option A. During VPLS Inter-AS networking, the link type and VC type between ASBRs shall be consistent. The disadvantage of this mode is that a sub-interface must be provided for each Inter-AS VC on an ASBR. This mode is applicable when few VCs are required for Inter-AS.

Option C is another VPLS Inter-AS solution. The SP network devices only establish an external-layer tunnel for PEs on different ASs. ASBRs neither maintain Inter-AS VPLS information nor provide interfaces for Inter-AS VPLS. VSI information of VPLS is exchanged only between PEs, consuming few resources and increasing no configuration workload. This solution is applicable when there are a great many of VPLSs requiring Inter-AS.

2.3.2.1 Martini VPLS

Working Principle

▾ Extended LDP Sessions

LDP sessions should be established between PEs before PEs can send the PW label mapping message for negotiation. Ordinary LDP sessions are only applicable to two PEs directly connected to each other, and thus cannot be established when two PEs in the network are not directly connected. The LDP extended discovery mechanism is used to extend the ordinary LDP sessions. In such a mechanism, two PEs not directly connected specify each other as its LDP target neighbor to establish an extended LDP session.

▾ Extended LDP

In Martini VPLS, LDP is used to establish and maintain PWs. LDP needs to provide a method describing the association relationship between a PW label and a certain PW instance so as to associate them. IETF defines an FEC structure describing the routing message in RFC3036, and an extended FEC element describing PW in RFC4447. The components are described as follows:

Figure 2-13

Pseudowire ID FEC (1 Octet) [=128]	C	Pseudowire Type (15 Bits)	Pseudowire Info Length (1 Octet)
Group ID (4 Octets)			
Pseudowire ID (4 Octets)			
Interface Parameters (Variable Length)			

- PW ID FEC: It indicates a PW ID FEC when the value is 128.
- Control word bit: It indicates whether the packet transmitted on a PW has a control word; If yes, the value is 1; otherwise, the value is 0.
- PW Type: The value range and meaning are described below:

Figure 2-14

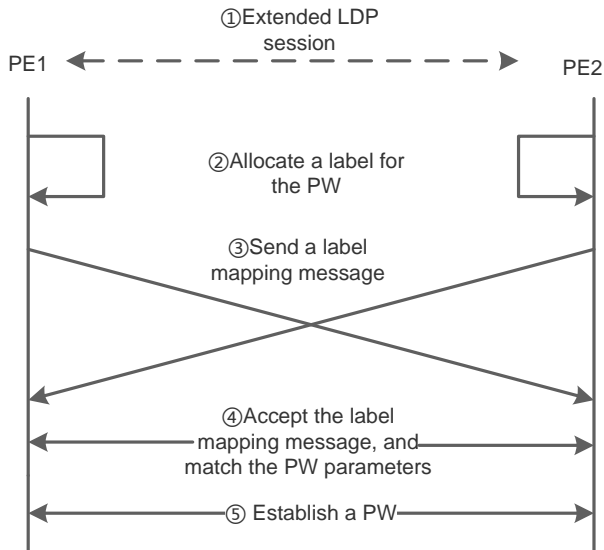

Pseudowire Type	Description
0x0001	Frame Relay data-link connection identifier (DLCI)
0x0002	ATM AAL5 service data unit (SDU) virtual channel connection (VCC)
0x0003	ATM Transparent Cell
0x0004	Ethernet VLAN
0x0005	Ethernet
0x0006	High-Level Data Link Control (HDLC)
0x0007	PPP

- Group ID: It is a 32-bit integer which is used to identify a group of PWs sharing some attributes, for example, the index numbers of interfaces connected to the CE. LDP uses the Group ID to perform label withdraw and label release for PW labels in batches. The Group IDs at the two ends of the PW can be different.
- PW ID: It is a 32-bit non-zero identifier used to distinguish different PWs. To successfully establish a PW, you need to set the same PW ID and PW type for the two ends of the PW.
- Interface parameters: They provide AC information, including MTU and interface description.

Process of Establishing a PW

Two types of LDP sessions can be used to establish a PW: LDP sessions established based on the discovery mechanism and LDP sessions established based on extended discovery mechanism. The process of establishing a PW is as follows:

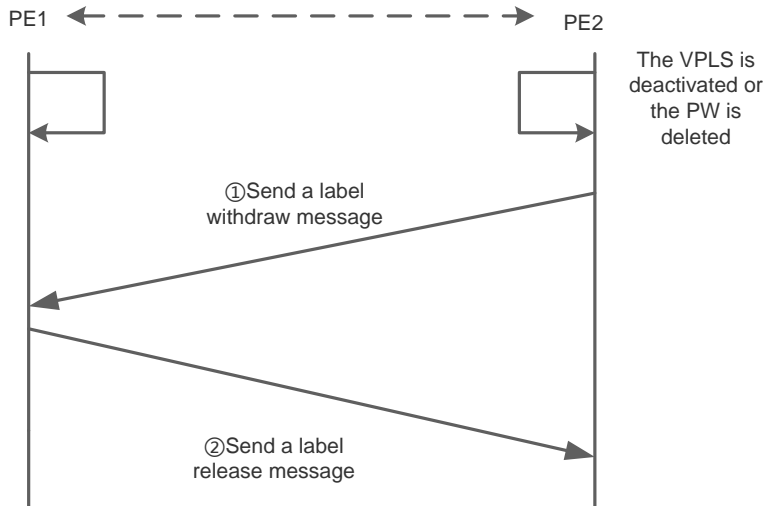

Figure 2-15

- The extended LDP discovery mechanism is used to send Hello packets between PEs not directly connected and establish an LDP session.
- When a PE configures its peer PE as its VPLS neighbor and the VPLS is activated, the PE allocates a label for a corresponding PW and binds the PW label to the PW ID.
- The PE encodes the label value and corresponding PW ID to FEC TLV, and sends the label mapping message to the peer PE through the LDP session.
- The peer PE receives the label mapping message, decodes the PW ID and label value, and checks whether there is a local PW ID matching the PW ID. If yes, the peer PE checks whether the interface parameters (such as MTU) and PW type are matched.
- After two ends of the session exchange the label values and PW IDs and interface parameters are valid, a PW is established.

When the VPLS instance on the PE is deactivated, all ACs go down, or all PWs are deleted, the PE sends a PW label withdraw message to the peer PE. Upon receiving the label withdraw message, the peer PE releases the corresponding PW label, and judges whether or not to send a label release message to the other PE according to parameters negotiated when the PW is established. As shown in the figure below, PE2 sends a label withdraw message to PE1, and PE1 sends a label release message to PE2 after receiving the label withdraw message.

Figure 2-16

Related Configuration

Configuring a Public Tunnel

LSP tunnels must be established on a public network to carry VCs. To run MPLS on a backbone network, the LDP must be run simultaneously on P and PE to establish a public tunnel. Distribution protocol should be configured for corresponding MPLS devices, and the MPLS-based forwarding function must be enabled for each interface.

Configuring a Remote LDP Peer

The remote LDP session is used to establish and maintain PWs. If there are other LSPs between PEs, the extended LDP discovery mechanism is used to establish remote LDP sessions between PEs and distribute PW labels on the sessions.

Configuring a Martini VPLS Instance

Specify a locally unique name and VPN ID for the VPLS instance you create. The VPLS name must map to the VPN ID.

Configuring VPLS Access

Configuring VPLS Access for a Switch

The created VPLS instance takes effect only when the user for which the VPLS instance is configured accesses the link. Currently, users can access VPLS services in the following three methods:

- VLAN access interface

Access through VLAN access interface is applicable for user packets that are not encapsulated by 802.1Q; that is, the packets contain no VLAN Tag.

- VLAN trunk interface

Access through VLAN trunk interface is applicable when multiple VPLS services are transmitted on the same physical AC and each VLAN corresponds to one VPLS instance. PE distinguishes to which VPLS instance a packet belongs based on the packet's VLAN Tag, and then provides a combo access interface.

- VLAN tunnel access

Access through a VLAN tunnel interface is applicable when the user service packet transmitted on the AC already contains a private VLAN Tag when the user accesses VPLS. In such a mode, the PE forwards intact all packets received from the interface, and VLAN member ports connecting the PE to the CE need to work in tunnel mode.

- PW

Access through PW is applicable when the access network is an MPLS network and the user has no direct link to VPLS PE. In an H-VPLS model, U-PE having no bridge can use PW to access N-PE, and provide VPLS access service for the user.

Configuring VPLS Access for a Router

2.3.2.2 Basic Kompella VPLS

Working Principle

↘ BGP Session

In the Kompella solution, BGP sessions need to be established between PEs, and the L2VPN VPLS address family needs to be enabled. BGP plays two roles in this solution:

Automatic discovery: It uses BGP to automatically discover PEs belonging to the same VPN, which greatly reduces the configuration workload of L2VPN.

Signaling: It uses BGP to distribute and recycle labels. When allocating its label block, a PE needs to notify PEs of the VPWS to complete the following two events:

4. Use the UPDATE packet to notify its label block information and VPLS site identifier to other PEs.
5. A CE connected to the PE uses a corresponding label to send data.

↘ Process of Establishing a PW

After the L2VPN VPLS address family is enabled, the BGP Update message contains RT, RD, VE ID, VE block deviation, VE block size, and label base number. RT indicates the L2VPN instances. The other five parameters indicate the messages reachable at the network layer, which are used to establish or remove a PW.

When an L2VPN instance is configured for the user's PE, the PE sends an Update message containing MP_REACH to an available BGP peer to notify BGP label and other information and establish PWs between PEs.

Related Configuration

↘ Configuring a Public Tunnel

LSP tunnels must be established on a public network to carry VCs. To run MPLS on a backbone network, the LDP must be run simultaneously on P and PE to establish a public tunnel. Distribution protocol should be configured for corresponding MPLS devices, and the MPLS-based forwarding function must be enabled for each interface.

↘ Configuring an L2VPN VPLS Address Family

Kompella VPLS uses MP-BGP4 as the signaling protocol and automatic discovery mechanism. PEs in the same VPLS instance exchange VPLS information through the L2VPN address family. L2VPN VPLS address family is not supported by default.

↘ Configuring a Kompella VPLS Instance

Run the **I2 vfi** command to create a Kompella VPLS instance, or enter the Kompella VPLS configuration mode. Run the **no I2 vfi** command to delete an VPLS instance. Specify a locally unique name and VPN ID for the VPLS instance you create, and enable automatic discovery for the VPLS instance. The VPLS name must map to the VPN ID. BGP is the default signaling protocol in the automatic discovery mode.

↘ Configuring VPLS Access

Configuring VPLS Access for a Switch

The created VPLS instance takes effect only when the user for which the VPLS instance is configured accesses the link. Currently, a switch can access VPLS services in the following three methods:

- VLAN access interface

Access through VLAN access interface is applicable for user packets that are not encapsulated by 802.1Q; that is, the packets contain no VLAN Tag.

- VLAN trunk interface

Access through VLAN trunk interface is applicable when multiple VPLSs are transmitted on the same physical AC and each VLAN corresponds to one VPLS instance. PE distinguishes to which VPLS instance a packet belongs based on the packet's VLAN Tag, and then provides a combo access interface.

- VLAN tunnel access

Access through a VLAN tunnel interface is applicable when the user service packet transmitted on an AC already contains a private VLAN Tag when the user accesses VPLS. In such a mode, the PE forwards intact all packets received from the interface, and VLAN member ports connecting the PE to the CE need to work in tunnel mode.

↘ Configuring Kompella VPLS Compatibility

L2VPN provides PW MTU of 1,500 bytes by default. If the same PW between two PEs have different MTU values, PW cannot be created for the two PEs. Devices of some manufacturers do not support MTU configuration in an L2VPN instance. When these devices are interconnected to devices of other manufacturers, to ensure that the VC is UP, you can run the **ingore match I2-extcommunity** command to disable the match inspection for MTU and Control Flag received.

2.3.2.3 Inter-AS Kompella VPLS

Working Principle

Multiple sites of one VPN may be connected to multiple service providers using different ASs or to multiple ASs of one service provider. Such an application that one VPN crosses multiple ASs is called Inter-AS VPN. Kompella VPWS has two Inter-AS solutions:

- Inter-AS Option A: It can be easily realized. This solution is applied when the number of Inter-AS L2VPNs on an ASBR is low.
- Inter-AS Option C: No VC needs to be created and maintained on an ASBR. This solution is applicable when each AS contains a great many Inter-AS L2VPNs, to avoid the ASBR scale expansion bottleneck.

Inter-AS Option A

Figure 2-17 Option A: Inter-AS VPWS

In such a mode, ASBRs of two ASs are directly connected, and ASBRs serve as PEs of each AS. Two ASBRs take each other as their CEs. As shown in the figure above, ASBR2-AS2 of AS2 is a CE for ASBR1-AS1 of AS1, and vice versa.

Option A has an advantage of easy realization, because no special Inter-AS configurations are required for two PEs serving as ASBRs, and no IP addresses are needed for interfaces between ASBRs. The disadvantage is that, a link should be allocated for ASBRs between two ASs when each Inter-AS L2VPN or PW is established. The link is either a logical or physical link. Pressure on ASBRs increases when there are a great many Inter-AS PWs, which limits the scale expansion.

The configuration method of this mode is similar to that of basic VPWS above, and thus is omitted here.

Inter-AS Option C

Figure 2-18 Option C: Inter-AS VPWS

In Option C in the figure above, an Inter-AS PW is established between PEs on two ASs to exchange PW labels, so as to realize Inter-AS L2VPN. The working principle is as follows:

An ASBR releases the label IPv4 routes to PEs inside its own AS through MP-IBGP and notifies the label IPv4 routes reaching PEs inside its own AS to the ASBR peer of the peer AS, so as to connect the two AS tunnels and establish an LSP

tunnel between the ingress PE and egress PE. Next, it establishes Inter-AS LDP remote session connection between PEs of different ASs and switches PW information.

In this solution, ASBR either needs to maintain Inter-AS L2VPN information nor needs to allocate a physical or logical interface for the Inter-AS L2VPNs. L2VPN information is exchanged directly between PEs, reducing pressure on ASBR and facilitating scale expansion.

Related Configuration

▾ Configuring MPLS Signaling

- Enable MPLS and LDP for PEs and P devices in each AS as well as for ASBR interfaces connecting to P devices or PEs inside the AS, so as to establish a basic MPLS network.

▾ Configuring a PE

- Configure PEs inside an AS to establish an IBGP session between PEs and the ASBR inside the AS and exchange the IPv4 routes carrying the labels.

▾ Configuring an ASBR

- Configure ASBR to establish an IBGP session between ASBR and PEs inside the same AS and establish an EBGP session with ASBR inside another AS. Enable IPv4 routes carrying labels for the two sessions. Configure a PE address on the ASBR which must be transmitted to another ASBR.

▾ Configuring an L2VPN Address Family

- Kompella VPLS uses MP-BGP4 as the signaling protocol and automatic discovery mechanism. PEs in the same VPLS instance exchange VPLS information through the L2VPN address family. L2VPN VPLS address family is not supported by default.

▾ Configuring a Kompella VPLS Instance

- Run the **I2 vfi** command to create a Kompella VPLS instance, or enter the Kompella VPLS configuration mode. Run the **no I2 vfi** command to delete an VPLS instance. Specify a locally unique name and VPN ID for the VPLS instance you create, and enable automatic discovery for the VPLS instance. The VPLS name must map to the VPN ID. BGP is the default signaling protocol in the automatic discovery mode.

▾ Configuring VPLS Access

- Configure the VPLS access mode.

2.4 Configuration

Configuration	Description and Command
---------------	-------------------------

Configuration		Description and Command	
Martini VPWS	Basic VPWS	 (Mandatory) It must be configured when Martini VPWS is used for Layer-2 interconnection between different sites.	
		vc-withdraw-expect-release	Specifies waiting for response from the peer or not after LDP sends the PW label withdraw message.
		xconnect encapsulation mpls	Configures PW simulation.
	Inter-AS VPWS	 (Optional) It is used for Layer-2 interconnection between sites in different ASs.	
		xconnect encapsulation mpls	Configures PW simulation.
Kompella VPWS	Basic Kompella VPWS	 (Mandatory) It must be configured when Kompella VPWS is used for Layer-2 interconnection between different sites.	
		address-family l2vpn vpws	Enters the L2VPN address family configuration mode.
		neighbor activate	Activates neighbors supporting the L2VPN address family.
		neighbor send-community	Enables extended BGP community attributes.
		l2 vfi	Creates an L2VPN VFI instance.
		rd	Defines the RD value for the Kompella L2VPN VFI instance.
		encapsulation mpls	Specifies the PW encapsulation type for the L2VPN VFI instance.
		route-target	Defines the RT attribute of a Kompella L2VPN instance.
		site-id	Configures sites of PEs in a Kompella L2VPN VFI instance.
	xconnect interface	Enables Kompella L2VPN.	
	Inter-AS VPWS	 (Optional) It is used for Layer-2 interconnection between sites in different ASs.	
	Other Kompella VPWS Parameters	 (Optional) It is used to set parameters of Kompella VPWS .	
		description	Describes an L2VPN VFI instance.
ignore match l2-extcommunity		Matches or not Layer-2 extended community attribute for Kompella PWs.	
	mtu	Configures the MTU value for an L2VPN VFI instance.	

Configuration		Description and Command	
		neighbor next-hop-unchanged	Specifies not to modify next hop when sending routes to the peer (group).
Static VC FTN and ILM		 (Optional) It is used to configure static VC_FTN and ILM entries.	
		mpls static l2vc-ftn	Configures a static VC FTN entry.
		mpls static ilm in-label forward-action pop-l2vc-destport	Adds an ILM entry to the ILM table.
Static PW		 (Optional) It is used to configure a static PW.	
		xconnect encapsulation mpls manual	Configures a static PW.
Martini VPLS		 (Mandatory) It must be configured when Martini VPLS is used for Layer-2 interconnection between different sites.	
		vc-withdraw-expect-release	Specifies waiting for response from the peer or not after LDP sends the PW label withdraw message.
		l2 vfi	Creates an L2VPN VFI instance.
		neighbor encapsulation mpls	Configures an VPLS neighbor.
		xconnect vfi	Enables Martini VPLS for the interface.
Kompella VPLS	Basic Kompella VPLS	 (Mandatory) It must be configured when Kompella VPLS is used for Layer-2 interconnection between different sites.	
		address-family l2vpn vpls	Enters the L2VPN address family configuration mode.
		neighbor activate	Activates neighbors supporting the L2VPN address family.
		neighbor send-community	Enables extended BGP community attributes.
		l2 vfi	Creates an L2VPN VFI instance.
		signal bgp	Specifies the PW signaling for the L2VPN VFI instance.
		rd	Defines the RD value for the Kompella L2VPN VFI instance.
		encapsulation mpls	Specifies the PW encapsulation type for the L2VPN VFI instance.
		route-target	Defines the RT attribute of a Kompella L2VPN instance.
site-id	Configures sites of PEs in a Kompella L2VPN VFI instance.		

Configuration		Description and Command		
		xconnect interface	Enables Kompella L2VPN.	
	Inter-AS Kompella VPLS	 (Optional) It is used for Layer-2 interconnection between sites in different ASs.		
	VPLS Compatibility	 (Optional) It is used to ensure smooth VCs for Kompella VPLSs of different providers.		
		l2 vfi	Creates an L2VPN VFI instance.	
		ignore match l2-extcommunity	Matches or not Layer-2 extended community attributes for Kompella PWs.	
Other VPLS Parameters	 (Optional) It is used to set VPLS parameters.			
	description	Describes an L2VPN VFI instance.		
	mtu	Configures the MTU value for an L2VPN VFI instance.		
	l2 vfi tunnel-protocol stp	Enables transparent STP packet transmission for the interface to which the VPLS instance is bound.		
	mac-address aging-time	Configures the MAC aging time for the VPLS instance.		
	mac-limit	Configures MAC address learning limit rules for the VPLS instance.		
	mpls static vfi mac-address	Configures the static MAC address for the VPLS instance.		
	neighbor next-hop-unchanged	Specifies not to modify next hop when sending routes to the peer (group).		

2.4.1 Martini VPWS

2.4.1.1 Basic VPWS

Configuration Effect

Configure Martini VPWS for Layer-2 interconnection between different sites.

Notes

- The MPLS forwarding function must be enabled globally and the label forwarding function must be enabled for public interfaces.

Configuration Steps

▾ Configuring a Public Tunnel

To run MPLS on a backbone network, the LDP must be run simultaneously on P and PE to establish a public tunnel. Distribution protocols should be configured for corresponding routes, and the MPLS forwarding function must be enabled for each interface.

- It is mandatory.
- Run the **mpls ip** command to enable MPLS globally.
- Run the **mpls router ldp** command to configure the LDP signaling and enter the MPLS route configuration mode.
- Run the **ldp router-id interface** loopback *id* [**force**] command to configure the LDP Router ID. The IP address of the Loopback interface is usually used as the Router ID.
- Exit the MPLS route configuration mode, and run the **interface type ID** command to configure public interfaces;
- Run the **ip address ip-address mask** command to set the IP address.
- Run the **label-switching** command to enable the MPLS packet forwarding function for public interfaces.
- Run the **mpls ip** command to enable LDP for the interface.

▾ Configuring a Remote LDP Session

A remote LDP session is used to establish and maintain PWs. If there are other LSRs between PEs, the remote LDP discovery mechanism is used to establish a remote LDP session between PEs and distribute PW labels on the session.

- It is mandatory.
- In the global configuration mode, run the **mpls router ldp** command to enable LDP and enter the LDP configuration mode.
- Run the **neighbor ip-address** command to configure a remote LDP session.

 The PW label message of LDP is forced to work in the DU and free label retention mode.

▾ Specifying Waiting for Response from the Peer or not after LDP Sends the PW Label Withdraw Message.

When the command is run, after sending a PW label withdraw message, LDP releases the label only after receiving a PW label release message from the peer. For example, when the command is run, LDP sends a PW label withdraw message because AC is disabled; if LDP does not receive a PW label release message from the peer, when PW is enabled again because AC is enabled, LDP will not send the PW label mapping message again until receiving a PW label release message from the peer, or the command is run to stop waiting.

- (Optional) It is used to specify not to wait for the PW label release message from the peer.
- LDP waits for the PW label release message from the peer by default.
- In the global configuration mode, run the **mpls router ldp** command to enable LDP and enter the LDP configuration mode.
- Run the **vc-withdraw-expect-release** command for configuration.

Configuring VPWS Access

Configuring Access Modes for a Switch

Only Ethernet-based VPWS can be provided for a switch. Based on whether the packet contains a VLAN Tag, the following access modes are provided:

- Access interface
- Trunk interface
- 802.1Q tunnel interface

-
- ⚠ Only VLAN interface (SVI interfaces of a switch) can provide VPWS, and the VLAN has only one member port. IP and VPWS cannot be enabled simultaneously on a VLAN interface.
 - ⚠ Only one VC instance can be bound to one VLAN interface, and the same VC instance cannot be bound to different VLAN interfaces.
 - ⚠ When the command is used, only Router ID can be specified as the neighbor address of the VC peer, which is a 32-bit address of the Loopback interface.
 - ⚠ The port protection mode is only valid for Trunk member ports at the AC end on L2VPN.
 - ⚠ Super VLAN interface cannot provide VPWS. When an ordinary VLAN is configured as a Super VLAN, the VPWS configurations on the ordinary VLAN are deleted.
-

VLAN access interface

Access through VLAN access interface is applicable to user packets that are not encapsulated by 802.1Q; that is, the packets contain no VLAN Tag.

- It is mandatory.
- In the global configuration mode, run the **interface type ID** command to enter the interface configuration mode.
- Run the **switchport mode access** command to set the interface to the access mode.
- Run the **switchport access vlan vlan-id** command to set the interface to be a member port of a VLAN.
- Exit the interface configuration mode, run the **interface vlan vlan-id** command to enter the VLAN interface configuration mode.
- Run the **xconnect vc_id vc_peer encapsulation mpls ethernet raw** command to create a VC and set the encapsulation mode to Raw.

-
- ℹ As for access through VLAN access interface and VLAN trunk, the PW type is Ethernet, and the Encapsulation mode is Raw.
-

VLAN trunk interface

Access through a VLAN trunk interface is applicable when multiple VPWSs are transmitted on the same AC. A PE distinguishes to which VPWS a packet belongs based on the packet's VLAN Tag, and then provides a combo access interface.

- It is mandatory.

- In the global configuration mode, run the **interface type ID** command to enter the interface configuration mode.
- Run the **switchport mode trunk** command to configure the interface to the Trunk mode.
- Run the **switchport trunk allow vlan add vlan-list** command to allow VLAN traffic to be transmitted on a trunk link.
- Exit the interface configuration mode, run the **interface vlan vlan-id** command to enter the VLAN interface configuration mode.
- Run the **xconnect vc_peer vc_id encapsulation mpls ethernetvlan tagged** command to create a VC and set the encapsulation mode to Tagged.

i For access through trunk interface, the PW encapsulation type is Ethernet VLAN, and the encapsulation mode is Tagged.

i It is not suggested to bind Native VLAN of a trunk interface to L2VPN.

VLAN Tunnel Interface

Access through a VLAN tunnel interface is applicable when the user service packet transmitted on an AC already contains a private VLAN Tag when the user accesses a VPWS. In such a mode, the PE forwards intact all packets received from the interface, and VLAN member ports connecting the PE to the CE need to work in tunnel mode.

- It is mandatory.
- In the global configuration mode, run the **interface type ID** command to enter the interface configuration mode.
- Run the **switchport access vlan-id** command to set VLAN member ports for the interface.
- Run the **switchport mode dot1q-tunnel** command to set the interface to work in the tunnel mode.
- Exit the interface configuration mode, run the **interface vlan vlan-id** command to enter the VLAN interface configuration mode.
- Run the **xconnect vc_id vc_peer encapsulation mpls ethernet raw** command to create a VC and set the encapsulation mode to Raw.

i Only basic QinQ, not flexible QinQ, is supported in this mode.

Verification

- Run the **show mpls l2transport vc [vc_id [ip-address]] | [interface interface_name] [detail]** to display the VPWS VC.
- Run the **show mpls ldp vc** command to display the VC signaling of Martini VPWS.

Related Commands

⌵ Specifying Waiting for Response from the Peer or not after LDP Sends the PW Label Withdraw Message

Command	vc-withdraw-expect-release
Parameter	-
Description	
Command	config-mpls-router

Mode	
Usage Guide	When the command is run, after sending a PW label withdraw message, LDP releases the label only after receiving a PW label release message from the peer. For example, when the command is run, LDP sends a PW label withdraw message because AC is disabled; if LDP does not receive a PW label release message from the peer, when PW is enabled again because AC is enabled, LDP will not send the PW label mapping message again until receiving a PW label release message from the peer, or the command is run to stop waiting.

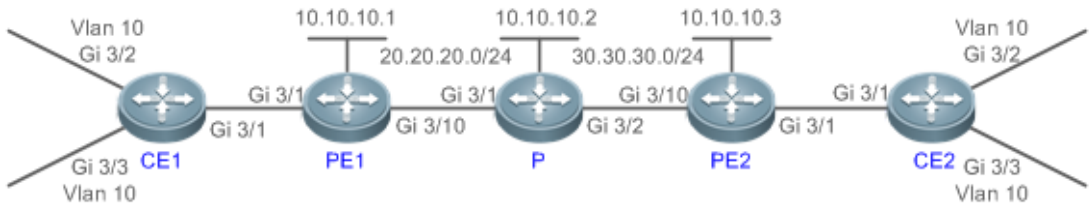

↘ **Enabling VPWS for the Interface**

Command	xconnect <i>vc_peer</i> <i>vc_id</i> encapsulation mpls [ethernet ethernetvlan] [{ raw tagged } [send-vlanrewrite-req not-send-vlanrewrite-req]] [<i>group-id</i>] [<i>mtu</i>] [manual]
Parameter Description	<p><i>vc_id</i>: specifies the identifier of the PW instance. The value range is [1..2147483647].</p> <p><i>vc_peer</i>: specifies A.B.C.D, and the peer LSR ID.</p> <p>ethernet: specifies the PW type to Ethernet.</p> <p>ethernetvlan: specifies the PW type to VLAN.</p> <p>raw: specifies the encapsulation mode to Raw (which is valid only when the PW type is Ethernet or Ethernet VLAN).</p> <p>tagged: specifies the encapsulation mode to Tag (which is valid only when the PW type is Ethernet or Ethernet VLAN).</p> <p>send-vlanrewrite-req: sends a VLAN rewrite request to the peer (which is valid only when the PW type is Ethernet VLAN).</p> <p>not-send-vlanrewrite-req: specifies not to send a rewrite request to the peer (which is valid only when the PW type is Ethernet VLAN).</p> <p><i>group-id</i>: specifies the PW group number. The default value is 0 and the value range is [0-4294967295].</p> <p><i>mtu</i>: specifies the PW MTU value. The value range is [46-9216].</p> <p>manual: specifies to configure VC-ftn and VC-ilm for a static PW.</p>
Command Mode	Interface configuration mode
Usage Guide	<p>MTU in the command specifies the size of packets which can be transmitted by the PW; that is, the length of users' Layer-2 packet and the PW encapsulated packet. By default, if no control word is enabled for the PW and two labels are encapsulated, the length of the Ethernet packets that can be transmitted is 1,492 bytes, including 8-byte PW encapsulated packet (the two labels). When the length of MTU for PW signaling protocol negotiation is modified, the length of MTU of the access interface must be adjusted (the length of PW MTU minus the length of PW encapsulation). Besides, the MTU of the egress interface on a public network must be consistent with the PW MTU; otherwise, the packet cannot be forwarded. You can run the mtu command to modify the interface MTU.</p> <p>When a static PW is created, no signal is required, but the egress and ingress labels of the PW must be manually specified.</p> <hr/> <p> For a Martini PW, the MTU values at two ends of the PW and the PW type must be consistent; otherwise, the PW cannot be enabled.</p>

! After the interface is bound to VPWS, the PW type, encapsulation mode, and MTU cannot be modified. To modify them, the VPWS bound to the interface must be deleted first.

Configuration Example

Switch Configuration Example: CE and PE Work at the Access Mode, and PW Works at the Ethernet Mode.

<p>Scenario Figure 2-19</p>	 <p>The interface connecting PE to CE works at the access mode; that is, CE is connected to PE through an access link. The PE creates a PW for the VLAN at the access interface. In Raw mode, frames transmitted through the PW between PE1 and PE2 have no VLAN Tag 10.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure an access interface on CE1 and CE2. ● Configure the access interface mode between CE and PE on CE1 and CE2. ● Configure a Loopback interface on PE1 and PE2. ● Configure a public LSP tunnel and remote LDP neighbor on PE1 and PE2, and enable label exchange only for Layer-3 interfaces. ● Configure the access interface mode between PE and CE on PE1 and PE2. ● Configure a PW for VLAN 10 on PE1 and PE2. ● Configure a public tunnel on P.
<p>CE1</p>	<pre>CE1# configure terminal CE1(config)# interface gigabitethernet 3/2 CE1 (config-if-Gigabitethernet 3/2)# switchport mode access CE1 (config-if-Gigabitethernet 3/2)# switchport access vlan 10 CE1 (config-if-Gigabitethernet 3/2)# exit CE1 (config)# interface gigabitethernet 3/3 CE1 (config-if-Gigabitethernet 3/3)# switchport mode access CE1 (config-if-Gigabitethernet 3/3)# switchport access vlan 10 CE1 (config-if-Gigabitethernet 3/3)# end CE1 (config)# interface gigabitethernet 3/1 CE1 (config-if-Gigabitethernet 3/1)# switchport mode access CE1 (config-if-Gigabitethernet 3/1)# switchport access vlan 10</pre>

Switch Configuration Example: CE and PE Work at the Trunk Mode, and PW works at the Ethernet VLAN Mode.

<p>Scenario Figure 2-20</p>	 <p>Both CE1 and CE2 have two VLANs, and a CE accesses a PE through a trunk interface. A PE creates one PW for each user's VLANs. In this mode, multiple VLAN interfaces share one physical port. PE1 and PE2 respectively create two PWs for VLAN 10 and VLAN 20. Frames transmitted on PWs carry the VLAN Tag 10 and VLAN Tag 20 respectively.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● On CE1 and CE2, configure the access interface and the trunk interface connected to the PE. ● On PE1 and PE2, configure the Loopback interface, public LSP tunnel, remote LDP neighbor, and the trunk interface connected to the CE. ● On PE1, create a PW for VLAN 10 and VLAN 20 respectively. ● On P, configure a public LSP tunnel.

Common Errors

- The MPLS forwarding function is not enabled globally.
- LDP is disabled for the interface.

2.4.1.2 Inter-AS VPWS

Configuration Effect

- Configure Layer-2 interconnection between sites in different ASs.

Notes

- The MPLS forwarding function must be enabled globally and the label forwarding must be enabled for public interfaces.

Configuration Steps

Figure 2-23 Option A: Inter-AS VPWS

In such a mode, ASBRs of two ASs are directly connected, and ASBRs serve as PEs of each AS. Two ASBRs take each other as their CEs. As shown in the figure above, ASBR2-AS2 of AS2 is a CE for ASBR1-AS1 of AS1, and vice versa.

Option A has an advantage of easy realization, because no special Inter-AS configurations are required for two PEs serving as ASBRs, and no IP addresses are needed for interfaces between ASBRs. The disadvantage is that, a link should be allocated for ASBRs between two ASs when each Inter-AS L2VPN or PW is established. The link is either a logical or physical link. Pressure on ASBRs increases when there are a great many Inter-AS PWs, which limits the scale expansion.

For configuration methods, see [Basic VPWS](#).

Configuration Method of Inter-AS Option C

Figure 2-24 Option C: Inter-AS VPWS

In Option C, an Inter-AS PW is established between PEs on two ASs to exchange PW labels, so as to realize Inter-AS L2VPN.

An ASBR releases the label IPv4 routes to PEs inside its own AS through MP-IBGP and notifies the label IPv4 routes reaching PEs inside its own AS to the ASBR peer of the peer AS, so as to connect the two AS tunnels and establish an LSP tunnel between the ingress PE and egress PE. Next, it establishes Inter-AS LDP remote session connection between PEs of different ASs and switches PW information.

In this solution, the ASBR neither needs to maintain Inter-AS L2VPN information nor needs to allocate a physical or logical interface for the Inter-AS L2VPNs, but has to provide an MPLS channel. L2VPN information is exchanged directly between PEs, reducing pressure on ASBR and facilitating scale expansion.

Configuration steps are as follows:

▾ Configuring MPLS Signaling

- It is mandatory.
- Enable MPLS and LDP for PEs and Ps in each AS as well as for ASBR interfaces connecting to Ps or PEs inside the AS, so as to establish a basic MPLS network. For configuration steps, see 2.4.1.1 "Basic VPWS."

▾ Configuring a PE

- Establish an IBGP session between PEs and ASBR inside the local AS and exchange the IPv4 routes carrying the labels.
- It is mandatory.
- In the global configuration mode, run the **router bgp** *asn-number* command to configure BGP and enter the BGP configuration mode.
- Run the **neighbor** *asbr-address* **remote-as** *asbr-asn-number* command to create an IBGP session between a PE and an ASBR.
- Run the **neighbor** *asbr-address* **update-source** *interface-name* command to use a Loopback address as the source address of the BGP session created between peers.
- Run the **address-family ipv4** command to enter the IPv4 address family.
- Run the **neighbor** *asbr-address* **send-label** command to enable the label exchange function for IPv4 routes.

▾ Configuring an ASBR

Establish an IBGP session between ASBR and PEs inside the same AS and establish an EBGP session with ASBR inside another AS. Enable IPv4 routes carrying labels exchange function for the two sessions. Configure a PE address on the ASBR which must be transmitted to another ASBR.

- It is mandatory.
- In the global configuration mode, run the **mpls ip** command to enable the MPLS forwarding function for the local device.
- Run the **ldp router-id interface Loopback id force** command to set the IP address of the Loopback interface as the Router ID.
- Run the **advertise-labels for bgp-routes** command to allocate labels for BGP routes.
- Exit the global configuration mode, and run the **router bgp** *asn-number* command to configure BGP and enter the BGP configuration mode.
- Run the **neighbor** *asbr-address* **remote-as** *asbr-asn-number* command to create an EBGP session with an ASBR.
- Run the **neighbor** *pe-address* **remote-as** *asn-number* command to create an IBGP session with a PE.

- Run the **neighbor asbr-address update-source interface-name** command to use a Loopback address as the source address of the BGP session created between peers.
- Run the **address-family ipv4** command to enter the IPv4 address family.
- Run the **network pe-address mask mask-value** command to introduce the reached PE route into BGP. The route can also be introduced through redistributed IGP.

 This step is optional. No **network** command is executed when the route is introduced through redistributed IGP.

- Run the **neighbor asbr-address send-label** command to enable the IPv4 route label exchange function for a BGP session with the ASBR in another AS.
- Run the **neighbor pe-address send-label** command to enable the IPv4 route label exchange function for a BGP session with the ASBR in the current AS.
- Run the **neighbor asbr-ip-address route-map name out** command to configure the route distribution policy. The command needs to be executed if you want to control which routes are distributed to the neighbor and control whether the routes carry tags during distribution.
- Run the **neighbor asbr-ip-address route-map name in** command to configure the route distribution policy. The command needs to be executed if you want to receive only routes with tags.

▾ Configuring a Remote LDP Session

Configure remote LDP peers on PEs in each AS and create an LDP remote session. The remote LDP peers are configured as follows:

- It is mandatory.
- Enter the global configuration mode. Run the **mpls router ldp** command to enable LDP and enter the LDP configuration mode.
- Run the **neighbor ip-address** command to specify the IP address of the remote peer.

▾ Configuring VPWS Access

- It is mandatory.
- For configuration details, see VPWS Accesses in Martini VPWS.

 To create an IBGP session between ASBR and PE in the same AS, run the **neighbor peer-address update-source loopback id** command to specify to use the Loopback interface address of the local device as the source address of the session; otherwise, it is unable to create an Inter-AS LSP tunnel.

 For direct connected EBGP session between ASBRs, addresses of the interfaces directly connected as the source address of the BGP session to ensure routes of ASBRs can reach each other. Do not run the **neighbor peer-address update-source loopback id** command to specify to use the Loopback interface address of the local device as the source address of the directly connected EBGP sessions. Instead, run the **neighbor ebgp-multihop** command to enable multi-hop EBGP and configure a static route on the ASBR, so that the route can reach the peer route. Configure a static FTN to ensure connectivity of the Inter-AS LSP tunnel.

- i** Note that the **label-switching** command must be executed to enable the MPLS packet forwarding function for the interface connecting the two ASBRs.

Verification

- Run the **show bgp ipv4 unicast labels** command to display the label allocated by BGP for IPv4 routes.
- Run the **show mpls ldp neighbor** command to display the LDP neighbor.
- Run the **show mpls l2transport vc [detail]** command to display the VC status.

Related Commands

Configuring PW Simulation

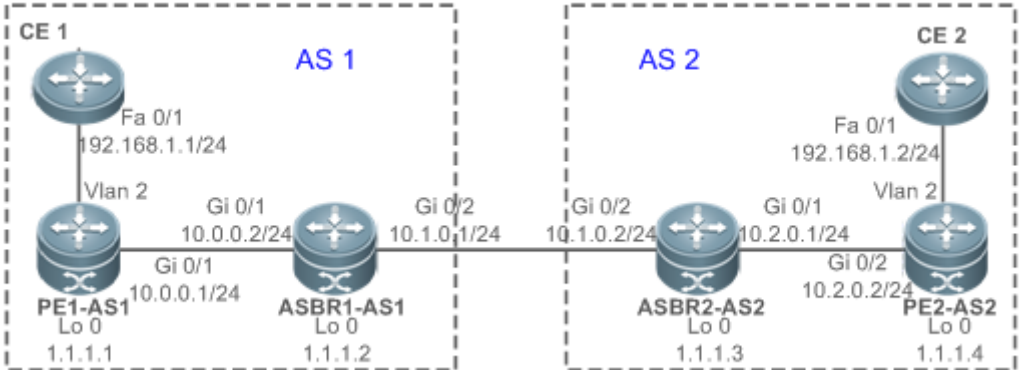

Command	xconnect <i>vc_peer</i> <i>vc_id</i> encapsulation mpls [[ethernet ethernetvlan] [raw tagged] [send-vlanrewrite-req not-send-vlanrewrite-req] [<i>group-id</i>] [<i>mtu</i>]
Parameter Description	<p>vc_id: specifies the identifier of the PW instance. The value range is [1..2147483647].</p> <p>vc_peer: specifies A.B.C.D, and the peer LSR ID.</p> <p>ethernet: specifies the PW type to Ethernet.</p> <p>ethernetvlan: specifies the PW type to VLAN.</p> <p>raw: specifies the encapsulation mode to Raw (which is valid only when the PW type is Ethernet or Ethernet VLAN).</p> <p>tagged: specifies the encapsulation mode to Tag (which is valid only when the PW type is Ethernet or Ethernet VLAN).</p> <p>send-vlanrewrite-req: sends a VLAN rewrite request to the peer (which is valid only when the PW type is Ethernet VLAN).</p> <p>not-send-vlanrewrite-req: specifies not to send a rewrite request to the peer (which is valid only when the PW type is Ethernet VLAN).</p> <p>group-id: specifies the PW group number. The default value is 0 and the value range is [0-4294967295].</p> <p>mtu: specifies the PW MTU value. The value range is [46-9216].</p>
Command Mode	Interface configuration mode
Usage Guide	<p>MTU in the command specifies the size of packets which can be transmitted by the PW; that is, the length of users' Layer-2 packet and the PW encapsulated packet. By default, if no control word is enabled for the PW and two labels are encapsulated, the length of the Ethernet packets that can be transmitted is 1,492 bytes, including 8-byte PW encapsulated packet (the two labels). When the length of MTU of PW signaling protocol negotiation is modified, the length of MTU of the access interface must be adjusted (the length of PW MTU minus the length of PW encapsulation). Besides, the MTU of the egress interface on the public network must be consistent with the PW MTU; otherwise, the packet cannot be forwarded. You can run the mtu command to modify the interface MTU.</p> <p>When a static PW is created, no signal is required, but the egress and ingress labels of the PW must be manually specified.</p> <p> For a Martini PW, the MTU values at two ends of the PW and the PW type must be consistent;</p>

otherwise, the PW cannot be enabled.

! After the interface is bound to VPWS, the PW type, encapsulation mode, and MTU cannot be modified. To modify them, the VPWS bound to the interface must be deleted first.

Configuration Example

Switch Configuration Example: Inter-AS VPWS in Option C

<p>Scenario Figure 2-25</p>	 <p>Option C is used to realize Inter-AS VPWS. PWs are established between PEs in different ASs. The ASBR does not maintain PE information. Each AS uses OSPF as IGP for interconnection inside the AS. Assuming that CE1 accesses a PE through the access interface, it is required that CE1 can be interconnected with CE2 through an L2VPN.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> On CE1 and CE2, configure the interface as a Layer-3 interface, and configure the IP address. On PE1-AS1 and PE2-AS2, configure the public routing protocol, MPLS signaling, and remote neighbor. Enable BGP and allow the user to access VPWS. On ASBR2-AS2 and ASBR2-AS2, configure the Loopback interface, public routing protocol, and MPLS signaling. Configure the IP address of the interface connected to ASBR2. Enable BGP and the label packet forwarding function for the interface. <p>! If CE1 and CE2 access PE in Trunk or other modes, adjust configuration of L2VPN in the VLAN interface mode. Configurations of Inter-AS BGP, public network IGP and MPLS do not need to be modified.</p>
<p>CE1</p>	<pre>Ruijie# configure terminal Ruijie(config)# interface FastEthernet 0/1 Ruijie(config-if-FastEthernet 0/1)# no switchport Ruijie(config-if-FastEthernet 0/1)# ip address 192.168.1.1 255.255.255.0 Ruijie(config-if-FastEthernet 0/1)# end</pre>

Verification	<ul style="list-style-type: none"> ● Check whether the PW is in UP state. ● CE1 can ping CE2.
PE1-AS1	<pre> PE1 # show mpls l2transport vc Local intf Dest address VC ID Status ----- V12 1.1.1.4 1 up </pre>
PE2-AS2	<pre> PE2#show mpls l2transport vc Local intf Dest address VC ID Status ----- V12 1.1.1.1 1 up </pre>

Common Errors

1. The EBGP peer neighbor uses the Loopback interface instead of the directly connected interface, and the EBGP multi-hop is not enabled. The EBGP neighbor cannot be pinged.
2. The PE has no remote peer.
3. The MPLS forwarding function is not enabled globally.
4. Send-label is disabled for the EBGP peer.

