Preface

Thank you for using our products. This manual matches the RGOS Release 10.4(3b75).

Audience

This manual is intended for:

- Network engineers
- Technical support and servicing engineers
- Network administrators

Obtaining Technical Assistance

- Ruijie Networks Website: http://www.ruijienetworks.com/
- Service Email: service_rj@ruijienetworks.com
- Technical Support: http://www.ruijienetworks.com/service.aspx
- Technical Support Hotline: +86-4008-111-000

Related Documents

Documents	Description
Command Reference	Describes the related configuration commands, including command modes, parameter descriptions, usage guides, and related examples.
Hardware Installation and Reference Guide	Describes the functional and physical features and provides the device installation steps, hardware troubleshooting, module technical specifications, and specifications and usage guidelines for cables and connectors.

Conventions

This manual uses the following conventions:

Convention	Description
boldface font	Commands, command options, and keywords are in **boldface**.
italic font	Arguments for which you supply values are in *italics*.
[ ]	Elements in square brackets are optional.
{ x | y | z }	Alternative keywords are grouped in braces and separated by vertical bars.
[x | y | z]	Optional alternative keywords are grouped in brackets and separated by

	vertical bars.

Symbols

Note Means reader take note. Notes contain helpful suggestions or references.

Caution Means reader be careful. In this situation, you might do something that could result in equipment damage or loss of data.

Basic Configuration

Configuring the Command Line Interface

This chapter describes how to configurethe command line interface(CLI) to manage network devices.

Command Mode

The management interface of Ruijie network devices has multiple modes and they determine the commands you can use.

To listusable commands in each mode, enter a question mark (?) at the command prompt.

After setting up a session connection to the network device management interface, you enteruser EXEC mode first. In the user EXEC mode, only a few commands are usable with limited functions, for example, the **show**command. The command results are also not saved.

To use all commands, enter privileged EXEC mode with the privileged password. Then you can use all privileged commands and enter global configuration mode.

Using commands in configuration (for example, global configuration or interface configuration) modewill influence the current configuration. If you have saved the configuration information, these commands will be saved and executed when the system restarts. To enter any of the configuration modes, enter global configuration mode in the first.

The following table describescommand modes, access methods, prompts, and exit methods.Suppose the device is named "Ruijie" by default.

The following table summariesmain command modes.

Command mode	Access method	Prompt	Exit or enter the next mode	Remark
User EXEC	Log in.	Ruijie>	To quit this mode, enter the **exit** command. To enter privileged EXEC mode, enter the**enable**command.	Performs basic tests and showssystem information.
Privileged EXEC	In the user EXEC mode, enter the**enable**command.	Ruijie#	To return touser EXEC mode, enter the**disable**command. To enter global configuration mode, enter command **configure**.	Verifiessettings. This mode is password-protected.
Global configuration	Inprivileged EXEC mode, enter the**configure terminal**command.	Ruijie(config)#	To return to privileged EXEC mode, enter command **end** or **exit** or press Ctrl+C. To access the interface configuration mode, enter command **interface**with an interface specified. To access VLAN configuration mode, enterthe **vlan***vlan_id*command.	Executes commands to configure global parameters influencing the entireswitch.

Command mode	Access method	Prompt	Exit or enter the next mode	Remark
Interface configuration	Inglobal configuration mode, enter the **interface**command.	Ruijie(config-if)#	To return to privileged EXEC mode, enter command **end** orpress Ctrl+C. To return to global configuration mode, enter the**exit**command. Moreover, you need specify an interface in the **interface** command.	Configures various interfaces of the device in this mode.
Config-vlan (Vlan Mode)	Inglobal configuration mode, enter the**vlan** vlan-idcommand.	Ruijie(config-vlan)#	To return to privileged EXEC mode, enter command **end** or pressCtrl+C. To return to global configuration mode, enter the**exit**command.	Configures VLAN parameters in this mode.

Obtaining Help

Enter a question mark(?) at the command prompt to obtain a list of commands that are available for each command mode. You can also obtain a list of command keywords beginning with the same character or parameters of each command. See the following table.

Command	Description
Help	Obtainsthe brief description of the help system under any command mode.

abbreviated-command-entry?	Obtains a list of commands that begin with a particular character.
	string.
	For example:
	`Ruijie# di?`
	`dir disable`

abbreviated-command-entry <Tab>	Completes a partial command name.
	For example:
	`Ruijie# show conf<Tab>`
	`Ruijie# show configuration`

?	Listskeywordsassociated witha command. For example: `Ruijie# show ?`
command keyword ?	Listsarguments associated witha command. For example: `Ruijie(config)# snmp-server community ?` WORD SNMP community string

Abbreviating Commands

To abbreviate a command, simply enter part of the command that can uniquely identify the command.

For example, **show configuration**can be abbreviated as follows:

```
Ruijie# show conf
```

Using the No Form and the Default Form

Most commands have the **no**formthatdisables a feature or function, or performs a reversed action of acommand. For example, the **no shutdown**command turns on aninterface, which is the reversed action of the **shutdown** command. You can use the commands without the keyword**no**to enable the features that have been disabled or are disabled by default.

Most configuration commands have the **default**formthat restoresa command setting to its default. The **default** form is disabled for most commands by default. In this case, the **default** and **no**formsgenerally serve the same purpose. However, the default form is enabled for some commandsby default. In this case, the **default** and **no**formsserve different purposes, where the **default**formenables the command and restores the arguments to the default settings.

Understanding CLI Error Messages

The following table describes the error messages that may occur when you use the CLI to manage devices.

Error Message	Meaning	How to Obtain Help
% Ambiguous command: "show c"	The switch cannot identify the unique command because you have entered insufficient characters.	Re-entersthe command with the question mark (?)next tothe ambiguous word. The possible keywords will be listed.
% Incomplete command.	You have not entered the required keywords or arguments.	Re-entersthe command withthespace followed by thequestion mark (?). The possible keywords or arguments will be displayed.
% Invalid input detected at '^' marker.	The symbol (^)indicates the positions of wrong words when user entersa wrong command.	Entersthequestion mark (?) at the command prompt to show the allowed keywords of the command.

Using Historical Commands

The system records the commands you have entered, whichis very useful when you entera long and complex command again.

To re-execute the commands you have entered, perform the following operations.

Operation	Result
Ctrl-P or **Up**	Allows you to browse the preceding command in the historical command records.You can inquire earlier records by repeating this operationfrom the latest record,.
Ctrl-N or **Down**	Allows you to return to a more recent command in the historical command records. You can inquire laterrecords by repeating this operation.

Caution Arrow keys are supported by standard terminals like VT100 series.

Using Editing Features

Editing Shortcut Keys

The following table describes the editing shortcut keys.

Function	Shortcut Key	Description
Move cursor in an editing line	Left direction key or Ctrl+B	Moves the cursor to left by one character.
	Right direction key or Ctrl+F	Moves the cursor to right by one character.
	Ctrl+A	Moves the cursor to the beginning of the command line.
	Ctrl+E	Moves the cursor to the end of the command line.
Delete the entered characters	Backspace	Deletes the character to the left of the cursor.
	Delete	Deletes the character to the right of the cursor.
Scroll up by one line or one page	Return	Scrolls up one line of the display contents anddisplaythe next line. This is used only before the end of the output.
	Space	Scrolls up one page of the displayed contents anddisplaythe next page appear. This is used only before the end of the output.

Sliding Window of Command Lines

You can use this function to edit acommand that exceeds the width of one line. When the editing cursor closes to the right border, the whole command line will move to the left by 20 characters. In this case, the cursor can still be moved back to the previous character or the beginning of the command line.

The following table describes shortcut keys used in this function:

Function	Shortcut key
Moves the cursor to the left by one character.	Left direction key or Ctrl+B
Moves the cursor to the head of a line.	Ctrl+A
Moves the cursor to the right by one character.	Right direction key or Ctrl+F
Moves the cursor to the end of a line.	Ctrl+E

For example, the contents of the **mac-address-table static** command may exceed the screen width. When the cursor approaches the line end for the first time, the whole line move left by 20 characters, and the hidden beginning part is replaced by the symbol ($) on the screen. The line moves left by 20 characters when the cursor reaches the right border.

access-list 199 permit ip host 192.168.180.220 host

$ost 192.168.180.220 host 202.101.99.12

$0.220 host 202.101.99.12 time-range tr

Now you can press **Ctrl+A** to return to the beginning of the command line. In this case, the hidden ending part is replaced by the symbol ($).

access-list 199 permit ip host 192.168.180.220 host 202.101.99.$

Caution The default line width on the terminal is 80 characters.

Combined with historical commands,the sliding window enables you to invoke complicated commands repeatedly. For details about shortcut keys, see the description about the section"Editing Shortcut Keys".

Filtering and Searching CLI Output Information

Filtering and Searching the Output Information of the show Command

Use the following command to search the specified content in theoutput informationof the **show** command.

Command	Description
Ruijie# **show** any-command |**begin**regular-expression	Searches the specified content in the outputinformation of the **show** command andexportsthe first line that contains the specified content and allinformation after the line.

Caution

- You can execute show command in any mode.
- The information to be searched is case sensitive, and the feature is also effective in the following.

Use the following commands to filter the specified content in the output information ofthe **show** command:

Command	Description
Ruijie# **show** any-command **|exclude**regular-expression	Filters the content inthe output information ofthe **show** command andexportsother information excluding the line that includes the specified content.
Ruijie#**show**any-command **|include**regular-expression	Filters the content inthe output information ofthe **show** command and exports the line that includes the specified content.Other information will be filtered.

Caution To search and filter the contents exportedby the **show** command, you must enter the pipeline sign, which is the vertical bar (|) followed by searchand filterrules and contents (characters or strings). The contents are case sensitive.

Using Command Aliases

The system provides the command alias function.You can specify any word as the alias of a command. For example, you can define the word “mygateway” as the alias of the **ip route 0.0.0.0 0.0.0.0 192.1.1.1** command.The effect of enteringthis word is equal to that of enteringthe entire command.

You can use one word to replace one command by configuring an alias for the command. For example, you can define an alias to represent the firstpart of acommand, and then continue to enter the rest parts.

The command that an alias represents must run under the mode you have defined in the current system. In global configuration mode, you can enter **alias?** to list all command modes that can configure aliases.

```
Ruijie(config)#alias ?
  aaa-gs              AAA server group mode
acl                  acl configure mode
  bgp                 Configure bgp Protocol
config              globle configure mode
......
```

An alias supports help information. An alias appears withtheasterisk (*) before it in the following format:

*command-alias=original-command

For example, in EXEC mode, the alias “s” indicates the **show** command by default. You can enter “s?” to obtain the help information on the command and the aliases beginning with ‘s’.

```
Ruijie#s?
*s=show  show  start-chat  start-terminal-service
```

If the command that an alias represents containsmore than one word, the command will be included by the quotation marks. As shown in the following example, you can configure the alias “sv” to replace the **show version**command in EXEC mode.

```
Ruijie#s?
*s=show  *sv=”show version” show  start-chat
start-terminal-service
```

An alias must begin with the first character of the command line entered without any spacebefore it. As shown in the precedingexample, the alias is invalid if you have entereda spacebefore the command.

```
Ruijie# s?
show  start-chat  start-terminal-service
```

An alias can also be used to obtain the help information of command parameters. For example, the alias “ia" represents the **ip address** commandin interface configuration mode.

```
Ruijie(config-if)#ia ?
  A.B.C.D  IP address
  dhcp    IP Address via DHCP
Ruijie(config-if)#ip address
```

The preceding informationlists the parameter information after the command **ip address**, and replaces the alias with the actual command.

A completealias must be entered for use. Otherwise, it can not be identified.

To view the setting of aliases in the system, use the **show aliases** command.

Accessing the CLI

Before using the CLI, you need to use a terminal or PC to connect toanetwork device. Power on the network device.After initializing the hardware and software, you can use the CLI. If the network device is used for the first time, you can only connect to the network deviceoverthe serial port (Console), which is referred to as out-band management. In addition, you can connect and manage the network device through the virtual terminal of Telnet. In either case, you can access the CLI.

Configuring LINE Mode

Configuring LINE Mode

Entering the LINE mode

After entering the specific LINE mode, you can configure the specified line. Use the following command to enter the specified LINE mode:

Command	Function
Ruijie(config)# **line [aux | console | tty | vty**] *first-line* [*last-line*]	Enters the specified LINE mode.

Increasing/Decreasing LINE VTY

The number of line vty is 5 by default. Use the following commands to increase or decrease line vty. 36 line VTYs are supported at most.

Command	Function
Ruijie(config)# **line vty** *line-number*	Increases the number of LINE VTY to the specified value.
Ruijie(config)# **no line vty** *line-number*	Decreases the number of LINE VTY to the specified value.

Configuring the Protocols to Communicate on the Line

Use this command to limit the communication protocol type supported on the line. By default, VTY supports communication of all protocols while TTY does not support the communication of any protocol.

Command	Description
Ruijie# **configure terminal**	Enters the configuration mode.
Ruijie(config)# **line vty *line number***	Enters the line configuration mode.
Ruijie(config-line)# **transport input {all | ssh | telnet | none**}	Configures the protocol to communicate on the line.
Ruijie(config-line)# **no transport input**	Disables the communication of any protocol on the line.
Ruijie(config-line)# **default transport input**	Restores the default value.

Configuring the Access Control List on the Line

Use this command to configure the access control list on the line. No access control list is configured on the line by default.That is, all incoming and outgoing connections are permitted.

Command	Description
Ruijie# **configure terminal**	Enters the configuration mode.
Ruijie(config)# **line vty** *line number*	Enters the line configuration mode.

Command	**Description**
Ruijie(config-line)# **access-class** *access-list-number* **{in | out}**	Configures the access control list on the line.
Ruijie(config-line)# **no access-class** *access-list-number* **{in | out}**	Removes the configuration.

System Upgrade and Maintenance

Overview

Upgrade and maintenance refers to upgrade the main program or CTRL program or upload and download files on the CLI . There are two ways to upgrade programs: use TFTP through a network interface or use Xmodem protocol through a serial interface.

Upgrade and Maintenance Method

Transferring Files by TFTP

There are two ways to transfer files by TFTP: download files from the host to the equipment, or upload files from the equipment to the host.

In the CLI command mode, download the files by performing the following steps:

Before download, first run the TFTP server software on the local host. Then, select the directory of the file to download. Finally, log in to the equipment. In the privileged mode, download the files by using the following commands. If no location is specified, you need to separately input the IP address of the TFTP server.

Command	Function
Ruijie# **copy tftp:** *//location/ filename* **flash:** *filename* [**vrf** *vrfname*]	Download the specified file from the URL on the host to the equipment.

In the CLI command mode, upload the files by performing the following steps:

Before upload, first run the TFTP server software on the local host. Then, select the destination directory for the file to upload at the host. Finally, upload the files by using the following commands in the privileged mode.

Command	Function
Ruijie# **copy flash:** *filename* **tftp:** *//location/filename* [**vrf** *vrfname*]	Upload the specified file from the equipment to the directory specified by the URL on the host. You can also rename the file.

Note

It is necessary to put the tftp link in quotes if the filename of the source file has space. For example:

Note

copy tftp:"//localtion/filename" **flash:**filename [**vrf** vrfname]

Note It is necessary to put the filename in quotes if the filename of the destination file has space. For example:

Note **copy tftp:**//localtion/filename **flash:**"filename" [**vrf** vrfname]

Transferring Files by TFTP IPv6

There are two ways to transfer files by TFTP: download files from the host to the equipment, or upload files from the equipment to the host.

In the CLI command mode, download the files by performing the following steps:

Before download, first run the TFTP server software on the local host. Finally, log in to the equipment. In the privileged mode, download the files by using the following commands.

Command	Function
Ruijie# **copy tftp:** *//location/ filename* **flash:** *filename*	Download the specified file from the URL on the host to the equipment.

In the CLI command mode, upload the files by performing the following steps:

Before upload, first run the TFTP server software on the local host. Then, select the destination directory for the file to upload at the host. Finally, upload the files by using the following commands in the privileged mode.

Command	Function
Ruijie# **copy flash:** *filename* **tftp:** *//location/filename*	Upload the specified file from the equipment to the directory specified by the URL on the host. You can also rename the file.

Caution If location is the local link address, use the following command to specify the egress:

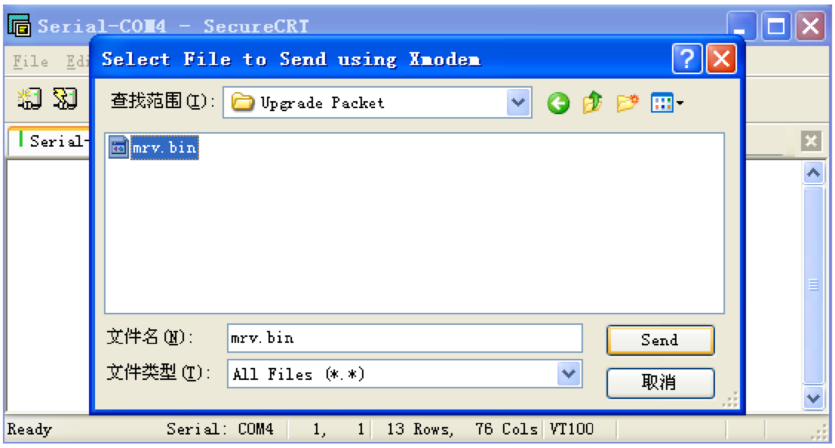
```
Ruijie#copy tftp: flash:
Address of remote host []?fe80::5efe:192.168.195.90
Output Interface: loopback 0
Source filename []?rgos.bin
Extended commands [n]:
Destination filename [rgos.bin]?
```

Transferring Files by XMODEM

There are two ways to transfer files by Xmodem: download files from the host to the equipment, or upload files from the equipment to the host.

In the CLI command mode, download the files by performing the following steps:

Prior to download, first log in to the out-band management interface of the device by using the Windows HyperTerminal. Then, download the files by using the following command in the privileged mode. Finally, select the “Send File” from the “Transfer” menu on the Windows HyperTerminal on the local host, as shown in the following figure:



查找范围(I): Upgrade Packet

文件名(N): mrv.bin

文件类型(T): All Files (*.*)

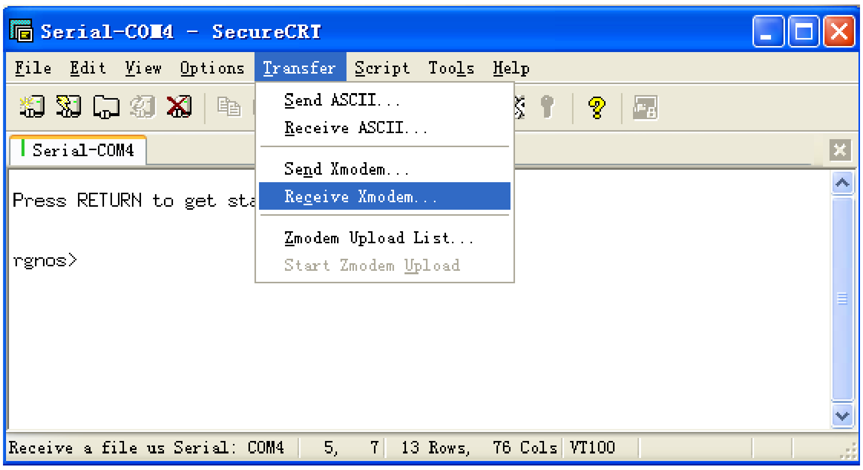
Ready Serial: COM4 1, 1 13 Rows, 76 Cols VT100

In the pop-up dialog box, select the file to download from the File Name field and Xmodem from the Protocol field. Click “Send”, and the Windows HyperTerminal will show the transmission process and packets.

Command	Function
Ruijie# **copy xmodem flash**:*filename*	Download the file from the host to the equipment and name it *filename*.

In the CLI command mode, upload the files by performing the following steps:

Prior to upload, first log in to the out-band management interface of the switch by using the Windows HyperTerminal. Then, upload the files by using the following command in the privileged mode. Finally, select the “Receive File” from the “Transfer” menu on the Windows HyperTerminal on the local host. It’s shown in the following figure:

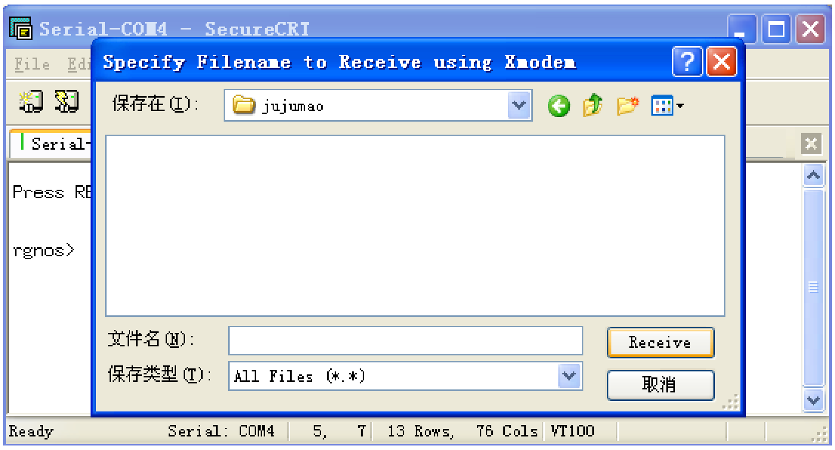


```
Press RETURN to get sta

rgnos>
```

Receive a file us Serial: COM4 5, 7 13 Rows, 76 Cols VT100

In the pop-up dialog box, select the storage location for the file to upload and select the “Xmodem” as the reception protocol. Click “Receive”, and the Windows HyperTerminal will further prompt the name of the locally stored file. Click “OK” to start reception. The operation is shown below:



Serial-COM4 - SecureCRT

Specify Filename to Receive using Xmodem

保存在(I): jujumao

Press RE

rgnos>

文件名(N):

保存类型(T): All Files (*.*)

Ready Serial: COM4 5, 7 13 Rows, 76 Cols VT100

Command	Function
Ruijie# **copy flash**:*filename* **xmodem**	Upload the file from the equipment to the host.

Caution It is necessary to put the filename with space in quotes. For example:

```
copy xmodem flash:”filename” OR copy flash:”filename” xmodem
```

Upgrading System

You can transfer the upgrading file to a device through TFTP or Xmodem, no matter the device is box-mount or chassis-mount. After transmission, restart the device. The upgrading file will automatically check and upgrade the system without manual interference.

The upgrade procedure on the box-mount equipment is slightly different from that on the chassis-mount equipment:

On the box-mount equipment, the upgrading file upgrades only its single supervisor engine. After upgrading, the system automatically resets. The equipment works normally after restart.

The chassis-mount equipment includes supervisor engines, line cards and multi-service cards. To upgrade the whole system with a upgrading file, first upgrade the supervisor engine. The system resets. When the equipment restarts, the automatic version synchronization function runs to upgrade line cards and multi-service cards.

Automatic Upgrade: a function running on the supervisor engine that verifies the version consistency for the slave supervisor engine, line cards and multi-service cards. When it is found that the version is not consistent with the one in the master supervisor engine, the function sends the upgrading files to those blades for upgrading so as to keep the version consistence in the whole system.

Caution Whenever you upgrade the master supervisor engine, the slave one (if any) is upgraded at the same time to keep the version consistent. The upgrade of a line card will upgrade all the line cards inserted into the device. Do not power off the device before the upgrade is complete. Otherwise, the upgrade program may be lost.

Caution

Before the chassis-mount device is upgraded, you can check whether the software version of all line cards and supervisor engines are consistent with the upgraded object version by the **show version** command. However, you cannot carry out master-slave switch (such as **redundancy force-switchover**). Otherwise, it will cause the upgrade failure and return to the original version.

Upgrade the chassis-mounted device by the upgrade file:

Confirm the filename of the upgrade file to be loaded is rgos.bin.

Download the file to the device by using the copy command.

If there is a slave supervisor engine on the device, you need to first upgrade the main programs of the master and slave supervisor engines successfully. After upgrading the main program successfully, the system prompts:

```
Upgrade Slave CM MAIN successful!!
Upgrade CM MAIN successful!!
```

Reset the equipment.

After reset, the upgrade file will run automatically. The system prompts:

```
Installing is in process ......
Do not restart your machine before finish !!!!!!
......
```

After the upgrade operation is completed, the system prompts:

```
Installing process finished ......
Restart machine operation is permitted now !!!!!!
```

After the operation of the upgrade file is completed, the system resets automatically and prompts:

```
System restarting, for reason 'Upgrade product !'.
```

After reset, the upgrading operation of the supervisor engines is completed. The system will load and operate the upgrade pack of boards. Moreover, it prompts information in Steps 5 to 6. Instead of the information in Step 7, it prompts:

```
System load main program from install package ......
```

Load the main program of the supervisor engine to operate from the upgrade file directly.

After the main program operates normally, the automatic upgrade function starts. If there is the slave supervisor engine or other modules in the chassis-mount device, the system prompts:

```
A new card is found in slot [1].
System is doing version synchronization checking ......
Current software version in slot [1] is synchronous.
System needn't to do version synchronization for this card ......
```

Or, the system prompts:

```
System is doing version synchronization checking ......
Card in slot [3] need to do version synchronization ......
```

Other Printing Information

```
Version synchronization begain ......
Keep power on, don't draw out the card and don't restart your machine before finished !!!!!!
```

Other Printing Information

```
Transmission is OK, now, card in slot [3] need restart ...
Software installation of card in slot [3] is in process ......
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
Software installation of card in slot [3] has finished successfully ......
The version synchronization of card in slot [3] get finished successfully.
```

The former indicates the version of the line card is synchronous and it is not necessary to upgrade again. The latter indicates the version of the line card, and it is necessary to upgrade the line card.

The system will carry out above operation for the slave supervisor engine and each module in turn.

After checking the version consistency on all modules and upgrading, the system will work normally

Caution

During the upgrade or automatic upgrade, the system may prompt that the reboot is not allowed. In this case, neither power off or reset the system nor plug or unplug other modules

Note

Automatic upgrading and checking also applies to the system with hot-plugging modules.

Upgrade the box-mount device by the upgrade file

To upgrade the box-mount device, do Steps 1 to 7, and then the system resets. After that, the equipment runs well.

Configuring Basic Management Features

Overview

Note

For more information about the CLI commands mentioned in this chapter, see the Device Management Command Reference.

Access Control through Command Authorization

Overview

A terminal's network access can be simply managed by using passwords and assigning privileged levels. Passwords restrict access to a netwdydyork or network device. Privileged levels define the commands you can use after logging in to a network device.

For security sake, passwords are stored in a configuration file. Passwords must be kept secure when the configuration file is transmitted, for example, over TFTP or across a network. Passwords are encrypted before they are saved into the configuration file. Plain text passwords becomes cipher text passwords. The **enable secret** command builds on a private encryption algorithm.

Configuring Default Passwords and Privileged Levels

No password at any level is available by default. The default privileged level is 15.

Configuring or Changing the Passwords at Different Levels

Our products provide the following commands for you to configure or change passwords at different levels.

Command	Function
Ruijie(config)# **enable password** [**level** *level*] {*password* | *encryption-type encrypted-password*}	Sets a static password. You can only set a level-15 password when no level-15 security password is configured. If you have set a non-level-15 password, the system will show a message and automatically convert it into a security password. If you have set the same level-15 static password as the level 15 security password, the system will show a warning message. If the encryption type is set to 0, the following password is configured in plain text. If the encryption type is set to 7, the following password is configured in cipher text.
Ruijie(config)# **enable secret** [**level** *level*] {*encryption-type encrypted-password*}	Sets the security password, which provides the same function but a better encryption algorithm than a static password. For security sake, it is recommended you use a security password.

Command	Function
Ruijie(config)#**service password-encryption**	Determines whether to encrypt the related password.
Ruijie# **enable** [*level*], and Ruijie# **disable** [*level*]	Switches between user levels. To move from a lower to a higher level, input the password for the higher level.

When you set a password, the keyword "level" is used to define the password for a specified privileged level. After setting, it only works for the users at that level.

Configuring Multiple Privileged Levels

By default, the system provides only two password-protected levels: normal user (level 1) and privileged user (level 15). You can configure up to 16 hierarchical command levels for each mode. By configuring different passwords at different levels, you can use different sets of commands for different levels.

When no password is set for the privileged user level, you can enter the privileged mode without password authentication. For security, it is recommended you set the password for the privileged user level.

Configuring Command Authorization

To expand the application scope of a command, you can assign it to users at lower levels. On the contrary, to narrow the scope, you can assign it to users at higher levels.

You can use the following commands to authorize users to use a command:

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **service display command privilege**	Enables command-level display. After this function is enabled, you can enter ? to view the level of a command key.
Ruijie(config)# **privilege** *mode* [**all**] {**level** *level* | **reset**} *command-string*	Sets a privileged level for a command. *mode* – The CLI command mode in which you authorize the command. For example, config indicates global configuration mode, exec indicates privileged command mode, and interface indicates interface configuration mode. **all** – Changes the privileges of all the sub-commands of a specified command to the same level. **level** *level* – Authorization level in the range from 0 to 15. **reset**：Restores the command privilege to the default level. *command-string:* Indicates the command you want to authorize.

To restore the configuration for a specified command, use the **no privilege** *mode* [**all**] **level** *level* command in global configuration mode.

Example of Command Authorization Configuration

The following example shows the configuration process that sets the **reload** command and all its sub-commands to level 1, and activates level 1 (by setting the command as “**test**”):

```
Ruijie# configure terminal
Ruijie(config)# service display command privielge
Ruijie(config)# privilege exec all level 1 reload
Ruijie(config)# enable secret level 1 0 test
Ruijie(config)# end
```

Enter level 1, and you can see the command and its subcommands:

```
Ruijie# disable 1
Ruijie> reload ?
  at                   reload at a specific time/date (privilege: 14)
  cancel                cancel pending reload scheme (privilege: 14)
  in                   reload after a time interval (privilege: 14)
  <cr>
```

The following example shows the configuration process that restores the privilege settings of the reload command and all its sub-commands to the default value:

```
Ruijie# configure terminal
Ruijie(config)# privilege exec all reset reload
Ruijie(config)# end
```

Enter the level 1, the privilege setting for the command is removed.

```
Ruijie# disable 1
Ruijie> reload ?
% Unrecognized command.
```

Configuring Line Password Protection

Our products offer password authentication for remote logins (such as Telnet). A password is required for protection. Execute the following command in line configuration mode:

Command	Function
Ruijie(config-line)# **password** [**0** | **7**] *line*	Specifies a line password. 0: The password is configured in plaintext. 7: The password is encrypted by a Ruijie device. Line: the character string of the password to be configured.
Ruijie(config-line)# **secret** { [**0**] *password* | **5** *encrypted-secret* }	Specifies the line's password encrypted by irreversible MD5 **0**: (Optional) specifies the plaintext password text and encrypts it with irreversible MD5 after configuration. *Password*: The password plaintext.. ***5*** *encrypted-secret*: Specifies the password text encrypted by irreversible MD5 and saves it as the encrypted password after configuration.
Ruijie(config-line)# **login**	Enables line password protection.

Note

If no login authentication is configured, password authentication on the line layer will be ignored even when a line password is configured. Login authentication will be discussed in the next section.

Note

If no login authentication is configured, password authentication on the line layer will be ignored even when a line password is configured. Login authentication will be discussed in the next section.

Supporting Session Locking

Our products allow you to lock the session terminal temporarily using the lock command, so as to prevent unauthorized access. To do so, enable the terminal locking function in the line configuration mode, and lock the terminal using the lock command in terminal EXEC mode: The system prompts you for a password for unlocking when you enter any character on a locked terminal. The terminal is locked when your password is authenticated.

Command	Function
Ruijie(config-line)# **lockable**	Enables the function of locking the line terminal.
Ruijie# lock	Locks the current line terminal.

Login Authentication Control

Overview

The previous section discusses how to control access to network devices by configuring a locally stored password. In addition to line password protection and local authentication, in AAA mode, we can authenticate users' management privilege based on usernames and passwords on some servers when they log in to the switch. Take an RADIUS server for example.

With an RADIUS server, the network device sends encrypted user information to the RADIUS server for authentication instead of authenticating them with locally stored credentials. The RADIUS server configures user information consistently like user name, password, shared key, and access policy to facilitate user access management and control and enhance the security of user information.

Configuring Local Users

Our products support identity authentication system based on a local database for local authentication of the method list in AAA mode and local authentication of line login management in non-AAA mode.

To enable username identity authentication, run the following commands in global configuration mode:

Command	Function
Ruijie(config)# **username** *name* [**password** *password* | *encryption-type encrypted password*]	Enables username identity authentication with encrypted password. Encryption type 0 defines a password in plaintext. Encryption type 7 defines an encrypted password.
Ruijie(config)# **username** *name* **secret** { [**0**] *password* | **5** *encrypted-secret* }	Sets the password encrypted by irreversible MD5 for the local user.
Ruijie(config)# **username** *name* [**privilege** *level*]	Sets the privilege level for the user (optional).

Confining the Simultaneously Online Amount of a Local Username

Ruijie products support local usernames confining the simultaneously online amount. By default, local usernames does not limit the simultaneously online amount.

Run the following commands to limit the simultaneously online amount of a local username:

Command	Function
Ruijie(config)# **username** *name* **online amount** *numbers*	Confines the simultaneously online amount of a local username.
Ruijie(config)# **no username** *name* **online amount**	Cancels the limit on the simultaneously online amount of a local username.

After the simultaneously online amount of a local username is set, the number of clients logging in with the username must be within the specified range. When the number exceeds the limit, the username is not allowed to be used for login.

When the simultaneously online amount of a local username is set to 0, no login is allowed with the username by any client, including console login and remote login through this user.

Confining Username Login Mode

Ruijie products support configuration of local username login mode. Login mode can be one type or several types among aux, console ssh and telnet. By default, when there is no restriction on local username login mode, the local username will not confine user login mode.

Run the following demands in global configuration mode to confine local username login mode:

Command	Function
Ruijie(config)#**username** *name* **login mode** { **aux | console | ssh | telnet** }	Confines local username login mode.
Ruijie(config)#**no username** *name* **login mode** { **aux | console | ssh | telnet** }	Cancels restriction on local username login mode.

This command is used to set local username login mode to one type or several types among aux, ssh and telnet. Only the configured login mode is allowed while the other modes are prevented.

Configuring Line Login Authentication

To enable line login identity authentication, run the following commands in line configuration mode:

Command	Function
Ruijie(config-line)# login local	Sets local authentication for line login in non-AAA mode.
Ruijie(config-line)# login authentication {default | list-name}	Sets AAA authentication for line login in AAA mode. The authentication methods in the AAA method list will be used for authentication, including Radius authentication, local authentication and no authentication.

Note

For more information on how to set AAA mode, configure Radius service, and configure the method list, see the sections relating to AAA configuration.

System Time Configuration

Overview

Every switch has its clock, which indicates date (year, month, day) and time (hour, minute, second) and week. When using a switch for the first time, you must configure the clock manually. Of course, you can adjust the clock when necessary. The clock is used for system login that requires you to record the time of an event.

Setting System Time and Date

You can configure the system time on the network device manually. Once configured, the clock will be running continuously even if the network device is powered off. Therefore, unless you need to modify the time, it is not necessary to reconfigure the time.

However, the configuration does not apply to network devices without hardware clock, as the manual time setting actually configures software clock. When the network devices are powered off, you cannot set the time manually.

Caution

RSR10 do not provide hardware clock.

😐 **Support** S2026G, S2026F and RSR10 do not provide hardware clock.

Command	Function
Ruijie# **clock set** hh:mm:ss month day year	Sets system date and time.

For example, change the system time to10:10:12, 2003-6-20:

```
Ruijie# clock set 10:10:12 6 20 2003                 //Set system time and date.
Ruijie# show clock                //Confirm the modification takes effect.
clock: 2003-6-20 10:10:54
```

Showing System Time and Date

You can show system time and date by using the **show clock** command in privileged mode. The following example shows the format:

```
Ruijie# sh clock    //Show the current system time and date.
clock: 2003-5-20 11:11:34
```

Updating Hardware Clock

Some platforms use hardware clock (calendar) to double as software clock. Since battery enables hardware clock to run continuously, hardware clock still runs even though the device is turned off or restarted.

If hardware clock and software clock are out of sync, software clock prevails. Execute the clock update-calendar command to copy date and time from software clock to hardware clock.

In privileged mode, execute the **clock update-calendar** command for software clock to overwrite hardware clock.

😐 **Support**	S2026G, S2026F and RSR10 do not provide hardware clock.

Command	Function
Ruijie# **clock update-calendar**	Updates hardware clock through software clock.

Execute the following command to copy current date and time from software clock to hardware clock.

```
Ruijie# clock update-calendar
```

Scheduled Restart

Overview

This section describes how to use the **reload** [*modifiers*] command to schedule system restarts at specified time. This feature facilitates your operation in some scenarios (for testing, for example). Modifiers is a set of options provided by the **reload** command to increase the command flexibility. The optional modifiers includes **in**, **at** and **cancel**. See the following examples for details:

- **reload in** *mmm* | *hhh:mm* [*string*]

This command sets up the system to restart at regular intervals in the format of mmm or hhh:mm. string is a help prompt. You can give the scheme a name using the string to indicate its purpose. string is a prompt. For example, to reload the system at intervals of 10 minutes for testing, type r**eload in** *10 test*.

- **reload at** hh:mm month day year [string]

This command sets up the system to restart at a specified future time. The parameter year is optional. The year recorded in the system clock is shown by default if no year is specified. As the time span is limited to 30 days, the current system date generally ranges between January 1 and November 30. Therefore, you do not need to specify the year. However, the restart time you have specified can be sometime next January if the system currently shows December. In this situation, you must specify a year to instruct the system to restart next January rather than this January. The system may fail as the restart time is considered to fall in this January by default. string is used in a similar way. For example, input **reload at** *08:30 11 1 newday* if the current system time is 14:31 on January 10, 2005 and you want the system to reload tomorrow. If the current system time is 14:31 on December 10, 2005 and you want the system to reload at 12:00 a.m. on January 1, 2006, input **reload at** *12:00 1 1 2006 newyear*.

- **reload cancel**

This command deletes a user-defined restart scheme. As mentioned earlier, you have specified the system to reload at 8:30 a.m. tomorrow, the setting will be canceled after you input **reload cancel**.

Note

If the system supports clock function, you can use option at. Before the use, it is recommended you configure the system clock as required. If a restart scheme has been set before, subsequent settings will overwrite previous settings. If you have set a restart scheme and you restart the system before the scheme takes effect, the scheme will be lost.

Note

The span between the time indicated in the restart scheme to the current time must be within the range of 200 days and must be later than the current system time. Besides, after you have set reload, you should not set system clock. Otherwise, your setting may fail if the system time is later than the reload time.

Specifying the System to Restart at the Specified Time

In privileged mode, you can configure system reload at the specified time using the following commands:

Command	Function
Ruijie# **reload at** *hh:mm month day* [*year*] [*reload-reason*]	Reloads at hh:mm,month day,year. reload-reason (if any); indicates the reason that the system reloads.

The following example shows an example of system reload at 12:00 a.m. January 11, 2005 (suppose the current system clock is 8:30 a.m. January 11, 2005):

```
Ruijie# reload at 12:00 1 11 2005 midday   //Set the reload time and date.
Ruijie# show reload //Confirm the modification takes effect.
Reload scheduled for 2005-01-11 12:00  (in 3 hours 29 minutes)16581 seconds.
At 2005-01-11 12:00
Reload reason: midday
```

Specifying the System to Restart after a Period of Time

In privileged mode, you can configure the system reload at the specified time using the following commands:

Command	Function
Ruijie# **reload in** *mmm* [*reload-reason*]	Configures the system reload in mmm minutes, where the reload reason is described in reload-reason (if entered)
Ruijie# **reload in** *hhh:mm* [*reload-reason*]	Configure the system reload in hhh hours and mm minutes, where the reload reason is described in reload-reason (if entered)

The following example shows how to reload the system in 125 minutes (assume that the current system time is 12:00 a.m. January 10, 2005):

```
Ruijie# reload in 125 test //Set the system reload time
Or
Ruijie# reload in 2:5 test     //Set the system reload time
Ruijie# show reload //Confirm whether the restart time change takes effect
System will reload in 7485 seconds.
```

Immediate Restart

The **reload** command without any parameter will restart the device immediately. In privileged mode, you can restart the system immediately by using the **reload** command.