2.4.2 Kompella VPWS

2.4.2.1 Basic Kompella VPWS

Configuration Effect

Kompella VPWS is used for Layer-2 interconnection between sites.

Notes

The MPLS forwarding function must be enabled globally and the label forwarding function must be enabled for public interfaces.

Configuration Steps

📌 Configuring a Public Tunnel

LSP tunnels must be established on a public network to carry VCs. To run MPLS on a backbone network, the LDP must be run simultaneously on P and PE to establish a public tunnel. Distribution protocol should be configured for corresponding MPLS devices, and the MPLS-based forwarding function must be enabled for each interface.

- It is mandatory.
- Run the **mpls ip** command to enable MPLS globally.
- Run the **mpls router ldp** command to enable LDP and enter the LDP configuration mode.
- Run the **ldp router-id interface** loopback *id* [**force**] command to configure LDP Router ID. The IP address of the Loopback interface is usually used as the Router ID.
- Exit the MPLS route configuration mode, and run the **interface type ID** command to configure public interfaces;
- Run the **label-switching** command to enable the MPLS forwarding function for the interface.
- Run the **mpls ip** command to enable LDP and the MPLS forwarding function for the interface.
- Exit the privileged mode, and run the **copy running-config startup-config** command to save configurations.

i LDP is a topology-driven protocol. The IPv4 routing protocol should be enabled and run normally so that LDP can run normally.

📌 Configuring an L2VPN Address Family

Kompella VPWS uses MP-BGP4 as the signaling protocol to transmit Layer-2 messages and VC labels and realize point-to-point VPNs. Besides, it can also use MP-BGP4 as an automatic discovery protocol to connect to remote CEs.

- It is mandatory.
- In the global configuration mode, run the **router bgp** *asn-num* command to create BGP and enter the BGP configuration mode.
- Run the **mpls router ldp** command to enable LDP and enter the LDP configuration mode.
- Run the **neighbor** *peer-address* **remote-as** *asn-number* command to create an IBGP session.
- Run the **neighbor** *peer-address* **update-source** *interface-name* command to specify the Loopback interface address as the source address of the IBGP session.
- Run the **address-family l2vpn vpws** command to enter the L2VPN VPWS address family.
- Run the **neighbor** *ip-address* **activate** command to activate L2VPN interaction on the BGP session.
- Run the **neighbor** {*ip-address* | *peer-group-name*} **send-community** [**both** | **standard** | **extended**] command to specify the extended community attribute sent to the BGP neighbor.
- Exit the privileged mode, and run the **copy running-config startup-config** command to save configurations.

▾ Configuring a Kompella VPWS Instance

Run the **I2 vfi** command to create a Kompella VPWS instance, or enter the Kompella VPWS configuration mode. Run the **no I2 vfi** command to delete a VFI instance. Specify a locally unique name and VPN ID for the VFI instance you create, and enable automatic discovery for the VFI instance. The VFI name must map to the VPN ID.

Run the **label-saving** command to enable the label saving mode and allocate a label for the specified remote site. Site Range is invalid in label saving mode.

- It is mandatory.
- In the global configuration mode, run the **I2 vfi** *vpls-name* **vpnid** *vpn-id* **point-to-point** command to create a Kompella VPWS instance and enter the VPWS configuration mode.
- Run the **rd** *rd_value* command to configure the RD value.
- Run the **encapsulation mpls** [**ethernet** | **ethernetvlan**] command to specify the PW encapsulation type for the Kompella L2VPN. The default encapsulation type is Ethernet.
- Run the **route-target** { **import** | **export** | **both** } *rt_value* command to configure RT. Multiple RTs can be configured.
- Run the **site-id** *id* [**site-range** *size*] command to configure the CE ID and site-range of the site. If not configured, the site-range is 16 by default. Multiple Site IDs can be configured for a Kompella VPWS.
- Run the **xconnect interface** *interface-type* *interface-number* **remote-ce-id** *id* command to bind a local interface and specify the remote CE ID.
- Exit the privileged mode, and run the to save configurations.

i Run the **I2 vfi** command to specify the point-to-point keywords for the Kompella VPWS instance.

i For convenient management, configure the same ID for VFI instances in the same VPN.

-
-  ID of each site is globally unique in the VFI instance.
 -  The VPWS PW type of VFI instances on PEs in the same VPN must be the same; otherwise, BGP signals cannot negotiate to create a PW.
 -  It is suggested to specify the PW type as Ethernet VLAN for VPWS accessed from a sub-interface, and Ethernet for VPWS accessed from an Ethernet interface. If the PW type of the accessing interface is inconsistent with the specified PW type, the PW can be established but CEs may fail to communicate with each other because the packet tag is processed differently due to different PW types. When the PW type is Ethernet VLAN, the VLAN Tag of the user packet is processed as an S-Tag; otherwise, it is processed as a C-Tag and the packet is transmitted transparently.
-

📌 Configuring VPWS Access

The created VFI instance takes effect only when the user for which the VFI instance is configured accesses the link. Multiple point-to-point VCs can be configured for one VFI.

Configuring VPWS Access for a Switch

Only Ethernet-based VPWS can be provided for a switch. Based on whether the packet contains a VLAN Tag, the following access modes are provided:

- Access interface
- Trunk interface
- VLAN tunnel interface

-
-  Only VLAN interface (SVI interfaces of a switch) can provide VPWS, and the VLAN has only one member port. IP and VPWS cannot be enabled simultaneously on the VLAN interface.
 -  Only one VC instance can be bound to one VLAN interface, and the same VC instance cannot be bound to different VLAN interfaces.
 -  The port protection mode is only valid for Trunk member ports at the AC end on L2VPN.
 -  For access from Ethernet interface, the PW encapsulation type should be Ethernet, and the encapsulation type at two ends of the PW must be the same.
 -  To create a Kompella VPWS, a remote CE ID must be specified.
 -  Super VLAN interface cannot provide VPWS. When an ordinary VLAN is configured as a Super VLAN, the VPWS configurations on the ordinary VLAN are deleted.
-

VLAN Access Interface

Access through VLAN access interface is applicable to user packets that are not encapsulated by 802.1Q; that is, the packets contain no VLAN Tag.

- It is mandatory.
- In the global configuration mode, run the **interface type ID** command to enter the interface configuration mode.
- Run the **switchport mode access** command to set the interface to the access mode.
- Run the **switchport access vlan vlan-id** command to set the interface to be a member port of a VLAN.

- Exit the interface configuration mode, and run the **I2 vfi vfi_name vpnid vpn_id point-to-point** command to enter the VFI configuration mode.
- Run the **rd rd_value** command to configure the RD value for a Kompella VPWS.
- Run the **route-target {import|export|both} rt_value** command to configure RT.
- Run the **encapsulation mpls ethernet** command to configure the VFI encapsulation type as Ethernet.
- Run the **site-id id [site-range size]** command to configure the VFI site.
- Run the **xconnect interface vlan vlan-id remote-ce-id id** command to connect the interface bound to the local VFI to a remote CE in the VFI.

 For access from a VLAN access interface, the PW encapsulation type should be Ethernet, and the encapsulation type at two ends of the PW must be the same.

VLAN Trunk Interface

Access through a VLAN trunk interface is applicable when multiple VPWSs are transmitted on the same access link. A PE distinguishes to which VPWS a packet belongs based on the packet's VLAN Tag, and then provides a combo access interface.

- It is mandatory.
- In the global configuration mode, run the **interface type ID** command to enter the interface configuration mode.
- Run the **switchport mode trunk** command to configure the interface to the Trunk mode.
- Run the **switchport trunk allow vlan add vlan-list** command to allow VLAN traffic to be transmitted on a trunk link.
- Exit the interface configuration mode, and run the **I2 vfi vfi_name vpnid vpn_id point-to-point** command to enter the VFI configuration mode.
- Run the **rd rd_value** command to configure the RD value for a Kompella VPWS.
- Run the **route-target { import | export | both } rt_value** command to configure RT.
- Run the **encapsulation mpls ethernetvlan** command to configure the VFI encapsulation type as Ethernet VLAN.
- Run the **site-id id [site-range size]** command to configure the VFI site.
- Run the **xconnect interface vlan vlan-id remote-ce-id id** command to connect the interface bound to the local VFI to a remote CE in the VFI.

 For access from VLAN trunk interface, the PW encapsulation type should be Ethernet VLAN, and the encapsulation type at two ends of the PW must be the same.

 It is not allowed to bind the Native VLAN of the trunk interface to L2VPN.

VLAN Tunnel Interface

Access through a VLAN tunnel interface is applicable when the user service packet transmitted on the access link already contains a private VLAN Tag when the user accesses VPWS. In such a mode, the PE forwards intact all packets received from the interface, and VLAN member ports connecting the PE to the CE need to work in tunnel mode.

- It is mandatory.

- In the global configuration mode, run the **interface** *type ID* command to enter the interface configuration mode.
- Run the **switchport access** *vlan-id* command to set VLAN member ports for the interface.
- Run the **switchport mode dot1q-tunnel** command to set the interface to work in the tunnel mode.
- Exit the interface configuration mode, and run the **I2 vfi** *vfi_name vpnid vpn_id point-to-point* command to enter the VFI configuration mode.
- Run the **rd** *rd_value* command to configure the RD value for a Kompella VPWS.
- Run the **route-target** { **import** | **export** | **both** } *rt_value* command to configure RT.
- Run the **encapsulation mpls ethernetvlan** command to configure the VFI encapsulation type as Ethernet VLAN.
- Run the **site-id** *id [site-range size]* command to configure the VFI site.
- Run the **xconnect interface vlan** *vlan-id remote-ce-id id* command to connect the interface bound to the local VFI to a remote CE in the VFI.

- i** For access from a VLAN access interface, the PW encapsulation type should be Ethernet, and the encapsulation type at two ends of the PW must be the same.
- i** Only basic QinQ, not flexible QinQ, is supported in this mode.

Verification

- In the privileged mode, run the **show bgp I2vpn vpws** {**all** [*id:offset*] | **neighbor** *ip-address* [**summary**]} command to display the L2VPN address family.
- In the privileged mode, run the **show mpls I2transport vc** command to display the PW status.

Related Commands

↘ Entering the L2VPN address family configuration mode

Command	address-family I2vpn { vpls vpws }
Parameter	vpls : indicates the L2VPN VPLS address family.
Description	vpws : indicates the L2VPN VPWS address family.
Command Mode	BGP configuration mode BGP scope configuration mode
Usage Guide	Run the address-family I2vpn vpls command to allow L2VPN VPLS interaction between PEs and enter the VPLS address family configuration mode. Run the address-family I2vpn vpws command to allow L2VPN VPWS interaction between PEs and enter the VPWS address family configuration mode. Run the exit-address-family command to exit the L2VPN address family configuration mode.

↘ Activating Neighbors Supporting L2VPN Address Family

Command	neighbor { <i>ip-address</i> <i>peer-group-name</i> } activate
Parameter	<i>ip-address</i> : indicates an IP address.
Description	<i>peer-group-name</i> : specifies a peer group name of no more than 32 characters.
Command	BGP L2VPN address family configuration mode

Mode	
Usage Guide	Run the command to activate BGP-based L2VPN switch for L2VPN VPLS or VPWS address family configuration.

↘ Enabling Extended BGP Community Attribute

Command	neighbor { <i>ip-address</i> <i>peer-group-name</i> } send-community [both standard extended]
Parameter Description	<p><i>ip-address</i>: indicates an IP address.</p> <p><i>peer-group-name</i>: specifies a peer group name of no more than 31 characters.</p> <p>both: sends standard and extended community attributes.</p> <p>standard: sends only standard community attributes.</p> <p>extended: sends only extended community attributes.</p>
Command Mode	BGP L2VPN address family configuration mode
Usage Guide	If a peer group is specified during configuration, all members of the peer group inherit the attributes configured by this command. When the neighbor activate command is run for the first time, this attribute is enabled by default.

↘ Creating an L2VPN VFI instance

Command	l2 vfi <i>name</i> [vpnid <1- 2147483647> [manual autodiscovery point-to-point]]
Parameter Description	<p><i>name</i>: indicates the name of L2VPN VFI instance, which is a string of up to 31 characters.</p> <p><1- 2147483647>: specifies an ID for the created VPLS instance.</p> <p>manual: manually configures an VPLS neighbor for Martini VPLS to create a PW.</p> <p>autodiscovery: creates a PW for Kompella VPLS through automatic discovery.</p> <p>point-to-point: automatically discovers PEs specified for Kompella VPWS VFI.</p>
Command Mode	Global configuration mode
Usage Guide	<p>L2VPN VFI name maps with its VPN ID. When this command contains no VPN ID, the VFI configuration mode is entered. The name parameter can only specify existing L2VPN VFI instance. An error message is displayed when there is any conflict.</p> <p>If the name, ID and configuration mode are the same to the original configurations, VFI configuration mode is entered.</p> <p>Automatic discovery takes effect only when the L2VPN VPLS or L2VPN VPWS address family in the BGP configuration mode is activated.</p> <p>Kompella VPLS is realized only when the keyword autodiscovery is specified. Kompella VPWS is realized only when the point-to-point mode is specified. When no keyword is specified or the keyword is manual, Martini VPLS is realized.</p> <p>The L2VPN VFI realization method cannot be modified after being selected. To modify the realization method, you need to delete the instance and configure it again. For example, to change a Kompella VPLS to a Martini VPLS, delete the Kompella VPLS instance, create a new VPLS instance and set its realization method to Martini.</p> <p>For Kompella VPLS or VPWS, a PW can be established only when the instance RD, Site ID, and Route</p>

	<p>Target are configured and the instance is bound to an interface.</p> <p>For Martini VPLS, a PW can be created only when the instance is bound to an interface or a Spoke VC neighbor is created.</p>
--	---

↘ **Defining a RD value for a Kompella L2VPN VFI Instance**

Command	<code>rd rd_value</code>
Parameter Description	<i>rd_value</i> : indicates the RD value.
Command Mode	VFI configuration mode
Usage Guide	<p>This command is valid only for Kompella VPLS and VPWS.</p> <p>For a Kompella L2VPN instance, RD should be configured before other parameters.</p> <p>The RD value configured for a Kompella L2VPN instance cannot be modified or deleted. To modify the RD value, you need to delete the Kompella L2VPN instance and create a new one and then configure the RD value. One L2VPN VFI instance has only one RD value.</p>

↘ **Specifying an Encapsulation Type for the PWs in the L2VPN VFI Instance**

Command	<code>encapsulation mpls [ethernet ethernetvlan ppp hdlc ip-interworking]</code>
Parameter Description	<p>mpls: specifies the encapsulation type.</p> <p>ethernet: specifies the VPWS PW type to Ethernet, and the VPLS PW type to Raw.</p> <p>ethernetvlan: specifies the VPWS PW type to Ethernet VLAN, and the VPLS PW type to Tag.</p>
Command Mode	VFI configuration mode
Usage Guide	<p>This command is valid only for Kompella L2VPN. The encapsulation types of Kompella VPLS are Ethernet and Ethernet VLAN, which specify the VPLS PW encapsulation type as Raw and Tag respectively.</p> <p>All PW encapsulation types are valid for Kompella VPWS and used for BGP signaling negotiation.</p> <p>For Kompella VPLS, the PW type at two ends of the PW must be the same; otherwise, the PW cannot be established through BGP signaling.</p> <hr/> <p> For Kompella VPLS, the PW encapsulation type of PEs on the same VPLS must be the same; otherwise, the packet cannot be forwarded because the VLAN Tags are different. If all PEs on a VPLS are accessed through Ethernet interface, the PW encapsulation type shall be Raw. If all PEs on a VPLS are accessed through Ethernet sub-interface, the PW encapsulation type shall be Tag.</p> <p> If the VFI instance is bound to an interface, the instance should be unbound first before its encapsulation type can be modified.</p>

↘ **Defines a RT Attribute of a Kompella L2VPN Instance**

Command	<code>route-target { import export both } rt_value</code>
Parameter Description	<p>import: sets the Import RT value.</p> <p>export: sets the Export RT value.</p> <p>both: sets both the Import and Export RT values.</p>

Command Mode	VFI configuration mode
Usage Guide	<p>This command is valid only for Kompella VPLS and VPWS.</p> <p>For a Kompella L2VPN instance, multiple RT attribute values can be configured and import/export/both can be specified. The multiple RTs can be the symbols of the L2VPN VFI instance.</p> <p>When import and export are specified simultaneously for one L2VPN VFI instance, it equals that RT attribute is specified to both.</p> <p>If two VFI instances on the same PE have the same RT, the two instances cannot be interconnected.</p>

↘ **Configuring Sites of PEs in a Kompella L2VPN VFI Instance**

Command	site-id <i>id</i> [site-range <i>range</i>]
Parameter Description	<p><i>id</i>: indicates the Site ID of the VFI instance. The value range is 1-256.</p> <p><i>range</i>: indicates the number of accessed sites. The value range is 1-256.</p>
Command Mode	VFI configuration mode
Usage Guide	<p>This command is valid only for Kompella VPLS and VPWS.</p> <p>The site-range parameter can be used to adjust the number of sites which can be accessed from the L2VPN VFI instance; that is, the number of connections from the LEVPN VFI instance to remote PEs on the same L2VPN. Users can modify the maximum number of remote PEs which can be accessed from the instance. If the number is changed to a larger one, the L2VPN is not affected. If the number is changed to a smaller one, the L2VPN may be disconnected and the packet can be forwarded until PW is established again.</p> <p>For Kompella L2VPN, you can run this command to enter the vfi-site configuration mode and bind the instance to local interfaces of VPWS or VPLS.</p> <hr/> <ul style="list-style-type: none">  Different VFI instances on one PE can have the same ID.  The local ID value shall be larger than or equal to the remote offset value but smaller than the sum of the remote size and offset value (that is, the site-range of the peer PE).  The maximum number of sites which can be accessed from instances in the same VPLS should be the same; otherwise, the above condition should be met.  Only one site ID can be configured for one L2VPN VPLS instance. To modify the site ID, delete the instance and configure a new site ID for the new instance.  Multiple site IDs can be configured for one L2VPN VPWS instance. Each site ID represents a VPWS site of the instance. The locally bound interface and remote sites to be connected should be specified in vfi-site configuration mode. If the specified remote site has a local ID, PW cannot be established.  For a Kompella VPWS instance, the site-range configured in the label saving mode cannot take effect.

↘ **Enabling Kompella L2VPN.**

Command	xconnect interface <i>interface-type interface-number</i> [remote-ce-id <i>id</i>]
----------------	--

Parameter Description	<i>interface-type</i> : indicates the interface type. <i>interface-number</i> : indicates the interface number. <i>id</i> : indicates the remote CE ID in VFI. It is only valid for Kompella VPWS.
Command Mode	VFI site configuration mode
Usage Guide	<p>When VPWS is accessed through local sub-interfaces, run the encapsulation mpls command to set the VPWS PW type to Ethernet VLAN. When VPWS is accessed through Ethernet interfaces, set the VPWS PW type to Ethernet.</p> <p>For Kompella VPWS, only one interface can be bound in a site configuration mode.</p> <p>If VPLS is accessed all through sub-interfaces, run the encapsulation mpls ethernetvlan command to set the VPLS PW encapsulation type to Tag. If VPLS is accessed all through Ethernet interfaced, set the PW encapsulation type to Raw.</p>

↘ **Displaying BGP L2VPN Information**

Command	show bgp l2vpn { vpls vpws } all [ve-id:offset neighbor ip-address summary
Parameter Description	vpls : displays the VPLS information. vpws : displays the VPWS information. all : displays NLRI of all VPLS or VPWS instances. <i>vpn-rd</i> : displays the VPLS instance of the specified RD. <i>vfi-name</i> : indicates the VFI instance name. neighbor ip-address : indicates the BGP neighbor address. <i>ve_id:offset</i> : displays the VFI instance of the specified ve_id:offset. summary : displays major information of BGP L2VPN, including the site ID, offset, label base, and next hop.
Command Mode	Privileged mode
Usage Guide	Run the show bgp l2vpn vpls command to display local VPLS information, including RD value, site ID, label block offset, and label base. BGP VPLS configurations are displayed only after the VPLS instance is configured.

Configuration Example

↘ **Switch example: CE and PE Work at the Access Mode, and PW Works at the Ethernet Mode.**

<p>Scenario Figure 2-27</p>	<p>● The interface connecting PE to CE works at the access mode; that is, CE is connected to PE through</p>
---	---

	<p>the access link.</p> <ul style="list-style-type: none"> PE creates a PW for the VLAN at the access interface. In the Raw mode, frames transmitted through PW between PE1 and PE2 have no VLAN Tag 10.
Configuration Steps	<p>Before configuring Kompella VPWS, you need to run IGP on the provider network to enable interconnection between PE1 and PE2 and enable CE to access PE through the trunk interface, and get Kompella VPWS configurations, including the VPWS instance description, RT value, CE ID, planned maximum site number, CE ID offset, interface.</p> <ul style="list-style-type: none"> Configure CE1 and CE2 to access PE through the access interface. On PE1 and PE2, configure the Loopback interface, public LSP tunnel, and remote LDP neighbor. Configure PE1 and PE2 to access CE through the access interface. Configure the L2VPN address family and VFI instance. On P, configure the public routing protocol and LSP tunnel.

➤ Switch example: CE and PE Work at the 802.1Q Tunnel Mode, and PW Works at the Ethernet Mode.

<p>Scenario Figure 2-29</p>	 <ul style="list-style-type: none"> To provide PW for a physical interface on a PE, configure CE to access PE through a 802.1Q tunnel and enable PW for the VLAN interface of the tunnel. In such a way, the VLAN Tag in the user frame can be transmitted transparently. In Raw mode, frames transmitted through the PW between PE1 and PE2 carry only one VLAN Tag which is the VLAN Tag of frames received from the CE.
<p>Configuration Steps</p>	<p>Before configuring Kompella VPWS, you need to run IGP on the provider network to enable interconnection between PE1 and PE2 and enable CE to access PE through the 802.1Q interface, and get Kompella VPWS configurations, including the VPWS instance description, RT value, CE ID, planned maximum site number, CE ID offset, interface.</p> <ul style="list-style-type: none"> Configure the access interface on CE1 and CE2, and configure the trunk interface connected to PE. On PE1 and PE2, configure the Loopback interface, public LSP tunnel, and remote LDP neighbor. Configure PE1 and PE2 to access CE through the 802.1Q tunnel. Configure the L2VPN address family and VFI instance. On P, configure the public routing protocol and LSP tunnel.
<p>CE1</p>	<pre> CE1# configure terminal CE1(config)# interface gigabitethernet 3/2 CE1(config-if-Gigabitethernet 3/2)# switchport mode access CE1(config-if-Gigabitethernet 3/2)# switchport access vlan 10 CE1(config-if-Gigabitethernet 3/2)# exit CE1(config)# interface gigabitethernet 3/3 CE1(config-if-Gigabitethernet 3/3)# switchport mode access CE1(config-if-Gigabitethernet 3/3)# switchport access vlan 20 CE1(config-if-Gigabitethernet 3/3)# end CE1# configure terminal CE1(config)# interface gigabitethernet 3/1 CE1(config-if-Gigabitethernet 3/1)# switchport mode trunk CE1(config-if-Gigabitethernet 3/1)# switchport trunk allow vlan add 10, 20 CE1(config-if-Gigabitethernet 3/1)# end </pre>

Common Errors

1. The MPLS IP is not enabled globally.
2. The label forwarding function is not enabled at the public interface.

2.4.2.2 Inter-AS VPWS

Multiple sites of one VPN may be connected to multiple service providers using different ASs or to multiple ASs of one service provider. Such an application that one VPN crosses multiple ASs is called Inter-AS VPN. VPWS provides two Inter-AS solutions:

- Inter-AS Option A: It can be easily realized. This solution is applied when the number of Inter-AS L2VPNs on an ASBR is low.
- Inter-AS Option C: No VC needs to be created and maintained on an ASBR. This solution is applicable when each AS contains a great many Inter-AS L2VPNs, to avoid the ASBR scale expansion bottleneck.

Configuration Effect

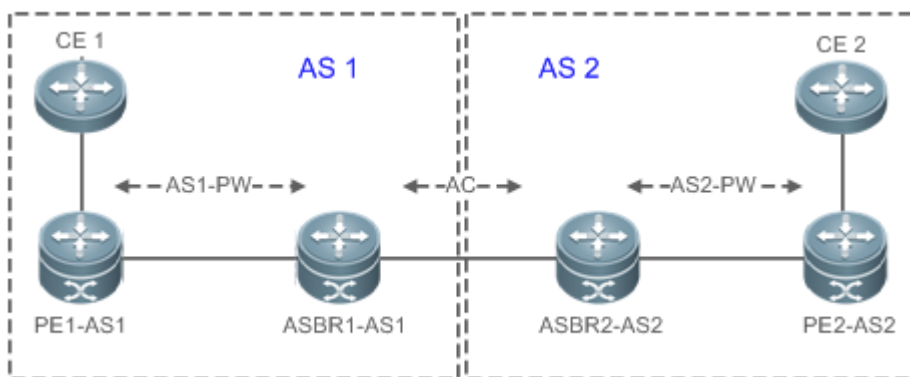

It is used for Layer-2 interconnection between sites in different ASs.

Notes

The MPLS forwarding function must be enabled globally and the label forwarding function must be enabled for public interfaces.

Configuration Method of Inter-AS Option A

Figure 2-31 Option A: Inter-AS VPWS

In such a mode, ASBRs of two ASs are directly connected, and ASBRs serve as PEs of each AS. Two ASBRs take each other as their CEs. As shown in the figure above, ASBR2-AS2 of AS2 is a CE for ASBR1-AS1 of AS1, and vice versa.

Option A has an advantage of easy realization, because no special Inter-AS configurations are required for two PEs serving as ASBRs, and no IP addresses are needed for interfaces between ASBRs. The disadvantage is that, a link should be allocated for ASBRs between two ASs when each Inter-AS L2VPN or PW is established. The link is either a logical or physical link. Pressure on ASBRs increases when there are a great many Inter-AS PWs, which limits the scale expansion.

Configuring a PE

1. Configuring a Public Tunnel

- It is mandatory.
- Run the **mpls ip** command to enable MPLS globally;
- Run the **mpls router ldp** command to enable LDP and enter the LDP configuration mode.
- Run the **ldp router-id interface** loopback *id* [**force**] command to configure LDP Router ID. The IP address of the Loopback interface is usually used as the Router ID.
- Exit the MPLS route configuration mode, and run the **interface type ID** command to configure a public interface.
- Run the **label-switching** command to enable the MPLS forwarding function for the interface.
- Run the **mpls ip** command to enable LDP and the MPLS forwarding function for the interface.

- Exit the privileged mode, and run the **copy running-config startup-config** command to save configurations.

2. Configuring a VPWS Address Family

- It is mandatory.
- In the global configuration mode, run the **router bgp *asn-num*** command to create a BGP and enter the BGP configuration mode.
- Run the **mpls router ldp** command to enable LDP and enter the LDP configuration mode.
- Run the **neighbor *peer-address* remote-as *asn-number*** command to create an IBGP session.
- Run the **neighbor *peer-address* update-source *interface-name*** command to specify the Loopback interface address as the source address of the IBGP session.
- Run the **address-family l2vpn vpws** command to enter the address family.
- Run the **neighbor *ip-address* activate** command to activate L2VPN interaction on the BGP session.
- Run the **neighbor {*ip-address* | *peer-group-name*} send-community [both | standard | extended]** command to specify the extended community attribute sent to the BGP neighbor.
- Exit the privileged mode, and run the **copy running-config startup-config** command to save configurations.

3. Configuring a Kompella VPWS Instance

- It is mandatory.
- In the global configuration mode, run the **l2 vfi *vpls-name* vpnid *vpn-id* point-to-point** command to create a Kompella VPWS instance and enter the VPWS configuration mode.
- Run the **rd *rd_value*** command to configure the RD value.
- Run the **encapsulation mpls [ethernet | ethernetvlan]** command to specify the PW encapsulation type of the Kompella L2VPN. The default encapsulation type is Ethernet.
- Run the **route-target { import | export | both } *rt_value*** command to configure RT. Multiple RTs can be configured.
- Run the **site-id *id* [site-range *size*]** command to configure the CE ID and site-range of the site. If not configured, the site-range is 16 by default. Multiple Site IDs can be configured for a Kompella VPWS.
- Run the **xconnect interface *interface-type* *interface-number* remote-ce-id *id*** command to bind a local interface and specify the remote CE ID.
- Exit the privileged mode, and run the **copy running-config startup-config** command to save configurations.

4. VPWS Accesses

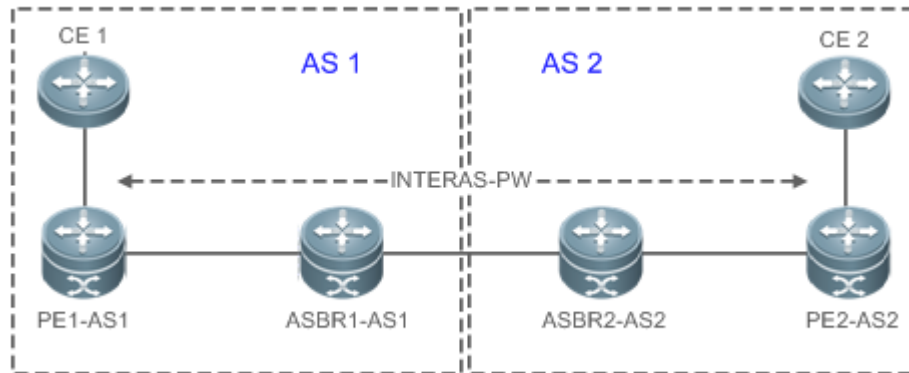

For details about VPWS accesses, see VPWS Accesses in 1.4.2.1 Basic Kompella VPWS.

↘ Configuring an ASBR

The ASBR configuration method is similar to the PE configuration method. The only difference is that the peer ASBR is served as a CE.

Configuration Method of Inter-AS Option C

Figure 2-32 Option C: Inter-AS VPWS

In Option C in the figure above, an Inter-AS PW is established between PEs on two ASs to exchange PW labels, so as to realize an Inter-AS L2VPN. The working principle is as follows:

An ASBR releases the label IPv4 routes to PEs inside its own AS through MP-IBGP and notifies the label IPv4 routes reaching PEs inside its own AS to the ASBR peer of the peer AS, so as to connect the two AS tunnels and establish an LSP tunnel between the ingress PE and egress PE. Next, it establishes Inter-AS LDP remote session connection between PEs of different ASs and switches PW information.

In this solution, ASBR either needs to maintain Inter-AS L2VPN information nor needs to allocate a physical or logical interface for the Inter-AS L2VPNs. L2VPN information is exchanged directly between PEs, reducing pressure on ASBR and facilitating scale expansion.

The configuration procedure is as follows:

▾ Configuring MPLS Signaling

- It is mandatory.
- Enable MPLS and LDP for PEs and P devices in each AS as well as for ASBR interfaces connecting to P devices or PEs inside the AS.

▾ Configuring a PE

Configure PEs inside an AS to establish an IBGP session between PEs and the ASBR inside the AS and exchange the IPv4 routes carrying the labels.

- It is mandatory.
- In the global configuration mode, run the **router bgp *asn-number*** command to configure BGP and enter the BGP configuration mode.

- Run the **neighbor** *asbr-address* **remote-as** *asbr-asn-number* command to create an IBGP session between a PE and an ASBR.
- Run the **neighbor** *asbr-address* **update-source** *interface-name* command to use a Loopback address as the source address of the BGP session created between peers.
- Run the **address-family ipv4** command to enter the IPv4 address family.
- Run the **neighbor** *asbr-address* **send-label** command to enable the label exchange function for IPv4 routes.

📌 Configuring an ASBR

Configure ASBR to establish an IBGP session between ASBR and PEs inside the same AS and establish an EBGP session with ASBR inside another AS. Enable IPv4 routes carrying the labels for the two sessions. Configure a PE address on the ASBR which must be transmitted to another ASBR.

- It is mandatory.
- In the global configuration mode, run the **mpls ip** command to enable the MPLS forwarding function for the local device.
- Run the **mpls router ldp** command to enable the LDP globally.
- Run the **ldp router-id interface Loopback id force** command to set the IP address of the Loopback interface as the Router ID.
- Run the **advertise-labels for bgp-routes** command to allocate labels for BGP routes.
- Exit the global configuration mode, and run the **router bgp** *asn-number* command to configure BGP and enter the BGP configuration mode.
- Run the **neighbor** *asbr-address* **remote-as** *asbr-asn-number* command to create an IBGP session between a PE and an ASBR.
- Run the **neighbor** *asbr-address* **update-source** *interface-name* command to use a Loopback address as the source address of the BGP session created between peers.
- Run the **address-family ipv4** command to enter the IPv4 address family.
- Run the **network** *pe-address* **mask** *mask-value* command to introduce the reached PE route into BGP through the network command. The route can also be introduced through redistributed IGP.

 This step is optional. No **network** command is executed when the route is introduced through redistributed IGP.

- Run the **neighbor** *asbr-address* **send-label** command to enable the IPv4 route label exchange function for a BGP session with the ASBR in another AS.
- Run the **neighbor** *pe-address* **send-label** command to enable the IPv4 route label exchange function for a BGP session with the ASBR in the current AS.
- Run the **neighbor** *asbr-ip-address* **route-map** *name* **out** command to configure the route distribution policy. The command needs to be executed if you want to control which routes are distributed to the neighbor and control whether the routes carry tags during distribution.
- Run the **neighbor** *asbr-ip-address* **route-map** *name* **in** command to configure the route distribution policy. The command needs to be executed if you want to receive only routes with tags.

-  To create an IBGP session between ASBR and PE in the same AS, run the **neighbor peer-address update-source loopback id** command to specify to use the Loopback interface address of the local device as the source address of the session; otherwise, it is unable to create an Inter-AS LSP tunnel.
-  For direct connected EBGP session between ASBRs, addresses of the interfaces directed connected as the source address of the BGP session to ensure routes of ASBRs can reach each other. Do not run the **neighbor peer-address update-source loopback id** command to specify to use the Loopback interface address of the local device as the source address of the directly connected EBGP sessions. Instead, run the **neighbor ebgp-multihop** command to enable the multi-hop EBGP and configure a static route on ASBR, so that the route can reach the peer route. Configure a static FTN to ensure connectivity of the Inter-AS LSP tunnel.
-  Note that the **label-switching** command must be executed to enable the MPLS packet forwarding function for the interface connecting the two ASBRs.

↘ **Configuring an L2VPN Address Family**

- It is mandatory.
- Configure the L2VPN address families for PEs in each AS. For details, see Configuring L2VPN Address Family in [Basic Configurations](#) in [Kompella VPWS](#)

↘ **Configuring a Kompella VPWS Instance**

- It is mandatory.
- Configure the L2VPN address families for PEs in each AS. For details, see Configuring a Kompella VPWS Instance in [Basic Configurations](#) in [Kompella VPWS](#).

↘ **Configuring VPWS Access**

- It is mandatory.
- For configuration details, see VPWS Accesses in Kompella VPWS.

Verification

- Run the **show bgp ipv4 unicast labels** command to display the label allocated by BGP for IPv4 route.
- Run the **show bgp l2vpn vpws all connections** command to display the Kompella VPWS connections.
- Run the **show mpls l2transport vc [detail]** command to display the VC status.

Related Commands

↘ **Displaying BGP L2VPN**

Command	show bgp l2vpn { vpls vpws } all [ve-id:offset neighbor ip-address summary]
Parameter Description	<p>vpls: displays the VPLS information.</p> <p>vpws: displays the VPWS information.</p> <p>all: displays NLRI of all VPLS or VPWS instances.</p> <p><i>vpn-rd:</i> displays the VPLS instance of the specified RD.</p>

	<p><i>vfi-name</i>: indicates the VFI instance name.</p> <p>neighbor ip-address: indicates the BGP neighbor address.</p> <p><i>ve_id:offset</i>: displays the VFI instance of the specified <i>ve_id:offset</i>.</p> <p>summary: displays major information of BGP L2VPN, including the site ID, offset, label base, and next hop.</p>
Command Mode	Privileged mode
Usage Guide	Run the show bgp l2vpn vpls command to display the local VPLS information, including RD value, site ID, label block offset, and label base. BGP VPLS configurations are displayed only after the VPLS instance is configured.

➤ **Displaying Information of VPWS PW and VPLS PW**

Command	show mpls l2transport vc [<i>vc_id</i> [<i>ip-address</i>] [detail] count interface <i>interface_name</i> [detail] [detail]]
Parameter Description	<p><i>vc_id</i>: displays only PWs having the specified ID.</p> <p><i>ip-address</i>: displays only PWs of which the peer LSR ID is the specified IP address.</p> <p>interface interface_name: displays only the VPWS PW bound to the interface. It is invalid for VPLS PW.</p> <p>count: displays the PW statistics.</p> <p>detail: displays the PW details.</p>
Command Mode	Privileged mode
Usage Guide	For a Martini VC, multiple PWs can share the same PW ID. Run the show mpls l2transport vc vc-id command to display information of multiple PWs, and run peer to filter these PWs.

Configuration Example

➤ **Switch example: Inter-AS VPWS in Option A**

<p>Scenario Figure 2-33</p>	<ul style="list-style-type: none"> ● Kompella VPWS adopts the Inter-AS networking topology in Option A, and the middle-layer interfaces are used by ASBR as AC access interfaces.
---	--

	<ul style="list-style-type: none"> ● CEs on Site A and Site B of Customer S are connected to each other through PE1 at AS 100 and PE2 at AS 200 of the provider, realizing the Layer-2 point-to-point interconnection. ● PE1 and PE2 are in different ASs, and ASBR1 and ASBR2 regard each other as a CE. That is, interfaces between ASBRs are regarded as an AC to access the VFI instance.
Configuration Steps	<p>Before configuring Kompella VPWS, you need to run IGP on the provider network to enable interconnection between PE and ASBR; establish an MP-IBGP peer between PE and ASBR in the AS; and get Kompella VPWS configurations, including the VPWS instance description, RT value, CE ID, planned maximum site number, CE ID offset, interface.</p> <ul style="list-style-type: none"> ● Configure CE1 and CE2 to access VLAN 2. ● On PE1, configure the Loopback interface address and OSPF protocol, create a public route so that PE and ASBR in the same AS can be mutually pinged. Configure LDP and enable MPLS globally. Configure the public tunnels between PEs and configure VPWS access modes. Configure the L2VPN address family and VFI instance. ● On ASBR 1, configure the Loopback interface address and OSPF protocol, create a public route so that PE and ASBR in the same AS can be mutually pinged. Configure LDP and enable MPLS globally. Configure the public tunnels between PEs and the family address. Configure the interface connecting ASBR 1 to ASBR 2, and configure the VPWS instance. ● On ASBR 2, configure the Loopback interface address and OSPF protocol, create a public route so that PE and ASBR in the same AS can be mutually pinged. Configure LDP and enable MPLS globally. Configure the public tunnels between PEs. Configure the L2VPN address family. Configure the interface connecting ASBR 1 to ASBR 2, and configure the VPWS instance. ● On PE 2, configure the Loopback interface address and OSPF protocol, create a public route so that PE and ASBR in the same AS can be mutually pinged. Configure LDP and enable MPLS globally. Configure the public tunnels between PEs and the L2VPN address family. Configure the interface connecting PE2 to CE, and configure the VPWS instance.

Switch Example: Inter-AS VPWS in Option C

Scenario
Figure 2-34

The diagram illustrates an Inter-AS VPWS in Option C topology. It shows two sites, Site A and Site B, connected via two Autonomous Systems (AS 100 and AS 200). Site A contains CE 1 and PE1. Site B contains CE 2 and PE2. AS 100 contains ASBR1. AS 200 contains ASBR2. Connections are shown between CE and PE, and between PE and ASBR in each AS. A dashed vertical line separates AS 100 and AS 200.

- When VPWS adopts the Inter-AS networking topology in Option C, the middle-layer interfaces are used by ASBR as AC access interfaces.
- PWs are created between PEs in different ASs. ASBR does not maintain PW information. Each AS uses OSPF as IGP for interconnection inside the AS.
- Assuming that CE1 accesses a PE through the access interface, it is required that CE1 can be interconnected with CE2 through an L2VPN.

Configuration Steps	<p>Before configuring Kompella VPWS, you need to run IGP on the provider network to enable interconnection between PE and ASBR; establish an MP-IBGP peer between PE and ASBR in the AS; and get Kompella VPWS configurations, including the VPWS instance description, RT value, CE ID, planned maximum site number, CE ID offset, interface.</p> <ul style="list-style-type: none"> ● Configure CE1 and CE2 to access VLAN 2. ● On PE1-AS1 and PE2-AS2, configure the public routing protocol and MPLS signaling. Configure the remote neighbor. Configure the BGP and VPWS access mode. Configure the L2VPN address family, and VFI instance. ● On ASBR1-AS1 and ASBR2-AS2, configure the Loopback interface address, public routing protocol, and MPLS signaling. Configure an IP address for the interface connected to ASBR2. Enable the label forwarding function for the interface and configure BGP. <p> If CE1 and CE2 access PE in Trunk or other modes, adjust configuration of L2VPN in the VLAN interface mode. Configurations of Inter-AS BGP, public IGP and MPLS need not be modified.</p>
CE1	<pre>CE1(config)# interface gigabitethernet 0/1 CE1(config-if-Gigabitethernet 0/1)# switchport access vlan 2 CE1(config-if-Gigabitethernet 0/1)# end</pre>

Common Errors

- MPLS IP is not enabled globally.
- The label forwarding function on the public network site is not enabled.
- After BGP synchronization is enabled, the BGP route is not redistributed to OSPF.
- The EBGp neighbor is not configured with multiple EBGp routes.
- The label forwarding function is not enabled for the interface between ASBRs.

2.4.2.3 Other Kompella VPWS Parameters

Configuration Effect

1. Configures the description of each VPWS instance.
2. When these devices are interconnected to devices of other manufacturers, to ensure that the VC is UP, you can run the **ignore match l2-extcommunity** command to disable the match inspection for MTU, EncapsType, and Control Flag received.
3. Configures an MTU value for the VPWS instance.

Configuration Steps

▾ Configuring a Descriptor for a VPWS Instance

- (Optional) It is used to add description to a VPWS instance.
- In the global configuration mode, run the **l2 vfi vfi-name** command to enter the VFI configuration mode.
- Run the **description vfi-description** command to configure the VFI description.

▾ Configuring VPWS Compatibility

L2VPN provides PW MTU of 1,500 bytes by default. If the same PW between two PEs have different MTU values, PW connection cannot be created for the two PEs. Devices of some manufacturers do not support MTU configuration in an L2VPN instance. When these devices are interconnected to devices of other manufacturers, to ensure that the VC is UP, you can run the **ignore match l2-extcommunity** command to disable the match inspection for MTU, EncapsType, and Control Flag received.

- (Optional) It is used to connect to a vendor and when the MTU, encapsulation type and control word match are ignored.
- In the global configuration mode, run the **l2 vfi vpls-name vpnid vpn-id autodiscovery** command to create a Kompella VPLS instance and enter the VPLS configuration mode.
- Run the **ignore match l2-extcommunity** command to ignore L2VPN extended community attribute match.

 It is valid only for Kompella L2VPN.

▾ Configuring an MTU Value for a VPWS Instance

(Optional) It is used to configure a MTU value for each VFI instance. The default value is 1,500. The MTU value in the command specifies the size of packets which can be transmitted by the PW; that is, the length of users' Layer-2 packet and the PW encapsulated packet. By default, if no control word is enabled for the PW and two labels are encapsulated, the length of the Ethernet packets that can be transmitted is 1,492 bytes, including 8-byte PW encapsulated packet (the two labels).

- (Optional) It is used to modify the VPWS MTU.
- In the global configuration mode, run the **l2 vfi name** command to enter the VFI configuration mode.
- Run the **mtu mtu** command to configure a MTU value for the VFI instance.

 The MTU value of the same VFI instance on different PEs must be the same; otherwise, no PW can be established through the signaling protocol.

 When the MTU value of PW signaling protocol negotiation is modified, the MTU value of the access interface must be adjusted (the length of PW MTU minus the length of PW encapsulation). Besides, the MTU of egress interface on the public network must be consistent with the PW MTU; otherwise, the packet cannot be forwarded. You can run the **mtu** command to modify the MTU value of the interface, and run the **mpls mtu** command to modify the MPLS MTU value of the interface.

↘ **Specifying not to Modify the Next Hop When Sending Routes to the Peer (Group)**

When Kompella L2VPN adopts the Inter-AS structure in Option C (Multihop MP-EBGP), if MP-EBGP connections are established between ASs through a route reflector, the next hop is modified to the local EBGP when a packet is sent to the EBGP peer by default. You need to run this command on the route reflector; otherwise, the packet cannot be forwarded in an Inter-AS mode.

- (Optional) It used to specify not to change the next hop.
- By default, the next hop is changed.
- Run the **neighbor { peer-address | peer-group-name } next-hop-unchanged** command to configure to not change the next hop in the BGP L2VPN address family mode.

Verification

- Run the **show mpls vfi** command to display VFI configurations.

Related Commands

↘ **Creating an L2VPN VFI Instance**

Command	I2 vfi name [vpnid <1- 2147483647> [manual autodiscovery point-to-point]]
Parameter Description	<p><i>name</i>: indicates the name of L2VPN VFI instance, which is a string of up to 31 characters.</p> <p><1- 2147483647>: specifies an ID for the created VPLS instance.</p> <p>manual: manually configures an VPLS neighbor for Martini VPLS to create a PW.</p> <p>autodiscovery: creates a PW for Kompella VPLS through automatic discovery.</p> <p>point-to-point: automatically discovers PEs specified for Kompella VPWS VFI.</p>
Command Mode	Global configuration mode
Usage Guide	<p>L2VPN VFI name maps with its VPN ID. When this command contains no VPN ID, the VFI configuration mode is entered. The name parameter can only specify existing L2VPN VFI instance. An error message is displayed when there is any conflict.</p> <p>If the name, ID and configuration mode are the same to the original configurations, VFI configuration mode is entered.</p> <p>Automatic discovery takes effect only when the L2VPN VPLS or L2VPN VPWS address family in the BGP configuration mode is activated.</p> <p>Kompella VPLS is realized only when the keyword autodiscovery is specified. Kompella VPWS is realized only when the point-to-point mode is specified. When no keyword is specified or the keyword is manual, Martini VPLS is realized.</p>

	<p>The L2VPN VFI realization method cannot be modified after being selected. To modify the realization method, you need to delete the instance and configure it again. For example, to change a Kompella VPLS to a Martini VPLS, delete the Kompella VPLS instance, create a new VPLS instance and set its realization method to Martini.</p> <p>For Kompella VPLS or VPWS, a PW can be established only when the instance RD, Site ID, and Route Target are configured and the instance is bound to an interface.</p> <p>For Martini VPLS, a PW can be created only when the instance is bound to an interface or a Spoke VC neighbor is created.</p>
--	--

↘ Configuring a Description for a L2VPN VFI Instance

Command	description desc
Parameter Description	desc: indicates the description of the L2VPN VFI instance. The description consists of up to 63 strings.
Command Mode	VFI configuration mode
Usage Guide	It is used to describe the L2VPN instance.

↘ Configuring Whether or not to Match Layer-2 Extended Community Attribute for Kompella PWs.

Command	ignore match l2-extcommunity
Parameter Description	-
Command Mode	VFI configuration mode
Usage Guide	<p>This command is valid only for Kompella VPLS and VPWS.</p> <p>When a PW is established through negotiation on Kompella L2VPN, the negotiation packet contains the encapsulation type and MTU information of the L2VPN carried by the BGP extended community attribute. By default, when the encapsulation type and MTU of two VFI instances are matched, a PW is established between the two VFI instances; otherwise, no PW is established. To establish a PW when the PW encapsulation type and MTU of the two VFI instances are not matched, run the ignore match l2-extcommunity command.</p>

↘ Configuring an MTU value for an L2VPN VFI Instance

Command	mtu mtu
Parameter Description	mtu: indicates the configured MTU value. The value range is [46-1530].
Command Mode	VFI configuration mode
Usage Guide	<p>The MTU value in the command specifies the size of packets (the length of the packet encapsulated with the MPLS label) which can be transmitted by the PW; that is, the length of users' Layer-2 packet and the PW encapsulated packet. By default, if no control word is enabled for the PW and two labels are encapsulated, the length of the Ethernet packets that can be transmitted is 1,492 bytes, including 8-byte</p>

	<p>PW encapsulated packet (the two labels).</p> <p>The VFI MTU is valid for all PWs of the VFI instance; that is, PWs uses the VFI instance's MTU for negotiation. By default, if MTUs negotiated at two ends of the PW are not matched, the PW cannot be established.</p>
--	--

➤ **Specifying not to Modify the Next Hop When Sending Routes to the Peer (Group)**

Command	neighbor { peer-address peer-group-name } next-hop-unchanged
Parameter Description	<p>peer-address: specifies the peer's address.</p> <p>peer-group-name: specifies a peer group name of no more than 32 characters.</p> <p>next-hop-unchanged: specifies not to modify the next hop when sending routes to the peer (group).</p>
Command Mode	BGP L2VPN address family mode
Usage Guide	<p>When Kompella L2VPN adopts the Inter-AS structure in Option C (Multihop MP-EBGP), if MP-EBGP connections are established between ASs through a route reflector, the next hop is modified to the local EBGP when a packet is sent to the EBGP peer by default. You need to run this command on the route reflector; otherwise, the packet cannot be forwarded in an Inter-AS mode.</p>

Configuration Example

➤ **Configuring a Descriptor for a VPWS Instance**

Configuration Steps	<ul style="list-style-type: none"> Configure a descriptor for a VPWS instance.

2.4.3 Static VC FTN and ILM

Configuration Effect

You can either use the PW signaling protocol to exchange VC labels to establish an FTN entry and ILM entry for the VC, or statically configure a FTN entry and ILM entry for the VC. The two methods cannot be used for the same VC instance simultaneously.

Notes

- Methods introduced in this section and in [Static PW \(Optional\)](#) are all used to realize the same function. Because it is relatively easier to configure a static PW, the method introduced in [Static PW \(Optional\)](#) is recommended.

Configuration Steps

Configuring a VC FTN

- (Optional) It is used to configure a static PW.
- In the global configuration mode, run the **mpls static l2vc-ftn** *vc-id vc-peer-ip out-label out-label* command to configure an FTN entry for a static VC instance.

Configuring a VC ILM

- (Optional) It is used to configure a static PW.
- In the global configuration mode, run the **mpls static ilm in-label** *in_label forward-action pop-l2vc-destport vc-id vc_peer_addr* command to configure an ILM entry for a static VC instance.

 When the PW is established through the VPWS dynamic signaling protocol, it is not suggested to configuring a static FTN and ILM for the VC. When a static VC forwarding entry is configured, a static public LSP must be configured at the same time. The VC takes effect only when there is a corresponding public LSP tunnel.

 Static FTN and ILM are invalid for Kompella VPWS VC instances, and only valid for Martini VPWS VC instances. That is, the static forwarding entry, instead of the forwarding entry generated through LDP signaling, is used.

 The functions of commands in this section are overwritten by commands used to configure the static PW. These commands are kept for previous versions. The commands used to configure the static PW are recommended for new version.

Verification

-

Related Commands

Configuring a Static VC FTN Entry

Command	mpls static l2vc-ftn <i>vc_id vc_peer_ip out_label label</i>
Parameter Description	<i>vc_id</i> : indicates the ID of the VC instance. <i>vc_peer_ip</i> : indicates the IP address of the peer PE of the VC instance. <i>label</i> : specifies the private network egress forwarding label for VC FTN.
Command Mode	Global configuration mode
Usage Guide	It is used to create an FTN entry for a VC instance. When the AC bound to the VC receives a data frame, it compresses a private network label to the frame based on the FTN entry, finds the LSP of the peer PE based on VC peer's IP address, and forwards the frame to the peer PE.

Adding an ILM Entry to the ILM Table

Command	mpls static ilm in-label <i>in_label forward-action pop-l2vc-destport vc_id vc-peer-addr</i>
Parameter	<i>vc_id</i> : indicates the ID of the VC instance.

Description	<i>vc_peer_ip</i> : indicates the IP address of the peer PE of the VC instance. <i>in_label</i> : indicates the ingress label value of the ILM entry.
Command Mode	Global configuration mode
Usage Guide	It is used to add an ILM entry to an ILM table. When a device for which MPLS is enabled receives an IP packet with a label, it finds the next hop based on the longest label value of the IP packet in the ILM table. If it finds a next hop, it exchanges and pops up the label of the IP packet.

2.4.4 Static PW

Configuration Effect

When you can access Martini VPWS by configuring CLI, you can specify a static VC, and configure the egress and ingress labels of VC, instead of adding the FTN entry and ILM entry to the VC using the LDP signaling.

Notes

- The key word manual is used.

Configuration Steps

- (Optional) It is used to configure a static PW.
- In the global configuration mode, run the **interface vlan *vlan-id*** command to enter the VLAN interface configuration mode.
- Run the **xconnect *vc_id* *vc_peer* encapsulation mpls ethernet raw** command to create a VC and set the encapsulation mode to RAW.
- Exit the interface configuration mode, and run the **mpls static-l2vc *ipv4-address* *vc-id* out-label *out-label-value* in-label *in-label-value*** command to configure egress and ingress labels for the static PW.

i Egress and ingress labels of the static PW are invalid for Kompella VPWS VC instances, and only valid for Martini VPWS VC instances. That is, the static forwarding entry, instead of the forwarding entry generated through LDP signaling, is used.

Verification

- Run the **show mpls l2transport vc** command for verification.
- Run the **show mpls ref vc** command for verification.

Related Commands

Configuring a Static PW

Command	xconnect <i>vc_peer</i> <i>vc_id</i> encapsulation mpls [[ethernet ethernetvlan] [raw tagged] [send-vlanrewrite-req not-send-vlanrewrite-req]] [<i>group-id</i>] [<i>mtu</i>] manual
Parameter	<i>vc_id</i> : specifies the identifier of the PW instance. The value range is [1..2147483647].

<p>Description</p>	<p><i>vc_peer</i>: specifies A.B.C.D, and the peer LSR ID.</p> <p>ethernet: specifies the PW type to Ethernet.</p> <p>ethernetvlan: specifies the PW type to VLAN.</p> <p>raw: specifies the encapsulation mode to Raw (which is valid only when the PW type is Ethernet or Ethernet VLAN).</p> <p>tagged: specifies the encapsulation mode to Tag (which is valid only when the PW type is Ethernet or Ethernet VLAN).</p> <p>send-vlanrewrite-req: sends a VLAN rewrite request to the peer (which is valid only when the PW type is Ethernet VLAN).</p> <p>not-send-vlanrewrite-req: specifies not to send a rewrite request to the peer (which is valid only when the PW type is Ethernet VLAN).</p> <p><i>group-id</i>: specifies the PW group number. The default value is 0 and the value range is [0-4294967295].</p> <p><i>mtu</i>: specifies the PW MTU value. The value range is [46-9216].</p>
<p>Command Mode</p>	<p>Interface configuration mode</p>
<p>Usage Guide</p>	<p>MTU in the command specifies the size of packets which can be transmitted by the PW; that is, the length of users' Layer-2 packet and the PW encapsulated packet. By default, if no control word is enabled for the PW and two labels are encapsulated, the length of the Ethernet packets that can be transmitted is 1,492 bytes, including 8-byte PW encapsulated packet (the two labels). When the length of MTU of PW signaling protocol negotiation is modified, the length of MTU of the access interface must be adjusted (the length of PW MTU minus the length of PW encapsulation). Besides, the MTU of the egress interface on the public network must be consistent with the PW MTU; otherwise, the packet cannot be forwarded. You can run the mtu command to modify the interface MTU.</p> <p>When a static PW is created, no signal is required, but the egress and ingress labels of the PW must be manually specified.</p> <hr/> <p> For a Martini PW, the MTU values at two ends of the PW and the PW type must be consistent; otherwise, the PW cannot be enabled.</p> <p> After the interface is bound to VPWS, the PW type, encapsulation mode, and MTU cannot be modified. To modify them, the VPWS bound to the interface must be deleted first.</p>

Configuration Example

Configuring a Static PW

<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● It is used to configure a static PW. ● It is used to configure a static <i>vc_ftn</i>. ● It is used to configure a static ILM.

<p>Verification</p>	<ul style="list-style-type: none"> ● Run the show mpls l2transport vc command to display the VC configurations.
	<pre>PE2#show mpls l2transport vc Local intf Dest address VC ID Status ----- Gi0/0 3.3.3.3 3 up show mpls ref vc Flags: * - enable fwd VC ID VC Type In Label Out Label Owner Type VPLS ID Intf Port Peer</pre>

2.4.5 Martini VPLS

Configuration Effect

- Martini VPLS is used to realize Layer-2 interconnection between sites.

Notes

- MPLS IP must be enabled globally.
- The label forwarding function must be enabled on the public network side.

Configuration Steps

📌 Configuring a Public Tunnel

LSP tunnels must be established on a public network to carry VPLSs. To run MPLS on a backbone network, the LDP must be run simultaneously on P and PE to establish a public tunnel. Distribution protocol should be configured for corresponding MPLS devices, and the MPLS-based forwarding function must be enabled for each interface.

- It is mandatory.
- Run the **mpls ip** command to enable MPLS globally;
- Run the **mpls router ldp** command to configure the LDP signaling and enter the MPLS route configuration mode;
- Run the **ldp router-id interface** loopback *id* [**force**] command to configure LDP Router ID. The IP address of the Loopback interface is usually used as the Router ID.

- Exit the LDP configuration mode, and run the **interface** *type ID* command to enter the public interface configuration mode.
 - Run the **label-switching** command to enable the MPLS packet forwarding function for public interfaces;
 - Run the **mpls ip** command to enable LDP and the MPLS forwarding function for the interface.
-
- i** LDP is a topology-driven protocol. The IPv4 routing protocol should be enabled and run normally so that LDP can run normally.
-

▾ Configuring a Remote LDP Session

- It is mandatory.

The remote LDP session is used to establish and maintain PWs. If there are other LSRs between PEs, the extended LDP discovery mechanism is used to establish remote LDP sessions between PEs and distribute PW labels on the session.

- In the global configuration mode, run the **mpls router ldp** command to enable LDP and enter the LDP configuration mode.
- Run the **neighbor ip_address** command to configure the remote LDP session.

i The PW label message of LDP is forced to work in the DU and free label retention mode.

▾ Specifying Whether or not to Wait for Response from the Peer after LDP Sends a PW Label Withdraw Message

When the command is run, after sending a PW label withdraw message, LDP releases the label only after receiving a PW label release message from the peer. For example, when the command is run, LDP sends a PW label withdraw message because AC is disabled; if LDP does not receive a PW label release message from the peer, when PW is enabled again because AC is enabled, LDP will not send the PW label mapping message again until receiving a PW label release message from the peer, or the no **vc-withdraw-expect-release** command is run to stop waiting.

- (Optional) It is used to specify not to wait for the PW label release message from the peer.
- LDP waits for the PW label release message from the peer by default.
- Run the **mpls router ldp** command to enable and configure LDP globally;
- Run the **vc-withdraw-expect-release** command for configuration.

▾ Configuring a Martini VPLS Instance

- It is mandatory.

Run the **I2 vfi** command to create a VPLS instance, or enter the VPLS configuration mode. The command **No** is used to delete a VPLS instance. Specify a locally unique name and VPN ID for the VPLS instance you create. The VPLS name must map to the VPN ID.

- In the global configuration mode, run the **I2 vfi vpls-name vpnid vpn-id** command to create a VPLS instance and enter the VPLS configuration mode.
- Run the **neighbor ip-address encapsulation mpls [vc-id vc-id] [hub-vc | spoke-vc] [ethernet | ethernetvlan]** command to configure a VPLS peer. The default PW type is Ethernet.

-  The VPLS peer must be unique in the VPLS instance. For convenient management, configure the same ID for instances in the same VPN.
-  PW ID and the VPLS peer's LSR ID are used as the PW key, which should be globally unique and contain the VPWS PW.
-  Run the **neighbor** command which overwrite the previous configuration of the peer each time.
-  The MTU and PW type of interfaces at two ends of the PW must be matched. The default PW Type of VPLS is Ethernet. The PW ID (VC ID) at two ends of the PW must be matched.
-  When the **neighbor** command is used, only Router ID can be specified as the neighbor address of the VC peer, which is a 32-bit address of the Loopback interface.

VPLS Accesses

Configuring VPLS Access Mode for a Switch

The created VPLS instance takes effect only when the user for which the VPLS instance is configured accesses the link. Currently, users can access VPLS services in the following three methods:

- VLAN access interface
- VLAN trunk interface
- VLAN tunnel access
- PW

 Super VLAN interface cannot provide VPLS. When an ordinary VLAN is configured to be a Super VLAN, the VPWS configurations on the ordinary VLAN are deleted.

VLAN Access Interface

Access through VLAN access interface is applicable for user packets that are not encapsulated by 802.1Q; that is, the packets contain no VLAN Tag.

- It is mandatory.
- In the global configuration mode, run the **interface type ID** command to enter the interface configuration mode.
- Run the **switchport mode access** command to set the interface to the access mode.
- Run the **switchport access vlan vlan-id** command to set the interface to be a member port of a VLAN.
- Exit the interface configuration mode, run the **interface vlan vlan-id** command to enter the VLAN interface configuration mode.
- Run the **xconnect vfi vpls-name** command to bind VLAN to the VPLS instance.

 In the access interface mode, it is suggested to configure the PW type at two ends of the PW to Ethernet.

VLAN Trunk Interface

Access through a VLAN trunk interface is applicable when multiple VPLSs are transmitted on the same physical access link and each VLAN corresponds to one VPLS instance. PE distinguishes to which VPLS instance a packet belongs based on the packet's VLAN Tag, and then provides a combo access interface.

- It is mandatory.
- In the global configuration mode, run the **interface type ID** command to enter the interface configuration mode.
- Run the **switchport mode trunk** command to configure the interface to the Trunk mode.
- Run the **switchport trunk allow vlan add vlan-list** command to allow VLAN traffic to be transmitted on a trunk link.
- Exit the interface configuration mode, run the **interface vlan vlan-id** command to enter the VLAN interface configuration mode.
- Run the **xconnect vfi vpls-name** command to bind VLAN to the VPLS instance.

i In the Trunk interface mode, it is suggested to configure the PW type at two ends of the PW to Ethernet VLAN.

i It is not allowed to bind the Native VLAN of the trunk interface to L2 VPN.

VLAN Tunnel Interface

Access through a VLAN tunnel interface is applicable when the user service packet transmitted on the access link already contains a private VLAN Tag when the user accesses VPLS. In such a mode, the PE forwards intact all packets received from the interface, and VLAN member ports connecting the PE to the CE need to work in tunnel mode.

- It is mandatory.
- In the global configuration mode, run the **interface type ID** command to enter the interface configuration mode.
- Run the **switchport access vlan-id** command to set VLAN member ports for the interface.
- Run the **switchport mode dot1q-tunnel** command to set the interface to work in the tunnel mode.
- Exit the interface configuration mode, run the **interface vlan vlan-id** command to enter the VLAN interface configuration mode.
- Run the **xconnect vfi vpls-name** command to bind VLAN to the VPLS instance.

i In the VLAN tunnel interface mode, it is suggested to configure the PW type at two ends of the PW to Ethernet.

i Only basic QinQ, not flexible QinQ, is supported in this mode.

PW

Access through a PW is applicable when the access network is an MPLS network and the user has no direct link to VPLS PE. In the H-VPLS model, U-PE having no bridge can use PW to access N-PE, and provide VPLS access service for the user.

- It is mandatory.
- In the global configuration mode, run the **I2 vfi name** command to enter the VPLS configuration mode.
- Run the **neighbor ip-address encapsulation mpls [vc-id vc-id] spoke-vc [ethernet | ethernetvlan]** command to configure a PW accessed by the user.

One VPLS instance can have multiple PWs for user access.

i When the user accesses VPLS through a PW, the **neighbor** command used to configure the PW must contain the key word **spoke-vc** and the **label-switching** command must be run for the interface accessing Spoke PW.

Verification

- CEs can be mutually pinged.
- Run the **show mpls l2transport vc** command to display the PW status.

Related Commands

↘ Specifying Waiting for Response from the Peer or not after LDP Sends the PW Label Withdraw Message

Command	vc-withdraw-expect-release
Parameter Description	-
Command Mode	config-mpls-router
Usage Guide	When the command is run, after sending a PW label withdraw message, LDP releases the label only after receiving a PW label release message from the peer. For example, when the command is run, LDP sends a PW label withdraw message because AC is disabled; if LDP does not receive a PW label release message from the peer, when PW is enabled again because AC is enabled, LDP will not send the PW label mapping message again until receiving a PW label release message from the peer, or the no vc-withdraw-expect-release command is run to stop waiting.

↘ Creating an L2VPN VFI instance

Command	l2 vfi name [vpnid <1- 2147483647> [manual autodiscovery point-to-point]]
Parameter Description	<i>name</i> : indicates the name of L2VPN VFI instance, which is a string of up to 31 characters. <1- 2147483647>: specifies an ID for the created VPLS instance. manual : manually configures an VPLS neighbor for Martini VPLS to create a PW. autodiscovery : creates a PW for Kompella VPLS through automatic discovery. point-to-point : automatically discovers PEs specified for Kompella VPWS VFI.
Command Mode	Global configuration mode
Usage Guide	L2VPN VFI name maps with its VPN ID. When this command contains no VPN ID, the VFI configuration mode is entered. The name parameter can only specify existing L2VPN VFI instance. An error message is displayed when there is any conflict. If the name, ID and configuration mode are the same to the original configurations, the VFI configuration mode is entered. Automatic discovery takes effect only when the L2VPN VPLS or L2VPN VPWS address family in the BGP configuration mode is activated. Kompella VPLS is realized only when the keyword autodiscovery is specified. Kompella VPWS is realized only when the point-to-point mode is specified. When no keyword is specified or the keyword is manual , Martini VPLS is realized. The L2VPN VFI realization method cannot be modified after being selected. To modify the realization method, you need to delete the instance and configure it again. For example, to change a Kompella VPLS

	<p>to a Martini VPLS, delete the Kompella VPLS instance, create a new VPLS instance and set its realization method to Martini.</p> <p>For Kompella VPLS or VPWS, a PW can be established only when the instance RD, Site ID, and Route Target are configured and the instance is bound to an interface.</p> <p>For Martini VPLS, a PW can be created only when the instance is bound to an interface or a Spoke VC neighbor is created.</p>
--	---

📌 **Configuring an VPLS Neighbor**

Command	neighbor <i>ip-address</i> encapsulation mpls [<i>vc-id vc-id</i>] [hub-vc spoke-vc] [ethernet ethernetvlan] [manual]
Parameter Description	<p><i>ip-address</i>: indicates the LSR ID of the VPLS neighbor.</p> <p>vc-id <i>vc-id</i>: specifies a PW ID. The VPN ID is used as the PW ID by default. The value range is 1-2147483647.</p> <p>hub-vc: specifies the PW to be a Hub PW.</p> <p>spoke-vc: specifies the PW to be a Spoke PW.</p> <p>ethernet: specifies the PW type to Ethernet.</p> <p>ethernetvlan: specifies the PW type to Ethernet VLAN.</p> <p>manual: specifies to configure VC-ftn and VC-ilm of the static PW.</p>
Command Mode	VFI configuration mode
Usage Guide	<p>This command is valid only for Martini VPLS.</p> <p>PW ID and the PW peer's LSR ID are used as the PW key, which should be globally unique and contain the VPWS PW.</p> <p>To avoid loops, VPLS adopts a fully meshed networking model, in which a PW is established between each two PEs. Such a connection mode is called as Hub-VC. When this command is used to configure the same neighbor, the previous configuration will be overwritten each time. When U-PE accesses N-PE through a PW in an H-VPLS model or the user accesses the VPLS through a PW in a basic VPLS model, the PE type of the VPLS N-PE or VPLS-PE must be configured to be a Spoke PW.</p> <hr/> <p> The MTU value and PW Type at two ends of both Spoke-VC and Hub-VC must be the same; otherwise, the PE cannot be established.</p> <p> The PW Type cannot be modified after the VPLS PW is configured. To modify the PW Type, you need to delete the PW, establish a new PW, and configure the PW Type again.</p>

📌 **Enabling Martini VPLS for an Interface**

Command	xconnect vfi <i>name</i>
Parameter Description	<i>name</i> : specifies the name of the VFI instance to be bound.
Command Mode	Interface configuration mode
Usage Guide	It is used to bind a Martini VPLS instance.

Configuration Example

Switch Example: Basic VPLS

Figure 2-37

CE1 and CE2 are connected to the same VPLS network through PE1 and PE2. PE1, P and PE2 form a public MPLS network to provide a VPLS. VLAN 10 on PE1 and PE2 is bound to the VPLS instance.

Configuration Steps

- On PE1 and PE2, configure the Loopback interface address and OSPF protocol, establish a public route, configure LDP, and globally enable MPLS. Enable LDP and MPLS for the public interface, and configure the VPLS instance and VPLS peer PE. Bind the VLAN interface to the VPLS instance, and configure an interface connecting PE to CE.
- On P, configure the Loopback interface address and OSPF protocol, and establish a public route. Configure LDP and enable MPLS globally. Enable LDP and MPLS for the interface.