Deleting the Configured Restart Scheme

In privileged mode, use the following command to delete the configured restart scheme:

Command	Function
Ruijie# **reload cancel**	Deletes the configured restart scheme.

If no reload scheme is used, an error message appears.

Configuring a System Name and Prompt

Overview

For easier management, you can configure a system name for the switch to identify it. If you configure a system name that contains more than 32 characters, the first 32 characters are used as the system prompt. The prompt varies with the system name. The system is named Ruijie by default.

Configuring a System Name

Our products provide the following commands to configure a system name in global configuration mode:

Command	Function
Ruijie(Config)# **hostname** *name*	Sets the system name. The name must contain up to 63 printable characters.

To restore the name to the default value, use the **no hostname** command in global configuration mode. The following example changes the device name to RGOS:

```
Ruijie# configure terminal     //Enter global configuration mode.
Ruijie(config)# hostname RGOS      //Set the equipment name to RGOS
RGOS(config)#                  //The name has been modified successfully.
```

Configuring a Command Prompt

The system name appears as the default if you have not configured any command prompt. (If the system name exceeds 32 characters, the first 32 characters will be blocked.) The prompt varies with the system name. You can use the **prompt** command to configure a command prompt in global configuration mode. The command prompt only applies in EXEC mode.

Command	Function
Ruijie# **prompt** *string*	Sets the command prompt with printable characters. If the name exceeds 32 characters, the first 32 characters are blocked.

To restore the prompt to the default value, use the **no prompt** command in global configuration mode.

Banner Configuration

Overview

When a user logs in to the switch, you may need to give the user useful information through a banner. There are two kinds of banners: message-of-the-day (MOTD) and login banner. The MOTD is unique to users who connect with switches. When users log in, the notification message will appear on the terminal. MOTD allows you to send urgent messages (for example, the system is shutting down) to network users. The login banner also appears on all connected terminals. It provides some common login messages. By default, no MOTD and login banners are configured.

Configuring a Message-of-the-Day

You can create a notification of single or multi-line messages that appears when a user logs in the switch. To configure the message of the day, execute the following commands in global configuration mode:

Command	Function
Ruijie(Config)# **banner motd** *c message c*	Specifies the message of the day, with c being the delimiter, for example, a pound sign (&). After entering the delimiter, press Enter. Now, you can type text. You need to input the delimiter and then press Enter. Note that if you type additional characters after the ending delimiter, these characters will be discarded by the system. Also note that you cannot use the delimiter in the message and the message can contain a maximum of 255 bytes.

To delete the MOTD, use the no banner motd command in global configuration mode. The following example describes how to configure a MOTD. The # symbol is used as the delimiter, and the text is "Notice: system will shutdown on July 6th."

```
Ruijie(config)# banner motd #                      //Start delimiter.
Enter TEXT message.  End with the character '#'.
Notice: system will shutdown on July 6th.#             //End delimiter.
Ruijie(config)#
```

Configuring a Login Banner

To configure a login banner, execute the following commands in global configuration mode:

Command	Function
Ruijie(Config)# **banner login** *c message c*	Specifies the text of the login banner, with c being the delimiter, for example, a pound sign (&). After entering the delimiter, press Enter. Now, you can start to type text. You need to input the delimiter and then press Enter. Note that if you type additional characters after the end delimiter, these characters will be discarded by the system. Also note that you cannot use the delimiter in the text of the login banner and the text can contain a maximum of 255 bytes.

To delete the login banner, use the **no banner login** command in global configuration mode.

The following example shows how to configure a login banner. The pound sign (#) is used as the starting and end delimiters and the text of the login banner is "Access for authorized users only. Please enter your password."

```
Ruijie(config)# banner login # //Start delimiter
Enter TEXT message. End with the character '#'.
Access for authorized users only. Please enter your password.
#   //End delimiter
Ruijie(config)#
```

Displaying a Banner

A banner is displayed when you log in the network device. See the following example:

```
C:\>telnet 192.168.65.236
 Notice: system will shutdown on July 6th.
 Access for authorized users only. Please enter your password.
 User Access Verification
Password:
```

“Notice: system will shutdown on July 6th." is a MOTD banner and "Access for authorized users only. Please enter your password." is a login banner.

Viewing System Information

Overview

You can check some system information using the show command on the command-line interface, such as version and device information.

Viewing System Information and Version

System information includes description, power-on time, hardware version, software version, BOOT-layer software version, and CTRL-layer software version.This information helps you know the system better. You can show system information using the following commands in privileged mode.

Command	Function
Ruijie# **show version**	Shows system information.

Note

For a sequence number, run the **show version** command on the main program interface to view SYSTEMUPTIME in the form of DD:HH:MM:SS.

Note

During upgrading, the running software version may differ from the version in the file system. In this case, the main program version shown by running the show version command is the one running in the memory, but the Boot/Ctrl version is the one stored in the flash memory.

Viewing Hardware Entity Information

Hardware information relate to physical devices, slots and modules assembled in a device. The information on a device includes description, number of slots,slot information, slot number, description of the module on the slot (empty description if no module is plugged in the slot), the number of physical ports of the module in the slot, and the maximum number of ports supported in the slot (the number of ports on the plugged module). You may use the following commands to show the information about the device and slots in privileged mode:

Command	Function
Ruijie# **show version devices**	Shows the current device information.
Ruijie# **show version slots**	Shows current information about slots and modules.

Setting Console Rate

Overview

The device provides a console interface for management. When using the switch for the first time, you need to perform configuration through the console interface. You can change the console rate on the device if necessary. Note that the rate of the terminal used to manage the switch must be the same as that of the console interface on the switch.

Setting Console Rate

In line configuration mode, execute the following command to set the console rate:

Command	Function
Ruijie(config-line)# **speed** *speed*	Sets transmission rate in bps on the console interface. For a serial interface, you can only set the transmission rate to any one of the following values: 9600, 19200, 38400, 57600 and 115200 bps, with 9600 bps by default.

This example shows how to configure the baud rate of the serial interface to 57600 bps:

```
Ruijie# configure terminal  //Enter global configuration mode.
Ruijie(config)# line console 0     //Enter the console line configuration mode
Ruijie(config-line)# speed 57600   //Set the console rate to 57600bps
Ruijie(config-line)# end       //Return to the privileged mode
Ruijie# show line console 0    //View the console configuration
CON    Type   speed   Overruns
* 0    CON    57600   0
Line 0, Location: "", Type: "vt100"
Length: 25 lines, Width: 80 columns
Special Chars: Escape  Disconnect  Activation
             ^^x    none       ^M
Timeouts:    Idle EXEC    Idle Session
             never         never
History is enabled, history size is 10.
Total input: 22 bytes
Total output: 115 bytes
```

```
Data overflow: 0 bytes
stop rx interrupt: 0 times
Modem: READY
```

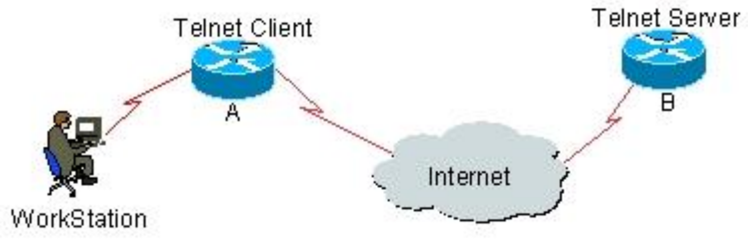
Configuring Telnet

Overview

Telnet, as an application layer protocol in the TCP/IP protocol suite, provides the specifications for remote login and virtual terminal communication. The Telnet Client service is used by a local or remote user who has logged onto the local network device to work with the Telnet Client program to access other remote system resources on the network. As shown below, after setting up a connection with Switch A through the terminal emulation program or Telnet, you can log in the Switch B for management and configuration using the telnet command.

Ruijie's telnet program supports IPV4 and IPV6 addresses. The telnet server can receive IPV4 and IPV6 telnet connection requests. The telnet client can send connection requests to an IPV4 or IPV6 host.

Figure 1



Using Telnet Client

You can log in to a remote device by using the **telnet** command on the switch.

Command	Function
Ruijie# **telnet** *host* [*port*] [/**source** {**ip** *A.B.C.D* **ipv6** *X:X:X::X* | **interface** *interface-name*}] [/**vrf** *vrf-name*]	Logs in to a remote device via Telnet. host may be an IPv4 or IPv6 host name or an IPv4 or IPv6 address. For optional parameters, refer to relevant Telnet command section in Basic Configuration Management Command.

The following example shows how to establish a Telnet session and manage the remote device with the IP address 192.168.65.119:

```
Ruijie# telnet 192.168.65.119  //Establish the telnet session to the remote device
Trying 192.168.65.119 ... Open
User Access Verification       //Enter into the login interface of the remote device
Password:
```

The following example shows how to establish a Telnet session and manage the remote device with the IPv6 address 2AAA:BBBB::CCCC:

```
Ruijie# telnet 2AAA:BBBB::CCCC //Establish the telnet session to the remote device
Trying 2AAA:BBBB::CCCC ... Open
User Access Verification       //Enter into the login interface of the remote device
```

```
Password:
```

Using Telnet Server

Use the following command to enable the Telnet server service for network devices:

Command	Function
Ruijie(config)# **enable service telnet-server**	Enables the Telnet server service. This command enables IPv4 and IPv6 services concurrently.

Setting Connection Timeout

Overview

You can control the connections of a device (including the accepted connections and sessions between the device and a remote terminal) by configuring the connection timeout for the device. When the idle time exceeds the set value and no input or output is found, this connection will be released.

Connection Timeout

When there is no information running through an accepted connection within a specified time, the server will release this connection.

Our products provide commands for you to configure the connection timeout in line configuration mode.

Command	Function
Ruijie(Config-line)#**exec-timeout** *minutes* [*seconds*]	Configures the timeout for the accepted connection. When the configured time is due and there is no input, this connection will be released. *minutes*: timeout in minutes; *seconds*: timeout in seconds.

You can cancel the connection timeout by using the **no exec-timeout** command in line configuration mode.

```
Ruijie# configure terminal  //Enter global configuration mode.
Ruijie# line vty 0          //Enter the line configuration mode
Ruijie(config-line)#exec-timeout 20    //Set the timeout to 20min
```

Session Timeout

When there is no input for the session established with a remote terminal over the current line within the specified time, the session will be released and the remote terminal becomes idle.

RGOS provides commands in line configuration mode to configure the timeout for sessions with a remote terminal.

Command	Function

Command	Function
Ruijie(Config-line)#**session-timeout** *minutes* [**output**]	Configures the timeout for the session set up with the remote terminal over the line. If there is no input within the specified time, this session will be released. *minutes*: timeout in minutes; **output**: Determines whether the session has expired using output data.

You can remove the timeout setting for the session set up with the remote terminal by using the **no exec-timeout** command in the line configuration mode.

```
Ruijie# configure terminal //Enter global configuration mode.
Ruijie(config)# line vty 0         //Enter the line configuration mode
Ruijie(config-line)# session-timeout 20    //Set the session timeout to 20min
```

Executing the Commands for Executable Batch Files

During the process of system management, it is sometimes necessary to enter multiple configuration commands to manage a function. It takes a long time to enter all the commands on CLI, causing errors. To solve this problem, you can include all the commands into a batch file by taking configuration steps. Then, you can execute the batch file for configuration when necessary.

Command	Function
Ruijie# **execute** {[**flash**:] *filename*}	Executes a batch file.

For example, the batch file line_rcms_script.text enables the reversed Telnet function on all the asynchronous interfaces as shown below:

```
configure terminal
line tty 1 16
transport input all
no exec
end
```

Result:

```
Ruijie# execute flash:line_rcms_script.text
executing script file line_rcms_script.text ......
executing done
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# line vty 1 16
Ruijie(config-line)# transport input all
Ruijie(config-line)# no exec
Ruijie(config-line)# end
```

Note

The file name and contents of a batch file can be specified. You can send an edited batch file to the flash memory of the network device in TFTP mode. The contents of the batch file will synchronize the input completely. Hence, it is necessary to edit the contents of the batch file in the sequence that CIL commands are configured. For some interactive commands, it is necessary to write corresponding response information into the batch file to ensure that the commands can be executed normally.

Caution

Files exceeding 128 KB may cause batch processing to fail. For batch processing, split a large file into a number of files, each of which is smaller than 128 KB.

Setting a Service Switch

During operations, you can adjust services dynamically to enable or disable specified services (SNMP Server/SSH Server/Telnet Server/Web Server).

Command	Function
Ruijie(Config)# **enable service snmp-agent**	Enables SNMP Server.
Ruijie(Config)# **enable service ssh-sesrver**	Enables SSH Server.
Ruijie(Config)# **enable service telnet-server**	Enables Telnet Server.
Ruijie(Config)# **enable service web-server**	Enables http and https servers.

In configuration mode, you can use the **no enable service** command to disable corresponding services.

```
Ruijie# configure terminal             //Enter global configuration mode.
Ruijie(config)# enable service ssh-server  //Enable SSH Server
```

To enable http service only, use the following command:

```
Ruijie(config)# enable service web-server http
```

To enable https service only, use the following command:

```
Ruijie(config)# enable service web-server https
```

Note

The **enable service web-server** command can be followed by three optional keywords:

enable service web-server [*http* | *https* | *all*]

If the command is followed by no keyword or by all, the command enables http and https services. Followed by http, the command enables http service only. Followed by https, the command enables https service only. This command and related HTTP service commands discussed later do not necessarily enable you to access the web management page through the browser. These commands only enable the HTTP service and provide an HTTP access channel. To access the web management page, upload a compressed web management work package in upd format to the flash memory of your device. These commands are not designed only for web management. Instead, they support HTTP detection, redirection, and flash file download on the device.

Caution

For the HTTP server to work after the HTTP service is enabled, store the server certificate and private key in the root directory of the file system on the device. Name the server certificate httpd_cert.crt and private key file httpd_key.pem, and upload these files to the root directory through a TFTP server.

Setting HTTP Parameters

When using the integrated Web for management, you can adjust HTTP parameters, and specify service ports or login authentication methods.

Command	Function
Ruijie(Config)# **ip http port** *number*	Specifies HTTP service port, 80 by default.
Ruijie(Config)# **ip http authentication** {**enable** | **local**}	Sets Web login authentication method, which is enable by default. **enable**: Uses the password set by the enable password or enable secret command for authentication, where the password must be 15 levels. **local**: Uses the username and password set by the username command for authentication, where the user must be bound with 15-level access rights.

In configuration mode, you can use the **no** form of the command to restore the setting to the default value. The following example enables the HTTP Server, sets the service port to 8080, and uses the local username for login authentication.

```
Ruijie# configure terminal             //Enter global configuration mode.
Ruijie(config)# enable service web-server http     //Enable http Server
Ruijie(config)# username name password pass //Set local user
Ruijie(config)# username name privilege 15     //Bind user right
Ruijie(config)# ip http port 8080          //Set service port
Ruijie(config)# ip http authentication local //Set authentication method
```

Use the following command to configure an HTTPS service port.

Command	Function
Ruijie(Config)# **ip http secure-port** *number*	Specifies the HTTP service port. (default:443)

In configuration mode, you can use the **no** form of the command to restore the setting to the default value. The following example enables the HTTP Server and sets the service port to 4443.

```
Ruijie# configure terminal             //Enter global configuration mode.
Ruijie(config)# enable service web-server https//Enable https Server
Ruijie(config)# ip http secure-port 4443
```

Use the following command to verify the status of WEB server.

```
Ruijie# show web-server status
http server status : enabled
http server port : 8080
https server status:  enabled
https server port: 4443
```

Caution

Avoid configuring http and https service ports to the same value. If https service is enabled after http service, and the port is configured to the same port as http service, you can only access https service through this port, and http service will be blocked temporarily until https service port is changed or the service is disabled.

Setting Multi-boot Function

Overview

By default, the device searches for the main program file and boots it in the built-in flash memory. If the main program file is damaged due to upgrade failure, formatted flash memory, for example, the device may fail to boot the system.

Some Ruijie products support the multi-boot function, which enables you to boot the device using main program files from local flash memory, a removable disk (USB drive or SD card) or a remote TFTP server. When the device starts, the system boots the main programs by boot pirority in descending order until it boots successfully or all programs are filed. Multi-boot function is mandatory for some environments with higher demands on reliability and availability.

Product support	Only the RSR20, RSR30, R2700 V5.0, RSR50, RSR50E and NPE50 series of routers and the S86 series of switches currently support the multi-boot function. Unless otherwise stated, this section applies to the above products.

This following examples describe how to use multi-boot for redundant backup of the main program.

Configuring the Main Boot Program

You can use the following command to configure the main boot program and specify the boot priority. The system will boot the main program based on priority in descending order with 1 being the highest and 10 being the lowest priority.

Command	Function
Ruijie(Config)#**boot system** *priority* prefix:/ [directory/] filename	Sets the main boot program and specify its priority. The boot priority is in the range of 1 to 10, with 1 being the highest.

Caution

Using URL prefix to locate a file is only supported in 10.4(2) and higher versions. For details, refer to the File System Configuration Guide. Path is used to locate a file in a version lower than 10.4(2), for example, usb0:/backup/rgos.bin represents rgos.bin in the backup directory on the first USB device.

flash:/rgos.bin indicates the rgos.bin file under the Flash root directory.

Caution

Supported URL prefixes vary with platforms. To show the currently supported URL prefixes, run the following command:

```
Ruijie (config) # boot system 2 ?
  flash:   Boot from flash: file system
  tftp:    Boot from tftp server
  usb0:   Boot from usb0: file system
  usb1:   Boot from usb1: file system
```

Caution

Multi-boot is not allowed during ISSU operations (see “Upgrading ISSU”).

By default, the bootable main program is flash:/rgos.bin with the priority of 5.

Caution

Since the system uses this command in the early stage of booting, the configuration is saved in the Boot ROM rather than in the configuration file.

Specifying a File in Local Flash Memory

The following example sets the file on the local flash memory as the main program.

```
Ruijie(config)# boot system 5 flash:/rgos.bin
```

Note

When you specify a local file through prefix, the path following “:” must be an absolute path.

When you configure the boot system command, the system will check the validity of the main program in the local flash memory. You can configure the command successfully only when the main program meets the following requirements.

- The main program must exist.
- The main program is a legal RGOS main program.
- The main program is complete and passes CRC check.

If any requirement is unmet, the systme will dispay an error message, for example:

```
Ruijie(config)# boot system 5 flash:/foo.bin
Set boot system file error:[ flash:/foo.bin] does not exist!
```

In addition, a priority can be set for more than one main program. Otherwise, the system will display an error message and print the current main program list for your selection. For instance:

```
Ruijie(config)# boot system 5 flash:/rgos.bin
Ruijie(config)# boot system 5 flash:/rgos_bak.bin
Set boot system file error: priority 5 has been assigned to file [ flash:/rgos.bin].
Boot system config:
=====================================================
Prio     Size            Modified  Name
---- --------- ------------------- ------------------
  1
  2
  3
  4
  5    3205120 2008-08-26 05:22:46 flash:/rgos.bin
  6
  7
  8
  9
 10
======================================================
Ruijie(config)# boot system 6 flash:/rgos_bak.bin
```

Specifying a File on a Removable Storage Device

The same procedure applies for saving the main program as a file on a removable storage device and in the local flash memory. The only difference is that the system does not check the file for existence or validity when you save it on a removable storage device.

Caution

The file is not checked so that you can configure the device remotely without having to insert a USB drive containing a valid main program into the device. However, you must enter a correct filename.

Do as follows to set up the device to boot from a USB drive:

```
Ruijie(config)# boot system 1 usb1:/rgos.bin
```

Note

Currently, the device cannot start a RGOS installation package earlier than 10.4 (3) from a USB drive.