PE1

```

➤ [Switch Example: H-VPLS \(Access Through a PW\)](#)

Scenario
Figure 2-39

CE1 and CE2 are connected to the same H-VPLS network through U-PE1 and U-PE2 which are connected to N-PE1 and N-PE2 respectively. N-PEs and U-PEs are connected through PWs. All U-PEs and N-PEs belong to an MPLS network and provide VPLS together.

The PW for N-PE to connect to U-PE must be a Spoke PW, but the PW at the U-PE can be of any type. If the U-PE supports VPLS, the PE from the U-PE to the N-PE can be a Hub PW or a Spoke PW. If U-PE does not support VPLS, the PW can be a VPWS PW.

In this example, U-PE1 and N-PE1 are accessed through a Hub PW, and U-PE2 and N-PE2 are accessed through a VPWS PW.

Configuration Steps

- On U-PE1, configure the Loopback interface address and OSPF protocol, establish a public route, configure LDP, and globally enable MPLS. Enable LDP and MPLS for the public interface. Configure a VPWS PW for the VLAN interface, and configure an interface connecting PE to CE.
- On N-PE1 and N-PE2, configure the Loopback interface address and OSPF protocol, establish a public route, configure LDP, and globally enable MPLS. Enable LDP and MPLS for the public interface, and configure the VPLS instance. Configure a Hub PW to other N-PEs, and configure a Spoke PW to the peer U-PEs.
- On P, configure the Loopback interface address and OSPF protocol, and establish a public route. Configure LDP and enable MPLS globally. Enable LDP and MPLS for the interface.

Switch Example: H-VPLS (Access Through QinQ in a Dual-Homed Mode)

Scenario
Figure 2-40

If there is only one Spoke PW between U-PE and N-PE, when the Spoke PW is invalid, the communication between U-PE and the outside is disconnected. The problem can be solved when U-PE is connected to N-PE in a Dual-Homed mode. Dual-Homed means that one U-PE has two or more Spoke PWs which are connected to different N-PEs belonging to the same VPLS network. Only one of the multiple Spoke PW is in the working status is called as the master connection, and the remaining PWs are called as slave connections. One of slave connection is used when the master connection fails.

In a Dual-Homed Layered VPLS network which is accessed through QinQ, STP is used to switch between the master connection and slave connection. However, because STP does not belong to the user and the packet can only be transmitted on a PE (U-PE and N-PE), to avoid impact of the STP packet (BPDU) on the user's packet, you need to create an VPLS instance on N-PE to be used to transmit the Dual-Homed BPDU packet transparently.

The above figure shows a Dual-Homed H-VPLS topology, in which CEs are connected to the same H-VPLS network through U-PEs, and U-PEs are connected to N-PEs through QinQ tunnels. Only N-PEs belong to the MPLS network. MPLS is not enabled for U-PEs, but N-PEs and U-PEs provide VPLS together. U-PEs use trunk interfaces as uplink interfaces and allow traffic of VLAN to which the interface connecting U-PE to CE belongs to pass through. QinQ is enabled for the interface connecting U-PE to CE. The Native VLAN of this QinQ cannot be the same to that of the interface connecting U-PE1 to N-PE or to that of the interface connecting N-PE to U-PE, because the QinQ Native VLAN of the interface connecting U-PE to CE is used to identify the VPLS instance provided for the user, while the Native VLAN of the Trunk interface connecting N-PE to U-PE is used to identify the VPLS instance which transmits the Dual-Homed BPDU packet transparently. A Hub PW should be established between each two N-PEs. When Dual-Homed is enabled for U-PE1, U-PE1 is connected to both N-PE1 and N-PE2. When only one VPLS instance is provided for the user but another VPLS instance dedicated for transmitting Dual-Homed BPDU packet transparent must be established, the another VPLS instance should be enabled for the N-PE to which the U-PE is connected in a Dual-Homed mode.

Configuration Steps

- On U-PE1, connect a Spoke PW to the peer N-PE1 and a Spoke PW to the peer N-PE2, configure an interface connecting PE to CE, enable STP only for U-PE adopting the Dual-Homed access mode.
- On U-PE2 and U-PE3, connect a Spoke PW to the peer N-PE1 and a Spoke PW to the peer N-PE2,

	<p>configure an interface connecting PE to CE, enable STP only for U-PE adopting the Dual-Homed access mode.</p> <ul style="list-style-type: none"> ● On N-PE1 and N-PE3, configure the Loopback interface address and OSPF protocol, and establish a public route. Configure LDP, enable MPLS globally, enable LDP and MPLS for the public interface, and configure the interface connecting N-PE to U-PE. Configure the VPLS instance for the user, establish a Hub PW to other N-PEs in the same VPLS instance, bind the QinQ VLAN interface to the VPLS instance, configure a VPLS instance to transmit the BPDU packet transparent, establish a Hub PW to other Dual-Homed N-PEs, and bind the Native VLAN interface which is used to transmit the BPDU packet transparently to the VPLS instance. ● On P, configure the Loopback interface address and OSPF protocol, and establish a public route. Configure LDP, enable MPLS, and enable LDP and MPLS for the interface. ● On N-PE2, configure the Loopback interface address and OSPF protocol, and establish a public route. Configure LDP, enable MPLS, and enable LDP and MPLS for the public interface. Configure an interface connecting N-PE to U-PE (connecting to two U-PEs at the same time), a VPLS instance for the user, and a Hub PW to other N-PEs in the same VPLS instance. Bind the QinQ VLAN interface to the VPLS instance, configure a VPLS instance to transmit the BPDU packet transparent, establish a Hub PW to other Dual-Homed N-PEs, and bind the Native VLAN interface which is used to transmit the BPDU packet transparently to the VPLS instance.

Common Errors

- The MPLS IP is not enabled globally.
- The label-switching is not enabled on the public network side.

2.4.6 Kompella VPLS

2.4.6.1 Basic Kompella VPLS

Configuration Effect

- Kompella VPLS is used to realize Layer-2 interconnection between sites.

Notes

- The MPLS IP shall be enabled globally.
- The label forwarding function shall be enabled on the public network side.

Configuration Steps

↳ Configuring a Public Tunnel

LSP tunnels must be established on a public network to carry VPLSs. To run MPLS on a backbone network, the LDP must be run simultaneously on P and PE to establish a public tunnel. Distribution protocol should be configured for corresponding MPLS devices, and the MPLS-based forwarding function must be enabled for each interface.

- It is mandatory.
- In the global configuration mode, run the **mpls ip** command to enable the MPLS forwarding function.
- Run the **mpls router ldp** command to enable LDP and enter the LDP configuration mode.
- Run the **ldp router-id interface** loopback *id* [**force**] command to configure LDP Router ID. The IP address of the Loopback interface is usually used as the Router ID.
- Exit the LDP configuration mode, run the **interface type ID** command to enter the public interface configuration mode.
- Run the **label-switching** command to enable the MPLS forwarding function for the interface.
- Run the **mpls ip** command to enable LDP and the MPLS forwarding function for the interface.
- Exit the privileged mode, and run the **copy running-config startup-config** command to save configurations.

i LDP is a topology-driven protocol. The IPv4 routing protocol should be enabled and run normally so that LDP can run normally.

↳ Configuring an L2VPN VPLS Address Family

Kompella VPLS uses MP-BGP4 as the signaling protocol and automatic discovery mechanism. PEs in the same VPLS instance exchange VPLS information through the L2VPN address family. L2VPN VPLS address family is not supported by default.

- It is mandatory.
- In global configuration mode, run the **router bgp asn-num** command to create BGP and enter the BGP configuration mode.
- Run the **neighbor peer-address remote-as asn-number** command to create an IBGP session.

- Run the **neighbor** *peer-address* **update-source** *interface-name* command to specify the Loopback interface address as the source address of the IBGP session.
- Run the **address-family l2vpn vpls** command to enter the address family.
- Run the **neighbor** *ip-address* **activate** command to activate L2VPN interaction on the BGP session.
- Run the **neighbor** {*ip-address* | *peer-group-name*} **send-community** [**both** | **standard** | **extended**] command to specify the extended community attribute sent to the BGP neighbor.

📌 Configuring a Kompella VPLS Instance

Run the **I2 vfi** command to create a Kompella VPLS instance, or enter the Kompella VPLS configuration mode. Run the **no I2 vfi** command to delete a VPLS instance. Specify a locally unique name and VPN ID for the VPLS instance you create, and enable automatic discovery for the VPLS instance. The VPLS name must map to the VPN ID. BGP is the default signaling protocol in the automatic discovery mode.

- It is mandatory.
- In the global configuration mode, run the **I2 vfi** *vpls-name* **vpnid** *vpn-id* **autodiscovery** command to create a Kompella VPLS instance and enter the VPLS configuration mode.
- Run the **signal bgp** command to configure the signaling protocol for the VPLS instance. The default signaling protocol is BGP.
- Run the **rd** *rd_value* command to configure the RD value.
- Run the **encapsulation mpls** [**ethernet** | **ethernetvlan**] command to specify the PW encapsulation type of Kompella VPLS. The default encapsulation type is Ethernet (Raw). If VPLS is accessed through a sub-interface, the PW encapsulation type should be Ethernet VLAN (Tag).
- Run the **route-target** { **import** | **export** | **both** } *rt_value* command to configure RT. Multiple RTs can be configured.
- Run the **site-id** *id* [**site-range** *size*] command to configure the CE ID and site-range of the site. If not configured, the site-range is 16 by default.
- Run the **xconnect interface** *interface-id* command to configure the interface bound to the site.
- Exit the privileged mode, and run **copy running-config startup-config** command to save configurations.

-
- ❗ To create a Kompella VPLS instance, the **I2 vfi** command must contain the key word **autodiscovery**.
 - ❗ Autodiscovery between PEs in a VPLS instance is based on MP-BGP. To configure a Kompella VPLS, you need to specify BGP as the VPLS PW signaling protocol.
 - ❗ For convenient management, configure the same ID for VPLS instances in the same VPN.
 - ❗ The PW encapsulation type of PEs in the same VPLS shall be the same; otherwise, the VPLS packet cannot be forwarded. Assume that there is a VPLS-X, if the PW encapsulation type of VPLS-X on PE1 is set to Ethernet (Raw), the PW encapsulation type of VPLS-S on PE2 cannot be set to Ethernet VLAN (Tag).
-

📌 VPLS Accesses

Configuring VPLS Access Mode for a Switch

The created VPLS instance takes effect only when the user for which the VPLS instance is configured accesses the link. Currently, a switch can access VPLS services in the following three methods:

- VLAN access interface
- VLAN trunk Interface
- VLAN tunnel access

 Super VLAN interface cannot provide VPLS. When an ordinary VLAN is configured to be a Super VLAN, the VPWS configurations on the ordinary VLAN are deleted.

VLAN Access interface

Access through VLAN access interface is applicable for user packets that are not encapsulated by 802.1Q; that is, the packets contain no VLAN Tag.

- It is mandatory.
- Run the **interface type ID** command in the global configuration mode to enter the interface configuration mode.
- Run the **switchport mode access** command to set the interface to the access mode.
- Run the **switchport access vlan vlan-id** command to set the interface to be a member port of a VLAN.
- Exit the interface configuration mode, and run the **I2 vfi vfi_name vpnid vpn_id point-to-point** command to enter the VFI configuration mode.
- Run the **site-id id [site-range size]** command to configure the VFI site.
- Run the **xconnect interface vlan id** command to configure an AC interface bound to the VPLS site.
- Exit the privileged mode, and run the **copy running-config startup-config** command to save configurations.

 In the access interface mode, the VPLS PE encapsulation type should be Ethernet (Raw).

VLAN Trunk Interface

Access through a VLAN Trunk interface is applicable when multiple VPLSs are transmitted on the same physical access link and each VLAN corresponds to one VPLS instance. PE distinguishes to which VPLS instance a packet belongs based on the packet's VLAN Tag, and then provides a combo access interface.

- It is mandatory.
- In the global configuration mode, run the **interface type ID** command to enter the interface configuration mode.
- Run the **switchport mode trunk** command to configure the interface to the trunk mode.
- Run the **switchport trunk allow vlan add vlan-list** command to allow VLAN traffic to be transmitted on a trunk link.
- Exit the interface configuration mode, and run the **I2 vfi vfi_name vpnid vpn_id autodiscovery** command to enter the VFI configuration mode.
- Run the **site-id id [site-range size]** command to configure the VFI site.
- Run the **xconnect interface vlan id** command to configure an AC interface bound to the VPLS site.
- Exit the privileged mode, and run the **copy running-config startup-config** command to save configurations.

- i** In the Trunk interface mode, the VPLS PW encapsulation type should be Ethernet VLAN (Tag).
- i** It is not allowed to bind the Native VLAN of the trunk interface to L2VPN.

VLAN Tunnel Access

Access through a VLAN tunnel interface is applicable when the user service packet transmitted on the access link already contains a private VLAN Tag when the user accesses VPLS. In such a mode, the PE forwards intact all packets received from the interface, and VLAN member ports connecting the PE to the CE need to work in tunnel mode.

- It is mandatory.
- Run the **interface type ID** command in the global configuration mode to enter the interface configuration mode.
- Run the **switchport access vlan-id** command to set VLAN member ports for the interface.
- Run the **switchport mode dot1q-tunnel** command to set the interface to work in the tunnel mode.
- Exit the interface configuration mode, and run the **I2 vfi vfi_name vpnid vpn_id autodiscovery** command to enter the VFI configuration mode.
- Run the **site-id id [site-range size]** command to configure the VFI site.
- Run the **xconnect interface vlan id** command to configure an AC interface bound to the VPLS site.
- Exit the privileged mode, and run **copy running-config startup-config** command to save configurations.

- i** In the VLAN tunnel interface mode, the VPLS PW encapsulation type should be Ethernet (Raw).
- i** Only basic QinQ, not flexible QinQ, is supported in this mode.

Verification

- Run the **show bgp I2vpn vpls { all [id:offset | neighbor ip-address | summary] }** command to display the L2VPN VPLS address family.
- Run the **show mpls vfi** command to display the VFI information.
- Run the **show mpls I2transport vc** command to display the PW status.
- CEs with the same network segment IP address can be mutually pinged.

Related Commands

↘ Entering the L2VPN Address Family Configuration Mode

Command	address-family I2vpn { vpls vpws }
Parameter Description	vpls: indicates the L2VPN VPLS address family. vpws: indicates L2VPN VPWS address family.
Command Mode	BGP configuration mode BGP scope configuration mode
Usage Guide	Run the address-family I2vpn vpls command to allow L2VPN VPLS interaction between PEs and enter VPLS address family configuration mode. Run the address-family I2vpn vpws command to allow L2VPN VPWS interaction between PEs and enter VPwS address family configuration mode. Run the

	exit-address-family command to exit the L2VPN family address configuration mode.
--	---

↘ Activating Neighbors Supporting L2VPN Address Family

Command	neighbor { <i>ip-address</i> <i>peer-group-name</i> } activate
Parameter	<i>ip-address</i> : indicates an IP address.
Description	<i>peer-group-name</i> : specifies a peer group name of no more than 32 characters.
Command Mode	BGP L2VPN address family configuration mode
Usage Guide	Run the command to activate BGP-based L2VPN switch for L2VPN VPLS or VPWS address family configuration.

↘ Enabling a BGP extended community attribute

Command	neighbor { <i>ip-address</i> <i>peer-group-name</i> } send-community [both standard extended]
Parameter	<i>ip-address</i> : indicates an IP address.
Description	<i>peer-group-name</i> : specifies a peer group name of no more than 31 characters. both : sends standard and extended community attributes. standard : sends only standard community attributes. extended : sends only extended community attributes.
Command Mode	BGP L2VPN address family configuration mode
Usage Guide	If a peer group is specified during configuration, all members of the peer group inherit the attributes configured by this command. When neighbor activate is run for the first time, this attribute is enabled by default.

↘ Creating an L2VPN VFI instance

Command	I2 vfi <i>name</i> [vpnid <1- 2147483647> [manual autodiscovery point-to-point]]
Parameter	<i>name</i> : indicates the name of L2VPN VFI instance, which is a string of up to 31 characters.
Description	<1- 2147483647>: specifies an ID for the created VPLS instance. manual : manually configures an VPLS neighbor for Martini VPLS to create a PW. autodiscovery : creates a PW for Kompella VPLS through automatic discovery. point-to-point : automatically discovers PEs specified for Kompella VPWS VFI.
Command Mode	Global configuration mode
Usage Guide	L2VPN VFI name maps with its VPN ID. When this command contains no VPN ID, the VFI configuration mode is entered. The name parameter can only specify existing L2VPN VFI instance. An error message is displayed when there is any conflict. If the name, ID and configuration mode are the same to the original configurations, VFI configuration mode is entered. Automatic discovery takes effect only when the L2VPN VPLS or L2VPN VPWS address family in BGP configuration mode is activated. Kompella VPLS is realized only when the keyword autodiscovery is specified. Kompella VPWS is realized

	<p>only when the point-to-point mode is specified. When no keyword is specified or the keyword is manual, Martini VPLS is realized.</p> <p>The L2VPN VFI realization method cannot be modified after being selected. To modify the realization method, you need to delete the instance and configure it again. For example, to change a Kompella VPLS to a Martini VPLS, delete the Kompella VPLS instance, create a new VPLS instance and set its realization method to Martini.</p> <p>For Kompella VPLS or VPWS, a PW can be established only when the instance RD, Site ID, and Route Target are configured and the instance is bound to an interface.</p> <p>For Martini VPLS, a PW can be created only when the instance is bound to an interface or a Spoke VC neighbor is created.</p>
--	---

📌 **Specifying the PW Signaling for the L2VPN VFI Instance**

Command	signal bgp
Parameter Description	-
Command Mode	VFI configuration mode
Usage Guide	This command is valid only for Kompella VPLS and VPWS. When autodiscovery is enabled, BGP is used as the signaling protocol by default.

📌 **Defining the RD Value for the Kompella L2VPN VFI Instance**

Command	rd rd_value
Parameter Description	<i>rd_value</i> : indicates the RD value.
Command Mode	VFI configuration mode
Usage Guide	<p>This command is valid only for Kompella VPLS and VPWS.</p> <p>For a Kompella L2VPN instance, RD should be configured before other parameters.</p> <p>The RD value configured for a Kompella L2VPN instance cannot be modified or deleted. To modify the RD value, you need to delete the Kompella L2VPN instance and create a new one and then configure the RD value. One L2VPN VFI instance has only one RD value.</p>

📌 **Specifying An Encapsulation Type for the PWs in the L2VPN VFI Instance**

Command	encapsulation mpls [ethernet ethernetvlan ppp hdlc ip-interworking]
Parameter Description	<p>mpls: specifies the encapsulation type.</p> <p>ethernet: specifies the VPWS PW type to Ethernet, and the VPLS PW type to Raw.</p> <p>ethernetvlan: specifies the VPWS PW type to Ethernet VLAN, and the VPLS PW type to Tag.</p>
Command Mode	VFI configuration mode
Usage Guide	This command is valid only for Kompella L2VPN. The encapsulation types of Kompella VPLS are Ethernet and Ethernet VLAN, which specify the VPLS PW encapsulation type as Raw and Tagged respectively.

	<p>All PW encapsulation types are valid for Kompella VPWS and used for BGP signaling negotiation.</p> <p>For Kompella VPLS, the PW type at two ends of the PW must be the same; otherwise, the PW connection cannot be created through BGP signaling.</p> <hr/> <p> For Kompella VPLS, the PW encapsulation type of PEs on the same VPLS must be the same; otherwise, the packet cannot be forwarded because the VLAN Tags are different. If all PEs on a VPLS are accessed through Ethernet interface, the PW encapsulation type shall be Raw. If all PEs on a VPLS are accessed through Ethernet sub-interface, the PW encapsulation type shall be Tag.</p> <p> If the VFI instance is bound to an interface, the instance should be unbound first before its encapsulation type can be modified.</p>
--	--

Defining an RT Attribute of a Kompella L2VPN Instance

Command	<code>route-target { import export both } rt_value</code>
Parameter Description	import: sets the Import RT value. export: sets the Export RT value. both: sets both the Import and Export RT values.
Command Mode	VFI configuration mode
Usage Guide	<p>This command is valid only for Kompella VPLS and VPWS.</p> <p>For a Kompella L2VPN instance, multiple RT attribute values can be configured and import/export/both can be specified. The multiple RTs can be the symbols of the L2VPN VFI instance.</p> <p>When import and export are specified simultaneously for one L2VPN VFI instance, it equals that RT attribute is specified to both.</p> <p>If two VFI instances on the same PE have the same RT, the two instances cannot be interconnected.</p>

Configuring a Site of PEs in a Kompella L2VPN VFI Instance

Command	<code>site-id id [site-range range]</code>
Parameter Description	id: indicates the Site ID of the VFI instance. The value range is 1-256. range: indicates the number of accessed sites. The value range is 1-256.
Command Mode	VFI configuration mode
Usage Guide	<p>This command is valid only for Kompella VPLS and VPWS.</p> <p>The site-range parameter can be used to adjust the number of sites which can be accessed from the L2VPN VFI instance; that is, the number of connections from the L2VPN VFI instance to remote PEs on the same L2VPN. Users can modify the maximum number of remote PEs which can be accessed from the instance. If the number is changed to a larger one, the L2VPN is not affected. If the number is changed to a smaller one, the L2VPN may be disconnected and the packet can be forwarded until PW is established again.</p> <p>For Kompella L2VPN, you can run this command to enter the vfi-site configuration mode and bind the instance to local interfaces of VPWS or VPLS.</p>

	<ul style="list-style-type: none">  Different VFI instances on one PE can have the same ID.  The local ID value shall be larger than or equal to the remote offset value but smaller than the sum of the remote size and offset value (that is, the site-range of the peer PE).  The maximum number of sites which can be accessed from instances in the same VPLS should be the same; otherwise, the above condition should be met.  Only one site ID can be configured for one L2VPN VPLS instance. To modify the site ID, delete the instance and configure a new site ID for the new instance.  Multiple site IDs can be configured for one L2VPN VPWS instance. Each site ID represents a VPWS site of the instance. The locally bound interface and remote sites to be connected should be specified in vfi-site configuration mode. If the specified remote site has a local ID, PW cannot be established.  For a Kompella VPWS instance, the site-range configured in the label saving mode cannot take effect.
--	---

↳ Enabling Kompella L2VPN.

Command	xconnect interface <i>interface-type interface-number</i> [remote-ce-id id]
Parameter Description	<i>interface-type</i> : indicates the interface type. <i>interface-number</i> : indicates the interface number. <i>id</i> : indicates the remote CE ID in VFI. It is only required for Kompella VPWS.
Command Mode	VFI site configuration mode
Usage Guide	When VPWS is accessed through local sub-interfaces, run the encapsulation mpls command to set the VPWS PW type to Ethernet VLAN. When VPWS is accessed through Ethernet interfaces, set the VPWS PW type to Ethernet. For Kompella VPWS, only one interface can be bound in a site configuration mode. If VPLS is accessed all through sub-interfaces, run the encapsulation mpls ethernetvlan command to set the VPLS PW encapsulation type to Tag. If VPLS is accessed all through Ethernet interfaced, set the PW encapsulation type to Raw.

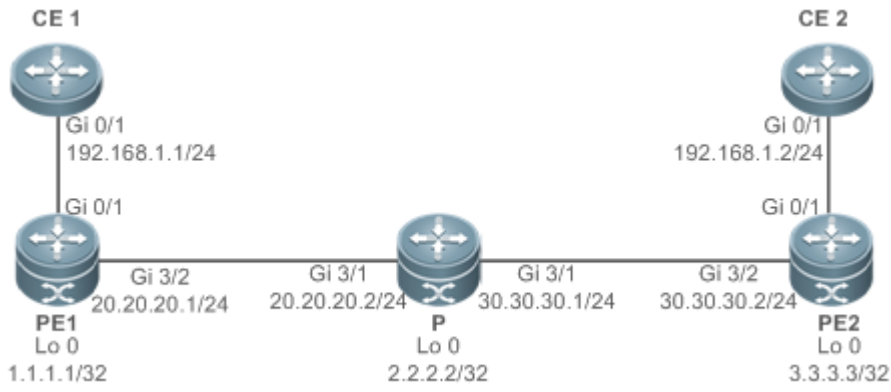

↳ Displaying BGP L2VPN Information

Command	show bgp l2vpn { vpls vpws } all [ve-id:offset neighbor ip-address summary]
Parameter Description	vpls : displays the VPLS information. vpws : displays the VPWS information. all : displays NLRI of all VPLS or VPWS instances. <i>vpn-rd</i> : displays the VPLS instance of the specified RD. <i>vfi-name</i> : indicates the VFI instance name. neighbor address : indicates the BGP neighbor address. <i>ve_id: offset</i> : displays the VFI instance of the specified ve_id:offset. summary : displays major information of BGP L2VPN, including the site ID, offset, label base, and next hop.

Command Mode	Privileged mode
Usage Guide	Run the show bgp l2vpn vpls command to display the local VPLS information, including RD value, site ID, label block offset, and label base. BGP VPLS configurations are displayed only after the VPLS instance is configured.

Configuration Example

Switch Example: Basic VPLS

<p>Scenario Figure 2-42</p>	 <ul style="list-style-type: none"> ● CE1 and CE2 access the same VPLS network through PE1 and PE2. ● PE1, P and PE2 form a public MPLS network. ● VLAN 10 on PE1 and PE2 is bound to the VPLS instance.
<p>Configuration Steps</p>	<p>Prerequisites for configuring Kompella VPLS are as follows:</p> <ul style="list-style-type: none"> ● PE1 and PE2 are interconnected through IGP on the PE. ● Get Kompella VPLS configurations, including the VPLS instance description, RT value, VE ID, planned maximum site number, VE ID offset, and interface. <p>Configuration steps are as follows:</p> <ul style="list-style-type: none"> ● On PE1 and PE2, configure the Loopback interface address and OSPF protocol, and establish a public route. Configure LDP, and globally enable MPLS. Enable LDP and MPLS for the public interface. Configure the VLAN interface and L2VPN address family, the interface connecting PE to CE, and the VPLS instance. ● On P, configure the Loopback interface address and OSPF protocol, and establish a public route. Configure LDP and enable MPLS globally.

Common Errors

- The MPLS forwarding function is not enabled globally.
- The label forwarding function on the public network site is not enabled.

2.4.6.2 Inter-AS Kompella VPLS

Configuration Effect

It is used for Layer-2 interconnection between sites in different ASs.

Notes

The MPLS forwarding must be enabled globally and the label forwarding must be enabled for public interfaces.

Configuration Methodin

Option A

Figure 2-44 Option A : Inter-AS VPLS

In such a mode, ASBRs of two ASs are directly connected, and ASBRs serve as PEs of each AS. Two ASBRs take each other as their CEs. As shown in the figure above, ASBR2-AS2 of AS2 is a CE for ASBR1-AS1 of AS1, and vice versa.

Option A has an advantage of easy realization, because no special Inter-AS configurations are required for two PEs serving as ASBRs, and no IP addresses are needed for interfaces between ASBRs. The disadvantage is that, a link should be allocated for ASBRs between two ASs when each Inter-AS L2VPN or PW is established. The link is either a logical or physical link. Pressure on ASBRs increases when there are a great many Inter-AS PWs, which limits the scale expansion.

Configuring PE

1. Configuring a Public Tunnel

- It is mandatory.
- In the global configuration mode, run the **mpls ip** command to enable MPLS.
- Run the **mpls router ldp** command to enable LDP and enter the LDP configuration mode.
- Run the **ldp router-id interface** loopback *id* [**force**] command to configure LDP Router ID. The IP address of the Loopback interface is usually used as the Router ID.
- Exit the MPLS route configuration mode, and run the **interface type ID** command to configure public interfaces.
- Run the **label-switching** command to enable the MPLS forwarding function for the interface.

- Run the **mpls ip** command to enable LDP and the MPLS forwarding function for the interface.
- Exit the privileged mode, and run the **copy running-config startup-config** command to save configurations.

2. Configuring a VPLS Address Family

- It is mandatory.
- In the global configuration mode, run the **router bgp *asn-num*** command to create BGP and enter the BGP configuration mode.
- Run the **mpls router ldp** command to enable LDP and enter the LDP configuration mode.
- Run the **neighbor *peer-address* remote-as *asn-number*** command to create an IBGP session.
- Run the **neighbor *peer-address* update-source *interface-name*** command to specify the Loopback interface address as the source address of the IBGP session.
- Run the **address-family l2vpn vpws** command to enter the address family.
- Run the **neighbor *ip-address* activate** command to activate L2VPN interaction on the BGP session.
- Run the **neighbor {*ip-address* | *peer-group-name*} send-community [both | standard | extended]** command to specify the extended community attribute sent to the BGP neighbor.
- Exit the privileged mode, and run **copy running-config startup-config** command to save configurations.

3. Configuring a Kompella VPLS Instance

- It is mandatory.
- In the global configuration mode, run the **l2 vfi *vpls-name* vpnid *vpn-id* autodiscovery** command to create a Kompella VPLS instance and enter the VPLS configuration mode.
- Run the **rd *rd_value*** command to configure the RD value.
- Run the **encapsulation mpls [ethernet | ethernetvlan]** command to specify the PW encapsulation type of the Kompella L2VPN. The default encapsulation type is Ethernet.
- Run the **route-target { import | export | both } *rt_value*** command to configure RT. Multiple RTs can be configured.
- Run the **site-id *id* [site-range *size*]** command to configure the CE ID and site-range of the site. If not configured, the site-range is 16 by default. Multiple Site IDs can be configured for a Kompella VPWS.
- Run the **xconnect interface *interface-type* *interface-number*** command to bind a local interface.
- Exit the privileged mode, and run the **copy running-config startup-config** command to save configurations.

4. VPLS Accesses

For details about accessing VPLS, see VPLS Accesses in 1.4.6.1 [Basic Kompella VPLS](#).

↘ Configuring an ASBR

The ASBR configuration method is similar to the PE configuration method. The only difference is that the peer ASBR is served as a CE.

Configuration Method of Inter-AS Option C

Figure 2-45 Option C: Inter-AS VPLS

In Option C in the figure above, an Inter-AS PW is established between PEs on two ASs to exchange PW labels, so as to realize an Inter-AS L2VPN. The working principle is as follows:

An ASBR releases the label IPv4 routes to PEs inside its own AS through MP-IBGP and notifies the label IPv4 routes reaching PEs inside its own AS to the ASBR peer of the peer AS, so as to connect the two AS tunnels and establish an LSP tunnel between the ingress PE and egress PE. Next, it establishes Inter-AS LDP remote session connection between PEs of different ASs and switches PW information.

In this solution, ASBR either needs to maintain Inter-AS L2VPN information nor needs to allocate a physical or logical interface for the Inter-AS L2VPNs. L2VPN information is exchanged directly between PEs, reducing pressure on ASBR and facilitating scale expansion.

The configuration procedure is as follows:

1. Configuring MPLS Signaling

- It is mandatory.
- Enable MPLS and LDP for PEs and P devices in each AS as well as for ASBR interfaces connecting to P devices or PEs inside the AS.

2. Configuring a PE

Configure PEs inside an AS to establish an IBGP session between PEs and the ASBR inside the AS and exchange the IPv4 routes carrying the labels.

- It is mandatory.
- In the global configuration mode, run the **router bgp** *asn-number* command to configure BGP and enter the BGP configuration mode.
- Run the **neighbor** *asbr-address* **remote-as** *asbr-asn-number* command to create an IBGP session between a PE and an ASBR.

- Run the **neighbor** *asbr-address* **update-source** *interface-name* command to use a Loopback address as the source address of the BGP session created between peers.
- Run the **address-family ipv4** command to enter the IPv4 address family.
- Run the **neighbor** *asbr-address* **send-label** command to enable the label exchange function for IPv4 routes.

3. Configuring an ASBR

Configure ASBR to establish an IBGP session between ASBR and PEs inside the same AS and establish an EBGP session with ASBR inside another AS. Enable IPv4 routes carrying the labels for the two sessions. Configure a PE address on the ASBR which must be transmitted to another ASBR.

- It is mandatory.
- In the global configuration mode, run the **mpls ip** command to enable the MPLS forwarding function for the local device.
- Run the **mpls router ldp** command to enable the LDP globally.
- Run the **ldp router-id interface Loopback id force** command to set the IP address of the Loopback interface as the Router ID.
- Run the **advertise-labels for bgp-routes** command to allocate labels for BGP routes.
- Exit the global configuration mode, and run the **router bgp asn-number** command to configure BGP and enter the BGP configuration mode.
- Run the **neighbor** *asbr-address* **remote-as** *asbr-asn-number* command to create an IBGP session between a PE and an ASBR.
- Run the **neighbor** *asbr-address* **update-source** *interface-name* command to use a Loopback address as the source address of the BGP session created between peers.
- Run the **address-family ipv4** command to enter the IPv4 address family.
- Run the **network** *pe-address* **mask** *mask-value* command to introduce the reached PE route into BGP through the network command. The route can also be introduced through redistributed IGP.

 This step is optional.

- Run the **neighbor** *asbr-address* **send-label** command to enable the IPv4 route label exchange function for a BGP session with the ASBR in another AS.
- Run the **neighbor** *pe-address* **send-label** command to enable the IPv4 route label exchange function for a BGP session with the ASBR in the current AS.
- Run the **neighbor** *asbr-ip-address* **route-map** *name* **out** command to configure a route distribution policy. You can define a Route Map to control which routes are distributed to the neighbor and whether the route carries a tag during distribution.

 This step is optional.

- Run the **neighbor** *asbr-ip-address* **route-map** *name* **in** command to configure a route distribution policy. You can define a Route Map to only receive routes carrying tags.

 This step is optional.

-
- ⚠ To create an IBGP session between ASBR and PE in the same AS, run `neighbor peer-address update-source loopback id` command to specify to use the Loopback interface address of the local device as the source address of the session; otherwise, it is unable to create an Inter-AS LSP tunnel.
 - ⚠ For direct connected EBGp session between ASBRs, addresses of the interfaces directed connected as the source address of the BGP session to ensure routes of ASBRs can reach each other. Do not run the **neighbor peer-address update-source loopback id** command to specify to use the Loopback interface address of the local device as the source address of the directly connected EBGp sessions. Instead, run `neighbor ebgp-multihop` command to enable the multi-hop EBGp and configure a static route on ASBR, so that the route can reach the peer route. Configure a static FTN to ensure connectivity of the Inter-AS LSP tunnel.
 - ⚠ Note that the **label-switching** command must be executed to enable the MPLS packet forwarding function for the interface connecting the two ASBRs.
-

4. Configuring an L2VPN Address Family

- It is mandatory.
- Configure the L2VPN address families for PEs in each AS. For details, see Configuring L2VPN Address Family in Basic Configurations in [Kompella VPLS](#).

5. Configuring a Kompella VPWS Instance

- It is mandatory.
- Configure the L2VPN address families for PEs in each AS. For details, see Configuring a Kompella VPLS Instance in [Kompella VPLS](#).

6. Configuring VPWS Access

- It is mandatory.
- For configuration details, see Accessing VPLS in [Kompella VPLS](#).

Verification

- Run the **show bgp ipv4 unicast labels** command to display the label allocated by BGP for IPv4 route.
- Run the **show bgp l2vpn vpls all connections** command to display connections of Kompella VPWS.
- Run the **show mpls l2transport vc [detail]** command to display the VC status.

Configuration Example

- ↘ **Switch Example: Inter-AS Configuration Example - Option A**

Scenario
Figure 2-46

- Kompella VPLS adopts the Inter-AS networking topology in Option A, and the middle-layer interfaces are used by ASBR as AC access interfaces.
- The LAN segments of a customer S at Site A and Site B are connected through PE1 at AS 100 and PE2 at AS 200 to form a virtual simulated LAN, that is, a VPLS.
- PE1 and PE2 are in different ASs, and ASBR1 and ASBR2 regard each other as a CE. That is, interfaces between ASBRs are regarded as an AC to access the VPLS instance.

Configuration Steps

Before configuring Kompella VPLS, you need to run IGP on the provider network to enable interconnection between PE and ASBR; establish an MP-IBGP peer between PE and ASBR in the AS; and get Kompella VPLS configurations, including the VPLS instance description, RT value, CE ID, planned maximum site number, CE ID offset, interface.

- Configure CE1 and CE2 to access VLAN 10.
- On PE1, configure the Loopback interface address and OSPF protocol, create a public route so that PE and ASBR in the same AS can be mutually pinged. Configure LDP and enable MPLS globally. Configure the public tunnels between PEs. Configure the L2VPN address family and CE-PE interface, and configure a VPLS instance.
- On ASBR 1, configure the Loopback interface address and OSPF protocol, create a public route so that PE and ASBR in the same AS can be mutually pinged. Configure LDP and enable MPLS globally. Configure the public tunnels between PEs and the VPLS accesses. Configure the L2VPN address family and VFI instance. Configure the interface connecting ASBR 1 to ASBR 2, and configure the VPLS instance.
- On ASBR 2, configure the Loopback interface address and OSPF protocol, create a public route so that PE and ASBR in the same AS can be mutually pinged. Configure LDP and enable MPLS globally. Configure the public tunnels between PEs and the VPLS accesses. Configure the L2VPN address family and VFI instance. Configure the interface connecting ASBR 1 to ASBR 2, and configure the VPLS instance.
- On PE 2, configure the Loopback interface address and OSPF protocol, create a public route so that

	<p>PE and ASBR in the same AS can be mutually pinged. Configure LDP and enable MPLS globally. Configure the public tunnels between PEs and the L2VPN address family. Configure the interface connecting PE2 to CE, and configure the VPLS instance.</p>

Switch Example: Inter-AS Configuration Example - Option C

Scenario
Figure 2-47

- Kompella VPLS adopts the Inter-AS networking topology in Option C.
- The LAN segments of a customer S at Site A and Site B are connected through PE1 at AS 1 and PE2 at AS 2 to form a virtual simulated LAN, that is, a VPLS.
- If PE1 and PE2 are in different ASs, PEs connected to the VPLS instance can be automatically discovered.
- ASBR does not maintain the VPLS label block message.

	<ul style="list-style-type: none"> ● The VPLS label block messages are directly exchanged between PEs.
<p>Configuration Steps</p>	<p>Prerequisites for configuring Kompella VPLS are as follows:</p> <ul style="list-style-type: none"> ● Run IGP on PE so that VPLS PEs and ASBRs in the same AS can be pinged. ● Establish a public tunnel between PEs and ASBRs in the same AS, and enable MPLS for the ASBR interfaces. ● Create IBGP between PEs and ASBRs in the same AS. ● Create EBGP between ASBRs, and enable send-label. ● Get Kompella VPLS configurations, including the VPLS instance description, RT value, CE ID, planned maximum site number, CE ID offset, and interface. <p>Configuration steps are as follows:</p> <ul style="list-style-type: none"> ● Configure CE1 and CE2 to access VLAN 10. ● On PE1, configure the Loopback interface address and OSPF protocol, and create a public route. Configure LDP and enable MPLS globally. Configure a public tunnel between PEs. Configure the L2VPN address cluster. Configure a VLAN interface and an interface connecting CE to PE. Configure a VPLS instance. ● On ASBR1, configure the Loopback interface address and OSPF protocol, and create a public route. Configure LDP protocol, enable MPLS globally, and configure a public tunnel between PEs. Configure an interface connecting ASBR 1 and ASBR 2, and configure ASBR to allocate a label for a PE route. ● On ASBR2, configure the Loopback interface address and OSPF protocol, and create a public route. Configure LDP protocol, enable MPLS globally, and configure a public tunnel between PEs. Configure an interface connecting ASBR 1 and ASBR 2, and configure ASBR to allocate a label for a PE route. ● On PE2, configure the Loopback interface address and OSPF protocol, and create a public route. Configure LDP and enable MPLS globally. Configure a public tunnel between PEs. Configure the L2VPN address family. Configure a VLAN interface and an interface connecting PE to CE, and configure a VPLS instance. <p> When Kompella L2VPN adopts the Inter-AS mode in Option C (Multihop MP-EBGP), if MP-EBGP connection is established through a route reflector between ASs to interact L2VPN NLRI, the next hop is changed when NLRI is sent to the EBGP peer by default. To realize a Kompella L2VPN in Option C, run the neighbor next-hop-unchanged command to not change the next hop when the reflector sends NLRI; otherwise, NLRI cannot be forwarded between different ASs.</p>

Common Errors

- MPLS IP is not enabled globally.
- The label forwarding function at the public network site is not enabled.
- After BGP synchronization is enabled, the BGP route is not redistributed to OSPF.
- The EBGp neighbor is not configured with multiple EBGp routes.
- The label forwarding function is not enabled for the interface between ASBRs.

2.4.6.3 VPLS Compatibility

Configuration Effect

- When these devices are interconnected to devices of other manufacturers, to ensure that the VC is UP, you can run the **ignore match I2-extcommunity** command to disable the match inspection for MTU, EncapsType, and Control Flag received.

Configuration Steps

L2VPN provides PW MTU of 1,500 bytes by default. If the same PW between two PEs have different MTU values, PW connection cannot be created for the two PEs. Devices of some manufacturers do not support MTU configuration in an L2VPN instance. When these devices are interconnected to devices of other manufacturers, to ensure that the VC is UP, you can run the **ignore match I2-extcommunity** command to disable the match inspection for MTU and Control Flag received.

- (Optional)
- In the global configuration mode, run the **I2 vfi vpls-name vpnid vpn-id autodiscovery** command to create a Kompella VPLS instance and enter the VPLS configuration mode.
- Run the **ignore match I2-extcommunity** command to ignore L2VPN extended community attribute match.

- Run the **copy running-config startup-config** command to save the configurations.

 It is valid only for Kompella L2VPN.

Verification

- Run the **show mpls vfi** command to display the configurations.

Related Commands

↳ Creating an L2VPN VFI Instance

Command	I2 vfi name [vpnid <1- 2147483647> [manual autodiscovery point-to-point]]
Parameter Description	<p><i>name</i>: indicates the name of L2VPN VFI instance, which is a string of up to 31 characters.</p> <p><1- 2147483647>: specifies an ID for the created VPLS instance.</p> <p>manual: manually configures an VPLS neighbor for Martini VPLS to create a PW.</p> <p>autodiscovery: creates a PW for Kompella VPLS through automatic discovery.</p> <p>point-to-point: automatically discovers PEs specified for Kompella VPWS VFI.</p>
Command Mode	Global configuration mode
Usage Guide	<p>L2VPN VFI name maps with its VPN ID. When this command contains no VPN ID, the VFI configuration mode is entered. The name parameter can only specify existing L2VPN VFI instance. An error message is displayed when there is any conflict.</p> <p>If the name, ID and configuration mode are the same to the original configurations, VFI configuration mode is entered.</p> <p>Automatic discovery takes effect only when the L2VPN VPLS or L2VPN VPWS address family in BGP configuration mode is activated.</p> <p>Kompella VPLS is realized only when the keyword autodiscovery is specified. Kompella VPWS is realized only when the point-to-point mode is specified. When no keyword is specified or the keyword is manual, Martini VPLS is realized.</p> <p>The L2VPN VFI realization method cannot be modified after being selected. To modify the realization method, you need to delete the instance and configure it again. For example, to change a Kompella VPLS to a Martini VPLS, delete the Kompella VPLS instance, create a new VPLS instance and set its realization method to Martini.</p> <p>For Kompella VPLS or VPWS, a PW can be established only when the instance RD, Site ID, and Route Target are configured and the instance is bound to an interface.</p> <p>For Martini VPLS, a PW can be created only when the instance is bound to an interface or a Spoke VC neighbor is created.</p>

↳ Configuring Whether or not to Match Layer-2 Extended Community Attribute for Kompella PWs.

Command	ignore match I2-extcommunity
Parameter Description	-
Command	VFI configuration mode

Mode	
Usage Guide	<p>This command is valid only for Kompella VPLS and VPWS.</p> <p>When a PW is established through negotiation on Kompella L2VPN, the negotiation packet contains the encapsulation type and MTU information of the L2VPN carried by the BGP extended community attribute. By default, when the encapsulation type and MTU of two VFI instances are matched, a PW is established between the two VFI instances; otherwise, no PW is established. To establish a PW when the PW encapsulation type and MTU of the two VFI instances are not matched, run the ignore match l2-extcommunity command.</p>

2.4.7 Other VPLS Parameters

Configuration Effect

- Configures the description of the VPLS instance.
- Configures an MTU value for the VPLS instance.
- Enables the VPLS instance to transmit BPDU transparently.
- Configures MAC aging time for the VPLS instance.
- Configures the MAC address capacity for the VPLS instance.
- Deletes the static MAC address of the VPLS instance.
- Deletes the dynamic MAC address of the VPLS instance.
- Specifies not to modify the next hop when sending routes to the peer (group).

Configuration Steps

▾ Configuring a Descriptor for the VPLS Instance

- (Optional) It is used to add description to the VPLS instance.
- In the global configuration mode, run the **I2 vfi** *vpls-name* command to enter the VPLS configuration mode.
- Run the **description** *vpls-description* command to configure the VPLS description.

▾ Configuring an MTU Value for the VPLS Instance

(Optional) It is used to configure a MTU value for each VPLS instance. The default value is 1,500. The MTU value in the command specifies the size of packets which can be transmitted by the PW; that is, the length of users' Layer-2 packet and the PW encapsulated packet. By default, if no control word is enabled for the PW and two labels are encapsulated, the length of the Ethernet packets that can be transmitted is 1,492 bytes, including 8-byte PW encapsulated packet (the two labels).

- (Optional) It is used to modify the MTU value of a VPLS instance.
- The default value is 1500.

- In the global configuration mode, run the **I2 vfi** *vpls-name* command to enter the VPLS configuration mode.
- Run the **mtu** *mtu* command to configure a MTU value for the VPLS instance.

 The MTU value of the same VPLS instance on different PEs must be the same; otherwise, no PW can be established through the signaling protocol.

 Currently, fragmented VPLS transmission is not supported. When the MTU value of PW signaling protocol negotiation is modified, the MTU value of the access interface must be adjusted (the length of PW MTU minus the length of PW encapsulation). Besides, the MTU of egress interface on the public network must be consistent with the PW MTU; otherwise, the packet cannot be forwarded. You can run the **mtu** command to modify the MTU value of the interface, and run the **mpls mtu** command to modify the MPLS MTU value of the interface.

▾ Configuring a VPLS Transparent Transmission Bridging Protocol for Packet Control

- (Optional) It is used to transmit a BPDU packet transparently on VPLS.
- The bridging protocol is disabled by default.
- Run the **interface** *type ID* command in global configuration mode to enter the interface configuration mode.
- Run the **I2 vfi tunnel-protocol stp** command to configure the interface to transmit an STP packet transparently.

 Typically, a BPDU packet carries no VLAN Tag. If CE accesses PE through a Trunk interface or a sub-interface and the BPDU packet shall be transmitted transparently at the interface, the BPDU packet sent by CE must carry a VLAN Tag, so that it can be identified by the VPLS instance and transmitted transparently in the VPLS instance.

▾ Configuring an MAC Address Aging time

- (Optional) It is used to modify an MAC address aging time.
- The default aging time is 300s.
- In the global configuration mode, run the **I2 vfi** *vpls-name* command to enter the VPLS configuration mode.
- Run the **mac-address aging-time** *interval* command to configure the MAC address aging time.

 If the MAC address aging time is modified, all MAC addresses are aged according to the latest aging time. If the aging time is set to m, the MAC addresses having no communication will be aged after a period of m.

▾ Configuring an MAC Address Capacity Limit

- (Optional) It is used to modify the MAC address capacity of a VPLS instance.
- The default value is 256.
- In the global configuration mode, run the **I2 vfi** *vpls-name* command to enter the VPLS configuration mode.
- Run the **mac-address-limit** { **action** { **discard** | **forward** } | **alarm** { **disable** | **enable** } | **maximum** *count* } command to configure VPLS MAC address capacity limit and the action when the limit is exceeded.

 By default, the alarm for capability limit exceeding is disabled. If the alarm is enabled, when the MAC address capacity of the VPLS instance exceeds the threshold for the first time, a log is printed. When the MAC address capacity falls down to the threshold, another log is printed.

➤ **Configuring a Static MAC Address**

- (Optional) It is used to configure a static bound MAC address and interface.
- In the global configuration mode, run the **mpls static vfi** *vpls-name* **mac-address** *H.H.H* { **neighbor** *ip-address* | **interface** *interface-id* } command to configure an MAC address for the VPLS instance.

i If a static MAC address is associated with PWs through configuring the neighbor address, it is valid only when the L2VPN instance has only one PW to the configured neighbor. If the VPLS instance has multiple PWs to the neighbor, the static MAC address is bound to one of PW randomly, and thus the packet cannot be forwarded.

➤ **Clearing a Dynamic MAC Address**

A VPLS instance can dynamically learn an MAC address from an AC and PW. Users can clear MAC addresses dynamically learnt by local and remote VPLS instances.

- (Optional)
- In the global configuration mode, run the **clear l2 vfi** *vpls-name* **mac-address local** [*mac-address*] command to delete an MAC address dynamically learnt by a local PE from the VPLS instance.

i Only MAC addresses of remote PEs in Martini VPLS can be cleared.

➤ **Specifying not to Modify Next Hop When Sending Routes to the Peer (Group).**

When Kompella L2VPN adopts the Inter-AS structure in Option C (Multihop MP-EBGP), if MP-EBGP connections are established between ASs through a route reflector, the next hop is modified to the local EBGP when a packet is sent to the EBGP peer by default. You need to run this command on the route reflector; otherwise, the packet cannot be forwarded in an Inter-AS mode.

- (Optional) It used to specify not to change the next hop.
- By default, the next hop is changed.
- Run the **neighbor** { *peer-address* | *peer-group-name* } **next-hop-unchanged** command to configure to not change the next hop in the BGP L2VPN address family mode.

i This command is valid only for Kompella VPLS.

Verification

- Run the **show mpls vfi** command to show the configurations.

Related Commands

➤ **Configuring a Description for a L2VPN VFI Instance**

Command	description <i>desc</i>
Parameter Description	<i>desc</i> : indicates the description of the L2VPN VFI instance. The description consists of up to 63 strings.
Command Mode	VFI configuration mode

Usage Guide	It is used to describe the L2VPN instance.
--------------------	--

▾ Configuring an MTU value for an L2VPN VFI Instance

Command	mtu <i>mtu</i>
Parameter Description	<i>mtu</i> : indicates the configured MTU value. The value range is [46-1530].
Command Mode	VFI configuration mode
Usage Guide	<p>The MTU value in the command specifies the size of packets (the length of the packet encapsulated with the MPLS label) which can be transmitted by the PW; that is, the length of users' Layer-2 packet and the PW encapsulated packet. By default, if no control word is enabled for the PW and two labels are encapsulated, the length of the Ethernet packets that can be transmitted is 1,492 bytes, including 8-byte PW encapsulated packet (the two labels).</p> <p>The VFI MTU is valid for all PWs of the VFI instance; that is, PWs uses the VFI instance's MTU for negotiation. By default, if MTUs negotiated at two ends of the PW are not matched, the PW cannot be established.</p>

▾ Enabling Transparent STP Packet Transmission for the Interface to Which the VPLS Instance is Bound

Command	I2 vfi tunnel-protocol stp
Parameter Description	-
Command Mode	Interface configuration mode
Usage Guide	<p>Typically, a BPDU packet carries no VLAN Tag. If CE accesses PE through a Trunk interface or a sub-interface and the BPDU packet shall be transmitted transparently at the interface, the BPDU packet sent by CE must carry a VLAN Tag, so that it can be identified by the VPLS instance and transmitted transparently in the VPLS instance.</p> <p>The I2 vfi tunnel-protocol stp command can be used no matter the interface is bound to an VPLS instance.</p>

▾ Configuring an MAC Aging Time for the VPLS Instance

Command	mac-address aging-time <i>interval</i>
Parameter Description	aging-time interval: configures an MAC address aging time for a VPLS instance. The unit of the interval parameter is second, and the value range is [5-65536].
Command Mode	VFI configuration mode
Usage Guide	<p>The aging time is valid only for dynamic MAC addresses. The static MAC address can be deleted only through the user static configuration.</p> <p>When an aging time is reset, the new aging time is applied to all MAC addresses in the VPLS instance. For example, if the aging time is modified from 5 minutes to 10 minutes, all MAC addresses in the VPLS instance will be aged 10 minutes letter. If the aging time is modified from 10 minutes to 5 minutes, all MAC</p>

	<p>addresses in the VPLS instance will be aged 5 minutes later.</p> <hr/> <p> When VPLS is forwarded through a switch, the MAC address aging time shall be globally configured through the command, and cannot be configured separately for each VPLS instance.</p>
--	--

↘ Configuring an MAC Address Learning Limit Rule for the VPLS Instance.

Command	mac-limit { action { discard forward } alarm { disable enable } maximum count }