Specifying a File on a Remote TFTP Server

Do as follows to set up the device to boot from a TFTP server:

```
Ruijie(config)# boot system 2 tftp://192.168.7.24/rgos.bin
```

Note

Currently, the device cannot start a RGOS installation package earlier than 10.4 (3) from a TFTP server.

For the device to download the main program through the TFTP protocol during the boot process, use the boot ip command to configure a correct local IP address used for TFTP address:

Command	Function
Ruijie(config)# **boot ip** *local-ip*	Configures a local IP address for TFTP transfer during the boot process.
Ruijie(config)# **no boot ip**	Clear the boot ip configuration.

Caution

This configuration is stored in the Boot ROM rather than in a configuration file, as the system must use the configuration early in the boot process.

Caution

Ensure that the built-in flash memory contains sufficient free space for the boot file when booting from a TFTP server. During the boot process, the file is hidden in the flash memory. Clear it before the next boot.

Do as follows to configure the IP address for the device to boot up:

```
Ruijie(config)# boot ip 192.168.7.11
```

If no boot ip address is specified, the device cannot load main program files from the TFTP server during the boot process due to communication failure. The following message appears on the screen:

```
Load program file: [tftp://192.168.7.24/rgos.bin]
[Failed] (Boot IP was not assigned)
Load program file: [/rgos.bin]
[OK]
Executing program, launch at: 0x00010000
......
```

Modifying the Boot Priority of Main Program

The **boot system** command can also be used to modify the boot priority of the main program. Aussme that the configured boot main program list is shown as follows:

```
Ruijie# show boot system
Boot system config:
=====================================================
Prio     Size            Modified  Name
---- --------- ------------------- ------------------
  1
  2
  3
  4
  5    3205120 2008-08-26 05:22:46 flash:/rgos.bin
  6
  7
  8    3205120 2008-08-26 05:25:09 flash:/rgos_bak.bin
  9
 10
======================================================
```

To set the boot priority of flash:/rgos_bak.bin to 1, run the following command:

```
Ruijie(config)# boot system 1 flash:/rgos_bak.bin
File [flash:/rgos_bak.bin] has been configured with priority 8,
Change the priority to [1]? [yes] yes
```

The result is as follows:

```
Ruijie# show boot system
Boot system config:
=====================================================
Prio     Size            Modified  Name
---- --------- ------------------- ------------------
  1    3205120 2008-08-26 05:25:09 flash:/rgos_bak.bin
  2
  3
  4
  5    3205120 2008-08-26 05:22:46 flash:/rgos.bin
  6
  7
  8
  9
 10
======================================================
```

Deleting the Main Boot Program

You can use the following command to delete the main boot program.

Command	Function
Ruijie(Config)# **no boot system** [*priority*]	Deletes the main boot program. The boot priority is in the range of 1 to 10. If no priority is specified, all the main boot programs will be reset.

Use the following command to delete the main program with the prioirty of 8. During the process of deletion, the system displays the corresponding main program name and prompts you for confirmation.

```
Ruijie(config)# no boot system 8
Delete boot system config: [Priority: 8; File Name: flash:/rgos_bak.bin]? [no] yes
```

Use the following command to clear all the main boot programs.

```
Ruijie(config)# no boot system
```

```
Clear ALL boot system config? [no] yes
```

Caution

If you have not configured the main boot program after using the **no boot system** command to clear all main boot programs, the system will automatically restore to the default setting during the next booting process (the bootable main program is flash:/rgos.bin with the priority of 5).

Showing the Configuration of Multi-boot

You can use the following command to show the configuration of multi-boot.

Command	Function
Ruijie# **show boot system**	Show the configuration of the main boot program.
Ruijie# **show boot ip**	Shows the local IP address used by the device during the boot process.

The local IP address for booting up the device is shown as follows:

```
Ruijie# show boot ip
System boot ip: [192.168.7.11]
```

Use the following command to show the main program and its boot priority.

```
Ruijie# show boot system
Boot system config:
=====================================================
Prio     Size            Modified  Name
---- --------- ------------------- ------------------
  1
  2
  3
  4
  5    3205120 2008-08-26 05:22:46 flash:/rgos.bin
  6
  7
  8    3205120 2008-08-26 05:25:09 flash:/rgos_bak.bin
  9
 10
======================================================
```

Note

The size and modification time are not shown for files on a remote TFTP server. The size and modification time are shown as N/A for such files.

Note

If the related main program does not exist when you run the **show boot system** command, the size and modification time of the file is also shown as N/A.

Configuration Example

The following example shows how the device boots up:

- The device boots from the USB drive in USB port 1 that contains a legal main program file in its root directory;
- The device boots from rgos.bin in the root directory of the built-in flash memory if no USB drive is available;
- The device will boot from the backup main program file rgos_bak.bin if rgos.bin is damaged or lost;
- The device will download and boot from a main program file from the remote TFTP server if the backup main program file fails possibly because the built-in flash memory is formatted.

Step 1: Configure the default main program.

```
Ruijie(config)# boot system 5 flash:/rgos.bin
```

Since the device is configure with the main program flash;/rgos.bin with priority of 5 during intialization, this step can be skipped.

Generally, it is recommended that you set the priority of an active main program to medium so that you can configure other main programs with a higher or lower priroity.

Step 2: configure the backup main program.

The backup main program should have a priority slightly lower than the active main program.

```
Ruijie(config)# boot system 8 flash:/rgos_bak.bin
```

Step 3: Configure the name of the main program for booting from a remote TFTP server and the boot IP address.

Normally, the device is set up to boot from a remote TFTP server only when its built-in flash memory is damaged. Therefore, boot from TFTP is set to the lowest priority:

```
Ruijie(config)# boot ip 192.168.7.11
Ruijie(config)# boot system 10 tftp://192.168.7.24/rgos.bin
```

Step 4: Configure the name of the main program for USB boot.

Boot from a USB drive applies when a temporary version must be quickly deployed for trial run.

For a device to boot first from a USB drive, insert the USB drive that contains only the temporary software version and restart the device. To clear the temporary version, remove the USB drive and restart the device. The device will automatically boot from the main program in the built-in flash memory. Booting from a USB drive simplifies the deployment of a temporary version and shortens the downtime due to version upgrade.

Do as follows to configure the name of the main program and set up the device to boot first from a USB drive:

```
Ruijie(config)# boot system 1 usb1:/rgos.bin
```

Step 5: Check the main program name and boot priority.

You can run the **show boot** system command to view confiugration.

```
Ruijie# show boot system
Boot system config:
=====================================================
Prio     Size            Modified  Name
---- --------- ------------------- ------------------
  1
  2
  3
  4
  5    3205120 2008-08-26 05:22:46 flash:/rgos.bin
  6
  7
  8    3205120 2008-08-26 05:25:09 flash:/rgos_bak.bin
  9
 10        N/A                 N/A tftp://192.168.7.24/
                                   rgos.bin
======================================================
```

Setting Startup Configuration File

Some Ruijie products can speficy a startup configuration file, which is stored in the flash memory, on a removable storage device (for example, USB drive, SD card) or remote TFTP server.

Once configured, a device can obtain a file from a specified location as the startup configuration file.

Product support	Only the RSR20, RSR30, R2700 V5.0, RSR50, RSR50E and NPE50 series of routers and the S86 series of switches currently support this function. Unless otherwise stated, this section applies to the above products.

This following examples describe how to specify a startup configuration file.

Configuring the Startup Configuration File

You can use the following command to configure the startup configuration file.

Command	Function
Ruijie(Config)#**boot config** *prefix:/ [directory/] filename*	Sets the startup configuration file.
Ruijie(Config)#**no boot config**	Clears the startup configuration file.

Note

You can view the configuration file using the command line help, for example:

```
Ruijie(config)#boot config ?
```

```
 flash:   Startup-config filename
 usb0:   Startup-config filename
 usb1:   Startup-config filename
```

The system loads a configuration file as follows:

- If the **service config** command is absent, configuration files are loaded in the following order: the startup configuration file specified by the **boot config** command, /config.text, the network startup configuration file configured by the **boot network** command, and the default factory configuration (null configuration).
- If the **service config** command is present, configuration files are loaded in the following order: the network startup configuration file configured by the **boot network** command, the startup configuration file specified by the **boot config** command, /config.text, and the default factory configuration (null configuration).
- While loading configuration files in order, the system will not load another configuration files until one configuration file is loaded successfully.

Caution

For the service config and boot config commands, refer to the following examples.
Because the system needs to use the configuration of this command in the early stage of booting, this configuration is stored in Boot ROM rather than in the configuration file.

When using the **write [memory]** command to store the startup configuration file, the system will save it as follows:

- If the **boot config** command is not used, the system stores the configuration in the flash:/config.text file in the built-in flash memory by default.
- If the **boot config** command is used to configure a startup configuration file and the file exists, the system stores the configuration in the startup configuration file.
- If the **boot config** command is used to configure a startup configuration file but the configuration file does not exist, then:
- If the device where the configuration file is located exists, the system will automatically create the specified configuration file and store it into the system configuration.
- If the device where the configuration file is located does not exist (for instance, the start cofniguration file is stored on a removable storage device such as a USB drive or SD card, but the device is not loaded when the system runs the **write [memory]** command), the system will prompt you whether to save the configuration into the default startup configuration file flash:/config.text and act as required.

The following example sets a file on the USB drive as the startup configuration file and demonstrates how to run the write command before and after removing the USB drive.

Set the file on the USB drive as the startup configuration file.

```
Ruijie(config)# boot config usb1:/config.text
```

Run the **write** command before removing the USB drive to save the current configuation into the file specified by the boot config command.

```
Ruijie# write
Building configuration...
```

```
Write to boot config file: [usb1:/config.text]
[OK]
```

Run the **write** command after removing the USB drive. The system will prompt you whether to save the current configuration into the default start configuraiton file /config.

```
Ruijie# usb remove 1
0:1:1:38 Ruijie: USB-5-USB_DISK_REMOVED: USB Device <USB Mass Storage Device> Removed!
Ruijie# write
Building configuration...
Write to boot config file: [usb1:/config.text]
[Failed]
The device [usb1] does not exist, write to the default config file [flash:/config.text]? [no]
yes
Write to the default config file: [flash:/config.text]
[OK]
```

Configuring the Network Start Configuration File

You can use the following command to configure the network startup configuration file.

Command	Function
Ruijie(Config)# **boot network tftp** :// *location* / *filename*	Configures the network startup configuration file.
Ruijie(Config)#**no boot network**	Clears the network startup configuration file.

When the device starts, the system loads the configuration file as follows;

- If the service config command is absent, configuration files are loaded in the following order: the startup configuration file specified by the boot config command, /config.text, the network startup configuration file cofnigured by the boot network command, and the default factory configuration (null configuration).
- If the service config command is present, configuration files are loaded in the following order: the network startup configuration file configured by the boot network command, the startup configuration file specified by the boot config command, /config.text, and the default factory configuration (null configuration).
- While loading configuration files in order, the system will not load another configuration files until one configuration file is loaded successfully.

Caution

The system can obtain remote files through TFTP only after you run the bootip command to configure the local IP address of the device used for initiation. Otherwise, TFTP transmission may fail during initiation. Because the system needs to use the configuration of this command in the early stage of booting, this configuration is stored in Boot ROM rather than the configuration file.

The following figure sets the boot IP address of the device and designates the network startup configuration file.

```
Ruijie(config)# boot ip 192.168.7.11
Ruijie(config)# boot network tftp://192.168.7.24/config.text
```

Configuring Preferrably Using the Network Start Configuration File

By default, the device loads the local startup configuration file specified by the **boot config** command. In some cases, if the device needs to use the network startup configuration file, run the **service config** command.

Command	Function
Ruijie(Config)# **service config**	Enables the device to preferably load the startup configuration file from the remote network server.
Ruijie(Config)#**no service config**	Disables the device to preferably load the startup configuration file from the remote network server.

This command should use in conjunction with the **boot config** and **boot network** commands.

When the device starts, the system loads the configuration file as follows;

- If the **service config** command is absent, configuration files are loaded in the following order: the startup configuration file specified by the boot config command, /config.text, the network startup configuration file configured by the boot network command, and the default factory configuration (null configuration).
- If the **service config** command is present, configuration files are loaded in the following order: the network startup configuration file configured by the boot network command, the startup configuration file specified by the boot config command, /config.text, and the default factory configuration (null configuration).
- While loading configuration files in order, the system will not load another configuration files until one configuration file is loaded successfully.

Caution

Because the system needs to use the configuration of this command in the early stage of booting, this configuration is stored in Boot ROM rather than the configuration file.

The following example loads the configuration file from a remote network server and configures the network startup configuration name.

```
Ruijie(config)# service config
Ruijie(config)# boot network tftp://192.168.7.24/config.text
```

Showing the Configuration of Start Configuration File

You can use the following command to show the configuration of a startup configuration file.

Command	Function
Ruijie# **show boot config**	Shows the configuration of a startup configuration file.
Ruijie# **show boot network**	Shows the configuration of a network startup configuration file.

The following example shows the configuration of a startup configuration file.

```
Ruijie# show boot config
Boot config file: [flash:/config_main.text]
Service config: [Disabled]
```

The following example shows the configuration of a network startup configuration file.

```
Ruijie# show boot network
Network config file: [tftp://192.168.7.24/config.text]
Service config: [Enabled]
```

Configuration Example

The following example sets up the device to first obtain the configuration file from a remote TFTP server and to use the backup configuration file in built-in flash memory when loading fails.

Step 1: Configure the device to first load the configuration file from a network server and configure the boot IP address.

```
Ruijie(config)# service config
Ruijie(config)# boot ip 192.168.7.11
```

Step 2: Configure the network startup configuration file.

```
Ruijie(config)# boot network tftp://192.168.7.24/router_1.text
```

Step 3: Configure the local startup configuration file.

```
Ruijie(config)# boot config flash:/router_1.text
```

Step 4: Show the configuration.

```
Ruijie# show boot network
Network config file: [tftp://192.168.7.24/router_1.text]
Service config: [Enabled]
Ruijie# show boot config
Boot config file: [flash:/router_1.text]
Service config: [Enabled]
```

Configuring Network Communication Detection Tools

Ping Connectivity Test

To test the connectivity of a network, many network devices support the **Echo** protocol. The protocol sends a special packet to a specified network address and waits for a response. This allows you to evaluate the connectivity, delay and reliability of a network. The ping tool provided by RGOS can effectively help users diagnose and locate the connectivity problems in a network.

The **Ping** command runs in ordinary user mode and privileged user mode. In ordinary user mode, only basic ping functions are available. However, in privileged user mode, extended ping functions are available.

Command	Function
Ruijie# **ping** [vrf *vrf-name*] [ip] [*address* [**length** *length*] [**ntimes** *times*] [data *data*][**source** *source*] [**timeout** *seconds*] [df-bit] [validate]]	Tests the network connectivity.

The basic ping function can be performed in either ordinary user mode or privileged user mode. By default, this command sends five 100-byte packets to the specified IP address. If the system receives a response within the specified time (2 seconds by default), it shows "!" . Otherwise, it shows ".". Finally, the system shows statistics. The following example shows an ordinary **ping**:

```
Ruijie# ping 192.168.5.1
Sending 5, 100-byte ICMP Echoes to 192.168.5.1, timeout is 2 seconds:
< press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/10 ms
```

The extended ping function can be performed in privileged user mode only. This function allows you specify the number of packets, packet length, and timeout time. As with the basic ping function, the extended ping also shows statistics. The following example shows an extended **ping**:

```
Ruijie ping 192.168.5.197 length 1500 ntimes 100 data ffff source 192.168.4.190 timeout 3
Sending 100, 1000-byte ICMP Echoes to 192.168.5.197, timeout is 3 seconds:
  < press Ctrl+C to break >
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
!!!!!!!!!!!!!
Success rate is 100 percent (100/100), round-trip min/avg/max = 2/2/3 ms
```

Ping IPv6 Connectivity Test

To test the connectivity of a network, many network devices support the **Echo** protocol. The protocol sends a special packet to a specified network address and waits for a response. This allows you to evaluate the connectivity, delay and reliability of a network. The ping tool provided by RGOS can effectively help users diagnose and locate the connectivity problems in a network.

The **Ping ipv6** command runs in ordinary user mode and privileged user mode. In ordinary user mode, only basic ping IPv6 functions are available. However, in privileged user mode, extended ping IPv6 functions are available.

Command	Function
Ruijie# **ping ipv6** [*address* **[length** *length*] [**ntimes** *times*] [**data** *data*] [**source** *source*] [**timeout** *seconds*]]	Tests the network connectivity.

The basic ping function can be performed in either ordinary user mode or privileged user mode. By default, this command sends five 100-byte packets to the specified IP address. If the system receives a response within the specified time (2 seconds by default), it shows "!" . Otherwise, it shows ".". If the response does not match the request, the system shows “C” and outputs statistics. The following example shows an ordinary **ping**:

```
Ruijie# ping ipv6 2000::1
Sending 5, 100-byte ICMP Echoes to 2000::1, timeout is 2 seconds:
< press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/10 ms
```

The extended ping function can be performed in privileged user mode only. This function allows you specify the number of packets, packet length, and timeout time. As with the basic ping function, the extended ping also shows statistics. The following example shows an extended **ping**:

```
Ruijie# ping ipv6 2000::1  length 1500 ntimes 100 data ffff source 2000::2 timeout 3
Sending 100, 1000-byte ICMP Echoes to 2000::1, timeout is 3 seconds:
  < press Ctrl+C to break >
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
!!!!!!!!!!!!!
Success rate is 100 percent (100/100), round-trip min/avg/max = 2/2/3 ms
```

Traceroute Connectivity Test

The **Traceroute** command is mainly used to check the network connectivity. It show all the gateways that a packet passes through from the source address to the destination address and exactly locates the fault when the network fails.

One of the network transmission rules is that the number in the TTL field in the packet will decrease by 1 every time when a packet passes through a gateway. When the number in the TTL field is 0, the gateway will discard this packet and send an address unreachable error message back to the source. According to this rule, the execution of the **traceroute** command is as follows: At first, the source sends a packet whose TTL is 1 to the destination address. The first gateway sends an ICMP error message back, indicating that this packet cannot be forwarded for TTL timeout. Then, the first gateway re-sends the packet after the TTL domain adds 1. Likewise, the second gateway returns a TTL timeout error and the process lasts until the packet reaches the destination address. By recording every address returning the ICMP TTL timeout message, you can draw the entire path passed by the IP packet from the source address to the destination address.

The **traceroute** command can run in ordinary user mode and privileged user mode. The command format is as follows:

Command	Function

Command	Function
Ruijie# **traceroute** [**vrf** *vrf-name* | **ip**] [*address* [**probe** *probe*] [**ttl** *minimum maximum*] [source *source*] [**timeout** *seconds*]]	Traces the path that a packet passes through.

The following are two examples that apply **traceroute**. In one example, network connectivity is good. In another example, some gateways in a network are not connected.

traceroute example where network connectivity is good:

```
Ruijie# traceroute 61.154.22.36
  < press Ctrl+C to break >
Tracing the route to 61.154.22.36
1      192.168.12.1      0 msec  0 msec  0 msec
2      192.168.9.2       4 msec  4 msec  4 msec
3      192.168.9.1       8 msec  8 msec  4 msec
4      192.168.0.10      4 msec  28 msec  12 msec
5      202.101.143.130   4 msec  16 msec  8 msec
6      202.101.143.154  12 msec  8 msec   24 msec
7      61.154.22.36     12 msec   8 msec   22 msec
```

As you can see, to access the host with an IP address of 61.154.22.36, the network packet passes throuth gateways 1 to 6 from the source address. Meanwhile, you can know the time that the network packet spennds to reach a gateway. This is very useful for network analysis.

a. **traceroute** example where some gateways in a network are not connected:

```
Ruijie# traceroute 202.108.37.42
< press Ctrl+C to break >
Tracing the route to 202.108.37.42
1      192.168.12.1      0 msec      0 msec      0 msec
2      192.168.9.2       0 msec      4 msec      4 msec
3      192.168.110.1     16 msec     12 msec     16 msec
4      *  *  *
5      61.154.8.129          12 msec     28 msec     12 msec
6      61.154.8.17           8 msec      12 msec     16 msec
7      61.154.8.250          12 msec     12 msec     12 msec
8      218.85.157.222        12 msec     12 msec     12 msec
9      218.85.157.130        16 msec     16 msec     16 msec
10     218.85.157.77         16 msec     48 msec     16 msec
11     202.97.40.65          76 msec     24 msec     24 msec
12     202.97.37.65          32 msec     24 msec     24 msec
13     202.97.38.162         52 msec     52 msec     224 msec
14     202.96.12.38          84 msec     52 msec     52 msec
15     202.106.192.226       88 msec     52 msec     52 msec
16     202.106.192.174       52 msec     52 msec     88 msec
17     210.74.176.158        100 msec    52 msec     84 msec
18     202.108.37.42         48 msec     48 msec     52 msec
```

As you can see, to access the host with an IP address of 202.108.37.42, the network packet passes through gateways 1 to 17 from the source address and there is failure in gateway 4.