Parameter Description	<p>action: indicates a forwarding action for the packet containing new source MAC address when the number of MAC addresses of the VPLS instance has exceeded the threshold.</p> <p>discard: indicates that the packet containing new source MAC address is discarded when the number of MAC addresses of the VPLS instance has exceeded the threshold.</p> <p>forward: indicates that the packet containing new source MAC address is forwarded when the number of MAC addresses of the VPLS instance has exceeded the threshold.</p> <p>alarm: indicates whether or not to print a log when the number of MAC address of the VPLS instance exceeds the threshold or falls below the threshold again.</p> <p>disable: indicates not to print a log when the number of MAC address of the VPLS instance exceeds the threshold or falls below 80% of the threshold.</p> <p>enable: indicates to print a log when the number of MAC address of the VPLS instance exceeds the threshold or falls below 80% of the threshold.</p> <p>maximum count: configures the threshold of MAC address of the VPLS instance. The value range is [0, 65536], wherein 0 indicates that the VPLS instance has no MAC address capacity limit.</p>
Command Mode	VFI configuration mode
Usage Guide	<p>When forwarding a packet, the VPLS instance learns the source MAC address in the packet at PW and AC. If the number of MAC addresses learnt by the VPLS instance exceeds the threshold, the VPLS instance stops learning new MAC address. You can run the maximum count command to increase the threshold of MAC addresses for the VPLS instance.</p> <p>If the maximum count command is used to adjust the MAC address threshold of the VPLS instance to a lower one, when the new MAC threshold is smaller than the number of static MAC addresses of the VPLS instance, the dynamic MAC addresses exceeding the threshold are aged immediately.</p> <p>Run the mac-limit action { discard forward } command to configure the VPLS instance to discard or forward packets containing new MAC addresses after the number of MAC addresses learnt by the VPLS instance has reached the threshold.</p> <p>Run the mac-limit alarm { disable enable } command to configure whether or not to print the message for the user when the number of MAC addresses learnt by the VPLS instance has reached the threshold or is reduced to the threshold. If the command mac-limit alarm enable is run, when the accumulated number of MAC addresses learnt by the VPLS instance has reached the threshold or the number of MAC addresses learnt by the VPLS instance has reached the threshold at a certain time, and the number of MAC addresses reaches 80% of the threshold for the first time after some MAC addresses are deleted through commands or due to MAC address aging, the logs are printed.</p>

↘ Configuring a Static MAC Address for the VPLS Instance

Command	mpls static vfi <i>name</i> mac-address <i>H.H.H</i> { neighbor <i>ip-address</i> interface <i>interface-name</i> }
Parameter Description	<p><i>name</i>: Indicates the VPLS instance name.</p> <p><i>H.H.H</i>: indicates a static MAC address.</p> <p>neighbor <i>ip-address</i>: indicates the VPLS neighbor address.</p> <p>interface <i>interface-name</i>: indicates the VPLS AC interface.</p>
Command Mode	Global configuration mode
Usage Guide	<p>This command is used to configure an MAC address for a VPLS neighbor or for an interface bound to the VPLS instance.</p> <p>The static MAC address configured for the VPLS neighbor takes effect only when the VPLS neighbor's PW is in UP state.</p> <p>When a static MAC address is configured for a VPLS AC interface, the interface must be bound to the VPLS instance; otherwise, the MAC address is invalid. If the interface is bound to and then unbound from a VPLS instance, the MAC address is also invalid.</p> <p>If the static MAC address is conflict with the dynamic MAC address, the learnt MAC entries are overwritten dynamically.</p> <hr/> <p> If a static MAC address is associated with PWs through configuring the neighbor address, it is valid only when the L2VPN instance has only one PW to the configured neighbor. If the VPLS instance has multiple PWs to the neighbor, the static MAC address is bound to one of PW randomly, and thus the packet cannot be forwarded.</p>

↘ Clearing All MAC Addresses Learnt from a PW by a Local or Remote VPLS Instance

Command	clear l2 vfi <i>name</i> mac-address { remote local [<i>mac-address</i>] }
Parameter Description	<p><i>name</i>: indicates the VPLS instance name.</p> <p>remote: uses LDP to send a MAC address withdraw message in which the number of MAC address is 0 to all PW peers of the specified VPLS instance.</p> <p>local <i>mac-address</i>: clears all MAC addresses of a specified VPLS instance or clears the specified dynamic MAC address.</p>
Command Mode	Privileged mode
Usage Guide	<p>The clear l2 vfi mac-address local command is used to delete all dynamic MAC addresses of a local VPLS instance. It is invalid to static MAC addresses.</p> <p>The remote parameter in this command is valid only for LDP VPLS. LDP is triggered to send an MAC withdraw message to a remote PE. The remote PE clears all MAC addresses except for the PW.</p>

↘ Specifying not to Modify the Next Hop When Sending Routes to the Peer (Group).

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } next-hop-unchanged
Parameter Description	<p><i>peer-address</i>: specifies the peer's address.</p> <p><i>peer-group-name</i>: specifies a peer group name of no more than 32 characters.</p> <p>next-hop-unchanged: Specifying not to modify the next hop when sending routes to the BGP peer</p>

	(group)
Command Mode	BGP L2VPN address family mode
Usage Guide	When Kompella L2VPN adopts the Inter-AS structure in Option C (Multihop MP-EBGP), if MP-EBGP connections are established between ASs through a route reflector, the next hop is modified to the local EBGP when a packet is sent to the EBGP peer by default. You need to run this command on the route reflector; otherwise, the packet cannot be forwarded in an Inter-AS mode.

3 Configuring BGP/MPLS IP VPN

3.1 Overview

Conventional virtual private networks (VPNs) transmit private network data in public networks over tunneling protocols such as Generic Routing Encapsulation (GRE), Layer 2 Tunneling Protocol (L2TP), and Point-to-Point Tunneling Protocol (PPTP). BGP/MPLS IP VPN is a VPN implementation mode between L2TP and Layer 3 Tunneling Protocol (L3TP). Label Switched Paths (LSPs) are established in public networks over the Label Distribution Protocol (LDP) for Multiprotocol Label Switching (MPLS). MPLS VPN connects the geographically different branches of a private network over LSPs to form a unified network. MPLS VPN supports the interworking between different VPNs.

Carriers implement MPLS in IP backbone networks to provide the VPN service to users' private networks. MPLS allows users to build VPNs using routers instead of dedicated VPN devices. MPLS also allows carriers to scale VPNs easily.

 The router devices and router icons in this document represent Layer-3 switches that run routing protocols.

3.2 Applications

Application	Description
Single-AS VPN Service Model	Carriers provide the VPN service to users' IP networks. Multiple sites of a user's VPN are connected to the same IP/MPLS autonomous system (AS).
Inter-AS VPN Service Model	Carriers provide the VPN service to users' IP networks. Multiple sites of a user's VPN are connected to different IP/MPLS ASs.
CSC Service Model	First carriers provide the VPN service to second carriers, and second carriers provide the access service or VPN service to users' IP networks.

3.2.1 Single-AS VPN Service Model

Scenario

Carriers provide the MPLS VPN service to users' IP networks. Multiple sites of a user's VPN are connected to the same IP/MPLS AS and communicate with each other by exchanging VPN routes across the AS.

In Figure 3-1, two sites of VPN1 are connected to the same IP/MPLS AS.

Figure 3-1

Deployment

- Provider edge (PE) 1 and PE2 communicate with the provider (P) device over the Open Shortest Path First (OSPF) and Label Distribution Protocol (LDP), in order to implement the MPLS public network function.
- The customer edge (CE) devices communicate with the PE devices over OSPF, and the PEs communicate with each other over the Border Gateway Protocol (BGP), in order to implement OSPF access to MPLS L3VPN.
- The CEs communicate with the PEs over the Routing Information Protocol (RIP), and the PEs communicate with each other over BGP, in order to implement RIP access to MPLS L3VPN.
- The CEs communicate with the PEs over the Intermediate System to Intermediate System (IS-IS), and the PEs communicate with each other over BGP, in order to implement IS-IS access to MPLS L3VPN.
- The CEs communicate with the PEs over BGP, and the PEs communicate with each other over BGP, in order to implement BGP access to MPLS L3VPN.
- The CEs and the PEs exchange routes based on static configurations, and the PEs communicate with each other over BGP, in order to implement static access to MPLS L3VPN.

3.2.2 Inter-AS VPN Service Model

Scenario

Carriers provide the MPLS VPN service to users' IP networks. Multiple sites of a user's VPN are connected to different IP/MPLS ASs and communicate with each other by exchanging VPN routes across different ASs.

In Figure 3-2, two sites of VPN1 are connected to two IP/MPLS ASs.

Figure 3-2

Deployment

- The MPLS public network function is implemented between AS1 and AS2.
- Autonomous system boundary routers (ASBRs) 1 and ASBR2 are CEs that implement MPLS L3VPN over inter-AS Option A.
- The PEs communicate with each other over BGP to implement MPLS L3VPN over inter-AS Option B.
- The PEs communicate with each other over BGP to implement MPLS L3VPN over inter-AS Option C.

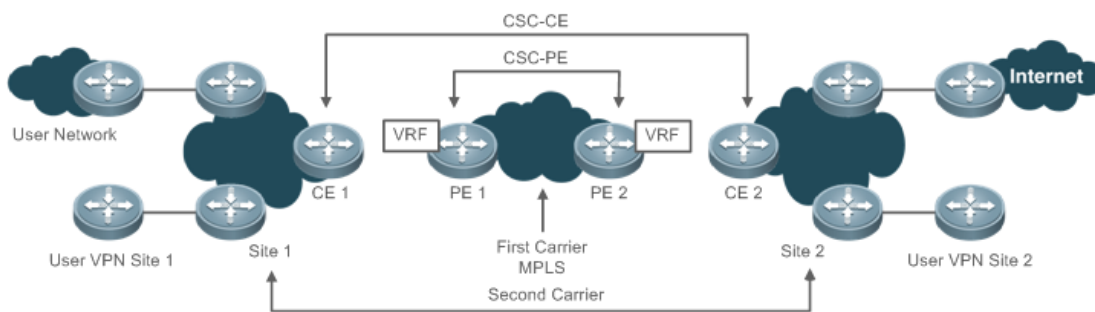

3.2.3 CSC Service Model

Scenario

First carriers provide the VPN service to second carriers, and second carriers provide the access service or VPN service to users' IP networks. Such a networking model is called Carrier's Carrier (CSC).

In Figure 3-3, the user network and the user VPN sites are connected to the second carrier, whose VPN sites are connected to the first carrier.

Figure 3-3

Deployment

- Site1 and Site2 communicate with each other over LDP and BGP to implement the basic L3VPN function of the second carrier.
- The first carrier function is implemented between PE1 and PE2.

3.3 Features

Overview

Feature	Description
BGP/MPLS IP VPN Basic Functions	Uses legacy IPv4 backbone networks to provide the VPN service to users' IPv4 networks.

Inter-AS VPN Service Model	Provides the VPN service to users' IPv4 networks across multiple IPv4 backbone networks.
CSC Service Model	First carriers provide the VPN service to second carriers, and second carriers provide the access service or VPN service to users' IP networks.
OSPF VPN Extended Attributes	Implements OSPF between PE and CE to simplify CE configuration and management.

3.3.1 BGP/MPLS IP VPN Basic Functions

Network Structure

CE, PE, and P play important roles in the BGP/MPLS VPN network structure, as shown in Figure 3-4.

Figure 3-4

- CEs are located on the edge of user networks and belong logically to users' VPNs. A port on each CE is connected directly to a PE. A CE can be a router, switch, or host, and it may or may not support MPLS.
- PEs are located on the edge of the service provider (SP)'s backbone network and belong logically to the SP. A PE can be a router, ATM switch, or frame relay (FR) switch. PEs are connected directly to CEs, and one PE can be connected to different CEs. PEs receive VPN information from CEs, send VPN information to other PEs, receive VPN information from other PEs, and distribute the received VPN information to corresponding CEs. PEs must support MPLS.
- The P router is the core device of the SP's backbone network. The P router implements routing and fast forwarding. It is not connected to CEs. The P router must support MPLS. It knows the route for any destination in the backbone network, but does not know the routes destined for the VPNs.

Application Features

- VPN tunnels are established on the SP's PEs, rather than on users' CEs. VPN routes are exchanged between PEs. Users do not need to maintain VPN information.
- Existing routing protocols are used to dynamically establish VPN tunnels and advertise routes, making it easy to scale VPNs.
- The use of overlapping addresses is supported, allowing different VPN users to use the same address space.
- VPN service content is exchanged by label switching rather than route distribution in the SP's network.
- VPNs deliver security comparable to that of leased lines.

Implementation

Mechanism

- LSP tunnels are established over LDP in the backbone network. (This process is completed when the SP's network topology is stable.)
- Packets are forwarded according to their labels and the local mapping table.
- MP-BGP and BGP extended attributes are used to transmit VPN routes and carry VPN attributes, labels, and other content.
- VPN routes are managed by creating multiple routing tables, maintaining VPN routes, and other methods.

VRF

A VPN routing and forwarding (VRF) table is used to solve local route conflicts.

Each PE-CE connection must be associated with a VRF table. A PE may have multiple VRF tables used to exchange routes with CEs. Each VRF table can be considered as a virtual router, which is connected to a CE and receives routes from the CE or advertises VPN routes to the CE. VRF tables allow PEs to support different VPNs that use the same address space without causing local route conflicts.

A VRF table consists of:

- An independent routing table
- A set of interfaces that belong to the VRF table
- A group of routing protocols only used by the VRF table

RD

A route distinguisher (RD) is an important attribute of VPN routes and used to solve route conflicts during the transmission process.

When routes are advertised over BGP in the backbone network to different VPNs with overlapping addresses, BGP selects the best route among those addresses for advertising; as a result, some VPNs cannot receive corresponding routes. To address this problem, different RDs are added to the overlapping addresses, allowing BGP, when making routing decisions, to distinguish those addresses according to the different RDs carried in VPN routes. In this way, all VPNs receive respective routes. RDs are only used to distinguish identical network addresses, and they are not required when different VPNs do not have overlapping addresses.

A unique RD is assigned to one VPN, so that different VPNs have different RDs to ensure normal transmission of routes over the backbone network. RDs are defined in the format of XX: XX, for example, RD 1: 100, in which 1 is an AS number in the backbone network and 100 is a user-assigned number. A VPN route carries only one RD.

An RD consists of the **Type** field, an Administrator sub-area, and an Assigned Number. Depending on the value of the **Type** field, the RD is encoded in one of the following three formats:

Figure 3-5 RD Structure

- When **Type** is **0**, the Administrator sub-area uses a two-byte public AS number, and the Assigned Number has four bytes and is managed by the SP.
- When **Type** is **1**, the Administrator sub-area uses a four-byte global IPv4 address, and the Assigned Number has two bytes and is managed by the SP.
- When **Type** is **2**, the Administrator sub-area uses a four-byte AS number, and the Assigned Number has two bytes and is managed by the SP.

Route-Target

The route target (RT) is an important attribute of VPN routes and used to indicate a route selection method.

RT attributes are classified into the export RT attribute and the import RT attribute. When a PE receives a VPN route from a CE, the PE adds the export RT attribute to the VPN route and advertises the route to the peer PE. When receiving a route from the peer PE, the PE determines whether to import the route to a VRF table according to the import RT attribute. The import principle is as follows: The PE imports the incoming VPN route to a VRF table only when the VPN route has an RT attribute the same as the import RT attribute of the VRF table. In this way, the distribution of VPN routes is controlled flexibly. A VPN route can carry multiple RT values.

The BGP extended community attribute defines the RT encoding structure, as shown in Figure 3-6.

Figure 3-6 RT Structure

The RT is defined in a way similar to the RD. The RT with **Type** set to 0x02 or 0x202 must have a public AS number. The RT with **Type** set to 0x102 must have a global IPv4 address.

MP-BGP

VPN routes are transmitted over BGP in the backbone network, and carry the export RT attribute according to the BGP extended community attribute.

The traditional BGP4 protocol only transmits IPv4 routes. BGP must be extended for transmitting RD-included VPN routes. BGP is highly scalable and supports the definition of new attributes. Multi-Protocol BGP (MP-BGP) introduces new attributes based on BGP to support multiple protocols. MP-BGP can carry VPN routing information in the format of RD+IP address prefix. When receiving IPv4 routes from VPN users, MP-BGP adds RDs to the IPv4 routes to convert the routes into VPN-IPv4 routes, and then transmits the VPN-IPv4 routes between PEs in the backbone network.

3.3.2 Inter-AS VPN Service Model

Inter-AS VPN allows different sites of a user's VPN located in different ASs to communicate with each other by exchanging VPN routes across those ASs.

RFC4364 proposes the following three inter-AS VPN solutions:

- Option A: VRF-to-VRF mode
- Option B: single-hop MP-EBGP mode
- Option C: multi-hop MP-EBGP mode

3.3.2.1 Option A: VRF-to-VRF Mode

The Option A (VRF-to-VRF) solution is easy to implement. The ASBRs in ASs create a VRF table for every VPN that requires inter-AS communication, and bind an interface to each VRF table. The VRF tables between ASBRs use their bound interfaces to exchange VPN routes.

The purposes of creating VRF tables and binding interfaces are:

- To receive VPN routes in the local AS
- To set up EBGP connections between VRF tables in different ASs to exchange IPv4 routes.

Figure 3-7 VRF-to-VRF Inter-AS VPN

In Figure 3-7, the VRF tables between the two ASBRs establish an EBGP session to exchange IPv4 routes, and the ASBRs and the PEs establish an MP-IBGP session to exchange VPN routes. The VRF tables engaged in the EBGP session consider the peer as a CE. VRF-to-VRF configuration is similar to intra-AS configuration, requiring to establish an MP-IBGP session between ASBR and PE to exchange VPN routes and establish an EBGP session between VRF tables on different ASBRs in BGP VRF address family configuration mode to exchange IPv4 routes.

Features and Limitations

The Option A (VRF-to-VRF) solution is easy to implement and deploy over MP-IBGP. However, ASBRs must configure and bind an interface (a logical sub-interface) to every VPN that requires inter-AS communication. The number of bound interfaces must be at least equal to the number of the VPNs. In addition, VPNs must be configured one by one on the ASBRs. This causes scalability issues. The creation of sub-interfaces for individual VPNs also poses additional requirements on ASBRs. Therefore, the Option A solution is applicable to networks with few VPNs that require inter-AS communication.

- Option A configuration is similar to BGP/MPLS VPN configuration. The configuration process is omitted in this document.

3.3.2.2 Option B: Single-hop MP-EBGP Mode

In the Option A solution, ASBRs must configure a VRF table for each VPN and bind an interface to the VRF table. This is because VPN routes can only be carried over MP-IBGP, but cannot be exchanged directly between EBGP peers. VRF configuration on ASBRs is not required if VPN routes can be exchanged directly between EBGP peers. The Option B solution extends MP-IBGP for direct distribution of VPN routes between ASBRs. The solution is also called single-hop MP-EBGP. Figure 3-8 shows the topology.

Figure 3-8 Option B Inter-AS VPN

Features and Limitations

The Option B solution removes the need to allocate sub-interfaces to sites of each VPN on ASBRs and the need to establish inter-AS LSPs. Instead, VPN routes are transmitted directly between single-hop MP-EBGP neighbors. Because VPN routes are stored and propagated by ASBRs between ASs, the ASBRs are under great burden when handling a large amount of VPN routes. The ASBRs also need to forward public IP packets. This poses high requirements on ASBRs. Because ASBRs

disable the RT filter function for handling incoming VPN routes, the VPN routes on a PE may be propagated to the ASBR in a different AS, which may cause VPN route leakage. To address this problem, SPs that exchange VPN routes must implement a confidence-based routing protocol, enabling ASBRs to trust each other and implement route filtering policies. The Option B solution is applicable to networks with many VPNs that require inter-AS communication.

Implementation

The Option B solution is implemented by the following methods:

- The ASBR retains the next hop in incoming VPN routes.
- The ASBR changes the next hop in incoming VPN routes.

The two methods are described in the following.

↘ Method 1: The ASBR Retains the Next Hop in Incoming VPN Routes

When an ASBR receives a VPN route from the peer ASBR in a different AS, the ASBR sends the VPN route with the next hop unchanged to its MP-IBGP neighbors in the local AS. The PEs and the ASBR in the same AS exchange VPN routes over an MP-IBGP session, and two ASBRs exchange VPN routes directly over an MP-EBGP session. Because the ASBR does not change the next hop in the VPN route received from the MP-EBGP peer, the PEs (MP-IBGP neighbors) in the local AS must have the route destined for the next hop (an ASBR in the other AS). To do this, the ASBR redistributes this route to IGP in the local AS, in order to make the destination ASBR reachable. Then an LSP is established over LDP.

The configuration procedure is as follows:

3. Configure PEs and CEs to exchange routes.
4. Configure IGP and MPLS signaling for ASs.
5. Disable the default RT filter function on ASBRs.
6. Configure the PEs and the ASBR in the same AS to exchange VPN routes.
7. Configure ASBRs to establish an MP-EBGP session.
8. (Optional) Configure a route map for filtering VPN routes.
9. Configure IGP redistribution of the route destined for the ASBR in the other AS.

↘ Method 2: The ASBR Changes the Next Hop in Incoming VPN Routes

When an ASBR receives a VPN route from the peer ASBR in a different AS, the ASBR changes the next hop in the incoming VPN route before sending the route to PEs in the local AS. The PEs and the ASBR in the same AS exchange VPN routes over an MP-IBGP session. The two ASBRs in different ASs exchange VPN routes over an MP-EBGP session. When receiving a VPN route from one ASBR, the other ASBR changes the route's next hop to itself before sending the route to MP-IBGP peers in the local AS.

The configuration procedure is as follows:

7. Configure PEs and CEs to exchange routes.
8. Configure IGP and MPLS signaling for ASs.
9. Disable the default RT filter function on ASBRs.

10. Configure the PEs and the ASBR in the same AS to establish an MP-IBGP session and enable the ASBR to change the next hop in incoming VPN routes to itself.
11. Configure ASBRs to establish an MP-EBGP session.
12. (Optional) Configure a route map for filtering VPN routes.

3.3.2.3 Option C: Multi-hop MP-EBGP Mode

The Option A and Option B solutions implement inter-AS VPN networking. A common feature of the two solutions is that ASBRs maintain and advertise VPN routes. ASBRs may become a bottleneck of network scalability when the ASBR in each AS needs to advertise a large amount of inter-AS VPN routes. The Option C (multi-hop MP-EBGP) solution is developed to address the scalability issue. The solution allows PEs in different ASs to exchange VPN routes directly over a multi-hop MP-EBGP session, removing the need for ASBRs to maintain and distribute VPN routes.

Figure 3-9 Multi-hop MP-EBGP

Features and Limitations

In multi-hop MP-EBGP mode, only PEs maintain VPN routes, whereas ASBRs do not store VPN user information. The configuration procedure is relatively complex. The solution is applicable to inter-AS VPN service provision in large scale.

Implementation

The Option C solution is implemented by the following methods:

- Enable IPv4 label distribution only between EBGP neighbors.
- Enable IPv4 label distribution between EBGP neighbors and between IBGP neighbors.

For Option C scalability, a route reflector (RR) is deployed in each AS, and the RRs between two ASs establish a multi-hop MP-EBGP session to exchange VPN routes. From the deployment perspective, Option C is also called the inter-RR multi-hop MP-EBGP solution.

The configuration of each Option C implementation method is described in the following.

Method 1: Enable IPv4 Label Switching Only Between EBGP Neighbors

In this implementation method, BGP routes must be redistributed using the IGP protocol (for example, OSPF or RIP) on ASBRs, so that each device in one AS has the route destined for each PE in the other AS. LSPs are established by distributing labels over LDP to the routes destined for PEs between ASs. IPv4 label switching is enabled between the directly connected inter-AS ASBRs. BGP assumes the role of MPLS signaling to distribute labels to the routes destined for PEs between ASs for LSP establishment.

The configuration procedure is as follows:

10. Configure PEs and CEs in each AS to exchange routes.
11. Configure IGP and MPLS signaling for ASs.
12. Configure ASBRs to establish an EBGP session in order to distribute labels to IPv4 routes.
13. Configure ASBRs to redistribute to IGP the routes of PEs that are learned over EBGP.
14. Configure a multi-hop MP-EBGP session.

📌 Method 2: Enable IPv4 Label Switching Between EBGP Neighbors and Between IBGP Neighbors

As Method 1 enables IPv4 label switching only between EBGP neighbors, IGP and LDP in one AS need to maintain the routes destined for PEs in the other AS. That is, the inter-AS routes of PEs must be propagated to all devices between ASs. In actual application, for AS security consideration, the routes of PEs in one AS should not be propagated to each device in the other AS. Rather, the routes must be maintained only by BGP and transparent to IGP and LDP in the same AS. To meet this requirement, you can enable IPv4 label switching between EBGP neighbors and between IBGP neighbors.

Different from Method 1, Method 2 does not require IGP on ASBRs to redistribute BGP routes and does not require LDP to distribute labels to BGP routes. LDP is only responsible for LSP establishment in the local AS. However, IPv4 label switching must be enabled between IBGP neighbors and between EBGP neighbors for inter-AS LSP establishment, and PEs must support stacking of three consecutive labels.

The configuration procedure is as follows:

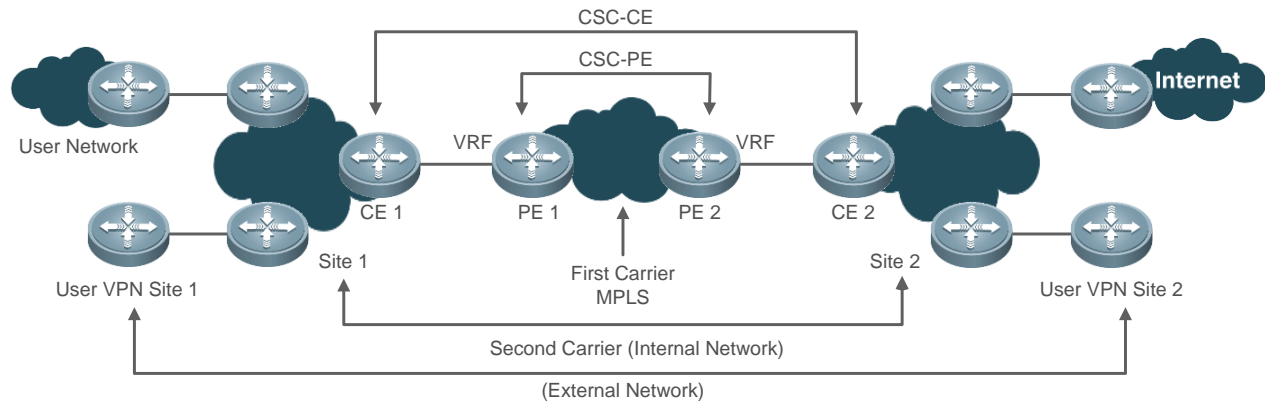

15. Configure PEs and CEs in each AS to exchange routes.
16. Configure IGP and MPLS signaling for ASs.
17. Configure PEs and ASBRs to establish an IBGP session in order to distribute labels to IPv4 routes.
18. Configure ASBRs to establish an EBGP session in order to distribute labels to IPv4 routes.
19. Configure a multi-hop MP-EBGP session.

3.3.3 CSC Service Model

Each site of a basic MPLS VPN is a traditional IP network with a simple structure. A VPN user may also be an SP who leases the VPN service of an MPLS VPN SP and then provides special services to users. In such a case, the MPLS VPN SP is called a provider carrier or first carrier, and the VPN user who also provides services is called a customer carrier or second carrier. Such a networking model is called CSC.

Networking Model

Figure 3-10 CSC Networking Model

➤ First Carrier

A first carrier is also called a provider carrier who provides the MPLS VPN service to second carriers. The PEs of first carriers must support the CSC technology to enable second carriers to provide services to users. The PEs of first carriers that provide the CSC service to second carriers are called CSC-PEs.

➤ Second Carrier

A second carrier is also called a customer carrier who leases the MPLS L3VPN service of a first carrier for building an internal network used to provide services to users. The CEs of the second carrier connected to the first carrier are called CSC-CEs.

➤ Internal Route

Internal routes are routes in the internal network of a second carrier, which are used for interworking between internal network devices. Internal routes are maintained by the second carrier and the PEs of the first carrier.

➤ External Route

As an SP, a second carrier may have its network connected to multiple third-party networks. External routes are the routes connecting the second carrier's network to third-party networks. If the second carrier provides the traditional IP service to users, external routes include the routes of user networks. If the second carrier is connected to the Internet, external routes include Internet routes. If the second carrier provides the MPLS VPN service to users, external routes include users' VPN routes.

The number of external routes is very large. For high scalability, external routes are maintained by second carriers rather than by first carriers.

➤ Private Tunnel

Private tunnels are LSP tunnels established between private network devices. In the CSC model, the LSP tunnels between devices of a second carrier are private tunnels.

➤ Routing and Label Distribution Between PE and CE

High scalability requires minimal routes maintained by first carriers. For this purpose, the CSC model transfers the maintenance of external routes to second carriers, with external traffic traversing the networks of first carriers over private tunnels. The CSC model requires that PEs of first carriers support private tunnels.

The use of private tunnels requires distribution of label binding information between CSC-PEs of first carriers and CSC-CEs of second carriers. A CSC-PE and a CSC-CE use the following protocols to exchange internal routes and distribute labels to internal routes, depending on whether the CSC-PE and CSC-CE are located in the same AS:

- If the CSC-PE and CSC-CE are located in the same AS, IGP is used for exchanging internal routes, and LDP is used for label switching.
- If the CSC-PE and CSC-CE are located in different ASs, EBGP is used for exchanging internal routes, and EBGP-based IPv4 label distribution is enabled for internal route label switching.

Scenario

Second carriers may be Internet service providers (ISPs) or MPLS SPs. The following describes typical application scenarios, which are classified according to the network types and service types of second carriers.

Scenario 1: IP Core Second Carrier

Figure 3-11 Scenario 1: IP Core Second Carrier

In Figure 3-11, the second carrier serves as the IP core offering users access to network services. ASBR1, ASBR2, CE1, and CE2 establish IBGP neighbor relationships to exchange external routes. CE1 and CE2 are RRs that reflect external routes between different sites. Users' Internet access traffic enters the second carrier's network from ASBR1, and exits from ASBR2. Traffic is forwarded over a private LSP tunnel from CE1 to CE2.

Scenario 2: MPLS Core Second Carrier

Figure 3-12 Scenario 2: MPLS Core Second Carrier

In Figure 3-12, the second carrier serves as the MPLS core offering users access to network services. ASBR1 and ASBR2 establish an IBGP neighbor relationship to exchange external routes. Users' Internet access traffic enters the second carrier's network from ASBR1, and exits from ASBR2. Traffic is forwarded from ASBR1 to ASBR2 over a private LSP tunnel.

Scenario 3: MPLS Core Second VPN SP

Figure 3-13 Scenario 3: MPLS Core Second VPN SP

In Figure 3-13, the second carrier serves as the MPLS core offering users access to the MPLS L3VPN service. PE3 and PE4 establish an MP-IBGP neighbor relationship to exchange users' VPN routes. The private LSP between PE3 and PE4 functions as the external tunnel for the user VPN.

3.3.4 OSPF VPN Extended Attributes

OSPF is typically used as an IGP internal routing protocol for users' VPNs in many application cases. No other routing protocols are required if OSPF is implemented between PE and CE, thus simplifying CE configuration and management.

The following describes the OSPF extended attributes between PE and CE.

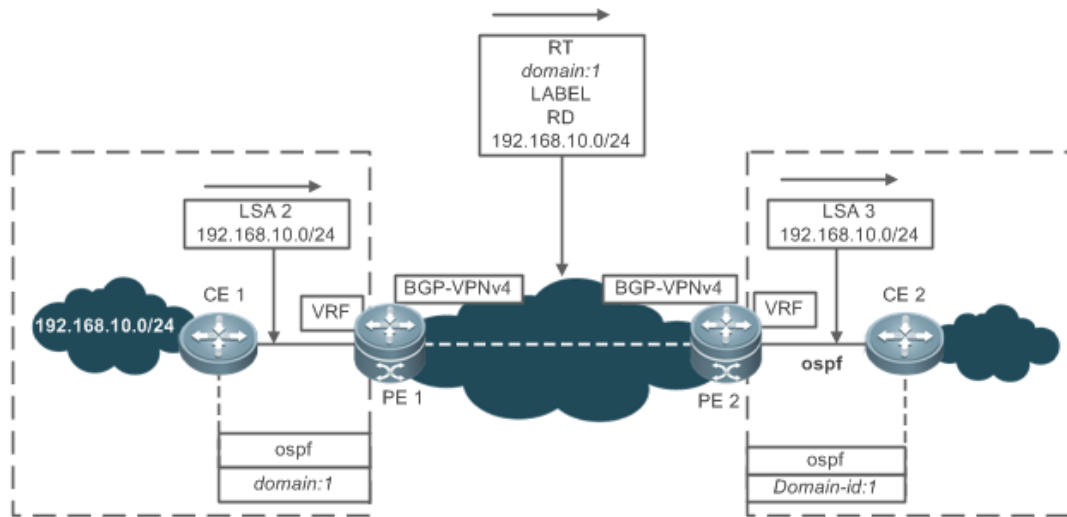

Domain ID

A domain ID indicates the OSPF domain to which a route belongs. When an OSPF route for a VPN site that a CE learns is advertised as a type 1, 2, or 3 link-state advertisement (LSA) to a PE and redistributed to BGP to form a VPN route, the domain ID is also redistributed with the route to BGP and advertised as an extended community attribute of the VPN route. When the peer PE receives the VPN route and redistributes it to a VRF OSPF instance, the domain ID is also redistributed

with the route to the VRF OSPF instance. If the VRF OSPF instance confirms that the domain ID of the route is the same as its domain ID, it advertises the route as an internal route to a CE. If the VRF OSPF instance confirms that the domain ID of the route is different from its domain ID, it advertises the route as an external route to the CE.

In Figure 3-14, CE1 advertises routes in the local OSPF domain as type 2 LSAs to PE1, which then forms VPN routes and advertises the routes to PE2. PE2 redistributes incoming routes to a VRF OSPF instance. Because the domain IDs of the VPN routes are the same as the domain ID of the VRF OSPF instance, the routes are advertised as internal routes to CE2.

Figure 3-14

DN Bit

The down-bit (DN bit) is used for loop detection between PE and CE running OSPF. Loops may occur when a PE advertises a learned VPN route to its connected VPN site and the VPN site transmits the route over OSPF to another connected PE, which then propagates the route.

In Figure 3-15, PE1 advertises the route 192.168.10.0/24 to PE2 and PE3. CE2 advertises the route to CE3 over OSPF, which then advertises the route to PE3. In this way, the route is redistributed to BGP on PE3, which preferentially selects OSPF for route redistribution and converts the route into a VPNv4 route before advertising the route. In this case, a loop may occur.

Figure 3-15

To avoid loops, PEs insert the DN bit as an optional field into type 3, 5, or 7 LSAs before advertising the LSAs to CEs. When other PEs receive LSAs containing the DN bit, OSPF on the PEs exclude the LSAs from OSPF route calculation.

VPN Route Tag

The VPN route tag provides another method of detecting loops between PE and CE running OSPF. When a PE and a CE communicate over OSPF, the corresponding VRF OSPF instance on the PE has a VPN route tag by default. When the VRF OSPF instance imports a VPN route and advertises it as a type 5 or 7 LSA to the CE, the LSA carries the VPN route tag. In an environment where one VPN site is connected to multiple PEs, when a PE receives a type 5 or 7 LSA that carries the same VPN route tag as that of its VRF OSPF instance, the LSA is excluded from OSPF route calculation.

Area Deployment

In normal cases, the link between a PE and a CE can be any OSPF area. If the PE-CE link is a non-0 area, the OSPF area where the CE is located considers the PE as an area border router (ABR). This may cause problems due to the following characteristics of OSPF with the ABR feature:

- The ABR calculates only type 3 LSAs of the backbone area.
- The ABR forwards only type 3 LSAs from the backbone area to other areas.

In Figure 3-16, if the PE-CE link is a non-0 area, the PE redistributes the VPNv4 route advertised over MP-BGP to OSPF and restores the route to a type 3 LSA before advertising it to CE1. Because CE1 does not calculate LSAs of non-backbone areas, the type 3 LSA is not advertised to the router in Area0. As a result, VPN sites may fail to learn routes between each other. Therefore, non-0 areas between PE and CE must be deployed correctly.

Figure 3-16

In L3VPN application, if PEs and CEs exchange VPN routes over OSPF, you are advised not to deploy the backbone area at a VPN site. In the actual condition, if the backbone area has PEs as well as routers of a VPN site, at least one router series product of the VPN site must be connected to a PE, and the CE-PE link must belong to Area0. In this way, inter-area routes and external routes can be transmitted between the PEs and the VPN site.

Sham Link

A sham link is not an actual link, but a virtual link between the VRF tables on two PEs. Like OSPF links, sham links have OSPF interfaces and can be used to send OSPF packets, establish neighbor relationships, and send LSAs. When LSAs are flooded out over sham links, all OSPF route types remain unchanged, as shown in Figure 3-17.

Figure 3-17

The sham link established between VRF OSPF instances on different PEs have the following functions:

- The sham link transmits VPN routes to the peer PE over MP-IBGP, and original OSPF routes are imported on a best-effort basis on the peer PE. The sham link does not support real communication of OSPF topology information. An OSPF link is established over a sham link to connect OSPF instances of various sites and maintain complete topology information.
- Different sites of the same VPN exchange routes over the MPLS backbone network. These sites are connected by a backdoor link to support inter-site communication when the MPLS backbone network is not available. Two sites of a VPN that are located in the same OSPF area and connected by a backdoor link exchange routes over the MPLS backbone network as well as the backdoor link. Because the intra-AS routes exchanged over the backdoor link take

precedence over the inter-AS routes exchanged over the MPLS network, routes of the two sites are forwarded preferentially over the backdoor link. This does not comply with the intention of VPN users connecting to the backdoor link. The sham link is introduced to ensure proper use of the backdoor link.

3.4 Configuration

! Interfaces used by BGP/MPLS IP VPN must be Layer-3 routing interfaces; otherwise, configuration fails.

Configuration	Description
Configuring BGP MPLS IP VPN Basic Functions	(Mandatory) It allows carrier networks to provide the single-AS VPN service.
Configuring the Inter-AS VPN Service Model: Option A	(Optional) It is applicable to carrier networks with light traffic of the inter-AS VPN service.
Configuring an Inter-AS VPN Service Model: Option B	(Optional) It is applicable to carrier networks with heavy traffic of the inter-AS VPN service.
Configuring an Inter-AS VPN Service Model: Option C	(Optional) It is applicable to carrier networks requiring large-scale VPN service provision.
Configuring the CSC Service Model	(Optional) It is applicable to the CSC networking model.
Configuring OSPF VPN Extended Attributes	(Optional) It is applicable to VPN sites that run OSPF.

3.4.1 Configuring BGP MPLS IP VPN Basic Functions

Configuration Effect

Build the BGP/MPLS VPN service in a single AS.

Figure 3-18

Notes

- The LDP router ID must consist of 32 bits.
- The BGP router ID must consist of 32 bits.

- The **mpls ip** and **label-switch** commands must be enabled on PEs' interfaces connected to a public network.

Configuration Steps

The configuration of BGP/MPLS VPN basic functions includes:

- (Mandatory) Configure an MPLS network.
- (Mandatory) Configure a VPN routing instance.
- (Mandatory) Configure PEs to exchange VPN routes.
- (Mandatory) Configure PEs and CEs to exchange routes.
- (Optional) Configure a method of VPN label distribution.
- (Optional) Configure VPN route import/export policies.
- (Optional) Configure static L3VPN FEC to NHLFE (FTN) and incoming label map (ILM).

▾ Configuring an MPLS Network

Before you implement MPLS in the backbone network, configure MPLS-specific LDP on the P and PE devices for public tunnel establishment. The configuration includes configuring LDP on corresponding MPLS devices and enabling MPLS packet forwarding on every interface.

Perform configuration on the P and PE devices according to the following table.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# mpls ip	Enables MPLS globally.
Ruijie(config)# mpls router ldp	Configures LDP and enters LDP configuration mode.
Ruijie(config-mpls-router)# ldp router-id interface loopback id [force]	Configures the LDP router ID, which typically uses the IP address of a loopback interface.
Ruijie(config-mpls-router)# exit	Exits LDP configuration mode.
Ruijie(config)# interface type ID	Enters interface configuration mode.
Ruijie(config-if-type ID)# ip address ip-address mask	Configures the interface IP address.
Ruijie(config-if-type ID)# label-switching	Enables MPLS packet forwarding on the interface connected to the public network.
Ruijie(config-if-type ID)# mpls ip	Enables LDP on the interface.
Ruijie(config-if-type ID)# show running-config	Displays existing configurations.

▾ Configuring a VPN Routing Instance

VPN routing instances are also called VRF tables, which are configured on the PEs. The CEs and the P do not have VRF tables.

To configure a VRF table, you need to define the VRF table, configure RD and RT values for the VRF table, and associate the VRF table with an interface.

Perform configuration on the PEs according to the following table.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# ip vrf vrf-name	Creates a VRF table and enters VRF configuration mode.
Ruijie(config-vrf)# rd rd-value	Configures an RD value.
Ruijie(config-vrf)# route-target { both export import } rt-value	Configures RT values.
Ruijie(config-vrf)# exit	Exits VRF configuration mode.
Ruijie(config-if-type ID)# interface type ID	Enters interface configuration mode.
Ruijie(config-if-type ID)# ip vrf forwarding vrf-name	Associates the VRF table with an interface.
Ruijie(config-if-type ID)# ip address address mask	Configures the interface IP address.
Ruijie(config-if-type ID)# show running-config	Displays existing configurations.

-  After an RD value is defined or BGP VRF is enabled for a VRF table on a PE, the RD value cannot be modified or deleted. To modify the RD value, delete the VRF table, create a new one, and then set its RD value.
-  The RD values of two different VRF tables on a PE must not be the same.
-  After the **ip vrf forwarding vrf-name** command is executed, the IP address of the specified interface is deleted. You need to configure an IP address again in interface configuration mode.

📌 Configuring PEs to Exchange VPN Routes

To configure PEs to exchange VPN routes (not IPv4 routes) over BGP, enter VPN address family configuration mode to enable the capability of transmitting VPN routes to the peer PE.

Perform configuration on the PEs according to the following table.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# router bgp asn-num	Creates BGP and enters BGP configuration mode.
Ruijie(config-router)# neighbor ip-address remote-as asn-number	Configures a BGP session.
Ruijie(config-router)# neighbor ip-address update-source interface-name	Specifies the address of a loopback interface as the source address for the MP-IBGP session.
Ruijie(config-router)# address-family vpnv4	Enters VPN address family configuration mode.
Ruijie(config-router-af)# neighbor ip-address activate	Activates the function of exchanging VPN routes over BGP.
Ruijie(config-router-af)# show running-config	Displays existing configurations.

📌 Configuring PEs and CEs to Exchange Routes

Four methods are available for configuring the VRF tables on PEs and the CEs to exchange routes.

... Method 1: Implement BGP Between PE and CE

After a BGP session is established between PEs, establish a BGP session between PE and CE to connect all CEs over BGP. Redistribute VPN routes between CEs and BGP to build a fully meshed VPN.

Enter VRF address family configuration mode on the PEs and configure a BGP session between PE and CE according to the following table.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# router bgp <i>pe-asn-num</i>	Creates BGP and enters BGP configuration mode.
Ruijie(config-router)# address-family ipv4 vrf <i>vrf-name</i>	Performs configuration and enters BGP VRF address family configuration mode.
Ruijie(config-router-af)# neighbor <i>ip-address remote-as ce-asn-num</i>	Establishes an EBGP session between PE and CE.

- i** If no RD value is defined for the specified VRF table, the system prompts that the RD value is not configured when you run the **address-family ipv4 vrf vrf-name** command, and you are not allowed to enter address family configuration mode under the VRF table.

Configure PE-CE BGP sessions on the CEs and introduce VPN routes to BGP according to the following table.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# router bgp <i>ce-asn-num</i>	Creates BGP and enters BGP configuration mode.
Ruijie(config-router)# neighbor <i>ip-address remote-as pe-asn</i>	Establishes an EBGP session between PE and CE.
Ruijie(config-router)# redistribute ospf <i>ospf-id</i>	Redistributes OSPF routes over BGP.
Ruijie(config-router)# exit	Exits BGP configuration mode.
Ruijie(config)# router ospf <i>ospf-id</i>	Enters OSPF configuration mode.
Ruijie(config-router)# redistribute bgp subnets	Redistributes BGP routes over OSPF.
Ruijie(config-router)# exit	Exits OSPF configuration mode.

- i** Users' VPNs may run any dynamic protocols or use static routes. OSPF is used as an example.

... Method 2: Implement OSPF Between PE and CE

If users' VPNs run OSPF, connect PEs and CEs over OSPF, and no additional configuration is required on the CEs.

On the PEs, configure an OSPF instance for each VRF table connected to a CE, and use the OSPF instance to exchange routes with the CE. By redistributing BGP routes, OSPF transmits VPN routes received from the peer PE to the corresponding CE. By redistributing OSPF routes, BGP transmits to the peer PE the VPN routes that CEs send to the connected PE.

- i** OSPF must be enabled on the CEs' interfaces connected to the PEs, and no passive port (or other restrictions on route exchange) must be configured.

Perform configuration on the PEs according to the following table.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# router ospf <i>ospf-id vrf-name</i>	Creates an OSPF instance and enters OSPF configuration mode.
Ruijie(config-router)# network <i>prefix mask area area-id</i>	Configures OSPF links.
Ruijie(config-router)# redistribute bgp subnets	Redistributes BGP routes over OSPF.
Ruijie(config-router)# exit	Exits OSPF configuration mode.
Ruijie(config)# router bgp <i>asn</i>	Configures BGP and enters BGP configuration mode.
Ruijie(config-router)# address-family ipv4 vrf <i>vrf-name</i>	Enters BGP VRF configuration mode.
Ruijie(config-router-af)# redistribute ospf <i>ospf-id</i>	Redistributes OSPF routes.
Ruijie(config-router-af)# show running-config	Displays existing configurations.

... Method 3: Implement RIP Between PE and CE

If users' VPNs run RIP, connect PEs and CEs over RIP, and no additional configuration is required on the CEs.

The VRF tables on PEs exchange routes with the CEs over RIP. By redistributing BGP routes, RIP transmits VPN routes received from the peer PE to the corresponding CE. By redistributing RIP routes, BGP transmits to the peer PE the VPN routes that CEs send to the connected PE.

-  RIP must be enabled on the CEs' interfaces connected to the PEs, and no restrictions on route exchange must be configured.

Perform configuration on the PEs according to the following table.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# router rip	Creates an RIP instance and enters RIP configuration mode.
Ruijie(config-router)# address-family ipv4 vrf <i>vrf-name</i>	Enters RIP VRF address family configuration mode.
Ruijie(config-router-af)# version 2	Configures the RIP version number.
Ruijie(config-router-af)# network <i>network-number [wildcard]</i>	Configures RIP for CE-PE communication.
Ruijie(config-router-af)# redistribute bgp	Redistributes BGP routes over RIP.
Ruijie(config-router-af)# exit	Exits address family configuration mode.
Ruijie(config)# router bgp <i>asn</i>	Configures BGP and enters BGP configuration mode.
Ruijie(config-router)# address-family ipv4 vrf <i>vrf-name</i>	Enters BGP VRF configuration mode.
Ruijie(config-router-af)# redistribute rip	Redistributes RIP routes.
Ruijie(config-router-af)# show running-config	Displays existing configurations.

... Method 4: Configure Static Routes Between PE and CE

Static routes are typically used in simple network environments.

Point static routes from PE to CE, and redistribute the static routes to BGP VRF tables. Point static routes from CE to PE, and introduce the static routes to users' VPNs.

Perform configuration on the PEs according to the following table.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# ip route vrf <i>vrf-name</i> prefix mask interface-name <i>nexthop</i>	Configures static routes.
Ruijie(config)# router bgp asn	Enters BGP configuration mode.
Ruijie(config-router)# address-family ipv4 vrf <i>vrf-name</i>	Enters BGP VRF address family configuration mode.
Ruijie(config-router-af)# redistribute static	Redistributes static routes.
Ruijie(config-router-af)# show running-config	Displays existing configurations.

 The configuration on the CEs is omitted.

▾ (Optional) Configuring a Method of VPN Label Distribution

The RFC4364 describes two label distribution methods for L3VPN: per-route label distribution and per-VRF label distribution. Per-route label distribution enables fast forwarding, whereby packets are forwarded to the next hop just by querying an ILM table. However, this method requires the maintenance of large-capacity ILM tables. Per-VRF label distribution allows all routes of a VRF table to share a label distributed to the VRF table, thus greatly reducing the ILM table capacity. However, this method is less efficient at forwarding packets than per-route label distribution, because the former requires two table queries. The first query gets the VRF table to which the packet belongs from the ILM table, and the second query gets the packet forwarding route from the VRF table based on the destination IP address.

By default, L3VPN adopts per-VRF label distribution. You can run the **alloc-label** command in VRF configuration mode to change the default label distribution method, and you can also apply different label distribution methods to different VRF tables.

Command	Description
Ruijie# config terminal	Enters global configuration mode.
Ruijie(config)# ip vrf <i>vrf-name</i>	Creates a VRF table and enters VRF configuration mode.
Ruijie(config-vrf)# alloc-label per-vrf	Distributes a label to all routes of the VRF table. All VPN routes distributed over MP-BGP use the same label.
Ruijie(config-vrf)# alloc-label per-route	Distributes a label to each route of the VRF table. Each VPN route distributed over MP-BGP uses a different label.
Ruijie(config-vrf)# show running-config	Displays existing configurations.

 When you change the label distribution method, MP-BGP cancels all VPN routes that have been advertised and re-advertises the routes.

▾ (Optional) Configuring VPN Route Import/Export Policies

You need to define the import RT attribute in VRF configuration mode to specify which routes are imported to VRF tables, and define the export RT attribute to specify which RT attributes are carried in distributed routes. The import and export RT

attributes take effect for all routes. In special application scenarios, you can control the import and export of VPN routes accurately based on policies.

Command	Description
Ruijie# config terminal	Enters global configuration mode.
Ruijie(config)# ip vrf <i>vrf-name</i>	Creates a VRF table and enters VRF configuration mode.
Ruijie(config-vrf)# import map <i>routemap-name</i>	Configures a policy for importing remote VPN routes to local VPN routes based on a route map.
Ruijie(config-vrf)# export map <i>routemap-name</i>	Sets the extended community attribute of the VPN routes distributed from the local end to the remote end based on a route map.
Ruijie(config-vrf)# show running-config	Displays existing configurations.

- i** The rules defined by the **import map** command take effect following the import-specific extended community attribute defined in VRF configuration mode. That is, the VPN routes received from the remote end must have the extended community attribute defined by the **route-target import** command in VRF configuration mode before the routes are filtered based on the rules defined by the **import map** command.

▾ (Optional) Configuring Static L3VPN FTN and ILM

In normal cases, labels are distributed to VPN routes over MP-BGP, and public LSP tunnels are established over LDP in public networks. You can configure static LSPs for VPN label distribution and private LSP tunnel establishment.

... Configuring L3VPN FTN on PEs

Command	Description
Ruijie# config terminal	Enters global configuration mode.
Ruijie(config)# mpls static l3vpn-ftn <i>vrf-name</i> <i>ip-address/mask out-label out-label remote-pe ip-address</i>	Configures a static private FTN, with the forwarding equivalence class (FEC) egress on the other PE. You need to specify a private label and the egress PE. The address of the egress PE is used for public LSP tunnel matching.
Ruijie(config)# mpls static l3vpn-ftn <i>vrf-name</i> <i>fec-prefix/fec-mask local-forward nexthop interface-name</i> <i>nexthop-ip</i>	Configures a static private FTN, with the FEC egress on the local PE. You need to specify the egress for the local PE and the next hop address. (The other VRF table is typically used as the outbound interface and the next hop.) This command is used when multiple VRF tables on the local PE belong to the same VPN.
Ruijie# show running-config	Displays existing configurations.

... Configuring L3VPN ILM on PEs

Command	Description
Ruijie# config terminal	Enters global configuration mode.
Ruijie(config)# mpls static ilm in-label <i>in-label</i> forward-action pop-l3vpn-nexthop vrf-name nexthop interface-name nexthop-ip-address fec ip-address/mask	Configures L3VPN ILM on the PE. You need to specify the incoming label, outbound interface, and next hop address.
Ruijie# show running-config	Displays existing configurations.

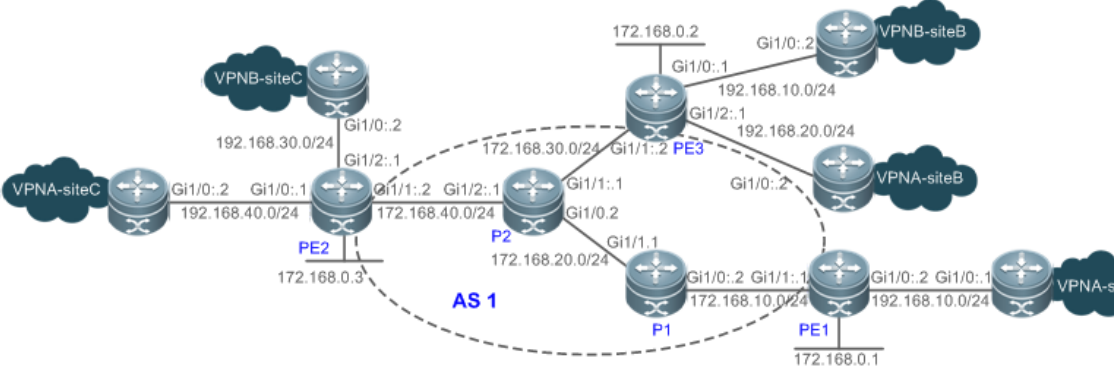

i The static private FTN and ILM configurations take effect after the corresponding public LSP tunnel is established. For how to establish a public LSP tunnel, see "Configuring an MPLS Network" in section 3.4.1 "Configuring BGP MPLS IP VPN Basic Functions." You can establish a public LSP tunnel over LDP or based on static configuration.

Verification

- Run the **show mpls forwarding-table** command to display the corresponding MPLS entries.
- Check that VPN sites can communicate with each other.

Configuration Example

↳ Intranet Configuration

<p>Scenario Figure 3-19</p>	 <p>Requirements: Two VPNs (VPNA and VPNB) exist. VPNA maintains sites at SiteA, SiteB, and SiteC, whereas VPNB maintains sites at SiteB and SiteC. Enable communication between users at different sites of VPNA and between users at different sites of VPNB, and disable communication between VPNA and VPNB.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● On PE1, configure a loopback interface, create a VRF table, define RD and RT values, and associate VPNA with the corresponding interface. Configure BGP, and establish an MP-IBGP session with PE2 and PE3 respectively. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. ● On PE2 and PE3, configure a loopback interface, create two VRF tables named VPNA and VPNB, define RD and RT values, and associate the VRF tables with the corresponding interfaces. Configure BGP, and establish an MP-IBGP session with the neighboring PE. Configure a CE neighbor

	<p>relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.</p> <ul style="list-style-type: none"> ● Configure VPNA-SiteA to establish an EBGP session with PE1. Configure VPNA-SiteB to establish an EBGP session with PE3. Configure VPNA-SiteC to establish an EBGP session with PE2. Configure VPNB-SiteB to establish an EBGP session with PE3. Configure VPNB-SiteC to establish an EBGP session with PE2. ● On P1 and P2, configure a loopback interface, configure backbone MPLS signaling, enable MPLS on the interface connected to the public network, and configure a backbone routing protocol.

➤ [Extranet Configuration](#)

Scenario
Figure 3-20

Requirements: Two VPNs (VPNA and VPNB) exist. Enable communication between users at different sites of VPNA and between users at different sites of VPNB, disable communication between VPNA and VPNB, and allow VPNA and VPNB to access partial shared resources. In Figure 3-20, VPNA and VPNB need to access the resources of VPN-SiteA.

Configuration Steps

- On PE1, configure a loopback interface, create a VRF table named VPN_EXTRA, define RD and RT values, and associate the VRF table with the corresponding interface. Configure BGP, and establish an MP-IBGP session with PE2 and PE3 respectively. Configure the capability of exchanging routes with the CE over OSPF. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.
- On PE2 and PE3, configure a loopback interface, create two VRF tables named VPNA and VPNB, define RD and RT values, and associate the VRF tables with the corresponding interfaces. Configure BGP, and establish an MP-IBGP session with PE3 or PE2. Configure the capability of exchanging VPN routes with the CEs over OSPF. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.
- Configure OSPF on VPNA-SiteA, VPNA-SiteB, VPNA-SiteC, VPNB-SiteB, and VPNB-SiteC for exchanging routes with PEs.
- On P1 and P2, configure a loopback interface, configure backbone MPLS signaling, enable MPLS on the interface connected to the public network, and configure a backbone routing protocol.

PE1