Traceroute IPv6 Connectivity Test

The **Traceroute ipv6** command is mainly used to check the network connectivity. It shows all the gateways that a packet passes through from the source address to the destination address and exactly locates the fault when the network fails.

For network transmission rules, refer to the previous section.

The **traceroute ipv6** command can run in ordinary user mode and privileged user mode. The command format is as follows:

Command	Function
Ruijie# **traceroute ipv6** [*address* [**probe** *probe*] [**ttl** *minimum maximum*] [**source** source] [**timeout** *seconds*]]	Traces the path that a packet passes through.

The following are two examples that apply **traceroute ipv6**. In one example, network connectivity is good. In another example, some gateways in a network are not connected.

traceroute ipv6 example where network connectivity is good:

```
Ruijie# traceroute ipv6 3004::1
 < press Ctrl+C to break >
Tracing the route to 3004::1
1     3000::1       0 msec  0 msec  0 msec
2     3001::1       4 msec  4 msec 4 msec
3     3002::1       8 msec  8 msec  4 msec
4     3004::1       4 msec  28 msec  12 msec
```

As you can see, to access the host with an IP address of 3004::1, the network packet passes throuth gateways 1 to 4 from the source address. Meanwhile, you can know the time that the network packet spennds to reach a gateway. This is very useful for network analysis.

traceroute ipv6 example where some gateways in a network are not connected:

```
Ruijie# traceroute ipv6 3004::1
 < press Ctrl+C to break >
Tracing the route to 3004::1
1     3000::1       0 msec  0 msec  0 msec
2     3001::1       4 msec  4 msec 4 msec
3     3002::1       8 msec  8 msec  4 msec
4     * * *
5     3004::1       4 msec  28 msec  12 msec
```

As you can see, to access the host with an IP address of 3004::1, the network packet passes through gateways 1 to 5 from the source address and there is failure in gateway 4.Configuring File System

Configuring File System

Understanding File System

Overview

The chapter describes the file system management on RGOS. The RGOS file management offers an unified cross-platform management function, providing the unified file management interface for different kinds of devices, storages and file transmission protocols.

Locally, there are many kinds of storage medias, for instance, Universal Serial BUS (USB) and FLASH, which can be distributed on different boards like primary and secondary management boards. Users can exchange files with remote devices through xModem and TFTP protocols. These functions can be realized using the same command.

Not all types of devices and file systems support all file system commands described here, because they support different types of file operations. The Help command shows the storage media and protocols supported by the file operation commands.

Basic Features

The file system management on a RGOS device offers an unified command interface for operations of various files on the device.

Using URL to Locate a File

The file system of RGOS uses Uniform Resource Locators (URLs) to uniformly locate files and directories in storage media on the local device or remote device. For example, you can copy a file from one place to another using the **copy** *source-url destination-url* command. The destination can be on the local device or a remote server.

URL representation varies by commands. The following sections describe URL usage:

- Locate a file on the server.
- Locate a local file.
- Description of URL prefixes

Locate a file on the server

To locate a file on the server, use the following command:

- **tftp:**[[//location]/directory]/filename

location: IP address or host name. *Path (directory and file name):* position for file transmission. For instance, the file transission directory specified by the TFTP server is C:\download, the file path specified by the device is the one under C:\download. tftp://192.168.0.1/binary/rgos.bin refers to the c:\download\binary\rgos.bin file on the TFTP server with the IP address of 192.168.0.1.

⚠ Caution TFTP can only transmit files smaller than 32M. To transmit files larger than 32M, use the FTP protocol. Set a device as the FTP server to upload files to or download files from the server.

Locate a Local File

Use the [*prefix*]:[*directory/*]*filename* syntax to locate a local file on FLASH, USB and the FLASH of the management board of the device.

For example:

flash:/config.text: the configuration file on the local FLASH

usb0:/backup/rgos.bin.bak: the file on the first USB

slave:/rgos.bin: files under the root directory of the secondary management board

Note Without prefix, the syntax refers to the file system type on the current path, for instance, if the current path is under the root directory of usb0, the syntax indicates usb0 if the file system does not specify prefix.

⚠ Caution When you use a prefix to specify a local file, the path after ":" must be an absolute path.

Description of URL Prefixes

URL prefixes are used to specify file systems. Different devices and file operation commands can run different file systems. You can show the file systems supported on the device by the **show file system** command.

The following table shows the URL prefixes:

Prefix	Description
flash:	FLASH storage media, which can be used on all devices. The startup program is generally stored in the FLASH of a device when the device is delivered.
Tftp:	TFTP network server
xmodem:	Receives and sends files through xModem.
slave:	FLASH on the secondary management board of the chassis-based device
Usb0:	The first USB device
Usb1:	The second USB device
sd0:	The first SD card
sw1-m1-disk0:	Management board on the M1 slot of the chassis with switch id 1 in the VSU mode.
sw1-m2-disk0:	Management board on the M2 slot of the chassis with switch id 1 in the VSU mode.
sw2-m1-disk0:	Management board on the M1 slot of the chassis with switch id 2 in the VSU mode.
sw2-m2-disk0:	Management board on the M2 slot of the chassis with switch id 2 in the VSU mode.

Note

Different file system commands and different platforms support different types of file systems. For details, use the help information in the command line, for example:

```
Ruijier#copy ?
WORD          Copy from current file system
  flash:          Copy from flash: file system
  running-config   Copy from current system configuration
  slave:         Copy from slave: file system
  startup-config   Copy from startup configuration
  tftp:           Copy from tftp: file system
  usb0:         Copy from usb0: file system
  usb1:         Copy from usb1: file system
sd0:            Copy from sd0: file system
  xmodem:      Copy from xmodem: file system
```

Note

Given the limitation of xModem, files transmitted through xModem will be slightly larger than the real one.

Note

For chassis-based devices, the **slave:** prefix is supported and the **sw1-m1-disk0:** series prefixes are not supported in non-VSU modes, while in VSU mode, the **sw1-m1-disk0:** series prefixes are supported and the **slave:** prefix is not. In VSU mode, **copy flash:/file1 sw1-m1-disk0:/file2** and **copy sw1-m1-disk0:/file1 flash:/file2** are supported (the copy between the FLASH on the primary and secondary management boards of the VSU system), and **copy sw1-m1-disk0:/file1 sw1-m1-disk0:/file2** is also supported (the copy on the same management board: the primary or secondary management boards of the VSU system), but neither **copy sw1-m1-disk0:/file1 sw2-m2-disk0:/file2** nor **copy usb0:/file1 sw1-m1-disk0:/file2** is supported (only the combination with the **flash:** prefix is supported). In VSU mode, you can operate file systems on the primary and secondary management boards of the VSU system using commands such as **dir sw1-m1-disk0:/**. The secondary management board on VSU master and slave chassis can only be used to increase bandwidth. Currently, you cannot operate file systems on the secondary management boards of VSU master and slave chassis on the primary management board of the VSU system.

Showing the File System Information

This command shows all the file systems supported on the device and their available spaces.

In privileged EXEC mode, use the following command:

```
Ruijie#show file systems

File Systems:
       Size(b)       Free(b)       Type     Flags     Prefixes
   ------------   ------------   ---------   -------   ----------
```

```
*      33488896      16191488      flash        rw       flash:
             -             -       flash       rw        usb0:
             -             -       flash       rw        usb1:
             -             -       flash       rw         sd0:
             -             -       flash       rw       slave:
             -             -     network        rw       tftp:
             -             -     network        rw      xmodem:
--------------------------------------------------------------------
```

In this informatin, “*” means the active file system, **Size** means the space of the file system and **Free** means the available space.

Caution

Free means the idle status of the file system, not the size of files that can be stored. Since the file system has its own management overhead, the size of files that the system finally can store is slightly smaller than the free space.

Managing Local Files

Local files refer to ones stored in various storage media on the device, for instance, FLASH, and USB. System files such as main program, configuration files, logs and web files are stored generallly in FLASH. Some devices come with USB interfaces. Management of files on the flash disk is also local file management. For a chassis-based device with two management boards, you can manage files in the FLASH of the secondary management board with the **slave** prefix of URL.

For local files, you can:

- Copy files
- Move files
- Delete files
- Create directories
- Delete directories
- Show directories
- Show the current working path
- Modify the working path

These operations apply to slave-, USB-, or FLASH-type file systems and can copy files between these file systems.

Caution

File name is case sensitive on the FLASH- and slave- file systems. For example, abc.txt and Abc.txt are different. The file name must be entered correctly to locate the corresponding file. On USB-type file system, however, file name is not case sensitive, namely abc.txt and Abc.txt are considered the same.

Caution

Number and size of files will affect the startup and operation speed of files considerably. Storing too many or large files in FLASH will slow down startup of the device and update of the system. When the device starts for the first time, using the **dir** command will result in longer waiting time. Generally, we recommend a file system space of less than 128M. When necessary, we recommend storing a large number of files on a flash disk. We recommend clearing some old and useless files manually on a regular basis.

For chassis-based devices, a timeout failure may occur when the file system on the secondary management board (or the secondary management board of the VSU system in the VSU mode) is operated if too many files are stored on the secondary management board, the device is just started or for the first time. In such case, wait for a while according to the prompt and try again later.

Caution

Some files are vital for the system to work properly. Deleting these files will cause malfunction. These system files include:

- RCMS configuration file (/rcms_config.ini)
- Web management package (/web_management_pack.upd)
- Main program files (for multi-boot-supported devices, the main program includes all the files in the boot system configuration)

The system will automatically recognize these files and alarm you before you delete them. If you need to delete system files, the system will print WARN-level logs as below:

Ruijie# **delete** *rgos.bin*
File [rgos.bin] is a system file. System may not work properly without it.
Are you sure you want to delete it? [no] yes
0:1:1:38 Ruijie: FS-4-SYSTEM_FILE_DELETED: System file [rgos.bin] deleted!

Note

The file name with a path should be no more than 4096 bytes. Wildcard is not supported for file name and path.

Transmitting Files through Communication Protocols

- Transmitting files through TFTP:

You can upload and download files to and from the TFTP server.

In CLI privileged EXEC mode, use the following command to download files:

```
Ruijie# copy tftp:[[//location]/directory]/filename destnation-url
```

In CLI privileged EXEC mode, use the following command to upload files:

```
Ruijie# copy source-url  tftp:[[//location]/directory]/filename
```

- Transmitting files through xModem:

In CLI privileged EXEC mode, use the following command to download files:

```
Ruijie# copy xmodem:  destnation-url
```

In CLI privileged EXEC mode, use the following command to upload files:

```
Ruijie# copy source-url xmodem:
```

Working Principles

None

Protocols Specifications

None

Default Configuration

None

Typical Configuration Example

Downloading Files from TFTP Server

The following example shows how to download a.dat from directory c:\download\ of the TFTP server to the local device:

1) Run the TFTP Server on the host and select C:\download where the file to be downloaded is located.

b. Use the **ping** command to test the connection between the device and the TFTP server.

c. Log on the device, enter privileged EXEC mode and run the following command:

```
Ruijie#copy tftp://192.168.201.54/a.dat flash:
Destination filename [a.dat]?
Accessing tftp://192.168.201.54/a.dat
!!!!!!!!!!!!!!!!!!!!!!
Transmission finished, file length 343040
```

d. Run the **dir** command to show the files on the device.

```
Ruijie#dir
Directory of flash:/
   Mode Link     Size             MTime Name
-------- ---- --------- ------------------- ------------------
          1    343040 2009-01-01 02:02:59 a.dat
          1  10838016 2009-01-01 00:08:38 rgos.bin
          1       399 2009-01-01 00:01:37 config.text
--------------------------------------------------------------
3 Files (Total size 11181455 Bytes), 9 Directories.
Total 33030144 bytes (31MB) in this device, 20492288 bytes (19MB) available.
```

Uploading Files to TFTP Server

The following example shows how to upload a.dat to the c:\download\ of TFTP server:

1) Run the TFTP Server on the host and select directory C:\download where the file to be uploaded is located.

e. Use the **ping** command to test the connection between the device and the TFTP server.

f. Log on the device, enter privileged EXEC mode and run the following command:

```
Ruijie#copy flash:/a.dat tftp://192.168.201.54/a.dat
Accessing flash:a.dat...
!!!!!!!!!!!!!!!!!!!!!!!
 Transmission finished, file length 343040
```

g. Check whether a.dat exists under C:\download on TFTP server.

Downloading Files through xModem

The following example shows how to download config.txt from PC to the local device through xModem:

1) Use a serial cable to connect the seiral interface of PC to the serial interface of the device.

h. Run hyperterminal of Windows to connect to the console of the device.

i. In privileged EXEC mode, use the following command to download the file:

```
Ruijie# copy xmodem: flash:/config.text
```

j. In the Windows hyperterminal of local deivce, select Transmit files of Transmit menu:

k. In the pop-up dialog box, select the file to download and xModem and click Transmit. The Windows hyperterminal shows the transmission progress and packets.

l. Run the **dir** command to show the files on the device.

```
Directory of flash:/
   Mode Link      Size             MTime Name
-------- ---- --------- ------------------- -------------------
          1    343040 2009-01-01 02:02:59 a.dat
          1  10838016 2009-01-01 00:08:38 rgos.bin
          1       399 2009-01-01 00:01:37 config.text
---------------------------------------------------------------
3 Files (Total size 11181455 Bytes), 0 Directories.
Total 33030144 bytes (31MB) in this device, 20492288 bytes (19MB) available.
```

Uploading Files through xModem

The following example shows how to upload config.txt from the local device to C:\Documents and Settings\ju of PC through xModem:

1) Use a serial cable to connect the serial interface of PC and the serial interface of the device.

m. Run the hyperterminal of Windows to connect to the console of the device.

n. In privileged EXEC mode, use the following command to upload file:

```
Ruijie# copy flash:/config.text xmodem
```

o. In the Windows hyperterminal of local deivce, select Receive files of Transmit menu:

p. In the pop-up dialog box, select the directory to save the uploaded file and xModem. Click Receive. The Windows hyperterminal prompts to set the name used to store the file. Click OK.

q. Check whether config.text exists under C:\Documents and Settings\ju on PC.

Moving Files from FLASH to USB Device

The following example shows how to move config.txt from FLASH to flash disk on USB0 and save it in the **backup** directory of flash disk:

```
Directory of flash:/
   Mode Link     Size            MTime     Name
-------- ---- --------- ------------------- ------------------
          1    343040 2009-01-01 02:02:59   a.dat
          1  10838016 2009-01-01 00:08:38   rgos.bin
          1      399  2009-01-01 00:01:37    config.text
--------------------------------------------------------------
3 Files (Total size 11181455 Bytes), 0 Directories.
Total 33030144 bytes (31MB) in this device, 20492288 bytes (19MB) available.
```

Enter the root directory of flash disk:

```
Ruijie#cd usb0:/
```

Confirm the current path:

```
Ruijie#pwd usb0:/
```

Create **backup** directory on flash disk:

```
Ruijie#mkdir backup
```

Copy the file to the flash disk:

```
Ruijie#copy flash:/config.text config.text
```

Check the result.

```
Ruijie#dir backup
Directory of usb0:/backup
   Mode Link     Size            MTime     Name
-------- ---- --------- ------------------- ------------------
          1      399   2009-01-01 00:01:37  config.text
--------------------------------------------------------------
Total 33030144 bytes (31MB) in this device, 20488192 bytes (19MB) available.
```

Moving Files from FLASH to SD Card

The following example shows how to move config.txt from FLASH to SD card and save it in the **backup** directory of SD card:

```
Directory of flash:/
   Mode Link     Size            MTime     Name
-------- ---- --------- ------------------- ------------------
          1    343040 2009-01-01 02:02:59   a.dat
          1  10838016 2009-01-01 00:08:38   rgos.bin
          1      399  2009-01-01 00:01:37    config.text
--------------------------------------------------------------
3 Files (Total size 11181455 Bytes), 0 Directories.
Total 33030144 bytes (31MB) in this device, 20492288 bytes (19MB) available.
```

Enter the root directory of SD card:

```
Ruijie#cd sd0:/
```

Confirm the current path:

```
Ruijie#pwd sd0:/
```

Create **backup** directory on the SD card:

```
Ruijie#mkdir backup
```

Make sure that the directory is created:

```
Ruijie#dir
Directory of sd0:/
   Mode Link     Size             MTime     Name
-------- ---- --------- ------------------- ------------------
   <DIR>   1    343040 2009-01-01 02:02:59    backup
--------------------------------------------------------------
3 Files (Total size 11181455 Bytes), 0 Directories.
Total 33030144 bytes (31MB) in this device, 20492288 bytes (19MB) available.
```

Copy the file to the SD card:

```
Ruijie# copy flash:/config.text backup/config.text
```

Check the result:

```
Ruijie#dir backup
Directory of sd0:/backup
   Mode Link     Size             MTime     Name
-------- ---- --------- ------------------- ------------------
          1      399   2009-01-01 00:01:37  config.text
--------------------------------------------------------------
Total 33030144 bytes (31MB) in this device, 20488192 bytes (19MB) available.
```

Copying Files between USB and SD Card

The following example shows how to copy rgos_10_4.bin from flash disk to SD card:

Check the available space on the SD card:

```
Ruijie#dir sd0:/
Directory of sd0:/
   Mode Link     Size             MTime Name
```

```
-------- ---- --------- ------------------- ------------------
   <DIR>    2         0 2035-02-11 23:24:34 backup/
            1   7650112 2035-02-11 23:42:25 rgos.bin
--------------------------------------------------------------
1 Files (Total size 7650112 Bytes), 1 Directories.
Total 528482304 bytes (504MB) in this device, 475058176 bytes (453MB) available.
```

Copy the file from flash disk to SD card:

```
Ruijie#copy usb0:/rgos_10_4.bin sd0:/rgos_10_4.bin
[OK 7,650,112 bytes]
```

Check the result:

```
Ruijie#dir sd0:/
Directory of sd0:/
    Mode Link      Size               MTime Name
-------- ---- --------- ------------------- ------------------
   <DIR>    2         0 2035-02-11 23:24:34 backup/
            1   7650112 2035-02-11 23:42:25 rgos.bin
            1   7650112 2035-02-11 23:47:36 rgos_10_4.bin
--------------------------------------------------------------
2 Files (Total size 15300224 Bytes), 1 Directories.
Total 528482304 bytes (504MB) in this device, 459571200 bytes (438MB) available.
```

Copy the file from SD card to flash disk:

```
Ruijie#copy sd0:/rgos_10_4.bin usb0:/new_rgos.bin
[OK 7,650,112 bytes]
```

Check the result:

```
Ruijie#dir usb0:/
Directory of usb0:/
    Mode Link      Size               MTime Name
-------- ---- --------- ------------------- ------------------
            1   7650112 2035-02-11 23:49:21 new_rgos.bin
            1   7650112 2035-02-11 23:45:42 rgos_10_4.bin
--------------------------------------------------------------
2 Files (Total size 15300224 Bytes), 0 Directories.
Total 528482304 bytes (504MB) in this device, 451784704 bytes (430MB) available.
```

Copying Files from Primary Management Board to Secondary Management Board

The following example shows how to copy rgos_10_4.bin from primary management board to secondary management board:

Check the FLASH space on secondary management board:

```
Ruijie#dir slave:/
```

```
Directory of slave:/
   Mode Link     Size             MTime     Name
-------- ---- --------- ------------------- ------------------
           1   11014633  2006-01-01 08:00:46  rgos.bin
           1    399      2006-01-01 08:01:37  config.text
--------------------------------------------------------------
2 Files (Total size 11181455 Bytes), 0 Directories.
Total 33030144 bytes (31MB) in this device, 20488192 bytes (19MB) available.
```

Copy rgos_10_4.bin from primary management board to the secondary one:

```
Ruijie#copy rgos_10.4.bin slave:/
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!! [ok 10,234,345 bytes]
```

Check the result:

```
Ruijie#dir slave:/
Directory of slave:/
   Mode Link     Size                MTime     Name
-------- ---- --------- ------------------- ------------------
          1     11014633   2006-01-01 08:00:46  rgos.bin
          1     11025788   2008-01-01 08:00:46  rgos_10.4.bin
          1     399        2006-01-01 08:01:37  config.text
--------------------------------------------------------------
3 Files (Total size 11181455 Bytes), 0 Directories.
Total 33030144 bytes (31MB) in this device, 9563693 bytes (9MB) available
```

Deleting Directories

The following example shows how to delete a non-empty aaa directory:

Show the current directory status:

```
Ruijie#dir
Directory of flash:/
   Mode Link     Size                MTime     Name
-------- ---- --------- ------------------- ------------------
          1      11014633 2006-01-01 08:00:46  rgos.bin
 <dir>    1      0        2006-01-01 08:00:00 aaa/
          1      399      2006-01-01 08:01:37 config.text
--------------------------------------------------------------
2Files (Total size 11015032 Bytes), 1 Directories
Total 33030144 bytes (31MB) in this device, 9563693 bytes (9MB) available
```

Check whether there is any file under the directory:

```
Ruijie#dir aaa
```

```
Directory of flash:/aaa
   Mode Link     Size                MTime     Name
-------- ---- --------- ------------------- -------------------
         1         149  2006-01-01 08:01:37 backup.txt
--------------------------------------------------------------
1Files (Total size 149 Bytes), 0 Directories
Total 33030144 bytes (31MB) in this device, 9563693 bytes (9MB) available
```

Delete a non-empty directory:

```
Ruijie# delete recursive aaa
```

Delete an empty directory:

```
Ruijie# rmdir aaa
```

Note

The devices locating files through URL such as S86 and S12000 distributed devices support URL parameters (to locate files) and does not support deleting the non-null directory recursively (recursive parameters are not supported)

Check the result:

```
Ruijie#dir
Directory of flash:/
   Mode Link     Size                MTime     Name
-------- ---- --------- ------------------- -------------------
         1     11014633 2006-01-01 08:00:46  rgos.bin
         1     399     2006-01-01 08:01:37 config.text
--------------------------------------------------------------
2Files (Total size 11015032 Bytes), 0 Directories
Total 33030144 bytes (31MB) in this device, 9563693 bytes (9MB) available
```

Configuring Syslog

Overview

During the operation of a device, there are various state changes, such as the link status up/down, and various events occurring, such as receiving abnormal messages and handling exceptions. Our product provides a mechanism to generate messages of fixed format (log message) in case of status change or event occurring. These messages can be displayed in related windows (console, VTY, etc.) or recorded in related media (memory buffer, FLASH), or sent to a group of log servers in the network for the administrators to analyze and locate problems. Meanwhile, in order to make it easy for administrators to read and manage log messages, these log messages can be labeled time stamps and serial numbers, and is graded according to the priority of log information.

Log Message Format

The format of the our log message is as follows:

```
<priority> seq no: timestamp sysname: %severity
%ModuleName-severity-MNEMONIC: description
```

Their meanings are as follows:

Command	Meaning
<priority>	Priority, priority value = Device value x 8 + Severity
seq no	System serial number, a six-digit integer. You can disable this information output by commands.
timestamp	Timestamp, local time by default. In the format of Mmm dd hh:mm:ss, Mmm indicates the English abbreviations of the 12 months. From January to December, they are abbreviated as: Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, and Dec.
sysname	System name, you can disable this information output by commands.
ModuleName	Abbreviation of functional module name.
severity	Log severity level.
MNEMONIC	Information abbreviation
description	Information description

For example:

```
<189> 226:Mar  5 02:09:10 Ruijie %SYS-5-CONFIG_I: Configured from console by console
```

Caution

The priority field is not attached to the log messages that are printed in the user window. It only appears in the log messages that are sent to the syslog server.

Log Configuration

Log Switch

The log switch is turned on by default. If it is turned off, the device will not print log information in the user window, or send log information to the syslog server, or record the log information in the related media (memory buffer, flash).

To turn on or off the log switch, run the following command in global configuration mode:

Command	Function
Ruijie(config)# **logging on**	Turns on the log switch
Ruijie(config)# **no on**	Turns off the log switch

Caution Do not turn off the log switch in general case. If it prints too much information, you can reduce it by setting different displaying levels for device log information.

Configuring the Device for Displaying the Log Information

When the log switch is turned on, the log information will be displayed on the console and also sent to different displaying devices. To configure different displaying devices to receive logs, run the following commands in global configuration mode or privileged user level:

Command	Function
Ruijie(config)# **buffered** [*buffer-size* | *level*]	Records log in memory buffer
Ruijie# **termninal monitor**	Allows log to be displayed on VTY window
Ruijie(config)# **logging server** *host*	Sends log information to the syslog sever on the network
Ruijie(config)# **logging file flash:***filename* [*max-file-size*] [*level*]	Records log on extended FLASH. This command creates a file based on the specified file name on the FLASH to store logs. The file size increases with the log size, but its upper limit is subject to the configured max-file-size.

Buffered will record log information in the memory buffer. The memory buffer for log is used in recycled manner. That is, when it is full, the oldest information will be overwritten. To show the log information in the memory buffer, run the **show logging** command at privileged user level. To clear the log information in the memory buffer, run the **clear logging** command at privileged user level.

Terminal monitor allows log information to be displayed on the current VTY (such as the telnet window).

Logging server host specifies the address of the syslog server that will receive the log information. Our product allows the configuration of at most 5 syslog servers. The log information will be sent to all the syslog servers at the same time. The configuration of the **logging host** command has the same results.

Caution To send the log information to the syslog server, it is required to turn on the timestamp switch or serial number switch of the log information. Otherwise, log information will not be sent to the syslog server.

Logging file flash: Records log information in FLASH. The filename for log shall not have any extension to indicate the file type. The extension of the log file is fixed as txt. Any configuration of extension for the filename will be refused.

More flash: The **filename** command shows the contents of the log file in the flash.

Caution

Some devices support extended FLASH. If the device has extended FLASH, the log information will be recorded there. If the device has no extended FLASH, the log information will be recorded in the serial FLASH.

Enabling the Log Timestamp Switch of Log Information

To add or delete timestamp in log information, run the following command in global configuration mode:

Command	**Function**
Ruijie(config)# **service timestamps** [*message-type* [**uptime** | **datetime** [**msec**] [**year**]]]	Enables the timestamp in the log information
Ruijie(config)# **no service timestamps** [*message-type*]	Disables the timestamp in the log information

The timestamp are available in two formats: device uptime and device datetime. Select the type of timestamp as required.

Message type: log or debug. The "log" type means the log information with severity levels 0-6. The "debug" type means that with severity level 7.

Caution

If the current device has no RTC, the configured time is invalid, and the device automatically uses the startup time as the timestamp for the log information. If the device has an RTC, the device time is used as the timestamp for the log information by default.

Enabling System Name Switches in Log System

By default, the system name is not included in the log information. To add or remove the system name in the log information, run the following commands in global configuration mode.

Command	**Function**
Ruijie(config)# **no service sysname**	Removes the system name in the log message.
Ruijie(config)# **service sysname**	Adds a system name to the log message.

Enabling Log Statistics

By default, the log statistics function is disabled. To enable or disable the log statistics function, run the following commands in global configuration mode.

Command	**Function**

Ruijie(config)# **no logging count**	Disables the log statistics function and delete the statistics about the log information.
Ruijie(config)# **logging count**	Enables the log statistics function.

Ruijie# show logging count

```
Module Name   Message Name     Sev Occur   Last Time
================================================================
LINEPROTO     UPDOWN            5   2      Aug 20 01:41:19
-------------------------------------------------------------
LINEPROTO TOTAL                        2
LINK         CHANGED            5   1      Aug 20 01:41:19
-------------------------------------------------------------
LINK TOTAL                             1
SYS          CONFIG_I           5   1      Aug 20 01:40:55
-------------------------------------------------------------
SYS TOTAL                              1
```

Ruijie #**config**

```
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie (config)#no logging count
Ruijie (config)#end
Ruijie #show logging count
Module Name   Message Name          Sev Occur   Last Time
===========================================================
```

Enabling the Serial Number Switch of Log Information

By default, the log information has no serial number. To add or delete the serial number in log information, run the following command in global configuration mode:

Command	Function
Ruijie(config)# **no service sequence-numbers**	Deletes the serial number in the log messages.
Ruijie(config)# **service sequence-numbers**	Adds a serial number to the log messages.

Note

The log serial number is a long integer, which increases in ascending order when a log is added. However, since only five digits of the serial number is displayed, when it increases from 1 to 100000 or reaches 2^32, a turnover occurs, that is the serial number is displayed from 00000 again.

Configuring Synchronization Between User Input and Log Output

By default, user input is asynchronous with log output. User input is interrupted if the log is output when the user is keying in characters. As following shows, the status of FastEthernet 0/12 changes and a log is printed after the user entered **vlan**, so that the user forgot which character he was entering previously, affecting the coherence of command entering.

```
Ruijie(config)#vlan Aug 20 16:46:49 %LINK-5-CHANGED: Interface FastEthernet 0/12, changed
state to down
Aug 20 16:46:49 %LINEPROTO-5-UPDOWN: Line protocol on Interface FastEthernet 0/12, changed
state to DOWN
% Incomplete command.
```

While after the synchronization function is configured, the contents that the user entered previously will be displayed even though a log is printed when the user is entering a command, ensuring integrity and coherence. As following shows, the status of FastEthernet 0/1 changes and a log is printed after the user entered **vlan**, but the log module automatically prints **vlan** after the log is printed for the user to continue.

```
Ruijie(config)#vlan
*Aug 20 10:05:19: %LINK-5-CHANGED: Interface GigabitEthernet 0/1, changed state to up
*Aug 20 10:05:19: %LINEPROTO-5-UPDOWN: Line protocol on Interface GigabitEthernet 0/1,
changed state to up
Ruijie(config)#vlan
To configure synchronization between user input and log output, run the following commands
in line configuration mode:
```

Command	Function
Ruijie(config-line)# **logging synchronous**	Sets synchronization between user input and log output.
Ruijie(config)# **no logging synchronous**	Removes synchronization between user input and log output.

Configuring Log Rate Limit

By default, log rate is not limited. However, when there are massive logs, no log rate limit will cause burden on the system. To configure log rate limit, run the following commands in global configuration mode:

Command	Function
Ruijie(config)# **logging rate-limit** *number*	Sets log rate limit on the log information.
Ruijie(config)# **no logging rate-limit**	Removes the setting of log rate limit.

Configuring the Log Information Displaying Level

Users can set the severity level of log information that is allowed to be displayed to view the log information of a specific severity level.

To configure the log information displaying level, run the following commands in global configuration mode:

Command	Function
Ruijie(config)# **logging console** [*level*]	Sets the level of log information that is allowed to be displayed on the console.
Ruijie(config)# **logging monitor** [*level*]	Sets the level of log information that is allowed to be displayed on the VTY window (such as telnet window).
Ruijie(config)# **logging buffered** [*buffer-size*] [*level*]	Sets the level of log information that is allowed to be recorded in memory buffer.

Ruijie(config)# **logging file flash:***filename* [*max-file-size*] [*level*]	Sets the level of log information that is allowed to be recorded in extended flash.
Ruijie(config)# **logging trap** [*level*]	Sets the level of log information that is allowed to be sent to syslog server.

The log information of Ruijie Networks products is classified into the following 8 levels:

Level Keyword	Level	Description
Emergencies	0	Emergency case, system cannot run normally
Alerts	1	Problems that need immediate remedy
Critical	2	Critical conditions
Errors	3	Error message
Warnings	4	Alarm information
Notifications	5	Information that is normal but needs attention
Informational	6	Descriptive information
Debugging	7	Debugging messages

Lower value indicates higher level. That is, level 0 indicates the information of the highest level.

When the level of log information that can be displayed is set for the specified device, the log information that is at or below the set level will be displayed. For example, after the **logging console *6*** command is executed, all log information at or below level 6 will be displayed on the console.

The log information that is allowed to be displayed on the console is at level 7 by default.

The log information that is allowed to be displayed on the VTY window is at level 7 by default.

The log information that is allowed to be sent to the syslog server is at level 6 by default.

The log information that is allowed to be recorded in the memory buffer is at level 7 by default.

The log information that is allowed to be recorded in the extended flash is at level 6 by default.

You can use the **show logging** command in privileged mode to show the level of log information allowed to be displayed on different devices.

Configuring the Device Value of the Log Information

The device value is one of the parts that form the priority field in the messages sent to the syslog server, indicating the type of device that generates the information.

To configure the log information device value, run the following command in global configuration mode:

Command	Function
Ruijie(config)# **logging facility** *facility-type*	Configures the device value of the log information.
Ruijie(config)# **no logging facility** *facility-type*	Restores the device value of the log information to the default value.

The meanings of various device values are described as below:

```
Numerical Code       Facility
         0            kernel messages
         1          user-level messages
         2          mail system
         3          system daemons
         4          security/authorization messages
         5          messages generated internally by syslogd
         6          line printer subsystem
         7          network news subsystem
         8          UUCP subsystem
         9          clock daemon
        10          security/authorization messages
        11          FTP daemon
        12          NTP subsystem
        13          log audit
        14          log alert
        15          clock daemon
        16          local use 0  (local0)
        17          local use 1  (local1)
        18          local use 2  (local2)
        19          local use 3  (local3)
        20          local use 4  (local4)
        21          local use 5  (local5)
        22          local use 6  (local6)
        23          local use 7  (local7)
```

The default device value of Ruijie products is 23.

Configuring the Source Address of Log Messages

By default, the source address of the log messages sent to the syslog server is the address of the port that sends the messages. You can fix the source address for all log messages through commands.

It is possible to directly set the source IP address of the log messages or the source port of the log messages.

To configure the source address of the log messages, run the following command in global configuration mode:

Command	Function
Ruijie(config)# **logging source interface** *interface-type interface-number*	Configures the source port of log information.
Ruijie(config)# **logging source** {**ip** *ip-address* | **ipv6** *ipv6-address*}	Configures the source IP address of log messages.

Note

If the configured source IP address of the log message is not configured on any interface of the device, the source IP address of the log message is this inexistent address. However, it is not recommended to perform such configuration in actual use.

Setting and Sending User Log

Command	Function
Ruijie(config)# **logging userinfo**	Sets user login/logoff log.
Ruijie(config)# **logging userinfo command-log**	Send a log when a configuration command is executed.

Log Monitoring

To monitor log information, run the following commands in privileged user mode:

Command	Function
Ruijie# **show logging**	Views the log messages in memory buffer as well as the log statistics.
Ruijie# **show logging count**	Views the statistics of logs in every module.
Ruijie# **clear logging**	Clears the log messages in the memory buffer.
Ruijie# **more flash:***filename*	Views the log files in the extended flash.

⚠ Caution

The format of the timestamp in the output result of the **show logging count** command is the format in the latest log output.

Examples of Log Configurations

Here is a typical example to enable the logging function. Connect the device to the log server, whose IP address is 192.168.200.2. Perform the following configuration to make all logs carry timestamps and allow logs of all levels to be sent to the log server:

```
Ruijie(config)# service timestamps debug datetime   //Enable debug information timestamp, in date format
Ruijie(config)# service timestamps log datetime    //Enable log information timestamp, in date format
Ruijie(config)# logging 192.168.200.2      //Specify the syslog server address
Ruijie(config)# logging trap debugging     //The log information of all levels will be sent to the syslog server
Ruijie(config)# end
```

Configuring Device Fault Management

Overview of Device Fault Management Module

Purpose

The device fault management module manages device faults, which generates alarms to alert router faults, protects devices against exceptions and adds some methods of preventing faults, such as displaying working status of various basic hardware devices, to enhance safe router running level.

Requirements and Notes

Hardware Requirements

Because fault alarms are closely related to hardware, many functions of the device fault management module are directly related to hardware. For example, hardware must support the detection of power voltage.

Caution

The device fault management module version 1.0 (DFM1.0) cannot display power voltage, fan performance and operating inlet temperature, and fails to allow MIB to search for this information.

System Support

Not all devices support alarm generation by interruption in the case of a device fault. As a result, scheduled detection is required. Here, the detection results obtained last time are used as displayed information and detection interval is set to five seconds that cannot be modified by users.

Running Mode

At present, all configuration of the device fault management module is carried out in privilege mode. As a result, to run the commands mentioned in this document, enter privilege mode first.

Checking Status Information

The command tree of status displaying of the total fault management:

Command	Function
show environment [alarms | all | fans | hardware | powers]	Displays environment of the managed faulty device.

Displaying Exception Alarm

Command	Function
show environment alarms	Displays information about alarm processing. For example, fans should be checked in the case of excessively high temperature

The following information is displayed for this command:

```
Ruijie# show environment alarms
Warning!!!
Power supplies have been changed since the router start, please check them
Warning!!!
Fans have been changed since the router start, please check them.
Warning!!!
Temperature is high, please check powers and fans.
Ruijie#
```

Displaying Operating Temperature

Command	Function
show temperature	Displays temperature of the current operating environment, namely temperature inside the chassis. Currently, inlet temperature cannot be detected.

The following information is displayed for this command:

```
Ruijie#show temperature
Device    Temperature(C)
------    -----------
 CM          43
```

Displaying Fan Information

Command	Function
show environment fans	Displays running situations and status information on one or multiple fans, including whether fans run normally and the number of fans. Currently, performance detection is not supported.

The following information is displayed for this command:

```
Ruijie# show environment fans
Environmental status update at 11:31:37 Jan 9, 1944.
Data is 13 second old, refresh in 20 second(s).
Fans working status:
Fan 0 is on.
Fan 1 is on.
Fan 2 is on.
Fan 3 is on.
Fan 4 is on.
Fan 5 is on.
Fan 6 is on.
Fan 7 is on.
```

Displaying Power Supply Information

Command	Function
show environment powers	Displays the current status information on the power supply, including rated operating voltage, the number of power supplies, and whether each power supply works normally. At present, the current operating voltage and threshold cannot be detected.

The following information is displayed for this command:

```
Ruijie# show environment powers
Environmental status update at 11:28:50 Jan 9, 1944.
Data is 10 second old, refresh in 20 second(s).
Power Supplies:
Power supply 1 is present. Unit is on.
Power supply 2 is present. Unit is on.
Power supply 3 is present. Unit is on.
```

Displaying Information Related to Hardware

Command	Function
show environment hardware	Displays the current status information on the hardware, including CPU name and speed.

The following information is displayed for this command:

```
Ruijie#show environment hardware
  Environmental status update at 16:25:26 2011-01-20.
  Data is 13 second old, refresh in 20 second(s).
  Hardware:
        CPU name: BCM1250.
        CPU Speed : 800M
```

Displaying All Information on Fault Management

Command	Function
show environment all	Displays device status information in the current device fault management.

The following information is displayed for this command:

```
Ruijie#show environment all
  Environmental status update at 16:26:46 2011-01-20.
  Data is 18 second old, refresh in 20 second(s).
  Power Supplies:
        Power supply 1 is not present. Unit is off.
        Power supply 2 is present. Unit is on.
        Power supply 3 is not present. Unit is off.
  Fans working status:
        Fan 1 is on.
```

```
      Fan 2 is on.
      Fan 3 is on.
      Fan 4 is on.
      Fan 5 is on.
      Fan 6 is on.
 Hardware:
      CPU name: BCM1250.
      CPU Speed : 800M
```

Configuring SNMP

SNMP Overview

Introduction

As the abbreviation of Simple Network Management Protocol, SNMP has been a network management standard (RFC1157) since the August, 1988. So far, the SNMP becomes the actual network management standard for the support from many manufacturers. It is applicable to the situation of interconnecting multiple systems from different manufacturers. Administrators can use the SNMP protocol to query information, configure network, locate failure and plan capacity for the nodes on the network. Network supervision and administration are the basic function of the SNMP protocol.