```

PE1# configure terminal
PE1(config)# interface loopback 0
PE1(config-if-Loopback 0)# ip address 172.168.0.1 255.255.255.255

PE1# configure terminal
PE1(config)# ip vrf VPN_EXTRA
PE1(config-vrf)# rd 1:100

P2	PE1, PE2, PE3, and P1 are pingable.

Hub-and-Spoke Configuration

Scenario
Figure 3-21

Requirements: Intra-VPN data cannot be exchanged directly, but must be exchanged over a control center. Only the control center has the right to know the resources of the VPN. Users of the VPN can access the resources only with the control center's permission. In Figure 3-21, VPNA-SiteA must access the resources of VPNA-SiteB over the control center VPNA-SiteC.

Configuration Steps

- On PE1, configure a loopback interface, create a VRF table named spoke1, define RD and RT values, and associate VPNA with the corresponding interface. Configure BGP, and establish an MP-IBGP session with PE2. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.
- On PE3, configure a loopback interface, create a VRF table named spoke2, define RD and RT

	<p>values, and associate the VRF table with the corresponding interface. Configure BGP, and establish an MP-IBGP session with PE2. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.</p> <ul style="list-style-type: none"> ● On PE2, configure a loopback interface, create two VRF tables named from-spoke and from-hub, define RD and RT values, and associate the VRF tables with the corresponding interfaces. Configure BGP, and establish an MP-IBGP session with PE1 and PE3 respectively. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. ● Configure VPNA-SiteA, VPNA-SiteB, and VPNA-SiteC to establish an EBGP session with PEs.

VPNA-SiteC	VPNA-SiteA and VPNA-SiteB are pingable.

Scenario
Figure 3-22

Requirements: Disable inter-VPN communication, and configure VPNs to access the Internet over a single device. In Figure 3-22, VPN1 and VPN2 must access the Internet over PE1, but the two VPNs are not allowed to communicate with each other.

Two isolation methods are available: centralized isolation control and distributed isolation control.

In centralized isolation control, to allow new VPN sites to access the Internet over a single egress, you only need to add filter rules on the egress CE, without the need to modify the configurations of other VPN sites.

This method provides good scalability. The disadvantage is that the isolated traffic is discarded only on the egress CE, which wastes network bandwidth.

Configuration Steps

- On PE2, configure a loopback interface, create a VRF table named VPN2, define RD and RT values, and associate the VRF table with the corresponding interface. Configure the capability of exchanging routes with CE2 over OSPF. Configure an IBGP neighbor relationship with PE1 for IP route distribution. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.
- On CE2, configure the IP address of the interface connected to PE2, and configure the capability of exchanging routes with PE2 over OSPF.
- On PE3, configure a loopback interface and create a VRF table named VPN1. Assume that the export and import RT attributes of VPN1 are both 1: 200. Define RD and RT values, and associate the VRF table with the corresponding interface. Configure the capability of exchanging routes with CE3 over OSPF. Configure an IBGP neighbor relationship with PE1 for IP route distribution. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.
- On PE1, configure a loopback interface and create a trunk interface. Create a VRF table named vrf_out, define RD and RT values, and associate the VRF table with the corresponding interface. Configure a default route destined for the Internet. Create a VRF table named vrf_in, define RD and RT values, and associate the VRF table with the corresponding interface. Configure the capability of exchanging routes with CE1 over EBGP. Configure an IBGP neighbor relationship with PE2 and PE3 respectively. Configure the route exchange function of the vrf_out VRF table. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.
- On CE1, create sub-interfaces, configure an EBGP neighbor relationship with PE1, create an access

control list (ACL), and configure ACL application on the Gi0/1.10 sub-interface.

 This example uses the configuration of the switch virtual interface (SVI) and the 802.1Q sub-interface to describe how to connect PE1 and CE1. Some devices may not support the two interfaces. PE1 and CE1 can be connected by any two links (physical or logical) based on two routing adjacencies between them. You can select a suitable connection method according to the actual condition.

➤ Distributed Isolation Control at the Internet Egress

Figure 3-23

The diagram illustrates a network topology for distributed isolation control. On the left, the Internet is connected to CE1 (20.10.10.0/24) via Gi0/1. CE1 connects to PE1 (Lo:1.1.1.1) via Gi1/3. PE1 connects to PE2 (Lo:2.2.2.2) via Gi1/2 and to PE3 (Lo:3.3.3.3) via Gi1/1. PE2 connects to CE2 (17.11.0.0/24) via Gi0/1 and Gi1/2. PE3 connects to CE3 (17.10.0.0/24) via Gi0/1 and Gi1/1. VPN1 and VPN2 are connected to CE3 and CE2 respectively. The diagram also shows various interfaces and IP addresses for the PE and CE devices.

Requirements: Disable inter-VPN communication, and configure VPNs to access the Internet over a single device. In Figure 3-23, VPN1 and VPN2 must access the Internet over PE1, but the two VPNs are not allowed to communicate with each other.

Two isolation methods are available: centralized isolation control and distributed isolation control. In distributed isolation control, to allow new VPN sites to access the Internet over a single egress, you need to add filter rules on the CEs for the original VPN sites that also access the Internet over the same egress. This method has poor scalability. The advantage is that traffic is discarded on the CEs for VPN sites, which saves network bandwidth.

Configuration Steps	<ul style="list-style-type: none"> ● On PE1, configure a loopback interface, create a VRF table named vrf_net, define RD and RT values, and associate the VRF table with the corresponding interface. Configure a default route destined for the Internet. Configure the capability of exchanging routes with CE1 over EBGP. Configure an IBGP neighbor relationship with PE2 and PE3 respectively. Configure the route exchange function of the vrf_net VRF table. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. ● On CE1, configure an EBGP neighbor relationship with PE1. ● On PE2, configure a loopback interface, create a VRF table named VPN2, define RD and RT values, and associate the VRF table with the corresponding interface. Configure the capability of exchanging routes with CE2 over OSPF. Configure an IBGP neighbor relationship with PE1 for IP route distribution. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. ● On CE2, create an ACL, configure ACL application on a sub-interface, configure the capability of exchanging routes with PE2, and configure a default static route. ● On PE3, configure a loopback interface and create a VRF table named VPN1. Assume that the export and import RT attributes of VPN1 are both 1: 200. Define RD and RT values, and associate the VRF table with the corresponding interface. Configure the capability of exchanging routes with CE3 over OSPF. Configure an IBGP neighbor relationship with PE1 for IP route distribution. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. ● On CE3, create an ACL, configure ACL application on a sub-interface, configure the capability of exchanging routes with PE3, and configure a default static route.

Multi-role Host Configuration

Scenario
Figure 3-24

Common hosts can only access other hosts of the same VPN site, whereas multi-role hosts can access other hosts of multiple VPNs. In Figure 3-24, PC1 and PC2 are located at a site of VPN1. PC2 is a multi-role host able to access the hosts at the sites of VPN1 and VPN2, whereas PC1 can only access hosts at the same site of VPN1.

Configuration Steps	<ul style="list-style-type: none">● Configure an MPLS backbone network.● Configure an MPLS L3VPN network.● Configure a multi-role host to access the VRF tables named VPN_MR for VPN1 and VPN2 respectively, and advertise the route of the multi-role host to other VPNs.● Configure policy-based routing (PBR) to redirect the access packets sent by the multi-role host to the VPN_MR VRF table.● Configure a default route on CE1.

➤ MCE-based Hierarchy VPN Configuration

<p>Scenario Figure 3-25</p>	<p>A multi-VPN-instance customer edge (MCE) is deployed to reconstruct the single-plane MPLS L3VPN network into a hierarchical network. Figure 3-25 shows the network topology. The MCE stores the routes of the connected VPN sites and the default routes distributed by PE2, but does not store the routes of other VPN sites. This poses relatively low requirements on capacity and performance. PE1 and PE2 must store all VPN routes, which poses relatively high requirements on capacity and performance.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● (MPLS network configuration) Configure interface addresses and OSPF on PE1 and PE2, and configure the MPLS feature. ● (MPLS L3VPN network configuration) Configure CE-to-PE access on PE1, PE2, CE1, and CE2. Configure MP-IBGP on PE1 and PE2. ● Configure the MCE and the connected CEs. ● Configure default route distribution for the MCE.
<p>PE1</p>	<pre>PE1#configure terminal</pre>

↳ Hierarchy VPN Configuration Based on BGP Routing Policies

<p>Scenario Figure 3-26</p>	 <p>BGP routing policies are implemented to reconstruct the single-plane MPLS L3VPN network into a hierarchical network. Figure 3-26 shows the network topology. PE1 and PE2 are lower-layer PEs that store only the routes of associated VPN sites and the default routes advertised by the upper-layer PEs. PE3 and PE4 are upper-layer PEs that store all VPN routes. PE3 is the upper-layer PE for PE1 and PE2.</p>
---	---

Configuration Steps	<ul style="list-style-type: none"> ● (MPLS network configuration) Configure interface addresses and OSPF on PE1, PE2, PE3, and PE4, and configure the MPLS feature. ● (MPLS L3VPN network configuration, with PE3 functioning as an RR) Configure CE-to-PE access on the PEs and CEs. Configure corresponding VRF tables on PE3, because PE3 needs to store VPN routes though it is not connected to any VPN site. Configure MP-IBGP on PE1, PE2, PE3, and PE4. ● Configure routing policies on PE3 to restrict VPN route advertisement to PE1 and PE2. ● Configure default VPN routes on PE3 and advertise the routes to PE1 and PE2 (do not advertise the routes to PE4). ● Configure VRF OSPF on PE1 and PE2 for default route advertisement.

Common Errors

- The router ID does not consist of 32 bits, causing the failure to establish LDP and BGP neighbor relationships.

3.4.2 Configuring an Inter-AS VPN Service Model: Option A

Configuration Effect

Build the BGP/MPLS VPN service across ASs.

In the Option A solution, the ASBR in each AS creates a VRF table for every VPN that requires inter-AS communication and binds an interface to the VRF table. The VRF tables between ASBRs exchange VPN routes over the bound interfaces.

Figure 3-27 VRF-to-VRF Inter-AS VPN

i The Option A solution requires that ASBRs configure and bind an interface (a logical sub-interface) to every VPN that requires inter-AS communication. The number of bound interfaces must be at least equal to the number of the VPNs. In addition, VPNs must be configured one by one on the ASBRs. This causes scalability issues. The creation of sub-interfaces for individual VPNs also poses additional requirements on ASBRs. Therefore, the Option A solution is applicable to networks with few VPNs that require inter-AS communication.

Notes

- The LDP router ID must consist of 32 bits.
- The BGP router ID must consist of 32 bits.
- ASBRs must configure and bind an interface to every VPN that requires inter-AS communication.

Verification

- Verify that CE3 is pingable but CE2 and CE4 are unpingable from CE1.
- Verify that CE4 is pingable but CE1 and CE3 are unpingable from CE2.
- Verify that CE1 is pingable but CE2 and CE4 are unpingable from CE3.
- Verify that CE2 is pingable but CE1 and CE3 are unpingable from CE4.

Configuration Steps

For how to configure the Option A solution, see section 3.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

Common Errors

No routing protocol is enabled between PE and CE if no VRF table is bound to an interface using the **ip vrf forwarding vrf_name** command. As a result, the **show ip route vrf vrf_name** command output does not contain any route at the CE end.

3.4.3 Configuring an Inter-AS VPN Service Model: Option B

Configuration Effect

Build the BGP/MPLS VPN service across ASs.

In the Option B solution, a single-hop MP-EBGP session is established between ASBRs for direct distribution of VPN routes.

Figure 3-28 Option B Inter-AS VPN

i The Option B solution removes the need to allocate sub-interfaces to sites of each VPN and the need to establish inter-AS LSPs. Instead, VPN routes are transmitted directly between single-hop MP-EBGP neighbors. Because VPN routes are stored and propagated by ASBRs between ASs, the ASBRs are under great burden when handling a large amount of VPN routes. The ASBRs also need to forward public IP packets. This poses high requirements on ASBRs. Because ASBRs disable the RT filter function for handling incoming VPN routes, the VPN routes on a PE may be propagated to the ASBR in a different AS, which may cause VPN route leakage. To address this problem, SPs that exchange VPN routes must implement a confidence-based routing protocol, enabling ASBRs to trust each other and implement route filtering policies. The Option B solution is applicable to networks with many VPNs that require inter-AS communication.

Notes

- The LDP router ID and BGP router ID must consist of 32 bits.
- ASBRs establish a single-hop EBGP session to exchange VPN routes. ASBRs may or may not change the next hop in VPN routes sent to the peer.

Implementation

The Option B solution is implemented by the following methods:

- The ASBR retains the next hop in incoming VPN routes.
- The ASBR changes the next hop in incoming VPN routes.

The two methods are described in the following.

3.4.3.1 Method 1: The ASBR Retains the Next Hop in Incoming VPN Routes

When an ASBR receives a VPN route from the peer ASBR in a different AS, the ASBR sends the VPN route with the next hop unchanged to its MP-IBGP neighbors in the local AS. The PEs and the ASBR in the same AS exchange VPN routes over

an MP-IBGP session, and two ASBRs exchange VPN routes directly over an MP-EBGP session. Because the ASBR does not change the next hop in the VPN route received from the MP-EBGP peer, the PEs (MP-IBGP neighbors) in the local AS must have the route destined for the next hop (an ASBR in the other AS). To do this, the ASBR redistributes this route to IGP in the local AS, in order to make the destination ASBR reachable. Then an LSP is established over LDP.

Configuration Steps

- (Mandatory) Configure PEs and CEs to exchange routes.
- (Mandatory) Configure IGP and MPLS signaling for ASs.
- (Mandatory) Disable the default RT filter function on ASBRs.
- (Mandatory) Configure the PEs and the ASBR in the same AS to exchange VPN routes.
- (Mandatory) Configure ASBRs to establish an MP-EBGP session.
- (Optional) Configure a route map for filtering VPN routes.
- (Mandatory) Configure IGP redistribution of the route destined for the ASBR in the other AS.

↘ Configuring PEs and CEs to Exchange Routes

For details, see "Configuring PEs and CEs to Exchange Routes" in section 3.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

↘ Configuring IGP and MPLS Signaling for ASs

For details, see "Configuring an MPLS Network" in section 3.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

↘ Disabling the Default RT Filter Function on ASBRs

By default, a PE rejects the VPN route received from the peer PE or an ASBR if the route is not imported to any of its VRF tables. To enable ASBRs to accept all VPN routes from other PEs or ASBRs without checking whether the VPN routes are imported to local VRF tables, you need to disable the RT filter function on ASBRs.

Perform configuration in privileged mode according to the following table.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# router bgp <i>asn-number</i>	Configures BGP and enters BGP configuration mode.
Ruijie(config-router)# no bgp default route-target filter	Disables the RT filter function.
Ruijie(config-router)# show running-config	Displays existing configurations.

↘ Configuring the PEs and the ASBR in the Same AS to Exchange VPN Routes

For details, see "Configuring PEs to Exchange VPN Routes" in section 3.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

↘ Configuring ASBRs to Establish an MP-EBGP Session

Configure inter-AS ASBRs to establish a single-hop MP-EBGP session in order to distribute VPN routes.

Perform configuration in privileged mode according to the following table.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# router bgp <i>asn-number</i>	Configures BGP and enters BGP configuration mode.
Ruijie(config-router)# neighbor <i>asbr-address</i> remote-as <i>asbr-asn-number</i>	Configures an EBGP session between ASBRs.
Ruijie(config-router)# address-family vpnv4	Enters BGP VPN address family configuration mode.
Ruijie(config-router-af)# neighbor <i>asbr-address</i> activate	Enables the capability of exchanging VPN routes between peers.
Ruijie(config-router-af)# show running-config	Displays existing configurations.

-  To forward MPLS packets over the link between ASBRs, run the **label-switching** command to enable MPLS packet forwarding on the interfaces connected between the ASBRs.
-  If ASBRs use the loopback interface address with a 32-bit mask (instead of a direct link address) as the source address for establishing an MP-EBGP session, do the following: (1) run the **neighbor ebgp-multi-hop** command to enable multi-hop EGBP; (2) configure a loopback static route destined for the peer end between ASBRs; (3) enable LDP or configure static FTN (set the outgoing label to 3, indicating that the ASBR is the penultimate hop).

▾ (Optional) Configuring a Route Map for Filtering VPN Routes

For AS security consideration, ASBRs are configured to send or receive only particular VPN routes based on specified policies. This security mechanism can be implemented using the RT extended community attribute for VPN route filtering. For ASBRs that disable the default RT filter function and therefore store all VPN routes, you can configure VPN routing policies to enable the ASBRs to receive only the inter-AS VPN routes from the PEs in the local AS, thus reducing the capacity burden on the ASBRs.

Configure filter policies in privileged mode according to the following table.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# ip extcommunity-list standard <i>extcommunity-name</i> <i>extcommunity-number</i> { permit deny } <i>rt</i> <i>rt-value</i>	Creates an extcommunity attribute list.
Ruijie(config)# show ip <i>extcommunity-list</i> [<i>list-number</i> <i>list-name</i>]	Verifies the configured extcommunity attribute list.
Ruijie(config)# route-map <i>route-map-name</i> permit [<i>number</i>]	Creates a route map and enters route map configuration mode.
Ruijie(config-route-map)# match extcommunity <i>extcommunity-name</i> <i>extcommunity-number</i>	Configures RT matching rules for the route map.
Ruijie(config-route-map)# show route-map <i>route-map-name</i>	Displays the route map.
Ruijie(config-route-map)# exit	Exits route map configuration mode.
Ruijie(config)# router bgp <i>as-num</i>	Configures BGP and enters BGP configuration mode.

Ruijie(config-router)# address-family vpnv4	Enters VPN address family configuration mode.
Ruijie(config-router-af)# neighbor peer-address route-map route-map-name in	Filters the VPN routes received from the ASBR in the other AS.
Ruijie(config-router-af)# neighbor peer-address route-map route-map-name out	Filters the VPN routes sent to the ASBR in the other AS.
Ruijie(config-router-af)# show running-config	Displays existing configurations.

📌 Configuring IGP Redistribution of the Route Destined for the ASBR in the Other AS

If the ASBR in one AS retains the next hop in incoming VPN routes, the IBGP peers (PEs) in the AS learn the VPN routes with the next hop still being the ASBR in the other AS. Therefore, the PEs must learn the route destined for the next hop. On the ASBRs that establish a single-hop MP-EBGP session enabled with BGP label distribution to IPv4 or VPN routes, MP-BGP automatically generates a direct host route (with a 32-bit mask) destined for the peer ASBR and an FTN entry (the outgoing label is 3), so that the tunnel egress is not terminated on the local ASBR. To allow the PEs to learn the route destined for the ASBR in the other AS, you only need to configure the ASBR in the local AS to redistribute the route to local IGP.

Perform configuration in privileged mode according to the following table.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# router igp	Enters IGP (OSPF, RIP, or IS-IS) configuration mode.
Ruijie(config-router)# redistribute connected subnets	Redistributes the direct segment route.
Ruijie(config-router)# show running-config	Displays existing configurations.

Verification

- Verify that CE3 is pingable but CE2 and CE4 are unpingable from CE1.
- Verify that CE4 is pingable but CE1 and CE3 are unpingable from CE2.
- Verify that CE1 is pingable but CE2 and CE4 are unpingable from CE3.
- Verify that CE2 is pingable but CE1 and CE3 are unpingable from CE4.

Configuration Example

📌 Inter-VPN Option B: Next Hop Unchanged

Figure 3-29

Requirements: A VPN has sites in two ASs. Enable inter-AS communication between the sites.

Configuration Steps

- On PE1-AS1, configure a loopback interface, create a VRF table named VPN1, define RD and RT values, and associate the VRF table with the corresponding interface. Configure BGP, and establish an MP-IBGP session with ASBR1. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.
- On PE1-AS2, configure a loopback interface, create a VRF table named VPN1, define RD and RT values, and associate the VRF table with the corresponding interface. Configure BGP, and establish an MP-IBGP session with ASBR2. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.
- On P1-AS1, configure a loopback interface, configure backbone MPLS signaling, enable MPLS on the interface connected to the public network, and configure a backbone routing protocol.
- On ASBR1, configure a loopback interface, configure BGP, and disable the BGP RT filter function. Establish a neighbor relationship with P1-AS1 and ASBR2 respectively. Configure MPLS signaling and enable MPLS on the interface connected to the public network. Configure OSPF for the backbone network to transmit routes, and redistribute the direct segment route. Configure the IP address of the interface connected to ASBR2, and enable label forwarding on the interface.
- On ASBR2, configure a loopback interface, configure BGP, and disable the BGP RT filter function. Establish a neighbor relationship with PE1-AS2 and ASBR1 respectively. Configure MPLS signaling and enable MPLS on the interface connected to the public network. Configure OSPF for the backbone network to transmit routes, and redistribute the direct segment route. Configure the IP address of the interface connected to ASBR1, and enable label forwarding on the interface.

PE1-AS1

```

--------------	---

Common Errors

- LDP sessions fail to be established, or the BGP RT filter function is not disabled. The direct subnet route is not redistributed to OSPF (that is, the **redistribute connected subnets** command is not executed); as a result, sites of CE-VPN1 are unpingable between each other.

3.4.3.2 Method 2: The ASBR Changes the Next Hop in Incoming VPN Routes

When an ASBR receives a VPN route from the peer ASBR in a different AS, the ASBR changes the next hop in the incoming VPN route before sending the route to PEs in the local AS. The PEs and the ASBR in the same AS exchange VPN routes over an MP-IBGP session. The two ASBRs in different ASs exchange VPN routes over an MP-EBGP session. When receiving a VPN route from one ASBR, the other ASBR changes the route's next hop to itself before sending the route to MP-IBGP peers in the local AS.

Configuration Steps

- (Mandatory) Configure PEs and CEs to exchange routes.
- (Mandatory) Configure IGP and MPLS signaling for ASs.
- (Mandatory) Disable the default RT filter function on ASBRs.
- (Mandatory) Configure the PEs and the ASBR in the same AS to establish an MP-IBGP session and enable the ASBR to change the next hop in incoming VPN routes to itself.
- (Mandatory) Configure ASBRs to establish an MP-EBGP session.
- (Optional) Configure a route map for filtering VPN routes.

📄 Configuring PEs and CEs to Exchange Routes

For details, see "Configuring PEs and CEs to Exchange Routes" in section 3.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

📄 Configuring IGP and MPLS Signaling for ASs

For details, see "Configuring an MPLS Network" in section 3.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

📄 Disabling the Default RT Filter Function on ASBRs

For details, see "Disabling the Default RT Filter Function on ASBRs" in section 3.4.3.1 "Method 1: The ASBR Retains the Next Hop in Incoming VPN Routes."

↘ **Configuring the PEs and the ASBR in the Same AS to Establish an MP-IBGP Session and Enabling the ASBR to Change the Next Hop in Incoming VPN Routes to Itself**

By default, when receiving a VPN route from the MP-EBGP peer, an ASBR does not change the next hop in the VPN route but sends the route as it is to MP-IBGP peers. You can configure the ASBR to change the next hop to itself. In this way, the PEs in the local AS do not need to know the address of the ASBR in the other AS. Compared with Method 1, Method 2 requires the additional configuration of next hop change.

Perform configuration in privileged mode according to the following table.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# router bgp <i>asn-num</i>	Configures BGP and enters BGP configuration mode.
Ruijie(config-router)# neighbor <i>pe-address</i> remote-as <i>asn-num</i>	Establishes an IBGP session with PEs.
Ruijie(config-router)# neighbor <i>pe-address</i> update-source <i>interface-name</i>	Specifies the local loopback interface as the source address for the IBGP session.
Ruijie(config-router)# address-family vpnv4	Enters BGP VPN address family configuration mode.
Ruijie(config-router-af)# neighbor <i>pe-address</i> activate	Enables the capability of exchanging VPN routes between peers.
Ruijie(config-router-af)# neighbor <i>pe-address</i> next-hop-self	Configures the ASBR to change the next hop in incoming VPN routes to itself before sending the routes to IBGP peers.
Ruijie(config-router-af)# show running-config	Displays existing configurations.

↘ **Configuring ASBRs to Establish an MP-EBGP Session**

For details, see "Configuring ASBRs to Establish an MP-EBGP Session" in section 3.4.3.1 "Method 1: The ASBR Retains the Next Hop in Incoming VPN Routes."

↘ **(Optional) Configuring a Route Map for Filtering VPN Routes**

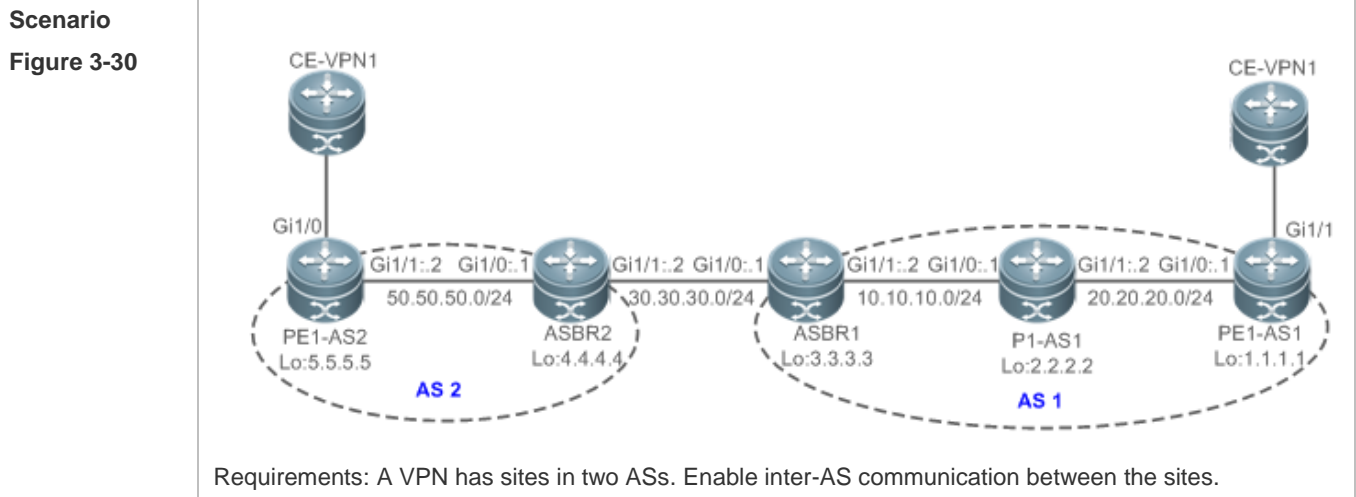

For details, see "Configuring a Route Map for Filtering VPN Routes" in section 3.4.3.1 "Method 1: The ASBR Retains the Next Hop in Incoming VPN Routes."

Verification

Run the ping command to check the connection between sites of the same VPN.

Configuration Example

↘ **Inter-VPN Option B: Next Hop Changed**

Configuration Steps

- On PE1-AS1, configure a loopback interface, create a VRF table named VPN1, define RD and RT values, and associate the VRF table with the corresponding interface. Configure BGP, and establish an MP-IBGP session with ASBR1. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.
- On PE1-AS2, configure a loopback interface, create a VRF table named VPN1, define RD and RT values, and associate the VRF table with the corresponding interface. Configure BGP, and establish an MP-IBGP session with ASBR2. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.
- On P1-AS1, configure a loopback interface, configure backbone MPLS signaling, enable MPLS on the interface connected to the public network, and configure a backbone routing protocol.
- On ASBR1, configure a loopback interface, configure BGP, and disable the BGP RT filter function. Establish a neighbor relationship with PE1-AS1 and ASBR2 respectively. Configure MPLS signaling and enable MPLS on the interface connected to the public network. Configure OSPF for the backbone network to transmit routes, and redistribute the direct segment route. Configure the IP address of the interface connected to ASBR2, and enable label forwarding on the interface. Configure ASBR1 to change the next hop in VPN routes to itself before sending the routes to IBGP neighbors.
- On ASBR2, configure a loopback interface, configure BGP, and disable the BGP RT filter function. Establish neighbor relationships with PE1-AS2 and ASBR1. Configure MPLS signaling and enable MPLS on the interface connected to the public network. Configure OSPF for the backbone network to transmit routes, and redistribute the direct segment route. Configure the IP address of the interface connected to ASBR1, and enable label forwarding on the interface. Configure ASBR2 to change the next hop in VPN routes to itself before sending the routes to IBGP neighbors.

Common Errors

- LDP sessions fail to be established, or the BGP RT filter function is not disabled. The ASBRs do not change the next hop in incoming VPN routes to itself before sending the routes to IBGP neighbors; as a result, sites of CE-VPN1 are unpingable between each other.

3.4.4 Configuring an Inter-AS VPN Service Model: Option C

Configuration Effect

Build the BGP/MPLS VPN service across ASs.

In the Option C solution, PEs in different ASs establish a multi-hop MP-EBGP session to directly exchange VPN routes.

Figure 3-31 Multi-hop MP-EBGP

i In multi-hop MP-EBGP mode, only PEs maintain VPN routes, whereas ASBRs do not store VPN user information. The configuration procedure is relatively complex. The solution is applicable to inter-AS VPN service provision in large scale.

Notes

- The LDP router ID must consist of 32 bits.
- The BGP router ID must consist of 32 bits.

Implementation

The Option C solution is implemented by the following methods:

- Enable IPv4 label distribution only between EBGP neighbors.
 - Enable IPv4 label distribution between EBGP neighbors and between IBGP neighbors.
 - Establish a multi-hop MP-EBGP session between RRs.
-
- i** For Option C scalability, an RR is deployed in each AS, and the RRs between two ASs establish a multi-hop MP-EBGP session to exchange VPN routes. From the deployment perspective, Option C is also called the inter-RR multi-hop MP-EBGP solution.
-

The configuration of each Option C implementation method is described in the following.

3.4.4.1 Method 1: Enable IPv4 Label Switching Only Between EBGP Neighbors

In this implementation method, BGP routes must be redistributed using the IGP protocol (for example, OSPF or RIP) on ASBRs, so that each device in one AS has the route destined for each PE in the other AS. LSPs are established by distributing labels over LDP to the routes destined for PEs between ASs. IPv4 label switching is enabled between the directly connected inter-AS ASBRs. BGP assumes the role of MPLS signaling to distribute labels to the routes destined for PEs between ASs for LSP establishment.

Configuration Steps

- (Mandatory) Configure PEs and CEs in each AS to exchange routes.
- (Mandatory) Configure IGP and MPLS signaling for ASs.
- (Mandatory) Configure ASBRs to establish an EBGP session in order to distribute labels to IPv4 routes.
- (Mandatory) Configure ASBRs to redistribute to IGP the routes of PEs that are learned over EBGP.
- (Mandatory) Configure a multi-hop MP-EBGP session.

↘ [Configuring PEs and CEs to Exchange Routes](#)

For details, see "Configuring PEs and CEs to Exchange Routes" in section 3.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

↘ [Configuring IGP and MPLS Signaling for ASs](#)

For details, see "Configuring an MPLS Network" in section 3.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

↘ [Configuring ASBRs to Establish an EBGP Session in Order to Distribute Labels to IPv4 Routes](#)

Establish an EBGP session between inter-AS ASBRs, and enable IPv4 label distribution. To introduce the routes of PEs to BGP, you can use the **network** command in BGP IPv4 address family configuration mode or the IGP redistribution command. For AS security consideration, IPv4 route distribution policies must be configured on ASBRs. You can define a route map to specify which routes are distributed to neighbors and whether the outgoing routes carry a label. Route maps can also be configured at the receive end.

Perform configuration in privileged mode according to the following table.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# router bgp <i>asn-num</i>	Configures BGP and enters BGP configuration mode.
Ruijie(config-router)# neighbor <i>asbr-address</i> remote-as <i>asbr-asn-num</i>	Establishes an EBGP session between ASBRs.
Ruijie(config-router)# address-family ipv4	Enters BGP IPv4 address family configuration mode.
Ruijie(config-router-af)# neighbor <i>asbr-address</i> send-label	Configures the function of exchanging labeled IPv4 routes with the peer ASBR in the other AS.
Ruijie(config-router-af)# network <i>pe-address</i> mask <i>mask</i>	(Optional) Configures the addresses of the PEs in the local AS that require BGP routing table injection, that is, the host routes destined for the PEs in the local AS.
Ruijie(config-router-af)# neighbor <i>asbr-address</i> route-map <i>routemap-name</i> out	(Optional) Configures route distribution policies. You can define a route map to specify which routes are distributed to neighbors and whether the outgoing routes carry a label.
Ruijie(config-router-af)# neighbor <i>asbr-address</i> route-map <i>routemap-name</i> in	(Optional) Configures route distribution policies. You can define a route map to specify reception of only labeled routes.
Ruijie(config-router-af)# show running-config	Displays existing configurations.

-  To forward MPLS packets over the link between ASBRs, run the **label-switching** command to enable MPLS packet forwarding on the interfaces connected between the ASBRs.
-  If ASBRs use the loopback interface address with a 32-bit mask (instead of a direct link address) as the source address for establishing an MP-EBGP session, do the following: (1) run the **neighbor ebgp-multi-hop** command to enable multi-hop EGBP; (2) configure a loopback static route destined for the peer end between ASBRs; (3) enable LDP or configure static FTN (set the outgoing label to 3, indicating that the ASBR is the penultimate hop).

In actual application, the ASBRs only need to distribute labels to the routes of PEs that carry the inter-AS VPN service. You can use the **set mpls-label** rule to enable such label distribution. This rule means setting a label for routes. You can create a route map to specify sending of only the inter-AS routes of PEs to the peer ASBR and set labels for those routes, and then run the **neighbor peer-address route-map** *rmap_name* **out** command in BGP IPv4 address family configuration mode to associate the route map.

The following example creates a route map, whereby MPLS labels are distributed to routes with the 1.1.1.1/32 prefix whereas ordinary IPv4 route updates instead of labels are distributed to routes with the 1.1.1.2/32 prefix. For routes that do not match ACL1 and ACL2, route updates are not sent to neighbors.

You can use the **match mpls-label** rule to specify reception of only labeled IPv4 routes. Configure a route map, and run the **neighbor peer-address route-map** *rmap_name* **in** command to associate the route map.

The following example creates a route map to specify reception of only labeled IPv4 routes from the BGP peer 30.30.30.2 while rejecting other routes.

Configuring ASBRs to Redistribute to IGP the Routes of PEs That Are Learned over EBGP

When an ASBR learns from the peer ASBR the routes of PEs in the other AS, it needs to send the routes to the PEs in the local AS and establish an LSP destined for the PEs in the other AS. To do this, configure ASBRs to redistribute to IGP the routes learned over EBGP, and enable LDP for distributing labels to BGP routes, in order to establish an LSP destined for the PEs in the other AS.

Perform configuration in privileged mode according to the following table.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# router igp	Enters IGP configuration mode.
Ruijie(config-router)# redistribute bgp subnets [route-map routemap-name]	Configures the protocol for BGP route redistribution. Route-map-based filtering is optional.
Ruijie(config-router)# exit	Exits IGP configuration mode.
Ruijie(config)# mpls router ldp	Enters LDP configuration mode.
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force	Configures the LDP router ID, which typically uses the IP address of a loopback interface.
Ruijie(config-mpls-router)# advertise-labels for bgp-routes [acl acl-name]	Distributes labels to BGP routes. ACL-based filtering is optional.
Ruijie(config-mpls-router)# show running-config	Displays existing configurations.

 By default, LDP only distributes labels to IGP routes but not to BGP routes. To distribute labels to BGP routes, run the **advertise-labels for bgp-routes** command.

In Method 1 of the Option C solution, you can run the **redistribute bgp subnets route-map routemap-name** command in IGP configuration mode to specify which BGP-learned routes are redistributed to IGP. You can run the **advertise-labels for bgp-routes acl acl-name** command in LDP configuration mode to specify which BGP routes are distributed with a label.

↘ Configuring a Multi-hop MP-EBGP Session

After an inter-AS LSP is established, establish a multi-hop MP-EBGP session between the two PEs in different ASs that need to carry the inter-AS VPN service, in order to allow the PEs to exchange VPN routes.

Configure the multi-hop MP-EBGP session in privileged mode according to the following table.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# router bgp asn-num	Configures BGP and enters BGP configuration mode.
Ruijie(config-router)# neighbor ebgp-peer-address remote-as ebgp-asn-num	Establishes a multi-hop EBGP session with the PE in the other AS.
Ruijie(config-router)# neighbor ebgp-peer-address update-source interface-name	Specifies the loopback interface used to establish a neighbor relationship with the EBGP peer.
Ruijie(config-router)# neighbor ebgp-peer-address ebgp-multi-hop	Configures multi-hop attributes.
Ruijie(config-router)# address-family vpnv4	Enters BGP VPN address family configuration mode.
Ruijie(config-router-af)# neighbor ebgp-peer-address activate	Enables the capability of exchanging VPN routes between peers.

Command	Description
Ruijie(config-router-af)# exit	Exits BGP VPN address family configuration mode.
Ruijie(config-router)# address-family ipv4	Enters BGP IPv4 address family configuration mode.
Ruijie(config-router-af)# no neighbor ebgp-peer-address activate	Disables the capability of exchanging IPv4 routes.
Ruijie(config-router)# show running-config	Displays existing configurations.

i Avoid the situation where the multi-hop MP-EBGP peers exchange IPv4 routes or the routes corresponding to the two addresses used for BGP session establishment. If such routes are exchanged over the multi-hop MP-EBGP session, one PE has two routes destined for the PE in the other AS. One route is advertised by the ASBR in the local AS, and the other is advertised over the multi-hop MP-EBGP session. Because EBGP routes take precedence over IBGP routes, BGP preferentially selects the route advertised over the multi-hop MP-EBGP session, causing constant flapping of the route destined for the peer PE. As a result, VPN routes become unreachable.

Verification

- Check that sites of the same VPN can communicate with each other but sites of different VPNs cannot communicate with each other.

Configuration Example

Inter-AS VPN Option C: Enabling IPv4 Label Switching Between EBGP Neighbors

<p>Scenario Figure 3-32</p>	<p>Requirements: A VPN has sites in two ASs. Enable inter-AS communication between the sites.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● On PE1-AS1, configure a loopback interface, create a VRF table named VPN1, define RD and RT values, and associate the VRF table with the corresponding interface. Configure a multi-hop MP-EBGP session. Disable the capability of exchanging IPv4 routes over EBGP. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. ● On PE1-AS2, configure a loopback interface, create a VRF table named VPN1, define RD and RT values, and associate the VRF table with the corresponding interface. Configure a multi-hop

	<p>MP-EBGP session. Disable the capability of exchanging IPv4 routes over EBGP. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.</p> <ul style="list-style-type: none"> ● On P1-AS1, configure a loopback interface, configure backbone MPLS signaling, enable MPLS on the interface connected to the public network, and configure a backbone routing protocol. ● On ASBR1, configure a loopback interface, and configure an ACL and a route map to distribute or set labels only for compliant routes. Establish an EBGP session with ASBR2. Configure a route map to set labels only for the compliant routes of PEs. (The route map is optional and used to specify which routes are distributed with a label over BGP.) Configure statically the routes of PEs in the local AS. Configure MPLS. Configure an ACL to distribute labels only to specified BGP routes. (The ACL is optional and used to reduce the number of undesired route entries.) Configure a backbone routing protocol, which redistributes only BGP routes compliant with the route map. (The route map is optional and used to reduce the number of undesired route entries.) Configure the IP address of the interface connected to ASBR2, and enable label forwarding on the interface. ● On ASBR2, configure a loopback interface, and configure an ACL and a route map to distribute or set labels only for compliant routes. Establish an EBGP session with ASBR1. Configure a route map to set labels only for the compliant routes of PEs. (The route map is optional and used to specify which routes are distributed with a label over BGP.) Configure statically the routes of PEs in the local AS. Configure MPLS. Configure an ACL to distribute labels only to specified BGP routes. (The ACL is optional and used to reduce the number of undesired route entries.) Configure a backbone routing protocol, which redistributes only BGP routes compliant with the route map. (The route map is optional and used to reduce the number of undesired route entries.) Configure the IP address of the interface connected to ASBR1, and enable label forwarding on the interface.

```

Common Errors

The capability of exchanging IPv4 routes over multi-hop EBGP is not disabled when a multi-hop MP-EBGP session is configured. LDP is not configured on ASBRs for distributing labels to BGP routes, causing a communication failure between VPN sites.

3.4.4.2 Method 2: Enable IPv4 Label Switching Between EBGP Neighbors and Between IBGP Neighbors

As Method 1 enables IPv4 label switching only between EBGP neighbors, IGP and LDP in one AS need to maintain the routes destined for PEs in the other AS. That is, the inter-AS routes of PEs must be propagated to all devices between ASs. In actual application, for AS security consideration, the routes of PEs in one AS should not be propagated to each device in the other AS. Rather, the routes must be maintained only by BGP and transparent to IGP and LDP in the same AS. To meet this requirement, you can enable IPv4 label switching between EBGP neighbors and between IBGP neighbors.

Different from Method 1, Method 2 does not require IGP on ASBRs to redistribute BGP routes and does not require LDP to distribute labels to BGP routes. LDP is only responsible for LSP establishment in the local AS. However, IPv4 label switching must be enabled between IBGP neighbors and between EBGP neighbors for inter-AS LSP establishment, and PEs must support stacking of three consecutive labels.

Configuration Steps

- (Mandatory) Configure PEs and CEs in each AS to exchange routes.
- (Mandatory) Configure IGP and MPLS signaling for ASs.
- (Mandatory) Configure PEs and ASBRs to establish an IBGP session in order to distribute labels to IPv4 routes.
- (Mandatory) Configure ASBRs to establish an EBGP session in order to distribute labels to IPv4 routes.
- (Mandatory) Configure a multi-hop MP-EBGP session.

↘ [Configuring PEs and CEs to Exchange Routes](#)

For details, see "Configuring PEs and CEs to Exchange Routes" in section 3.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

↘ [Configuring IGP and MPLS Signaling for ASs](#)

For details, see "Configuring an MPLS Network" in section 3.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

↘ [Configuring PEs and ASBRs to Establish an IBGP Session in Order to Distribute Labels to IPv4 Routes](#)

In Method 1, the routes of PEs learned over EBGP are redistributed to IGP between ASs, whereas in Method 2, the inter-AS routes of PEs are transmitted over the IBGP session between ASBR and PE, and labels are distributed to those routes over BGP.

Perform configuration in privileged mode according to the following table.

Command	Description
Ruijie# config terminal	Enters global configuration mode.
Ruijie(config)# router bgp <i>asn-number</i>	Configures BGP and enters BGP configuration mode.
Ruijie(config-router)# neighbor <i>peer-address</i> remote-as <i>asn-number</i>	Establishes an IBGP session with the ASBR (PE).
Ruijie(config-router)# neighbor <i>peer-address</i> update-source <i>interface-name</i>	Specifies the address of a loopback interface as the source address for the BGP session established with the peer ASBR (PE)
Ruijie(config-router)# address-family ipv4	Enters IPv4 address family configuration mode.
Ruijie(config-router-af)# neighbor <i>peer-address</i> send-label	Configures the capability of exchanging labeled IPv4 routes with the peer ASBR (PE).
Ruijie(config-router-af)# show running-config	Displays existing configurations.

- i** Before you enable IPv4 label switching over the IBGP session between IBGP peers, run the **neighbor update-source** command to specify the address of a loopback interface as the source address for the IBGP session; otherwise, an inter-AS LSP cannot be established.

↘ [Configuring ASBRs to Establish an EBGP Session in Order to Distribute Labels to IPv4 Routes](#)

For details, see "Configuring ASBRs to Establish an EBGP Session in Order to Distribute Labels to IPv4 Routes" in section 3.4.4.1 "Method 1: Enable IPv4 Label Switching Only Between EBGP Neighbors."

↘ [Configuring a Multi-hop MP-EBGP Session](#)

For details, see "Configuring a Multi-hop MP-EBGP Session" in section 3.4.4.1 "Method 1: Enable IPv4 Label Switching Only Between EBGP Neighbors."

Verification

- Check that sites of the same VPN can communicate with each other but sites of different VPNs cannot communicate with each other.

Configuration Example

↘ [Inter-AS VPN Option C: Enabling IPv4 Label Switching Between EBGP Neighbors and Between IBGP Neighbors](#)

Scenario
Figure 3-33

Requirements: A VPN has sites in two ASs. Enable inter-AS communication between the sites.

Configuration Steps

- On PE1-AS1, configure a loopback interface, create a VRF table named VPN1, define RD and RT values, and associate the VRF table with the corresponding interface. Configure a multi-hop MP-EBGP session. Disable the capability of exchanging IPv4 routes over EBGP. Establish an IBGP session with ASBR1. Enable IPv4 label switching. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.
- On PE1-AS2, configure a loopback interface, create a VRF table named VPN1, define RD and RT values, and associate the VRF table with the corresponding interface. Configure a multi-hop MP-EBGP session. Disable the capability of exchanging IPv4 routes over EBGP. Establish an IBGP session with ASBR2. Enable IPv4 label switching. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.
- On P1-AS1, configure a loopback interface, configure backbone MPLS signaling, enable MPLS on the interface connected to the public network, and configure a backbone routing protocol.
- On ASBR1, configure a loopback interface, and configure an ACL and a route map to distribute or set labels only for compliant routes. Establish an EBGP session with ASBR2. Configure a route map to set labels only for the compliant routes of PEs. (The route map is optional and used to specify which routes are distributed with a label over BGP.) Configure statically the routes of PEs in the local AS. Configure MPLS signaling and enable MPLS on the interface connected to the public network. Configure OSPF for the backbone network to transmit routes. Configure the IP address of the interface connected to ASBR2, and enable label forwarding on the interface.
- On ASBR2, configure a loopback interface, and configure an ACL and a route map to distribute or set labels only for compliant routes. Establish an EBGP session with ASBR1. Configure a route map to set labels only for the compliant routes of PEs. (The route map is optional and used to specify which routes are distributed with a label over BGP.) Configure statically the routes of PEs in the local AS. Configure MPLS signaling and enable MPLS on the interface connected to the public network. Configure OSPF for the backbone network to transmit routes. Configure the IP address of the

	interface connected to ASBR1, and enable label forwarding on the interface.

Common Errors

The capability of exchanging IPv4 routes over multi-hop EBGP is not disabled when a multi-hop MP-EBGP session is configured. IPv4 label switching is not configured between IBGP neighbors, causing a communication failure between VPN sites.

3.4.4.3 Method 3: Establish Multi-hop MP-EBGP Between RRs

The Option C solution requires inter-AS VPN sites to be fully meshed. A new VPN site must set up a multi-hop MP-EBGP connection with PEs in the other AS. This hampers VPN site scalability. To address this problem, you can deploy an RR in each AS and enable the RRs in different ASs to set up a multi-hop MP-EBGP connection for exchanging VPN routes.

Figure 3-34 Establishment of Inter-RR Multi-hop MP-EBGP for Option C

Configuration Steps

- (Mandatory) Configure PEs and CEs in each AS to exchange routes.
- (Mandatory) Configure IGP and MPLS signaling for ASs.
- (Mandatory) Configure RRs to establish an MP-IBGP session with PEs, and configure IPv4 label switching.

- (Mandatory) Configure RRs to establish an IBGP session with ASBRs, and configure IPv4 label switching.
- (Mandatory) Configure ASBRs to establish an EBGP session in order to distribute labels to IPv4 routes.
- (Mandatory) Configure a multi-hop MP-EBGP session.

▾ Configuring PEs and CEs to Exchange Routes

For details, see "Configuring PEs and CEs to Exchange Routes" in section 3.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

▾ Configuring IGP and MPLS Signaling for ASs

For details, see "Configuring an MPLS Network" in section 3.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

▾ Configuring RRs to Establish an MP-IBGP Session with PEs, and Configuring IPv4 Label Switching

Configure RRs to establish an MP-IBGP session with PEs for exchanging VPN routes, and enable IPv4 label switching over the MP-IBGP session.

Perform configuration in privileged mode according to the following table.

Command	Description
Ruijie# config terminal	Enters global configuration mode.
Ruijie(config)# router bgp <i>asn-number</i>	Configures BGP and enters BGP configuration mode.
Ruijie(config-router)# neighbor <i>peer-address</i> remote-as <i>asn-number</i>	Establishes an IBGP session.
Ruijie(config-router)# neighbor <i>peer-address</i> update-source <i>interface-name</i>	Specifies the address of a loopback interface as the source address for the IBGP session.
Ruijie(config-router)# address-family ipv4	Enters IPv4 address family configuration mode.
Ruijie(config-router-af)# neighbor <i>peer-address</i> activate	Enables the capability of exchanging IPv4 routes.
Ruijie(config-router-af)# neighbor <i>peer-address</i> send-label	Enables IPv4 label switching.
Ruijie(config-router-af)# neighbor <i>peer-address</i> route-reflector-client	Configures peer PEs as the clients for reflecting IPv4 routes on the RRs.
Ruijie(config-router-af)# exit	Exits IPv4 address family configuration mode.
Ruijie(config-router)# address-family vpnv4	Enters VPN address family configuration mode.
Ruijie(config-router-af)# neighbor <i>peer-address</i> activate	Enables the capability of exchanging VPN routes between peers.
Ruijie(config-router-af)# neighbor <i>peer-address</i> route-reflector-client	Configures peer PEs as the clients for reflecting VPN routes on the RRs.
Ruijie(config-router-af)# show running-config	Displays existing configurations.

▾ Configuring RRs to Establish an IBGP Session with ASBRs, and Configuring IPv4 Label Switching

Configure ASBRs to establish an MP-IBGP session with RRs, so that ASBRs receive from RRs the routes destined for PEs in the local AS, and send RRs the routes destined for PEs in the other AS. You also need to enable IPv4 label switching over the MP-IBGP session.

Perform configuration in privileged mode according to the following table.

Command	Description
Ruijie# config terminal	Enters global configuration mode.
Ruijie(config)# router bgp <i>asn-number</i>	Configures BGP and enters BGP configuration mode.
Ruijie(config-router)# neighbor <i>peer-address</i> remote-as <i>asn-number</i>	Establishes an IBGP session.
Ruijie(config-router)# neighbor <i>peer-address</i> update-source <i>interface-name</i>	Specifies the address of a loopback interface as the source address for the IBGP session.
Ruijie(config-router)# address-family ipv4	Enters IPv4 address family configuration mode.
Ruijie(config-router-af)# neighbor <i>peer-address</i> activate	Enables the capability of exchanging IPv4 routes.
Ruijie(config-router-af)# neighbor <i>peer-address</i> send-label	Enables IPv4 label switching.
Ruijie(config-router)# show running-config	Displays existing configurations.

-  When you configure RRs to establish an IBGP session with ASBRs, you do not need to configure the ASBRs as the clients of the RRs, unless the ASBRs also function as PEs.

↘ [Configuring ASBRs to Establish an EBGp Session in Order to Distribute Labels to IPv4 Routes](#)

For details, see "Configuring ASBRs to Establish an EBGp Session in Order to Distribute Labels to IPv4 Routes" in section 3.4.4.1 "Method 1: Enable IPv4 Label Switching Only Between EBGp Neighbors."

↘ [Configuring a Multi-hop MP-EBGP Session](#)

Establish a multi-hop MP-EBGP session between the RRs in two different ASs for exchanging inter-AS VPN routes. You also need to disable the capability of exchanging IPv4 routes over the MP-EBGP session. Routes arriving at one PE are transmitted by the corresponding ASBR to the other AS.

Perform configuration in privileged mode according to the following table.

Command	Description
Ruijie# config terminal	Enters global configuration mode.
Ruijie(config)# router bgp <i>asn-number</i>	Configures BGP and enters BGP configuration mode.
Ruijie(config-router)# neighbor <i>rr-address</i> remote-as <i>ebgp-asn-numbe</i>	Establishes an EBGp session.
Ruijie(config-router)# neighbor <i>rr-address</i> update-source <i>interface-name</i>	Specifies the address of a loopback interface as the source address for the EBGp session.
Ruijie(config-router)# neighbor <i>rr-address</i> ebgp-multi-hop	Configures multi-hop EBGp attributes.
Ruijie(config-router)# address-family ipv4	Enters IPv4 address family configuration mode.
Ruijie(config-router-af)# no neighbor <i>rr-address</i> activate	Disables the capability of exchanging IPv4 routes over the MP-EBGP session.

Ruijie(config-router-af)# exit	Exits IPv4 address family configuration mode.
Ruijie(config-router)# address-family vpnv4	Enters VPN address family configuration mode.
Ruijie(config-router-af)# neighbor rr-address activate	Enables the capability of exchanging VPN routes with the RR in the other AS.
Ruijie(config-router-af)# neighbor rr-address next-hop-unchanged	(Optional) Configures next hop retention for VPN routes advertised to the peer.
Ruijie(config-router)# show running-config	Displays existing configurations.

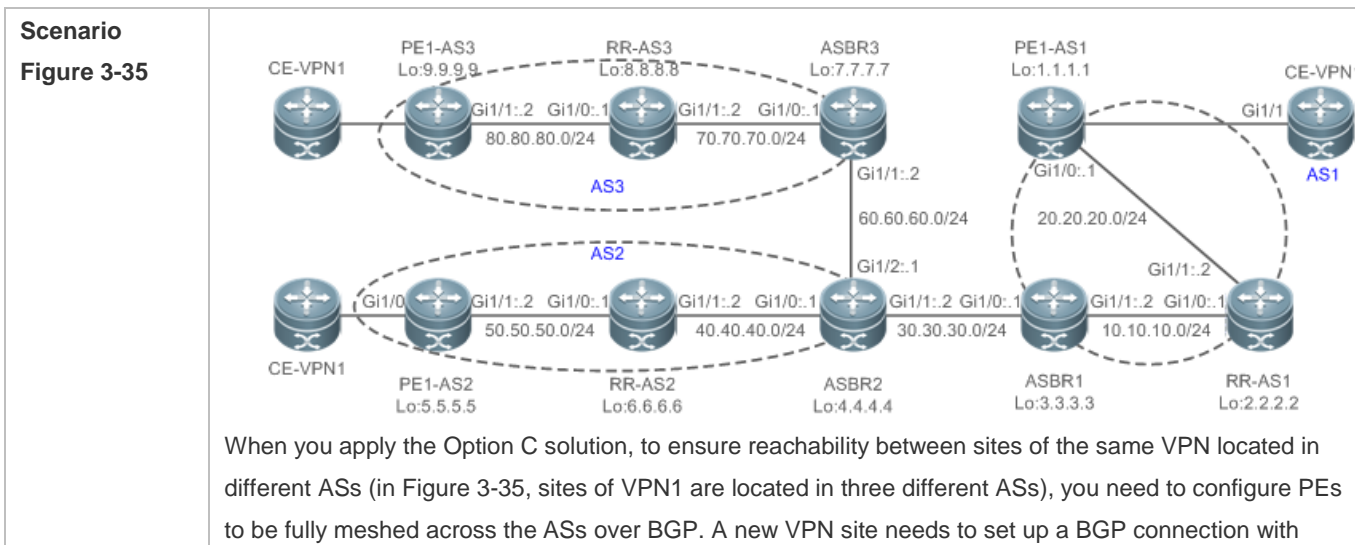

- i** By default, the next hop in VPN routes advertised to the EBGP peer is changed to the sender. Then the PEs in the other AS determine that the next hop in incoming VPN routes is an RR, causing all inter-AS VPN traffic to pass through the RR. Such a forwarding path is not the best path, and RRs require higher performance to forward traffic. To avoid the preceding situation, run the **neighbor next-hop-unchanged** command in VPNv4 address family configuration mode to configure next hop retention for VPNv4 routes sent to the BGP peer when you configure a multi-hop MP-EBGP connection on RRs.
- i** Avoid the situation where the multi-hop MP-EBGP peers exchange IPv4 routes or the routes corresponding to the two addresses used for BGP session establishment. If such routes are exchanged over the multi-hop MP-EBGP session, one PE has two routes destined for the PE in the other AS. One route is advertised by the ASBR in the local AS, and the other is advertised over the multi-hop MP-EBGP session. Because EBGP routes take precedence over IBGP routes, BGP preferentially selects the route advertised over the multi-hop MP-EBGP session, causing constant flapping of the route destined for the peer PE. As a result, VPN routes become unreachable.

Verification

- Check that sites of the same VPN can communicate with each other but sites of different VPNs cannot communicate with each other.

Configuration Example

Inter-AS VPN Option C: RR Networking

	<p>existing VPN sites. This limits the Option C application. To ensure scalability, you can add an RR to each AS and set up a multi-hop MP-EBGP connection between RRs in different ASs to exchange inter-AS VPN routes. Then establish an MP-IBGP session between the PE and the RR in each AS.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● On PE1-AS1, PE1-AS2, and PE1-AS3, configure a loopback interface, create a VRF table named VPN1, define RD and RT values, and associate the VRF table with the corresponding interface. Establish an MP-IBGP session with the RR in the same AS, and enable IPv4 label switching. Configure a CE neighbor relationship over EBGP. ● On RR-AS1, RR-AS2, and RR-AS3, configure a loopback interface, establish an MP-IBGP session with the PE in the same AS, specify the PE as the RR client, and enable IPv4 label switching. Establish a multi-hop MP-EBGP session with the peer RR, and configure next hop retention for VPN routes exchanged with the peer RR. Disable the capability of exchanging IPv4 routes with the peer RR. Establish an IBGP session with the ASBR in the same AS. Enable IPv4 label switching. Configure MPLS, and configure OSPF for the backbone network to transmit routes. ● On ASBR1, ASBR2, and ASBR3, configure a loopback interface, and configure an ACL and a route map. Establish an EBGP session with the peer ASBR. Enable IPv4 label switching. Configure a route map to set labels only for the compliant routes of PEs. (The route map is optional and used to specify which routes are distributed with a label over BGP.) Establish an IBGP session with the RR in the same AS. Enable IPv4 label switching. Configure a route map to set labels only for the compliant inter-AS routes of PEs. Configure statically the route of the PE in the local AS. Configure MPLS signaling and enable MPLS on the interface connected to the public network. Configure OSPF for the backbone network to transmit routes. Configure the IP address of the interface connected to the peer ASBR, and enable label forwarding on the interface.

Common Errors

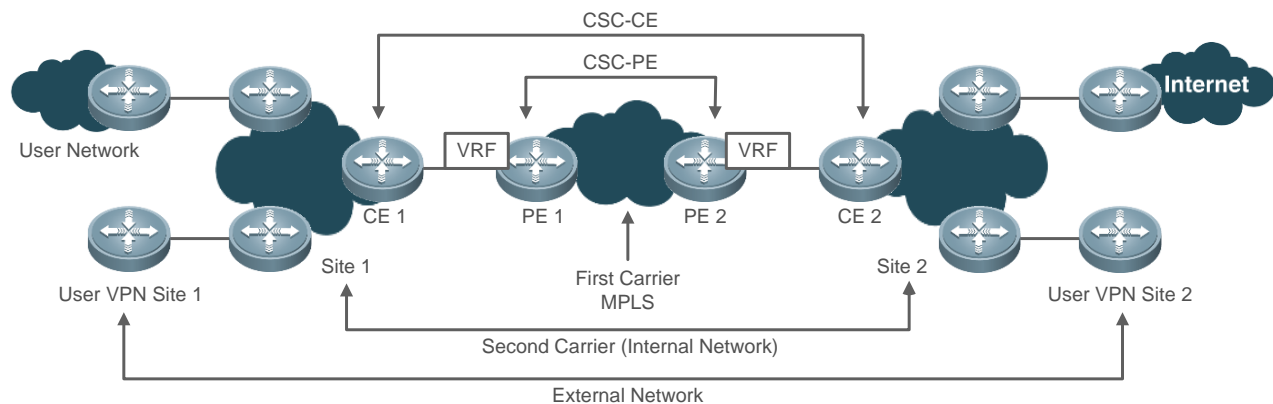

- The capability of exchanging IPv4 routes is not disabled when a multi-hop MP-EBGP session is configured between RRs, or next hop retention is not configured for VPN routes exchanged over the multi-hop MP-EBGP session, causing a communication failure between VPN sites.

3.4.5 Configuring the CSC Service Model

Configuration Effect

In the CSC model, first carriers provide the VPN service to second carriers, and second carriers provide the IP access service and VPN service to users.

Figure 3-36 CSC Networking Model

Notes

- The LDP router ID and BGP router ID must consist of 32 bits.

Configuration Steps

- Configure BGP/MPLS VPN basic functions for the first carrier.
- Enable the CSC feature for the first carrier.
- Configure the second carrier in three application scenarios.
- Configure the user access service capability of the second carrier.

📌 Configuring BGP/MPLS VPN Basic Functions for the First Carrier

The configuration of BGP MPLS IP VPN basic functions includes:

- Configuring an MPLS network

For details, see "Configuring an MPLS Network" in section 3.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

- Configuring VRF tables

For details, see "Configuring a VPN Routing Instance" in section 3.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

i Run the **alloc-label per-route** command in VRF configuration mode to select the per-route label distribution method for each VRF table.

- Configuring an MP-IBGP neighbor relationship

For details, see "Configuring PEs to Exchange VPN Routes" in section 3.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

- Configuring the capability of exchanging routes between PE and CE

For details, see "Configuring PEs and CEs to Exchange Routes" in section 3.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

i In Scenario 1, if the IP core second ISP uses EBGP to exchange internal routes between PE and CE, configure a route map between PE and CE for filtering external routes, in order to avoid external route leakage to the first carrier's PEs. This is because external routes are also transmitted over BGP and CEs function as RRs.

▾ Enabling the CSC Feature for the First Carrier

Configure the CSC feature on the first carrier's PEs. You can select either of the following configuration schemes, depending on the protocol used for exchanging routes between PE and CE:

- Label distribution between PE and CE over LDP
- Label distribution between PE and CE over EBGP

... Scheme 1: Label Distribution Between PE and CE over LDP

If routes are exchanged between PE and CE over IGP, run the following commands on PEs and CEs to configure PE-CE label distribution over LDP.

Perform configuration on PEs according to the following table.

Command	Description
Ruijie(config)# mpls router ldp <i>vrf-name</i>	Enables LDP for the VRF table (PE).
Ruijie(config-mpls-router)# ldp router-id interface <i>interface-name force</i>	Configures the LDP router ID.
Ruijie(config-mpls-router)# advertise-labels for bgp-routes [acl acl-name]	Configures label distribution for BGP routes. By default, LDP does not distribute labels to BGP routes.
Ruijie(config-mpls-router)# exit	Exits LDP instance configuration mode.
Ruijie(config)# interface <i>type ID</i>	Configures the interface connected to the CE.
Ruijie(config-if- <i>type ID</i>)# label-switching	Enables MPLS forwarding on the interface.
Ruijie(config-if- <i>type ID</i>)# mpls ip	Enables LDP on the interface.
Ruijie(config-if- <i>type ID</i>)# end	Exits interface configuration mode.
Ruijie# show running-config	Displays existing configurations.
Ruijie# show mpls ldp bindings vrf <i>vrf-name</i>	Displays the LDP label binding information under the VRF instance.

Perform configuration on CEs according to the following table.

Command	Description
Ruijie(config)# mpls router ldp	Enables LDP on the CE.
Ruijie(config-mpls-router)# ldp router-id interface interface-name force	Configures the LDP router ID.
Ruijie(config-mpls-router)# exit	Exits LDP instance configuration mode.
Ruijie(config)# interface type ID	Configures the interface connected to the PE.
Ruijie(config-if-type ID)# label-switching	Enables MPLS forwarding on the interface.
Ruijie(config-if-type ID)# mpls ip	Enables LDP on the interface.
Ruijie(config-if-type ID)# end	Exits interface configuration mode.
Ruijie# show running-config	Displays existing configurations.
Ruijie# show mpls ldp bindings	Displays the LDP label binding information.

... Method 2: Label Distribution Between PE and CE over EBGp

If routes are exchanged between PE and CE over EBGp, run the following commands on PEs and CEs to configure PE-CE label distribution over EBGp.

Perform configuration on PEs according to the following table.

Command	Description
Ruijie(config)# interface type ID	Configures the interface connected to the CE.
Ruijie(config-if-type ID)# label-switching	Enables MPLS forwarding on the interface.
Ruijie(config-if-type ID)# router bgp asn	Enters BGP configuration mode.
Ruijie(config-router)# address-family ipv4 vrf vrf-name	Enters IPv4 address family configuration mode.
Ruijie(config-router-af)# neighbor { peer-address peer-group-name } send-label	Enables BGP to distribute labels to IP routes.
Ruijie(config-router-af)# end	Returns to privileged mode.
Ruijie# show running-config	Displays existing configurations.
Ruijie# show bgp vpnv4 unicast vrf vrf-name labels	Displays BGP labels.

Perform configuration on CEs according to the following table.

Command	Description
Ruijie(config)# interface type ID	Configures the interface connected to the PE.
Ruijie(config-if-type ID)# label-switching	Enables MPLS forwarding on the interface.
Ruijie(config-if-type ID)# router bgp asn	Enters BGP configuration mode.
Ruijie(config-router)# address-family ipv4	Enters IPv4 address family configuration mode.
Ruijie(config-router-af)# neighbor { peer-address peer-group-name } send-label	Enables BGP to distribute labels to IP routes.
Ruijie(config-router-af)# end	Returns to privileged mode.
Ruijie# show running-config	Displays existing configurations.
Ruijie# show ip bgp labels	Displays BGP labels.

↘ Configuring the Second Carrier

Before you perform the following configuration, configure IGP in the second carrier's network to ensure network connectivity. Select a proper configuration scheme based on the second carrier's application scenario. There are three types of application scenarios:

- Scenario 1: The second carrier provides the Internet service based on the IP core
- Scenario 2: The second carrier provides the Internet service based on the MPLS core
- Scenario 3: The second carrier provides the VPN service based on the MPLS core

... Scenario 1: The Second Carrier Provides the Internet Service Based on the IP Core

An IBGP neighbor relationship is established between ASBR and CE to exchange external routes. CEs function as RRs to reflect external routes between sites.

● Configuring an Intra-site IBGP Session

Establish an IBGP session between the ASBR and the CSC-CE of the same site, and configure the CSC-CE as an RR.

Command	Description
Ruijie(config)# router bgp <i>asn</i>	Configures BGP.
Ruijie(config-router)# neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>asn</i>	Configures a BGP neighbor relationship.
Ruijie(config-router)# neighbor { <i>peer-address</i> <i>peer-group-name</i> } route-reflector-client	Configures an RR client for the CSC-CE.
Ruijie(config-router)# neighbor { <i>peer-address</i> <i>peer-group-name</i> } update-source <i>interface-name</i>	Configures the BGP source address.
Ruijie(config-router)# neighbor { <i>peer-address</i> <i>peer-group-name</i> } next-hop-self	Configures the ASBR to change the next hop in BGP-advertised routes to itself.

● Establishing an IBGP Session Between CSC-CEs of Different Sites

Establish a fully meshed IBGP session between CEC-CEs of different sites to exchange external routes of all sites.

Command	Description
Ruijie(config)# router bgp <i>asn</i>	Configures BGP.
Ruijie(config-router)# neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>asn</i>	Configures a BGP neighbor relationship.
Ruijie(config-router)# neighbor { <i>peer-address</i> <i>peer-group-name</i> } update-source <i>interface-name</i>	Configures the BGP source address.
Ruijie(config-router)# neighbor { <i>peer-address</i> <i>peer-group-name</i> } route-reflector-client	(Optional) Configures the CSC-CE of the other site as an RR client.
Ruijie(config-router)# exit	Exits BGP configuration mode.
Ruijie(config)# recursive-route lookup lsp	Enables the capability of resolving the next hop in BGP routes to the LSP tunnel.

● Configuring a Route Map

When internal routes are exchanged over BGP, CSC-CEs transmit both external and internal routes. To avoid routing loop or disorder, you need to ensure that only internal routes are transmitted over the EBGP session between CSC-CE and CSC-PE, and only external routes are transmitted over the IBGP session between CSC-CEs and the IBGP session between CSC-CE and ASBR. For this purpose, run the **neighbor route-map** {in | out} command on IBGP neighbors and EBGP neighbors to filter corresponding routes. For ease of use, you can use the filter rules applicable to AS paths. You can also use other filter rules.

Command	Description
Ruijie(config)# ip as-path access-list <i>access-list-number</i> { permit deny } <i>regex</i>	Configures an AS path ACL.
Ruijie(config)# route-map <i>route-map-name</i> { permit deny } <i>sequence-number</i>	Configures a route map.
Ruijie(config-route-map)# match as-path <i>access-list-number</i>	Matches the AS path ACL.
Ruijie(config-route-map)# exit	Returns to global configuration mode.
Ruijie(config)# router bgp <i>asn</i>	Configures BGP.
Ruijie(config-router)# neighbor { <i>peer-address</i> <i>peer-group-name</i> } route-map <i>route-map-name</i> { in out }	Applies the route map to BGP neighbors.

... Scenario 2: The Second Carrier Provides the Internet Service Based on the MPLS Core

The second carrier's network is the MPLS core, and external routes are exchanged directly over the IBGP neighbor relationship between ASBRs, whereas CSC-CEs do not need to transmit external routes.

● Configuring the MPLS Network at Each Site

Configure the MPLS network at each site of the second carrier. For details, see "Configuring an MPLS Network" in section 3.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

-  To build the MPLS network, enable LDP on the CSC-CE of each site to establish sessions with other intra-site devices. If routes are learned between CSC-CE and CSC-PE over BGP, run the **advertise-labels for bgp-routes** command on CSC-CEs to enable LDP for distributing labels to BGP routes.

● Establishing an IBGP Session Between ASBRs of Various Sites

Establish a BGP session between ASBRs of the same site and between ASBRs of different sites to transmit external routes.

Command	Description
Ruijie(config)# router bgp <i>asn</i>	Configures BGP.
Ruijie(config-router)# neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>asn</i>	Configures a BGP neighbor relationship.
Ruijie(config-router)# neighbor { <i>peer-address</i> <i>peer-group-name</i> } update-source <i>interface-name</i>	Configures the BGP source address.
Ruijie(config-router)# neighbor { <i>peer-address</i> <i>peer-group-name</i> } next-hop-self	Configures the ASBR to change the next hop in external routes to itself when advertising the routes.
Ruijie(config-router)# exit	Exits BGP configuration mode.

Ruijie(config)# recursive-route lookup lsp	Enables the capability of resolving the next hop in BGP routes to the LSP tunnel.
---	---

- i** To reduce the configuration overhead for a fully meshed IBGP session, you can deploy an RR at each site. A BGP session is established between the ASBR and the RR of the same site, and only a BGP session is established between RRs of different sites.

... Scenario 3: The Second Carrier Provides the VPN Service Based on the MPLS Core

The second carrier's network is the MPLS core, and VPN routes are exchanged over the MP-IBGP neighbor relationship between PEs of the second carrier.

● Configuring the MPLS Network at Each Site

Configure the MPLS network at each site of the second carrier. For details, see "Configuring an MPLS Network" in section 3.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

- i** To build the MPLS network, enable LDP on the CSC-CE of each site to establish sessions with other intra-site devices. If routes are learned between CSC-CE and CSC-PE over BGP, run the **advertise-labels for bgp-routes** command on CSC-CEs to enable LDP for distributing labels to BGP routes.

● Establishing an MP-IBGP Session Between PEs of Various Sites

Establish an MP-IBGP session between PEs of the same site and between PEs of different sites of the second carrier to transmit VPN routes. For configuration details, see "Configuring PEs to Exchange VPN Routes" in section 3.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

- i** To reduce the configuration overhead for a fully meshed MP-IBGP session, you can deploy an RR at each site. An MP-IBGP session is established between the PE and the RR of the same site, and only an MP-IBGP session is established between RRs of different sites.

📄 Configuring the User Access Service Capability of the Second Carrier

The following configuration is related to the services provided by the second carrier, but is unrelated to the CSC model. If the second carrier provides the IP service to users, see the section about IP route configuration. If the second carrier provides the MPLS VPN service to users, see the section about MPLS VPN configuration.

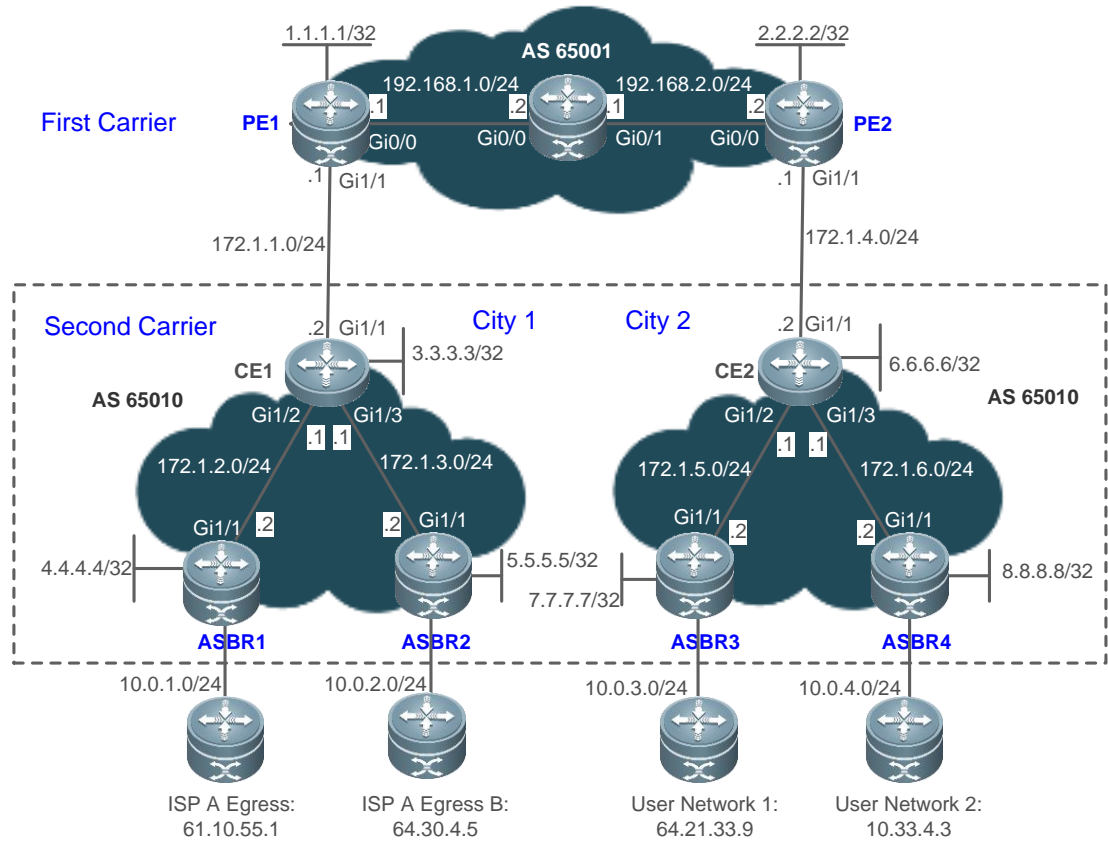

Verification

- Check that sites of the same VPN can communicate with each other but sites of different VPNs cannot communicate with each other.

Configuration Example

📄 CSC: The Second Carrier Provides the Internet Service Based on the IP Core

Scenario
Figure 3-37

A carrier operates an internal network in City 1, and the network has a BGP egress connected to ISP A and a BGP egress connected to ISP B. The carrier uses the internal network to provide the Internet service to users in City 1. To extend business to City 2, the carrier leases the MPLS VPN service of a VPN SP, in order to connect sites in City 1 and City 2 over VPN, allowing users in City 2 to access the Internet over the existing Internet egresses. In the networking model, internal routes are exchanged over IGP (OSPF), and external routes are exchanged over BGP.

Configuration Steps

- (Configuration of BGP/MPLS VPN basic functions for the first carrier) Configure a loopback interface. Enable MPLS and LDP in global configuration mode and interface configuration mode. Configure IGP (OSPF). Configure an MP-IBGP neighbor relationship. Configure a VRF table. Set up a CE-PE connection. Configure the capability of exchanging routes between PE and CE.
- (Enabling the CSC feature) Enable the CSC feature on the PE, and configure LDP to distribute labels to BGP routes. Enable MPLS and LDP on the CE.
- (Configuration of the second carrier) Configure interfaces and IGP. On the ASBR, configure a BGP neighbor relationship with the CE. On the CE, configure the ASBRs in the local AS and the CE in the other AS as RR clients. Enable the capability of resolving the next hop in BGP routes to the LSP tunnel.
- (Configuration of the user access service capability) You can configure user access over EBGP.

Scenario
Figure 3-38

A carrier provides the Internet service to users in City 1. In order to provide the MPLS service in the future, the carrier enables MPLS in the backbone network. The carrier builds an MPLS network in City 2 to extend business there. To connect the core networks in City 1 and City 2, the carrier leases the VPN service of an MPLS VPN SP. In such a networking model, the carrier is a second carrier, and the MPLS VPN SP is a first carrier.

PEs of the first carrier and CEs of the second carrier exchange internal routes over BGP. ASBRs of the second carrier responsible for service provision establish a BGP neighbor relationship to exchange external routes. Incoming traffic from external networks is forwarded over a tunnel across the second carrier's network.

Configuration Steps

- (Configuration of BGP/MPLS VPN basic functions for the first carrier) Configure a loopback interface. Enable MPLS and LDP in global configuration mode and interface configuration mode. Configure IGP (OSPF). Configure an MP-IBGP neighbor relationship. Configure a VRF table. Set up a CE-PE connection. Configure the capability of exchanging routes between PE and CE.
- (Enabling the CSC feature) Enable the CSC feature on the PE, and configure MPLS label switching for IPv4 routes. Enable MPLS and LDP on the CE.
- (Configuration of the second carrier) Configure interfaces and IGP. On the ASBR, configure a BGP neighbor relationship with the CE. On the CE, configure the ASBRs in the local AS and the CE in the other AS as RR clients. Enable the capability of resolving the next hop in BGP routes to the LSP tunnel.

- (Configuration of the user access service capability) You can configure user access over EBGp.
-  To build the MPLS network, enable LDP on the CSC-CE to establish sessions with other intra-site devices. If routes are learned between CSC-CE and CSC-PE over BGP, run the **advertise-labels for bgp-routes** command on CSC-CEs to enable LDP for distributing labels to BGP routes.

Scenario
Figure 3-39

A carrier operates an MPLS core network in City 1 and provides the MPLS VPN service to users in City 1. The carrier builds an MPLS core network in City 2 to extend business there. To connect the core networks in City 1 and City 2, the carrier leases the VPN service of an MPLS VPN SP. In this CSC networking model, PEs of the first carrier and CEs of the second carrier exchange internal routes over BGP. PEs of the second carrier establish an MP-IBGP neighbor relationship to exchange VPN routes. PEs of the second carrier and CEs of user VPNs exchange routes over OSPF.

Configuration Steps

- (Configuration of BGP/MPLS VPN basic functions for the first carrier) Configure a loopback interface. Enable MPLS and LDP in global configuration mode and interface configuration mode. Configure IGP (OSPF). Configure an MP-IBGP neighbor relationship. Configure a VRF table. Set up a CE-PE connection. Configure the capability of exchanging routes between PE and CE.
- (Enabling the CSC feature) Enable the CSC feature on the PE, and configure MPLS label switching for IPv4 routes. Enable MPLS and LDP on the CE.
- (Configuration of the second carrier) Configure interfaces and IGP. On PE3 to PE6, configure a BGP neighbor relationship with the CE. On the CE, configure the ASBRs in the local AS and the CE in the other AS as RR clients. Enable the capability of resolving the next hop in BGP routes to the LSP tunnel.
- (Configuration of the user access service capability) Configure VPN access. That is, configure a VRF table and bind an interface to it, and configure the capability of exchanging routes over OSPF.

Common Errors

The capability of resolving the next hop in BGP routes to the LSP tunnel is not enabled, causing VPN routes to be unpingable.

3.4.6 Configuring OSPF VPN Extended Attributes

Configuration Effect

When VPN user networks run OSPF, implement OSPF between PE and CE to simplify CE configuration and management.

Notes

- The LDP router ID must consist of 32 bits.

Configuration Steps

- (Optional) Configure a domain ID.
- (Optional) Configure a VPN route tag.
- (Optional) Configure a sham link.
- (Optional) Configure capability vrf-lite.
- (Optional) Configure extcommunity-type.

▾ (Optional) Configuring a Domain ID

A domain ID indicates the domain to which an OSPF instance belongs. Typically, all VRF OSPF instances of the same VPN are configured with the same domain ID. The default domain ID of an OSPF instance is Null, and the default type is 0x0005.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# router ospf <i>ospf-id</i> vrf <i>vrf-name</i>	Creates an OSPF instance and enters OSPF configuration mode.
Ruijie(config-router)# domain-id { <i>ip-address</i> [<i>secondary</i>] null type { 0005 0105 0205 8005 } value <i>hex-value</i> [secondary] }	Configures the domain ID of the OSPF instance.
Ruijie(config-router)# show running-config	Displays existing configurations.

- i** The **domain-id** command takes effect only for VRF OSPF instances.
- i** A VRF OSPF instance can be configured with multiple domain IDs, but only one domain ID is the primary domain ID, and the other domain IDs are secondary domain IDs. The primary domain ID is configured using the **domain-id value** command, and the secondary domain IDs are configured using the **domain-id value secondary** command. The VPN route converted from an OSPF route contains only the primary domain ID.
- i** The primary and secondary domain IDs can be configured using the **domain-id ip-address** command or the **domain-id type { 0005 | 0105 | 0205 | 8005 } value** command.
- i** You can configure the domain IDs of different VRF OSPF instances to be the same. The VRF OSPF instances of the same VPN must be configured with the same domain ID to ensure correct route advertisement.

▾ (Optional) Configuring a VPN Route Tag

By default, the VPN route of an OSPF instance is marked by the AS number of local BGP.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# router ospf <i>ospf-id</i> vrf <i>vrf-name</i>	Creates an OSPF instance and enters OSPF configuration mode.
Ruijie(config-router)# domain-tag <i>value</i>	Configures a VPN route tag for the OSPF instance. The value range is <1–4294967295>.
Ruijie(config-router)# show running-config	Displays existing configurations.

- i** The **domain-tag value** command takes effect only for VRF OSPF instances.
- i** If VRF-specific **domain-tag** is not configured manually, the default value is the AS number of local BGP.

In L3VPN, if a VPN site is connected to multiple PEs, the VPN route that a PE learns over MP-BGP is advertised to the VPN site over a type 5 or 7 LSA. If another PE connected to the VPN site learns and advertises the VPN route, a loop occurs. To avoid the loop, configure the same VPN route tag for the VRF OSPF instances of the PEs connected to the same VPN site. The type 5 or 7 LSA that a VRF OSPF instance sends to the VPN site carries a VPN route tag. When another PE receives the type 5 or 7 LSA, it checks whether the VPN route tag in the LSA is the same as that of the corresponding OSPF instance. If they are the same, the LSA is excluded from OSPF route calculation.

- i** Typically, OSPF instances of the same VPN are configured with the same VPN route tag.