As a protocol in the application layer, the SNMP protocol works in the client/server mode, including three parts as follows:

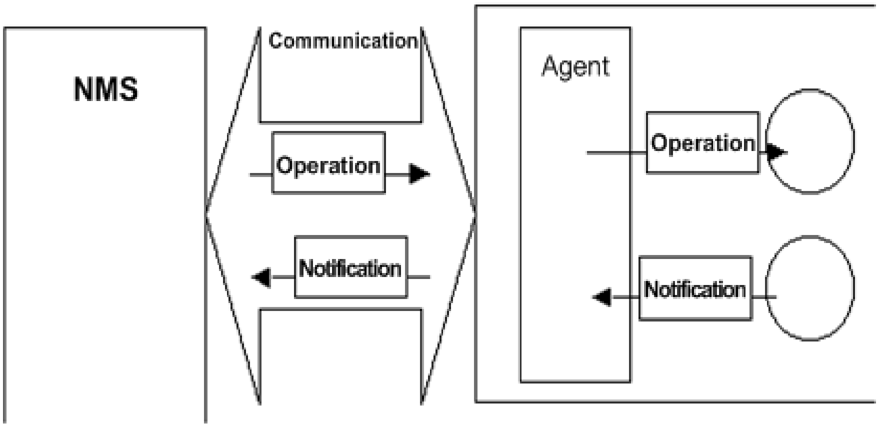
- SNMP network manager
- SNMP agent
- MIB (management information base)

The SNMP network manager, also referred to as NMS (Network Management System), is a system to control and monitor the network using the SNMP protocol.

The SNMP Agent is the software running on the managed devices. It receives, processes and responds the monitoring and controlling messages from the NMS, and also sends some messages to the NMS.

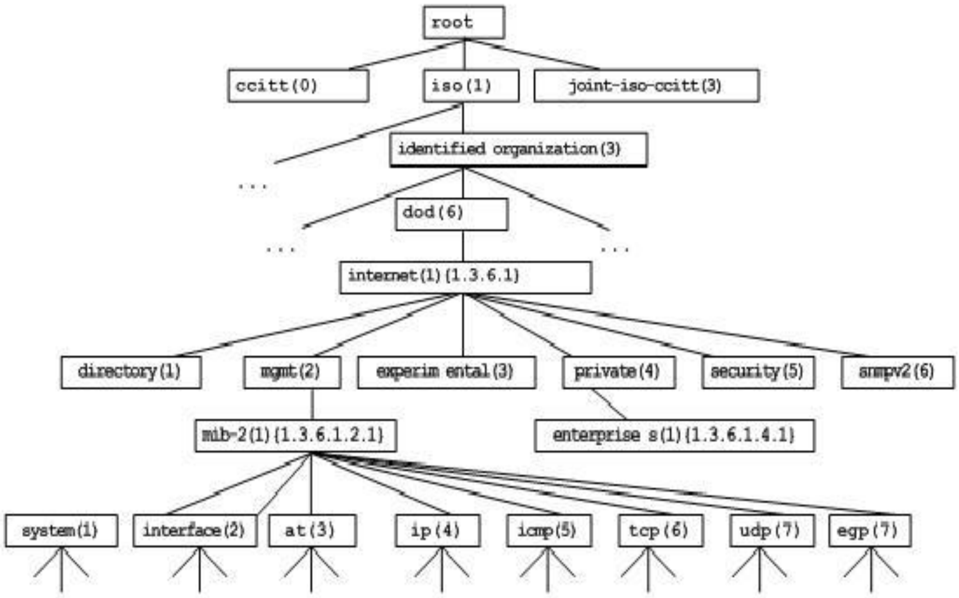
The relationship between the NMS and the SNMP Agent can be indicated as follows:

Figure 1 Relationship between the NMS and the SNMP Agent



The MIB (Management Information Base) is a virtual information base for network management. There are large volumes of information for the managed network equipment. In order to uniquely identify a specific management unit in the SNMP message, the tree-type hierarchy is used to by the MIB to describe the management units in the network management equipment. The node in the tree indicates a specific management unit. Take the following figure of MIB as an example to name the objectives in the tree. To identify a specific management unit **system** in the network equipment uniquely, a series of numbers can be used. For example, the number string {1.3.6.1.2.1.1} is the object identifier of a management unit, so the MIB is the set of object identifiers in the network equipment.

Figure 2 Tree-type MIB hierarchy



SNMP Versions

This software supports these SNMP versions:

- SNMPv1: The first formal version of the Simple Network Management Protocol, which is defined in RFC1157.
- SNMPv2C: Community-based Administrative Framework for SNMPv2, an experimental Internet protocol defined in RFC1901.
- SNMPv3: Offers the following security features by authenticating and encrypting packets:

r. Ensure that the data are not tampered during transmission.

s. Ensure that the data come from a valid data source.

t. Encrypt packets to ensure the data confidentiality.

Both the SNMPv1 and SNMPv2C use a community-based security framework. They restrict administrator’s operations on the MIB by defining the host IP addresses and community string.

With the GetBulk retrieval mechanism, SNMPv2C sends more detailed error information type to the management station. GetBulk allows you to obtain all the information or a great volume of data from the table at a time, and thus reducing the times of request and response. Moverover, SNMPv2C improves the capability of handing errors, including expanding error codes to distinguish different kinds of errors, which are represented by one error code in SNMPv1. Now, error types can be distinguished by error codes. Since there may be the management workstations supporting SNMPv1 and SNMPv2C in a network, the SNMP agent must be able to recognize both SNMPv1 and SNMPv2C messages, and return the corresponding version of messages.

SNMP Management Operations

For the information exchange between the NMS and the SNMP Agent, six types of operations are defined:

u. Get-request: The NMS gets one or more parameter values from the SNMP Agent.

v. Get-next-request: The NMS gets the next parameter value of one or more parameters from the SNMP Agent.

w. Get-bulk: The NMS gets a bulk of parameter values from the SNMP Agent.

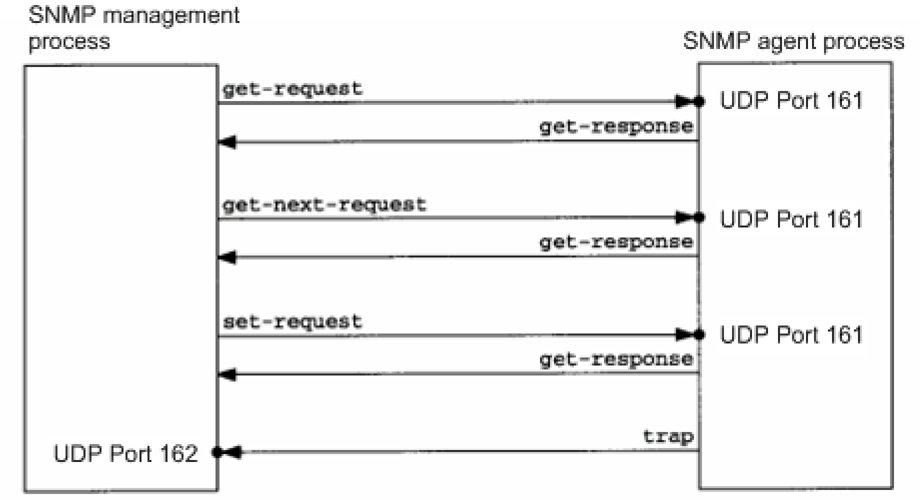
x. Set-request: The NMS sets one or more parameter values for the SNMP Agent.

y. Get-response: The SNMP Agent returns one or more parameter values, the response of the SNMP Agent to any of the above 3 operations of the NMS.

z. Trap: The SNMP Agent proactively sends messages to notify the NMS that some event will occur.

The first four messages are sent from the NMS to the SNMP Agent, and the last two messages are sent from the SNMP Agent to the NMS (Note: SNMPv1 does not support the Get-bulk operation). These operations are described in the following figure:

Figure 3 Message types in SNMP



NMS sends messages to the SNMP Agent in the first three operations and the SNMP Agent responds a message through the UDP port 161. However, the SNMP Agent sends a message in the Trap operation through the UDP port 162.

Caution

When managing the R2700 switching card (NM2-24ESW/NM2-16ESW) via SNMP, NM2-16ESW obtains the inexistent error message of port 17-26, while NM2-24ESW obtains the inexistent error message of port 25-26.

SNMP Security

Both SNMPv1 and SNMPv2 use the community string to check whether the management workstation is entitled to use MIB objects. In order to manage devices, the community string of NMS must be identical to a community string defined in the devices.

A community string features:

- Read-only: Authorized management workstations are entitled to read all the variables in the MIB.
- Read-write: Authorized management workstations are entitled to read and write all the variables in the MIB.

Based on SNMPv2, SNMPv3 can determine a security mechanism for processing data by security model and security level. There are three types of security models: SNMPv1, SNMPv2C and SNMPv3.

The table below describes the supported security models and security levels.

Model	Level	Authentication	Encryption	Description
SNMPv1	noAuthNoPriv	Community string	None	Ensures the data validity through community string.
SNMPv2c	noAuthNoPriv	Community string	None	Ensures the data validity through community string.
SNMPv3	noAuthNoPriv	User name	None	Ensures the data validity through user name.
SNMPv3	authNoPriv	MD5 or SHA	None	Provides HMAC-MD5 or HMAC-SHA-based authentication mechanism.
SNMPv3	authPriv	MD5 or SHA	DES	Provides HMAC-MD5 or HMAC-SHA-based authentication mechanism and CBC-DES-based encryption mechanism.

SNMP Engine ID

The engine ID is designed to identify a SNMP engine uniquely. Every SNMP entity contains a SNMP engine, a SNMP engine ID identifies a SNMP entity in a management domain. So every SNMPV3 entity has a unique identifier named SNMP Engine ID.

The SNMP Engine ID is an octet string of 5 to 32 bytes, which is defined in RFC3411:

- The first four bytes indicate the private enterprise number of an enterprise (assigned by IANA) in hex system.
- The fifth byte indicates how to identify the rest bytes.

0: Reserved

1: The following 4 bytes indicate an IPv4 address.

2: The following 16 bytes indicate an IPv6 address.

3: The following 6 bytes indicate an MAC address

4: Texts of up to 27 bytes defined by manufacturers

5: A hexadecimal value of up to 27 bytes defined by manufacturers

6-127: Reserved

128-255: In the format specified by manufacturers.

SNMP Configuration

The SNMP configuration is performed in global configuration mode on network devices. To configure SNMP, enter the global configuration mode.

Setting the Community String and Access Authority

SNMPv1 and SNMPv2C adopt community string-based security scheme. The SNMP Agent supports only the management operations from the management workstations of the same community string. The SNMP messages without matching the community string will be discarded. The community string serves as the password between the NMS and the SNMP Agent.

- Configure an ACL rule to allow the NMS of the specified IP address to manage devices.
- Set the community's operation permission,: ReadOnly or ReadWrite.
- Specify a view for view-based management. By default, no view is configured. That is, the management workstation is allowed to access to all MIB objects.
- Indicate the IP address of the NMS who can use this community string. If it is not indicated, any NMS can use this community string. By default, any NMS can use this community string.

To configure the SNMP community string, run the following command in global configuration mode:

	Command	Function
Step 1	Ruijie(config)# **snmp-server community** *string* [**view** *view-name*] [**ro** | **rw**] [**host** *host-ip*] [**ipv6** *ipv6-aclname*][*aclnum* | *aclname*]	Sets the community string and its right.

One or more coummnity strings can be specified for the NMS of different rights. To remove the community name and its right, run the **no snmp-server community** *string* command in global configuration mode.

Configuring MIB Views and Groups

With view-based access control model, you can determine whether the object of a management operation is in a view or not. Only the management objects in a view are allowed to be accessed. For access control, generally some users are associated with a group and then the group is associated with a view. The users in a group have the same access right.

- Set an inclusion view and an exclusion view.
- Set a Read-only view and a Read-write view for a group.
- Set security levels, whether to authenticate, and whether to encrypt for SNMPv3 users.

To configure the MIB views and groups, run the following commands in global configuration mode:

	Command	Function
Step 1	Ruijie(config)# **snmp-server view** *view-name* *oid-tree* **{include | exclude}**	Creates a MIB view to include or exclude associated MIB objects.

Step 2	Ruijie(config)# **snmp-server group** *groupname* {**v1 | v2c |v3 {auth | noauth | priv**}} [read *readview*] [**write** *writeview*] [**access** {[**ipv6** *ipv6_aclname*] [*aclnum* | *aclname*] }]	Creates a group and associate it with the view.

You can delete a view by using the **no snmp-server view** *view-name* command, or delete a tree from the view by using the **no snmp-server view** *view-name oid-tree* command. You can also delete a group by using the **no snmp-server group** *groupname* {**v1 \| v2c \| v3**} command.

Configuring SNMP Users

User-based security model can be used for security management. In this mode, you should configure user information first. The NMS can communicate with the SMP Agent by using a valid user account.

For SNMPv3 users, you can specify security level, authentication algorithm (MD5 or SHA), authentication password, encryption algorithm (only DES now) and encryption password.

To configure a SNMP user, run the following commands in global configuration mode:

Command	Function
Ruijie(config)# **snmp-server user** *username roupname* {**v1 | v2c | v3 [encrypted] [auth { md5|sha }** *auth-password*] **[priv des56** *priv-password*] } [**access {[ipv6** *ipv6_aclname*] [*aclnum* | *aclname*] }]	Configures the user information.

To remove the specified user, use the **no snmp-server user** *username groupname* {**v1 \| v2c \| v3**} command.

Configuring Host Address

In special cases, the SNMP Agent may also proactively send messages to the NMS.

To configure the NMS host address that the SNMP Agent proactively sends messages to, run the following commands in global configuration mode:

Command	Function
Ruijie(config)# **snmp-server host** { *host-addr* | ipv6 *ipv6-addr* } [**vrf** *vrfname*] [**traps**] [**version { 1 | 2c | 3 { auth | noauth | priv** }] *community-string* [**udp-port** *port-num*] [*notification-type*]	Sets the SNMP host address, host port, vrf options, message type, community string, (user name in SNMPv3) and security level (only supported in SNMPv3).

Configuring SNMP Agent Parameters

You can configure the basic parameters of the SNMP Agent, including contact, device location and sequence number. With these parameters, the NMS knows the contact, location and other information of the device.

To configure the SNMP agent parameters, run the following commands in global configuration mode:

Command	Function
Ruijie(config)# **snmp-server contact** *text*	Configures the contact for the system.
Ruijie(config)# **snmp-server location** *text*	Configure the location of the system.

Command	Function
Ruijie(config)# **snmp-server chassis-id** *number*	Configure the sequence number of the system.

Defining the Maximum Message Size of the SNMP Agent

In order to reduce influence on network bandwith, you can configure the maximum packet size of the SNMP Agent. To configure the maximum packet size of the SNMP Agent, run the following command in global configuration mode:

Command	Function
Ruijie(config)# **snmp-server packetsize** *byte-count*	Sets the maximum packet size of the SNMP Agent.

Shielding the SNMP Agent

The SNMP Agent service is a service provided by Ruijie product and it is enabled by default. You can shield the SNMP agent service and related configuration by executing the following command in global configuration mode:

Command	Function
Ruijie(config)# **no snmp-server**	Shields the SNMP agent service.

Disabling the SNMP Agent

Ruijie products provide a different command from the shield command to disable the SNMP Agent. This command will directly disable all SNMP services (the SNMP agent function is disabled, no message is received and no response or Trap message is sent) instead of shielding the configuration information of the SNMP Agent. To disable the SNMP agent service, run the following command in global configuration mode:

Command	Function
Ruijie(config)# **no enable service snmp-agent**	Disables the SNMP agent service.

Configuring the SNMP Agent to Send the Trap Message to the NMS Initiatively

The TRAP message is a message automatically sent by the SNMP Agent to the NMS, and is used to report some critical and important events. By default the SNMP Agent is not allowed to automatically send the TRAP message. To enable it, run the following command in global configuration mode:

Command	Function
Ruijie(config)# **snmp-server enable traps** [*type*] [*option*]	Allows the SNMP Agent to send the TRAP message proactively.
Ruijie(config)# **no snmp-server enable traps** [*type*] [*option*]	Forbids the SNMP Agent to send the TRAP message proactively.

Configuring LinkTrap Policy

You can configure whether to send the LinkTrap message on an interface. When this function is enabled and the link status of the interface changes, the SNMP will send the LinkTrap message. Otherwise, it will not. By default, this function is enabled.

Command	Function
Ruijie(config)# **interface** *interface-id*	Enters interface configuration mode.
Ruijie(config-if)# [**no**] **snmp trap link-status**	Enables or disables sending the LinkTrap message on the interface.

The following example configures not to send LinkTrap message on the intereface:

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if)# no snmp trap link-status
```

Configuring the Parameters for Sending the Trap Message

To set the parameters for the SNMP Agent to send the Trap message, run the following commands:

Command	Function
Ruijie(config)# **snmp-server trap-source** *interface*	Specifies the source port sending the Trap message.
Ruijie(config)# **snmp-server queue-length** *length*	Specifies the queue length of each Trap message.
Ruijie(config)# **snmp-server trap-timeout** *seconds*	Specifies the interval at which the Trap message is sent.

Configuring SNMP Attack Protection

Enable SNMP attack protection by confining limited times of failed SNMP consecutive authentications and specifying the solution after consecutive authentications fail. After SNMP authentications fail, the system will blacklist the source IP. When the failed times exceed the limit, the system will restrict the source IP address according to the solutions configured by the device:

- The source IP address that is prevented from authentication permanently cannot try access authentication again unless it is relieved by the administrator manually.
- The source IP address that is prevented from authentication for a while can try access authentication again when the **lock-time** times out or it is relieved by the administrator manually.
- When you try access authentication again, the non-restricted source IP address will pass it as long as you use correct community (for SNMPv1and SNMPv2c) or username (for SNMPv3)..

Run this command in global configuration mode to limit the times of failed SNMP consecutive authentications and specify the solution after consecutive authentications fail.

Command	Function

Command	Function
Ruijie(config)# **snmp-server authentication attempt** *times* **exceed** { **lock** | **lock-time** *minutes* | **unlock** }	Sets limited times of failed SNMP consecutive authentications and specifies the solution after authentications fail. **attempt** *times*: The limit of failed SNMP authentications. **Lock**: The source IP address is prevented from access authentication permanently. It is blacklisted unless relieved by the administrator manually. **lock-time** *minutes*: The source IP address is prevented from access authentication for a while and then allowed to be authenticated again. *minutes* refers to the period when the source IP address is prevented. **unlock**: The source IP address continues to be allowed after consecutive authentications fail, similar to the case that SNMP attack protection is not enabled.

Run the **no snmp-server authentication attempt** command to restore SNMP attack protection. By default, the solution taken after consecutive authentications fail is **unlock**. Namely, the IP address is allowed to try access authentication.

SNMP Monitoring and Maintenance

Checking the Current SNMP Status

To monitor the SNMP status and troubleshoot SNMP configurations, Ruijie product provides monitoring commands for SNMP, with which it is possible to easily check the SNMP status of the current network device. In privileged user mode, run the **show snmp** command to check the current SNMP status.