📌 (Optional) Configuring a Sham Link

A sham link is applicable in the scenario where VPN sites are connected by a backdoor link. If you require that VPN data be still transmitted over the MPLS backbone network, create a sham link between the VRF OSPF instances on two PEs. In this way, the VRF OSPF instances establish an OSPF neighbor relationship over the sham link to distribute LSA packets.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# router ospf <i>ospf-id</i> vrf <i>vrf-name</i>	Creates an OSPF instance and enters OSPF configuration mode.
Ruijie(config-router)# area <i>area-id</i> sham-link <i>source-address</i> <i>destination-address</i> [cost <i>number</i>] [dead-interval <i>seconds</i>] [hello-interval <i>seconds</i>] [retransmit-interval <i>seconds</i>] [transmit-delay <i>seconds</i>] [authentication [message-digest null]] [[authentication-key [0 7] <i>key</i>] [message-digest-key <i>key-id</i> md5 [0 7] <i>key</i>]]	Configures the area ID, source address, and destination address of the sham link.
Ruijie(config-router)# show running-config	Displays existing configurations.

A sham link must be configured on two PEs. A single PE does not support sham link creation.

The two PEs for sham link creation must meet the following configuration requirements:

- The PEs must be configured with the same area ID of the sham link.
- The PEs must be configured with the same <source address, destination address> combination of the sham link.
- The source address and destination address of the sham link must be the 32-bit loopback interface addresses bound to the VRF tables on PEs.

- i** OSPF routes advertised over a sham link are not used for forwarding because the routes do not have a VPN route tag. Forwarding is still implemented by BGP VPNv4 routes. Therefore, ensure that routes learned over the sham link can also be learned over MP-BGP.
- i** The source address used for sham link creation must be used by VPNv4 route advertisement over BGP, but the source address cannot be used by VRF OSPF instances for route calculation.

📌 (Optional) Configuring capability vrf-lite

By default, VRF OSPF instances support the PE-CE OSPF feature (LSA conversion based on the domain ID, DN bit, and VPN route tag). You can run the **capability vrf-lite** command to disable the PE-CE OSPF feature for VRF OSPF instances.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# router ospf <i>ospf-id</i> vrf <i>vrf-name</i>	Creates an OSPF instance and enters OSPF configuration mode.
Ruijie(config-router)# capability vrf-lite [auto]	Disables the PE-CE OSPF feature for VRF OSPF instances.
Ruijie(config-router)# show running-config	Displays existing configurations.

- i** The **capability vrf-lite** command takes effect only for VRF OSPF instances.
- i** The loop detection function can be disabled for VRF OSPF instances in some application scenarios. For example, if VPN routes are exchanged between MCE and PE over OSPF, you need to run the **capability vrf-lite** command to disable the loop detection function for the VRF OSPF instance on the MCE to allow for route learning between VPN sites.

📌 (Optional) Configuring **extcommunity-type**

After an OSPF route is redistributed to BGP to form a VPN route, the VPN route carries the extended community attributes of the OSPF route, including the router-id and route-type extended community attributes. By default, the router-id extended community attribute belongs to the 0x0107 type, and the route-type extended community attribute belongs to the 0x0306 type. You can use a command to manually configure the types of the router-id and route-type extended community attributes.

Command	Description
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# router ospf <i>ospf-id</i> vrf <i>vrf-name</i>	Creates an OSPF instance and enters OSPF configuration mode.
Ruijie(config-router)# extcommunity-type { router-id { 0107 8001 } route-type { 0306 8000 } }	Configures the OSPF router-id and route-type extended community attributes.
Ruijie(config-router)# show running-config	Displays existing configurations.

- i** The **extcommunity-type** command takes effect only for VRF OSPF instances.
- i** The router-id type configuration is intended for compatibility with different vendors. For example, when you interwork with a vendor that only supports the 0x0107 type, you need to run the **extcommunity-type** command to change the type of router-id to 0x0107.
- i** The route-type type configuration is intended for compatibility with different vendors. For example, when you interwork with a vendor that only supports the 0x8000 type, you need to run the **extcommunity-type** command to change the type of route-type to 0x8000.

Verification

- Check that VPN sites can communicate with each other.

Configuration Example

Configuring a Domain ID

<p>Scenario Figure 3-40</p>	<p>Two sites of a customer exchange VPN routes over the MPLS backbone network. The sites access PEs over OSPF. The OSPF routes that are exchanged over the MPLS backbone network must be restored to the maximum extent to OSPF routes supported by the sites.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> On SiteA and SiteB, configure OSPF used for exchanging routes between PE and CE. On PE1 and PE2, configure a loopback interface, create a VRF table named VPNA, define RD and RT values, and associate the VRF table with the corresponding interface. Associate the CE-connected interface with the VRF table. Configure BGP, and establish an MP-IBGP session with PE2. Configure the capability of exchanging routes with the CE over OSPF. Set the domain ID of the OSPF instance to 10. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. On P1 and P2, configure backbone MPLS signaling, enable MPLS on the interface connected to the public network, and configure a backbone routing protocol.

Configuring a Sham Link

<p>Scenario Figure 3-41</p>	<p>The diagram illustrates a network topology for configuring a sham link. At the top, two sites are shown: VPNA-SiteB (left) and VPNA-SiteA (right). SiteB is connected to a public network (192.168.40.0/24) and has a loopback interface (192.168.40.0/24). SiteA is connected to a public network (192.168.20.0/24) and has a loopback interface (192.168.20.0/24). A 'Backdoor Link' connects SiteB (G11/1:1) and SiteA (G11/1:2) with IP 192.168.20.0/24. Below, two PE routers (PE2 and PE1) are connected to a central MPLS backbone. PE2 (left) has interfaces G11/0:2 (connected to SiteB), G11/2:1 (connected to backbone), and a loopback (172.168.40.0/24). PE1 (right) has interfaces G11/0:2 (connected to SiteA), G11/2:1 (connected to backbone), and a loopback (172.168.10.0/24). A 'Sham-link' is established between PE2 (G11/2:1) and PE1 (G11/2:1) with IP 172.168.0.2/24. The backbone also includes a central router with interfaces G11/1:2 and G11/2:1 (connected to PE2) and G11/0:2 and G11/1:1 (connected to PE1).</p> <p>Two sites of a customer exchange VPN routes over the MPLS backbone network. A backdoor link is established between the sites to exchange VPN routes when the MPLS backbone network fails.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> On SiteA, configure OSPF for communicating with PE1 and configure OSPF over the backdoor link for communicating with SiteB. Set the OSPF cost in interface configuration mode. On SiteB, configure OSPF for communicating with PE2 and configure OSPF over the backdoor link for communicating with SiteA. Set the OSPF cost in interface configuration mode. On PE1, configure a loopback interface, create a VRF table named VPNA, define RD and RT values, and associate the VRF table with the corresponding interface. Associate the CE-connected interface with the VRF table. Configure a loopback interface for the VRF table for establishing a sham link. Configure BGP, and establish an MP-IBGP session with PE2. Configure the capability of exchanging routes with the CE over OSPF. Establish a sham link with the OSPF instance on PE2. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. On PE2, configure a loopback interface, create a VRF table named VPNA, define RD and RT values, and associate the VRF table with the corresponding interface. Associate the CE-connected interface with the VRF table. Configure a loopback interface for the VRF table for establishing a sham link. Configure BGP, and establish an MP-IBGP session with PE1. Configure the capability of exchanging routes with the CE over OSPF. Establish a sham link with PE1. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. On P1, configure backbone MPLS signaling, enable MPLS on the interface connected to the public network, and configure a backbone routing protocol.

➤ **Configuring Multiple OSPF Instances per MCE**

	<p>be exchanged over the MPLS backbone network and different services be isolated from each other.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● On MCE-A and MCE-B, configure a trunk link between PE and CE, configure two VRF tables for different services, and bind an interface to each VRF table. Configure the two VRF tables to communicate with the PE over OSPF. ● On PE1 and PE2, configure a loopback interface, configure a trunk link between PE and CE, create two VRF tables named VPN1 and VPN2 for different services, and associate the VRF tables with corresponding interfaces. Associate the CE-connected interface with a VRF table. Configure BGP, and establish an MP-IBGP session with the peer PE (PE2 or PE1). Configure the capability of exchanging routes with the CE over OSPF. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. ● On P1, configure backbone MPLS signaling, enable MPLS on the interface connected to the public network, and configure a backbone routing protocol. <p> This example uses the configuration of the SVI and the 802.1Q sub-interface to describe how to connect PE1 and MCE-A. Some devices may not support the two interfaces. PE1 and MCE-A can be connected by any two links (physical or logical) based on two routing adjacencies between them. You can select a suitable connection method according to the actual condition.</p>
<p>MCE-A</p>	<pre> MCE-A# configure terminal MCE-A(config)# interface GigabitEthernet 1/0 MCE-A(config-if-GigabitEthernet 1/0)# switchport mode trunk MCE-A(config-if-GigabitEthernet 1/0)# end MCE-A# configure terminal MCE-A(config)# ip vrf VPN1 MCE-A(config-vrf)# exit MCE-A(config)# vlan 10 MCE-A(config)# interface vlan 10 MCE-A(config-if-Vlan 10)# ip vrf forwarding VPN1 MCE-A(config-if-Vlan 10)# ip address 192.168.10.2 255.255.255.0 MCE-A(config-if-Vlan 10)# exit MCE-A(config)# ip vrf VPN2 MCE-A(config-vrf)# exit MCE-A(config)# vlan 20 MCE-A(config)# interface vlan 20 MCE-A(config-if-Vlan 20)# ip vrf forwarding VPN2 MCE-A(config-if-Vlan 20)# ip address 192.168.20.2 255.255.255.0 </pre>

Common Errors

An LDP session fails to be established because the router ID does not consist of 32 bits.

3.5 Monitoring

Clearing

Description	Command
Resets the VPNv4 unicast address family of BGP.	clear bgp vpnv4 unicast { * <i>as-number</i> <i>peer-address</i> } [soft] [in out]
Clears VPNv4 route flapping information and cancels VPNv4 route suppression.	clear bgp vpnv4 unicast dampening [<i>ip-address</i> [<i>mask</i>]]
Resets all EBGP connections under the VPNv4 address family.	clear bgp vpnv4 unicast external [soft] [in out]

Description	Command
Clears route flapping statistics under the VPNv4 address family.	clear bgp vpnv4 unicast flap-statistics [<i>ip-address</i> [<i>mask</i>]]
Resets the VPNv4 address family for all members of the BGP peer group.	clear bgp vpnv4 unicast peer-group <i>peer-group-name</i> [soft] [in out]
Resets the VPNv6 unicast address family of BGP.	clear bgp vpnv6 unicast { * <i>as-number</i> <i>peer-address</i> } [soft] [in out]
Clears VPNv6 route flapping information and cancels VPNv6 route suppression.	clear bgp vpnv6 unicast dampening
Resets all EBGP connections under the VPNv6 address family.	clear bgp vpnv6 unicast external [soft] [in out]
Clears route flapping statistics under the VPNv6 address family.	clear bgp vpnv6 unicast flap-statistics
Resets the VPNv6 address family for all members of the BGP peer group.	clear bgp vpnv6 unicast peer-group <i>peer-group-name</i> [soft] [in out]
Resets the BGP session under a VRF table.	clear ip bgp vrf <i>vrf-name</i> { * <i>address</i> <i>as-num</i> } [soft] [in out]

Displaying

Description	Command
Displays the IPv4 routes with an MPLS label that are learned and sent over BGP.	show bgp ipv4 unicast labels
Displays the IPv6 routes with an MPLS label that are learned and sent over BGP.	show bgp ipv6 unicast labels
Displays the VPNv4 routes or the neighbor information that are learned and sent over BGP.	show bgp vpnv4 unicast all [<i>network</i> neighbor [<i>peer-address</i>] summary label]
Displays the VPNv4 routes or the neighbor information that are learned and sent over BGP under the specified VRF table.	show bgp vpnv4 unicast vrf <i>vrf_name</i> [<i>network</i> summary label]
Displays the VPNv4 routes or the neighbor information that are learned and sent over BGP under the specified RD.	show bgp vpnv4 unicast rd <i>rd_value</i> [<i>network</i> summary label]
Displays the VPNv6 routes or the neighbor information that are learned and sent over BGP.	show bgp vpnv6 unicast all [<i>network</i> neighbor [<i>peer-address</i>] summary label]
Displays the VPNv6 routes or the neighbor information that are learned and sent over BGP under the specified VRF table.	show bgp vpnv6 unicast vrf <i>vrf_name</i> [<i>network</i> summary label]
Displays the VPNv6 routes or the neighbor information that are learned and sent over BGP under the specified RD.	show bgp vpnv6 unicast rd <i>rd_value</i> [<i>network</i> summary label]
Displays the configurations of an extcommunity list.	show ip extcommunity-list [<i>extcommunity-list-num</i> <i>extcommunity-list-name</i>]

Description	Command
Displays the OSPF sham link information.	show ip ospf [<i>process-id</i>] sham-links [area <i>area-id</i>]
Displays the configured single-protocol VRF information.	show ip vrf [brief detail interfaces] [<i>vrf-name</i>]
Displays brief information about VRF tables (single- and multi-protocol VRF tables).	show vrf brief [<i>vrf-name</i>]
Displays brief information about the IPv4 address family for VRF tables (single- and multi-protocol VRF tables).	show vrf ipv4 [<i>vrf-name</i>]
Displays brief information about the IPv6 address family for multi-protocol VRF tables.	show vrf ipv6 [<i>vrf-name</i>]
Displays detailed information about VRF tables (single- and multi-protocol VRF tables).	show vrf detail [<i>vrf-name</i>]

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Enables BGP MPLS debugging.	debug ip bgp mpls
Enables MPLS entry debugging.	debug mpls
Enables MPLS message debugging.	debug mpls msg [send recv]

4 Configuring MPLS GR

- i** The routers and router icons described in this chapter refer to general routers as well as Layer-3 switches running routing protocols. We use "router series" or "switch series" to refer to specific devices.

4.1 Overview

The Internet Engineering Task Force (IETF) extends the Multiprotocol Label Switching (MPLS) signaling protocol – Label Distribution Protocol (LDP). In this way, when LDP is restarted, a device can notify its neighbor to retain MPLS forwarding entries for a period and mark these entries as "Old". Peripheral devices assist the device in information synchronization so that the device can return to the condition before the LDP restart within a short time. If the packet forwarding path is not changed during the LDP restart, the system can forward data continuously, thereby providing reliable MPLS services.

Virtual Private Wire Service (VPWS) and Virtual Private LAN Service (VPLS) use basic MPLS networks to establish public tunnels and use extended LDP to distribute virtual circuit (VC) labels and establish VCs. Therefore, for continuous VPWS and VPLS forwarding, extended LDP Graceful Restart (GR) must be implemented. Despite different MPLS forwarding entries, extended LDP GR and basic LDP GR are implemented in the same way. Therefore, extended LDP GR and basic LDP GR can be processed uniformly.

Layer-3 Virtual Private Network (L3VPN) GR enables continuous L3VPN forwarding. When the control plane of a device fails, VPN forwarding continues, which protects VPNs.

4.2 Applications

Application	Description
L2VPN GR	Deploying Graceful Restart (GR) on a device that enables Multiprotocol Label Switching Layer-2 Virtual Private Network (MPLS L2VPN) (for example, a Provider Edge (PE) device) ensures that users can forward their services in case of any fault, thereby improving reliability.
L3VPN GR	Deploying GR on a device that enables MPLS L3VPN (for example, a PE device) ensures that users can forward their services in case of any fault, thereby improving reliability.

4.2.1 L2VPN GR

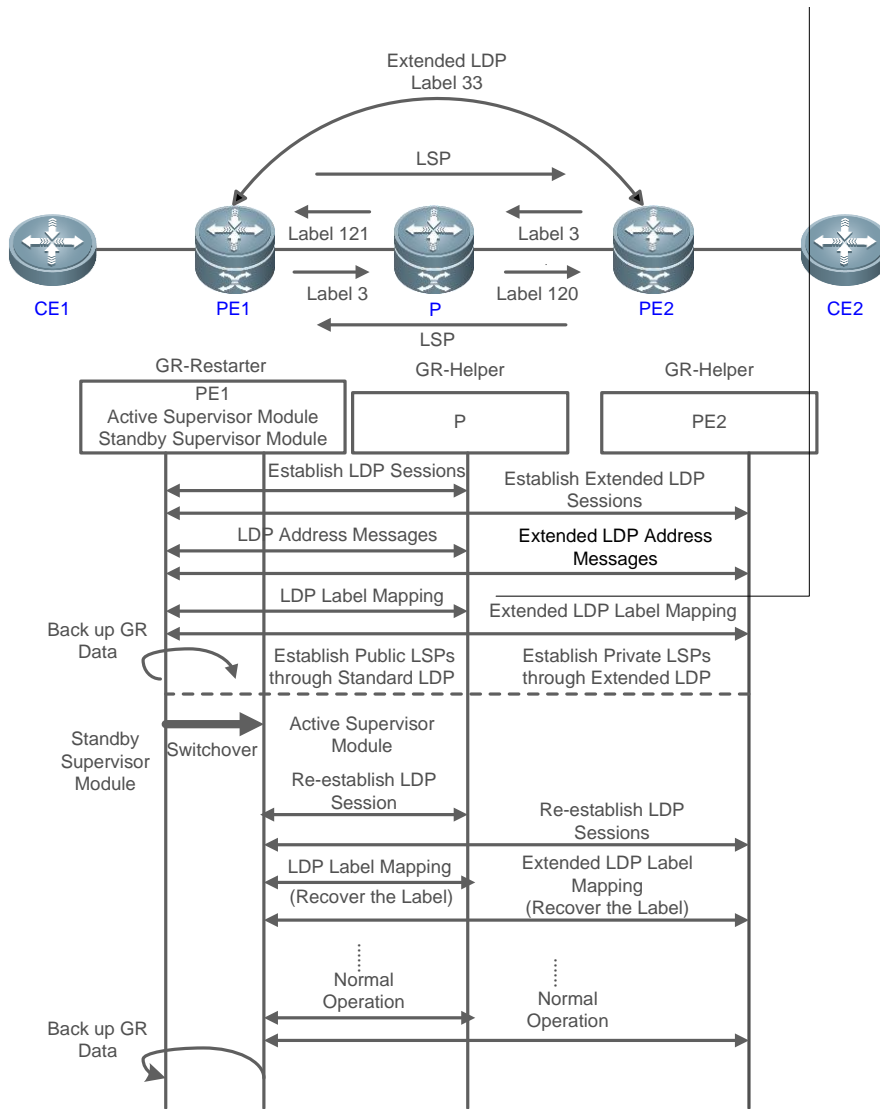

- i** L2VPN GR described in this section refers to GR of VPWS and VPLS implemented in Martini mode.
- i** The following describes the working principle of VPWS GR. VPLS GR is omitted.
- i** The control plane and forwarding plane of the GR-Capable router described in this document are separated. When the control plane is restarted, data forwarding on line cards will not be affected.

Scenario

- When the active and standby supervisor modules are switched over, routing protocol flapping is minimized.

! When the active and standby supervisor modules are switched over on a neighbor device, GR cannot guarantee that traffic will not be interrupted.

Figure 4-1

Remarks	<p>The CustomerEdge (CE) devices represent a customer network and run the Interior Gateway Protocol (IGP). The PE and P devices form a provider network and run the IGP and Link Detection Protocol (LDP). PE1, P and PE2 establish public network tunnels through LDP and establish Label Switched Paths (LSPs). PE1 and PE2 establish private network tunnels through extended LDP. IGP and LDP have the GR capability. The PE devices are GR-Capable routers, and the P device is a GR-Aware router.</p>
---------	---

The following describes the GR process on PE1. The active and standby supervisor modules are switched over on PE1. PE1 serves as a GR Restarter, while P and PE2 serve as GR Helpers.

▾ Before the Active/Standby Supervisor Module Switchover

PE1 negotiates with P about LDP and IGP GR, negotiates with CE1 about IGP GR, and negotiates with PE2 about extended LDP GR. PE1 respectively sends P and PE2 an initialization message with FT session TLV options to establish a GR-capable LDP session.

The devices exchange addresses and label mapping messages. In this way, GR-capable LSPs are established for data forwarding.

To support GR, when the active supervisor module works normally, you need to back up the protocol GR data to the standby supervisor module.

▾ During the Active/Standby Supervisor Module Switchover

After the GR data is backed up to the standby supervisor module, PE1 switches over active and standby supervisor modules. PE2 and P detect Transmission Control Protocol (TCP) sessions in Down state and mark the corresponding LSPs as "Old". The devices enable the forwarding entry aging timer. Packet forwarding will be continued before a timeout. CEs work in a similar way although they process IGP GR.

▾ After the Active/Standby Supervisor Module Switchover

On PE1, the standby supervisor module becomes an active supervisor module and the active supervisor module becomes a standby supervisor module. PE1 checks the GR data backed up to the new active supervisor module for forwarding entries before the protocol restart. Then devices initialize their Command Line Interfaces (CLIs) and enable GR. During LDP and IGP GR, devices notify all IGP and LDP neighbors to re-establish connections.

- IGP convergence:

PE1 sends P a GR-capable initialization message, and re-establishes the session upon receipt of a response to obtain topology and routing information. Then PE1 re-calculates the routing table and deletes "Old" routes. In this way, IGP converges.

- LDP processing:

PE1 sends a GR-capable initialization message to P and PE2, respectively. A GR-capable LDP session is established when P and PE2 receive the message. The devices re-exchange addresses and label mapping messages and delete or retain the "Old" flag for MPLS forwarding entries. After GR, the devices delete "Old" MPLS forwarding entries.

i IGP GR and LDP GR are processed in no particular order. IGP routes converge first and then advertised to LDP.

! Before all protocols finish GR, PE1 only updates the routing information base (RIB) of the active supervisor module.

! After all protocols finish GR, PE1 updates the forwarding information base (FIB) of the interface module.

Deployment

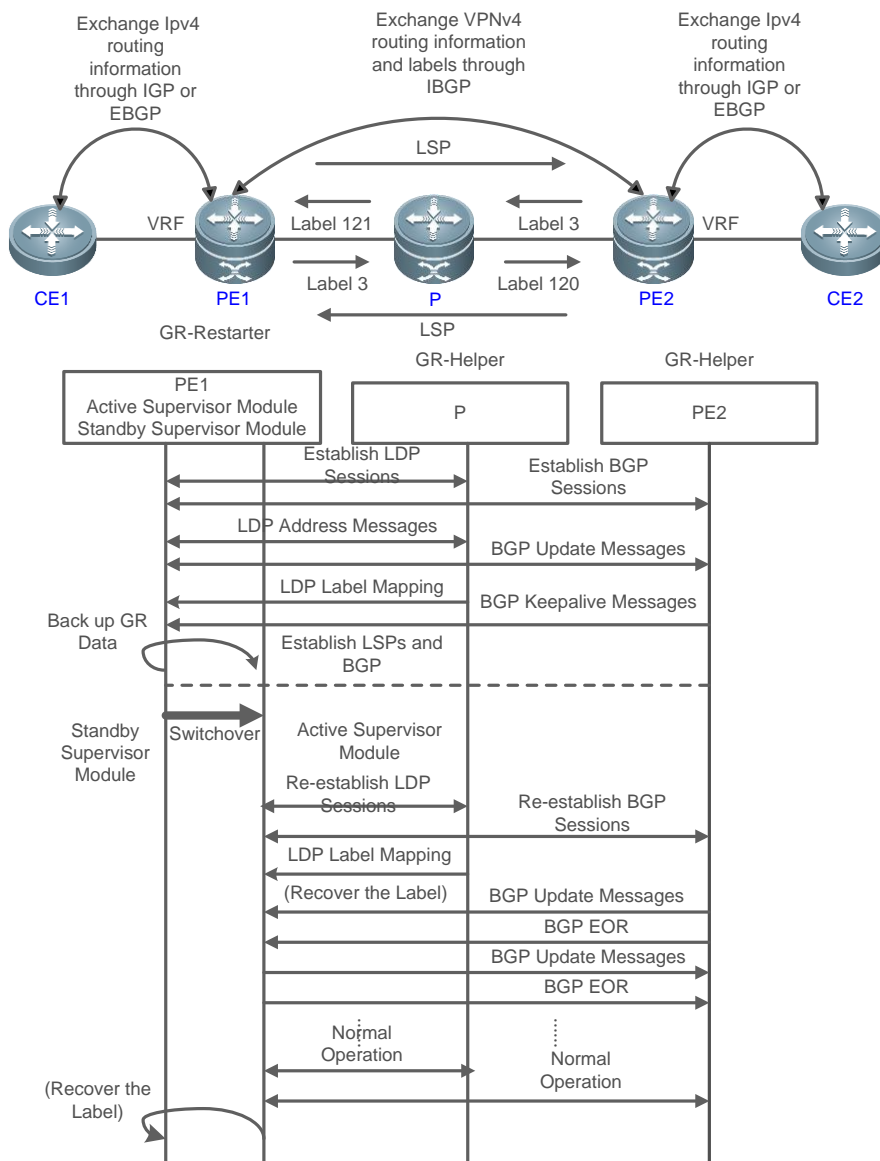

i The prerequisite for implementing Virtual Private Wire Service (VPWS) GR is that the continuous forwarding of routing protocols must be supported and the hardware must support 1 + 1 redundant backup for management modules.

i The continuous forwarding of routing protocols means that a unicast routing protocol must support GR; that is, the device must support Open Shortest Path First (OSPF) GR, Intermediate System to Intermediate System (IS-IS) GR, or Border Gateway Protocol (BGP) GR.

- PE1, P and PE2 create a VPWS environment where VPWS is configured and provided for users.
- IGP GR is configured for CE1, PE1, P, PE2 and CE2 to continuously forward routing protocols.
- LDP GR is configured for PE1, P and PE2 to continuously forward public MPLS and VPWS.

4.2.2 L3VPN GR

Figure 4-2

Remarks	<p>CE devices represent a customer network and run the IGP or External Border Gateway Protocol (EBGP).</p> <p>PE and P devices form a provider network and run the IGP.</p> <p>PE1, P and PE2 establish public network tunnels through LDP and establish LSPs.</p> <p>PE1 and PE2 establish private network tunnels through extended Internal Border Gateway Protocol (IBGP).</p> <p>IGP, BGP and LDP have the GR capability.</p> <p>PE devices are GR-Capable routers, and the P device is a GR-Aware router.</p>
---------	--

The following describes the GR process on PE1. The active and standby supervisor modules are switched over on PE1. PE1 serves as a GR Restarter, while P and PE2 serve as GR Helpers. Active and standby supervisor modules are switched over in three phases:

↳ Before the Active/Standby Supervisor Module Switchover

PE1 negotiates with CE1 about IGP or External BGP (EBGP) GR, negotiates with P about IGP and LDP GR, and negotiates with PE2 about Internal BGP (IBGP) GR.

PE1 sends P an initialization message with FT session TLV options to establish a GR-capable LDP session. Then the devices exchange addresses and label mapping messages. In this way, GR-capable LSPs are established for data forwarding.

PE1 sends PE2 a GR-capable <AFI=IPv4, SAFI=Unicast> and <AFI=IPv4, SAFI=VPNv4> Open message to establish a GR-capable IBGP session.

When the active supervisor module works normally, you need to back up the GR data to the standby supervisor module so that after active and standby supervisor modules are switched over, PE1 can read the data during the GR protocol restart and use it for GR.

↳ During the Active/Standby Supervisor Module Switchover

After the GR data is backed up to the standby supervisor module, PE1 switches over active and standby supervisor modules.

P detects TCP sessions in Down state and marks the corresponding LSPs as "Old". The device enables the forwarding entry aging timer. Packet forwarding will be continued before a timeout.

When detecting disconnected TCP, PE2 immediately mark the routes learned from PE1 as "Old" and enables a restart timer for PE1. If PE2 does not receive the Open message before a timeout, it will delete the "Old" flag; if PE2 receives the Open message, it will delete the restart timer. PE1 and PE2 continue traffic forwarding through original routes.

↳ After the Active/Standby Supervisor Module Switchover

On PE1, the standby supervisor module becomes an active supervisor module and the active supervisor module becomes a standby supervisor module. PE1 checks the GR data backed up to the new active supervisor module for forwarding entries before the protocol restart. Then devices initialize their CLIs and enable GR. During IGP, BGP, and LDP GR, the devices notify all IGP and LDP neighbors to re-establish connections.

- IGP convergence

PE1 sends P a GR-capable initialization message, and re-establishes the session upon receipt of a response to obtain topology and routing information. Then PE1 re-calculates the routing table and deletes "Old" routes. In this way, IGP converges.

- BGP processing

PE1 and CE1 exchange routing information. Then PE1 updates the routing table and forwarding entries based on route forwarding information and replaces invalid routing information. In this way, BGP converges.

PE1 and PE2 establish a new BGP session in between. First, PE1 sends PE2 an Open message with GR options. Then PE1 receives an Update message from PE2 and processes the message. The Update message includes IP address prefixes. PE1 selects BGP routes when receiving an End-of-RIB (EOR) flag. PE1 sends PE2 the Update message with IP address prefixes and then sends PE2 the EOR flag. PE2 selects routes upon receipt of the EOR flag. In this way, the network converges.

- LDP processing

PE1 sends P a GR-capable initialization message. A GR-capable LDP session is established when P receives the message. The devices re-exchange addresses and label mapping messages and delete or retain the "Old" flag for MPLS forwarding entries. After GR, the devices delete "Old" MPLS forwarding entries.

i IGP GR, BGP GR, and LDP GR are processed in no particular order. Unicast routes converge first and then are advertised to LDP.

! Before all protocols finish GR, PE1 only updates the RIB of the active supervisor module.

! After all protocols finish GR, PE1 updates the FIB of the interface module.

Deployment

i The prerequisite for implementing L3VPN GR is that the continuous forwarding of routing protocols must be supported and the hardware must support 1 + 1 redundant backup for management modules.

i continuous forwarding of routing protocols means that a unicast routing protocol must support GR; that is, the device must support Open Shortest Path First (OSPF) GR, Intermediate System to Intermediate System (IS-IS) GR, or BGP GR.

- PE1, P and PE2 create an L3VPN environment where L3VPN is configured to provide L3VPN services for users.
- IGP GR is configured for CE1, PE1, P, PE2 and CE2 to continuously forward routing protocols.
- BGP GR is configured for PE1 and PE2 to continuously forward private routes.
- LDP GR is configured for PE1, P and PE2 to continuously forward public MPLS.

4.3 Features

Basic Concepts

▾ GR Capability-related Router

In terms of the GR capability, GR-Capable routers, GR-Aware routers, and GR-Unaware routers are available.

- GR-Capable router

A GR-Capable router has the GR capability. It is usually equipped with dual supervisor modules, which enables 1+1 redundancy. During the active/standby supervisor module switchover, the router notifies neighbors to retain its forwarding entries. After the switchover, the router re-establishes the routing table without route flapping, and the packet forwarding path is not changed. In this way, continuous forwarding is enabled.

- GR-Aware router

A GR-Aware router is aware of GR. It may not have dual supervisor modules, but it is aware of GR on neighbors and can help neighbors finish GR.

- GR-Unaware router

A GR-Unaware router is unaware of GR on neighbors and cannot help neighbors finish GR because software does not have a GR feature or the GR feature is disabled.

GR Role-related Router

During the router restart, in terms of the role, GR Restarters and GR Helpers are available.

- GR Restarter

A GR Restarter restarts because of the administrator operation or failures. It must be a GR-Capable router.

- GR Helper

A GR Helper is the neighbor of a GR Restarter. It is at least a GR-Aware router.

Overview

Feature	Description
LDP GR	When the MPLS device is faulty, the function maintains the neighbor relationship and sessions between routers, and recovers the session connection and label information subsequently to prevent common MPLS and L2VPN forwarding from being interrupted.

4.3.1 LDP GR

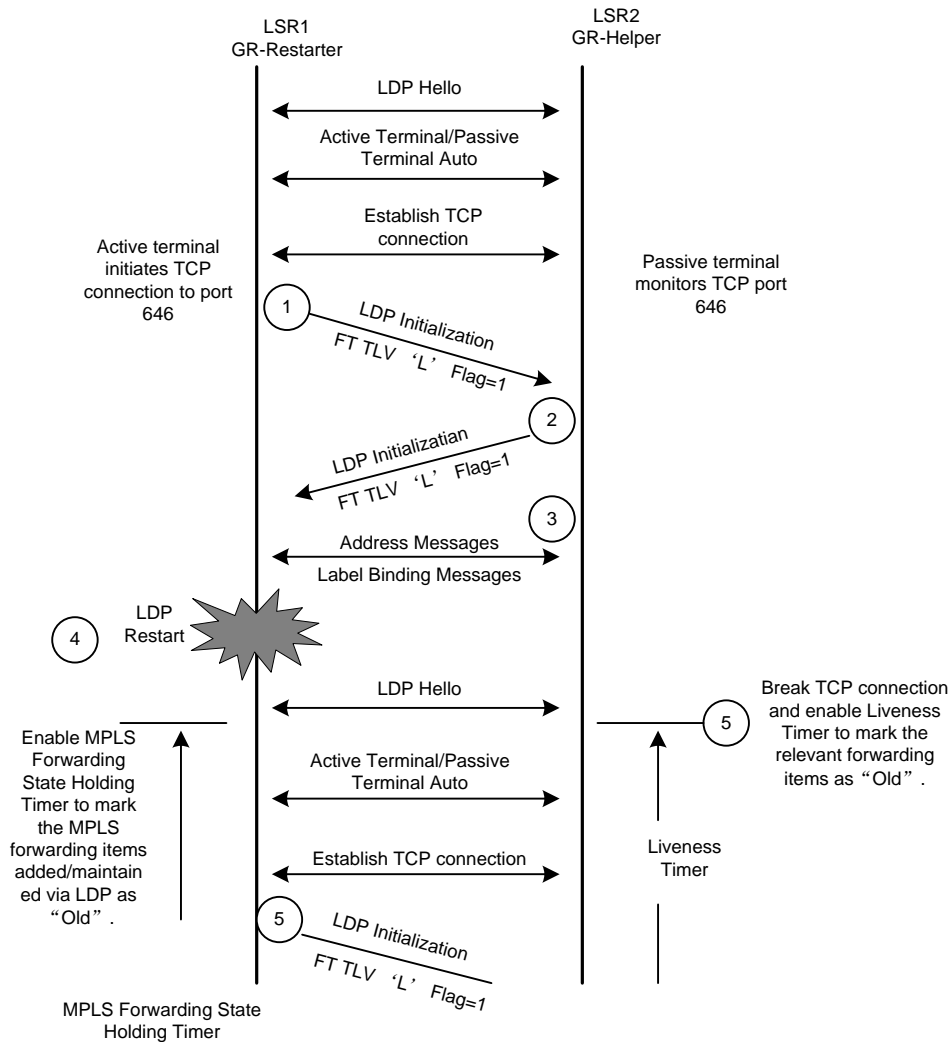

By using LDP GR together with IGP GR, you can achieve uninterrupted common MPLS or L2VPN forwarding. If further using BGP GR, you can achieve uninterrupted L3VPN forwarding.

To establish a GR-capable LDP session, both ends must support and enable LDP GR. If one end does not support GR, only ordinary LDP sessions can be established. If the active side supports and enables LDP GR, it will add FT Session TLV to an initialization message.

If the passive side receives an initialization message with FT Session TLV, it can decide whether to add FT Session TLV to an initialization message. If it supports and enables LDP GR, it will add FT Session TLV to an initialization message and thereby a GR-capable LDP session is established; otherwise, it will not add FT Session TLV to an initialization message and thereby an ordinary LDP session is established. If the passive side receives an initialization message without FT Session TLV, an ordinary LDP session will be established whether the passive side adds FT Session TLV to an initialization message. The following figure shows the process of LDP session establishment between two GR-capable LSRs.

Working Principle

Figure 4-3

Related Configuration

Enabling LDP GR

By default, LDP GR is enabled on devices enabling LDP.

In LDP mode, by running the **graceful-restart** command, you can enable or disable LDP GR.

The GR capability of LDP can take effect only when LDP sessions are restarted.

Configuring LDP GR

By default, the Time To Live (TTL) of an LDP neighbor is 120 seconds; the time for re-connecting LDP sessions is 300 seconds; the LDP recovery time is 120 seconds.

- Run the **graceful-restart timer neighbor-liveness** command to configure the TTL of an LDP neighbor. During this period of time, the Helper waits for the Restarter to restart and then they re-establish the session. If it takes a long time for the Restarter to restart, you can extend the TTL.
- Run the **graceful-restart timer reconnect** command to configure the LDP session reconnection time. During this period of time, the Restarter holds the MPLS forwarding entries (corresponding to the MPLS forwarding state holding timer shown in the figure). If it takes a long time to recover a large number of MPLS forwarding entries, you can extend the time.
- Run the graceful-restart timer recovery command to configure the LDP session recovery time. During this period of time, the Helper assists the Restarter in recovering MPLS forwarding entries after the session is re-established. If it takes a long time to recover a large number of MPLS forwarding entries, you can extend the time.

4.4 Configuration

Configuration	Description and Command
LDP GR	 (Mandatory) It is used to configure LDP GR.
	graceful-restart Enables the GR capability of LDP.
	 (Optional) It is used to configure the LDP GR timer.
	graceful-restart timer reconnect Configures the time for re-connecting LDP sessions.
	graceful-restart timer neighbor-liveness Configures the TTL of an LDP neighbor.
	graceful-restart timer recovery Configures the time for recovering LDP sessions.

4.4.1 LDP GR

Configuration Effect

After MPLS LDP GR is configured, when MPLS devices fail, the neighbor relationship and sessions between routers can be maintained, and session connection and labels can be recovered.

Notes

-  The routing interface for configuring IP addresses must be a Layer-3 routing interface, or configuration will fail.
-  Topological changes during GR (for example, changes in the IP address or link of the Link-State Request (LSR) ID used before GR is deleted) may disable GR and interrupt service traffic.

You need to finish the following tasks before configuring MPLS LDP GR:

- Configuring IGP GR
- Configuring MPLS LDP sessions

Before configuring MPLS LDP GR, you need to configure the following:

- The LDP session reconnection time
- The TTL of an LDP neighbor
- The LDP session recovery time

Configuration Steps

↳ Enabling LDP GR

- Mandatory.
- Run the **no graceful-restart** command to disable the GR capability of LDP.
- Enable GR by default to support process restart. Except otherwise required, do not disable LDP GR.

i Enabling LDP GR will not affect LDP sessions; that is, LDP sessions will not be restarted. LDP GR takes effect only when LDP sessions are restarted.

↳ Configuring LDP GR

- Optional.
- Run the **graceful-restart timer neighbor-liveness** command to configure the TTL of an LDP neighbor. During this period of time, the Helper waits for the Restarter to restart and then they re-establish the session. If it takes a long time for the Restarter to restart, you can extend the TTL.
- Run the **graceful-restart timer reconnect** command to configure the LDP session reconnection time. During this period of time, the Restarter holds the MPLS forwarding entries (corresponding to the MPLS forwarding state holding timer shown in the figure). If it takes a long time to recover a large number of MPLS forwarding entries, you can extend the time.
- Run the **graceful-restart timer recovery** command to configure the LDP session recovery time. During this period of time, the Helper assists the Restarter in recovering MPLS forwarding entries after the session is re-established. If it takes a long time to recover a large number of MPLS forwarding entries, you can extend the time.

Verification

- After GR is configured, the sessions previously established will not be affected, and the function will take effect only when new sessions are established.
- You can run the **show mpls ldp graceful-restart** command to display GR-capable sessions.
- You can run the **show mpls ldp neighbors** command to check whether a session has the GR capability.

Related Commands

↳ Enabling LDP GR

Command	graceful-restart
Parameter	N/A

Description	
Command Mode	This configuration is performed in config-mpls-router configuration mode.
Usage Guide	<p>The following describes how to use this command:</p> <p>If LDP GR is enabled on a dual-engine device, when the active supervisor module fails (or active and standby supervisor modules are switched over manually), traffic forwarding will not be interrupted, and the MPLS forwarding state will not be changed after the LDP restart.</p> <p>By default, GR is enabled whether a device serves as a GR Restarter or a GR Helper.</p> <p>The changed configuration of LDP GR takes effect only when LDP sessions are restarted.</p>

↘ Configuring the LDP Session Reconnection Time

Command	graceful-restart timer reconnect <i>seconds</i>
Parameter Description	<i>seconds</i> : Configures the LDP session reconnection time, which ranges from 30 to 3,600 seconds.
Command Mode	This configuration is performed in config-mpls-router configuration mode.
Usage Guide	<ul style="list-style-type: none"> ● During GR, both GR Restarter and GR Helper use the LDP session reconnection time. ● A GR Restarter uses the LDP session reconnection time to retain "Old" entries. ● A GR Helper enables the liveness timer based on its neighbor-liveness time or received reconnection time, whichever is shorter, and retains the "Old" entries before a timeout. ● If it takes a long time to reconnect to a neighbor because of a large number of services, you need to adjust the reconnection time and neighbor-liveness time. In a typical L3VPN scenario, the time increases by 1 minute every 100 VPNs. ● The LDP session reconnection time takes effect only when LDP sessions are restarted.

↘ Configuring the TTL of an LDP Neighbor

Command	graceful-restart timer neighbor-liveness <i>seconds</i>
Parameter Description	<i>seconds</i> : Configures the TTL of an LDP neighbor, which ranges from 5 to 3,600 seconds.
Command Mode	This configuration is performed in config-mpls-router configuration mode.
Usage Guide	<ul style="list-style-type: none"> ● Only a GR Helper uses the TTL. ● A GR Helper enables the liveness timer based on its neighbor-liveness time or received reconnection time, whichever is shorter, and retains the "Old" entries before a timeout. ● The TTL of an LDP neighbor takes effect only when LDP sessions are restarted.

↘ Configuring the LDP Session Recovery Time

Command	graceful-restart timer recovery <i>seconds</i>
Parameter Description	<i>seconds</i> : Configures the LDP session recovery time, which ranges from 15 to 600 seconds.
Command	This configuration is performed in config-mpls-router configuration mode.

Mode	
Usage Guide	<ul style="list-style-type: none"> ● Only a GR Helper uses the LDP session recovery time. ● A GR Helper enables the recovery timer based on its recovery time or received recovery time, whichever is shorter, and retains the "Old" entries before a timeout. ● The LDP session recovery time takes effect only when LDP sessions are restarted.

📄 **Displaying Configuration Effect**

Command	show mpls ldp graceful-restart [all vrf vrf-name]
Parameter Description	all: Displays all VPN routing and forwarding (VRF, including global VRF) LDP GR sessions and session parameters. vrf vrf-name: Displays specified VRF LDP GR sessions and session parameters.
Command Mode	This configuration is performed in privileged user mode.
Usage Guide	Displays LDP GR sessions and session parameters.

Common Errors

- The basic MPLS, L2VPN or L3VPN environment is incomplete, which results in forwarding failure.
- The Restarter is configured with GR, while the neighboring Helper is not.
- IGP GR or BGP GR is not configured.
- There are many routes but the timer time is not long enough, which disables GR before all entries are recovered.
- Topology or configuration changes during GR, which interrupts service traffic.

4.4.1.1 LDP GR Configuration Example

<p>Scenario</p> <p>Figure 4-4</p>	<p style="text-align: center;">Provider network</p> <ul style="list-style-type: none"> ● PEs and P form an MPLS network. ● PEs and P support LDP and have the GR capability. ● This section describes LDP GR configuration on PE1 and P. PE1 is a GR-Capable router and serves as a GR Restarter. P is a GR-Aware router and serves as a GR Helper.
Configuration	<ul style="list-style-type: none"> ● Configure the interface IP address, configure OSPF, and enable OSPF GR.

Steps	<ul style="list-style-type: none">● Enable global MPLS forwarding, and enable MPLS labeled packet forwarding and LDP on an interface.● Configure LDP to enable MPLS traffic forwarding.● Enable LDP GR.● Configure LDP GR.● Restart LDP sessions.