```
Ruijie# show snmp
Chassis: 1234567890 0987654321
Contact: wugb@i-net.com.cn
Location: fuzhou
2381 SNMP packets input
    5 Bad SNMP version errors
    6 Unknown community name
    0 Illegal operation for community name supplied
    0 Encoding errors
    9325 Number of requested variables
    0 Number of altered variables
    31 Get-request PDUs
    2339 Get-next PDUs
```

```
   0 Set-request PDUs
2406 SNMP packets output
   0 Too big errors (Maximum packet size 1500)
   4 No such name errors
   0 Bad values errors
   0 General errors
   2370 Get-response PDUs
   36 SNMP trap PDUs
SNMP global trap: disabled
SNMP logging: enabled
SNMP agent: enabled
.
```

The above statistics is explained as follows:

Showing Information	Description
Bad SNMP version errors	SNMP version is incorrect.
Unknown community name	The community name cannot be identified.
Illegal operation for community name supplied	Illegal operation
Encoding errors	Code error
Get-request PDUs	Get-request message
Get-next PDUs	Get-next message
Set-request PDUs	Set-request message
Too big errors (Maximum packet size 1500)	Too large response message
No such name errors	The specified management unit does not exist.
Bad values errors	Specified value type error
General errors	General error
Get-response PDUs	Get-response message
SNMP trap PDUs	SNMP trap message

Checking the MIB Objects Supported by the Current SNMP Agent

To check the MIB objects supported by the current SNMP Agent, run the **show snmp mib** command in privileged user mode:

```
Ruijie# show snmp mib
sysDescr
sysObjectID
sysUpTime
sysContact
sysName
sysLocation
sysServices
sysORLastChange
snmpInPkts
snmpOutPkts
```

```
...
```

Viewing SNMP Users

To view the SNMP users configured on the current SNMP agent, run the **show snmp user** command in privileged user mode:

```
Ruijie# show snmp user
User name: test
Engine ID: 8000131103000000000000
storage-type: permanent    active
Security level: auth priv
Auth protocol: SHA
Priv protocol: DES
Group-name: g1
```

Viewing SNMP Views and Groups

To view the group configured on the current SNMP agent, run the **show snmp group** command in privileged user mode:

```
Ruijie# show snmp group
groupname: g1
securityModel: v3
securityLevel:authPriv
readview: default
writeview: default
notifyview:
groupname: public
securityModel: v1
securityLevel:noAuthNoPriv
readview: default
writeview: default
notifyview:
groupname: public
securityModel: v2c
securityLevel:noAuthNoPriv
readview: default
writeview: default
notifyview:
```

To view the view configured on the current SNMP agent, run the **show snmp view** command in privileged user mode:

```
Ruijie# show snmp view
default(include) 1.3.6.1
test-view(include) 1.3.6.1.2.1
```

Viewing Host Information

To view the host information configured on the SNMP agent, run the **show snmp host** command in privileged user mode:

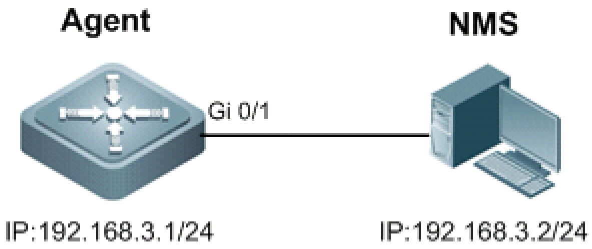
```
Ruijie# show snmp host
Notification host: 192.168.64.221
udp-port: 162   type: trap
user: public    security model: v1
Notification host: 2000:1234::64
udp-port: 162   type: trap
user: public    security model: v1
```

Typical SNMP Configuration Example

SNMP v1/v2 Configuration Example

Topological Diagram

Figure 4 Topology for SNMP v1/2 application



Application Requirements

The Network Management Station (NMS) manages the network device (Agent) by applying the community-based authentication model, and the network device can control the operation permission (read or write) of the community to access the specified MIB objects. For example, community "user1" can only read and write objects under System (1.3.6.1.2.1.1) node.

The network device can only be managed by NMS with a specific IP (i.e., 192.168.3.2/24).

The network device can actively send messages to NMS.

The NMS can acquire the basic system information of the device, such as contact, location, and ID.

Configuration Tips

By creating MIB view and associating authentication name (Community) and access permission (Read or Write), the first application need can be met.

While configuring the community string and access permission, associate ACL or specify the IP of administrator using this community string to meet the second application need (this example associates the ACL).

Configure the address of SNMP host and enable the Agent to actively send Trap messages.

Configure the parameters of SNMP agent.

Configuration Steps

Step 1: Configure MIB view and ACL.

! Create an MID view named "v1", which contains the associated MIB object (1.3.6.1.2.1.1).

```
Ruijie(config)#snmp-server view v1 1.3.6.1.2.1.1 include
```

! Create an ACL named "a1" to permit the IP address of 192.168.3.2/24.

```
Ruijie(config)#ip access-list standard a1
Ruijie(config-std-nacl)#permit host 192.168.3.2
Ruijie(config-std-nacl)#exit
```

Step 2: Configure community string and access permission.

! Configure Community of "user1", associate write permission for MIB view of "v1", and associate the ACL of "a1".

```
Ruijie(config)#snmp-server community user1 view v1 rw a1
```

Step 3: Configure the Agent to actively send messages to NMS.

! Configure the address of SNMP host as 192.168.3.2, message format as Version 2c and community string as "user1".

```
Ruijie(config)#snmp-server host 192.168.3.2 traps version 2c user1
```

! Enable the Agent to actively send traps.

```
Ruijie(config)#snmp-server enable traps
```

Step 4: Configure parameters of SNMP agent.

! Configure system location.

```
Ruijie(config)#snmp-server location fuzhou
```

! Configure system contact.

```
Ruijie(config)#snmp-server contact ruijie.com.cn
```

! Configure system serial number.

```
Ruijie(config)#snmp-server chassis-id 1234567890
```

Step 5: Configure the IP address for the Agent.

! Configure the IP address of Gi 0/1 as 192.168.3.1/24.

```
Ruijie(config)#interface GigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)#ip address 192.168.3.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/1)#exit
```

Verification

Step 1: Display configurations of the device.

```
Ruijie#show running-config
!
ip access-list standard a1
 10 permit host 192.168.3.2
!
interface GigabitEthernet 0/1
 no ip proxy-arp
 ip address 192.168.3.1 255.255.255.0
!
snmp-server view v1 1.3.6.1.2.1.1 include
snmp-server location fuzhou
snmp-server host 192.168.3.2 traps version 2c user1
snmp-server enable traps
snmp-server contact ruijie.com.cn
snmp-server community user1 view v1 rw a1
snmp-server chassis-id 1234567890
```

Step 2: Display information about SNMP view and group.

```
Ruijie#show snmp view
v1(include) 1.3.6.1.2.1.1                //define MIB object of “v1”
default(include) 1.3.6.1                 //default MIB object
Ruijie#show snmp group
groupname: user1                  //Configure Community as SNMP group
securityModel: v1
securityLevel:noAuthNoPriv
readview: v1
writeview: v1
notifyview:
groupname: user1
securityModel: v2c
securityLevel:noAuthNoPriv
readview: v1
writeview: v1
notifyview:
```

Step 3: Install MIB-Browser. Type in device IP of "192.168.3.1" in the field of IP Address; type in "user1" in the field of Community Name; click **Add Item** button and select the specific management unit for MIB query, such as the System shown below. Click **Start** to implement MIB query of network device. The query result is shown in the bottommost box:

Figure 5

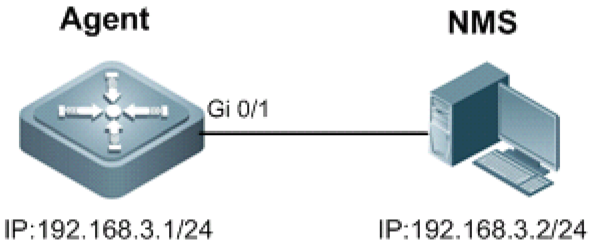
SNMP v3 Configuration Example

Topological Diagram

Figure 6 SNMPv3 application topology



Application Requirements

Network Management Station manages the network device (Agent) by applying user-based security model. For example: the user name is "user1", authentication mode is MD5, authentication key is "123", encryption algorithm is DES56, and the encryption key is "321".

The network device can control user's permission to access MIB objects. For example: "User1" can read the MIB objects under System (1.3.6.1.2.1.1) node, and can only write MIB objects under SysContact (1.3.6.1.2.1.1.4.0) node.

The network device can actively send authentication and encryption messages to the network management station.

Configuration Tips

Create MIB view and specify the included or excluded MIB objects.

Create SNMP group and configure the version as "v3"; specify the security level of this group, and configure the read/write permission of the view corresponding to this group.

Create user name and associate the corresponding SNMP group name to further configure the user's permission to access MIB objects; meanwhile, configure the version number as "v3" and the corresponding authentication mode, authentication key, encryption algorithm and encryption key.

Configure the address of SNMP host, configure the version number as "3" and configure the security level to be adopted.

Configuration Steps

Step 1: Configure MIB view and group.

! Create an MIB view of "view1" and include the MIB object of 1.3.6.1.2.1.1; further create an MIB view of "view2" and include the MIB object of 1.3.6.1.2.1.1.4.0.

```
Ruijie(config)#snmp-server view view1 1.3.6.1.2.1.1 include
Ruijie(config)#snmp-server view view2 1.3.6.1.2.1.1.4.0 include
```

! Create a group named "g1" and select the version number of "v3"; configure security level to "priv" to read "view1" and write "view2".

```
Ruijie(config)#snmp-server group g1 v3 priv read view1 write view2
```

Step 2: Configure SNMP user.

! Create a user named "user1", which belongs to group "g1"; select version number of "v3" and configure authentication mode as "md5", authentication key as "123", encryption mode as "DES56" and encryption key as "321".

```
Ruijie(config)#snmp-server user user1 g1 v3 auth md5 123 priv des56 321
```

Step 3: Configure the address of SNMP host.

! Configure the host address as 192.168.3.2 and select version number of "3"; configure security level to "priv" and associate the corresponding user name of "user1".

```
Ruijie(config)#snmp-server host 192.168.3.2 traps version 3 priv user1
```

! Enable the Agent to actively send traps to NMS.

```
Ruijie(config)#snmp-server enable traps
```

Step 4: Configure the IP address of Agent.

! Configure the IP address of Gi 0/1 as 192.168.3.1/24.

```
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)#ip address 192.168.3.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/1)#exit
```

Verification

Step 1: Display configurations of device.

```
Ruijie#show running-config
```

```
!
interface GigabitEthernet 0/1
 no ip proxy-arp
 ip address 192.168.3.1 255.255.255.0
!
snmp-server view view1 1.3.6.1.2.1.1 include
snmp-server view view2 1.3.6.1.2.1.1.4.0 include
snmp-server user user1 g1 v3 encrypted auth md5 7EBD6A1287D3548E4E52CF8349CBC93D priv des56
D5CEC4884360373ABBF30AB170E42D03
snmp-server group g1 v3 priv read view1 write view2
snmp-server host 192.168.3.2 traps version 3 priv user1
snmp-server enable traps
```

Step 2: Display SNMP user.

```
Ruijie# show snmp user
User name: user1
Engine ID: 800013110300d0f8221120
storage-type: permanent    active
Security level: auth priv
Auth protocol: MD5
Priv protocol: DES
Group-name: g1
```

Step 3: Display SNMP view.

```
Ruijie#show snmp view
view1(include) 1.3.6.1.2.1.1
view2(include) 1.3.6.1.2.1.1.4.0
default(include) 1.3.6.1
```

Step 4: Display SNMP group.

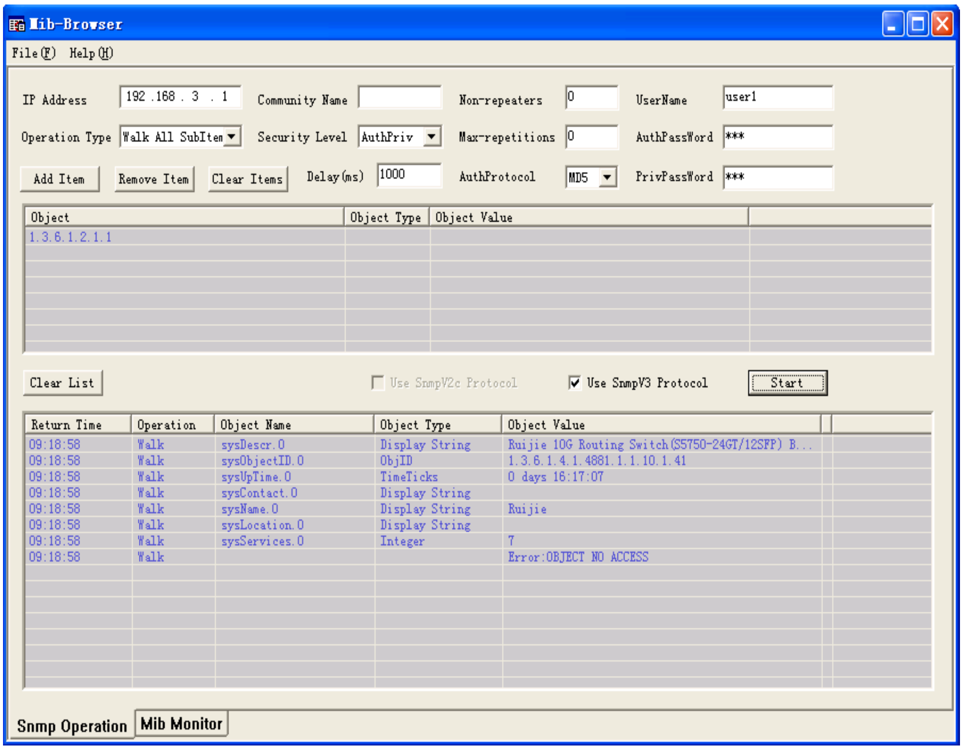
```
Ruijie# show snmp group
groupname: g1
securityModel: v3
securityLevel:authPriv
readview: view1
writeview: view2
notifyview:
```

Step 5: Display host information configured by the user.

```
Ruijie#show snmp host
Notification host: 192.168.3.2
udp-port: 162
type: trap
user: user1
security model: v3 authPriv
```

Step 6: Install MIB-Browser. Type in device IP of "192.168.3.1" in the field of IP Address; type in "user1" in the field of UserName; select "AuthPriv" from Security Level; type in "123" in the field of AuthPassWord; select "MD5" from AuthProtocol; type in "321" in the field of PrivPassWord. Click **Add Item** button and select the specific management unit for querying MIB, such as the System shown below. Click **Start** to implement MIB query of network device. The query result is shown in the bottommost box:

Figure 7



IP Address	192 .168 . 3 . 1	Community Name		Non-repeaters	0	UserName	user1
Operation Type	Walk All SubItem	Security Level	AuthPriv	Max-repetitions	0	AuthPassWord	***

Configuring CWMP

Overview

CPE WAN Management Protocol (CWMP) provides a general framework of unified device management, related message specifications, management methods, and data models, so as to solve difficulties in unified management and maintenance of dispersed customer-premises equipment (CPEs), improve troubleshooting efficiency, and save O&M costs.

CWMP provides the following functions:

- **Auto configuration and dynamic service provisioning.** CWMP allows an Auto-Configuration Server (ACS) to automatically provision CPEs who initially access the network after start. The ACS can also dynamically re-configure running CPEs.
- **Firmware management.** CWMP manages and upgrades the firmware and its files of CPEs.
- **Software module management.** CWMP manages modular software according to data models implemented.
- **Status and performance monitoring.** CWMP enables CPEs to notify the ACE of its status and changes, achieving real-time status and performance monitoring.
- **Diagnostics.** The ACE diagnoses or resolves connectivity or service problems based on information from CPEs, and can also perform defined diagnosis tests.

Protocols and Standards

For details about TR069 protocol specifications, visit http://www.broadband-forum.org/technical/trlist.php.

Listed below are some major CWMP protocol specifications:

- TR-069_Amendment-4.pdf: CWMP standard
- TR-098_Amendment-2.pdf: Standard for Internet gateway device data model
- TR-106_Amendment-6.pdf: Standard for CPE data model
- TR-181_Issue-2_Amendment-5.pdf: Standard for CPE data model 2
- tr-098-1-4-full.xml: Definition of Internet gateway device data model
- tr-181-2-4-full.xml: Definition 2 of CPE data model 2

Applications

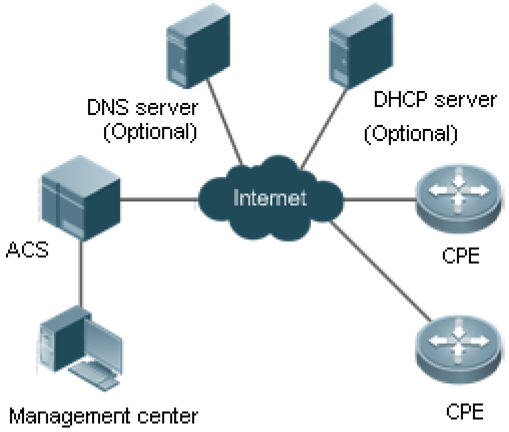
Typical Application	Scenario
CWMP Network Application Scenario	Initiate CPE-ACS connection, so as to upgrade the CPE firmware, upload the configuration files, restore the configuration, and realize other features.

CWMP Network Application Scenario

Application Scenario

The major components of a CWMP network architecture are CPEs, an ACS, a management center, a DHCP server, and a Domain Name System (DNS) server. The management center manages a population of CPEs by controlling the ACS on a Web browser.

Figure 0-1



Note

- If the Uniform Resource Locator (URL) of the ACS is configured on CPEs, the DHCP server is optional. If not, the DHCP is required to dynamically discover the ACS URL.
- If the URLs of the ACS and CPEs contain IP addresses only, the DNS server is optional. If their URLs contain domain names, the DNS server is required to resolves the names.

Functional Deployment

HTTP runs on both CPEs and the ACS.

Features

Basic Concept

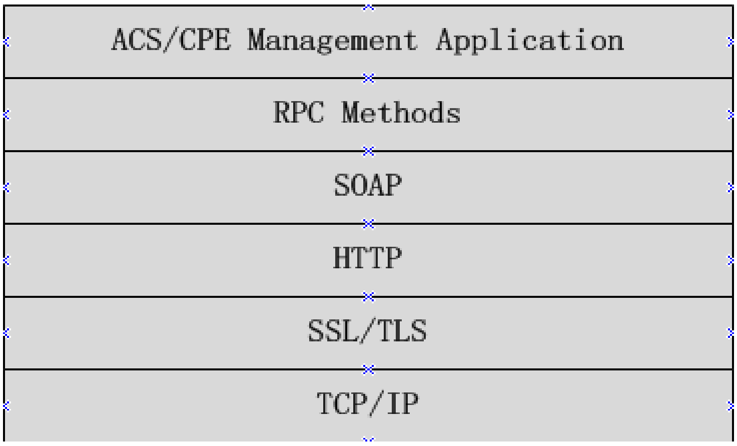
↘ Major Terminologies

- **CPE**: Customer Premises Equipment
- **ACS**: Auto-Configuration Server
- **RPC**: Remote Procedure Call
- **DM**: Data Model

↘ Protocol Stack

Figure 0-2 shows the protocol stack of CWMP.

Figure 0-2 CWMP Protocol Stack



As shown in 错误!未找到引用源。, CWMP defines six layers with respective functions as follows:

- **ACS/CPE Application**

The application layer is not a part of CWMP. It is the development performed by various modules of the CPEs/ACS to support CWMP, just like the Simple Network Management Protocol (SNMP), which does not cover the MIB management of functional modules.

- **RPC Methods**

This layer provides various RPC methods for interactions between the ACS and the CPEs.

- **SOAP**

The Simple Object Access Protocol (SOAP) layer uses a XML-based syntax to encode and decode CWMP messages.. Thus, CWMP messages must comply with the XML-based syntax.

- **HTTP**

All CWMP messages are transmitted over Hypertext Transfer Protocol (HTTP). Both the ACS and the CPEs can behave in the role of HTTP clients and servers. The server function is used to monitor reverse connections from the peer.

- **SSL/TLS**

The Secure Sockets Layer (SSL) or Transport Layer Security (TLS) layer guarantees CWMP security, including data integrity, confidentiality, and authentication.

- **TCP/IP**

This layer is the (Transmission Control Protocol/Internet Protocol (TCP/IP) protocol stack.

RPC Methods

The ACS manages and monitors CPEs by calling mostly the following RPC methods:

- **Get RPC Methods**

The Get methods enable the ACS to remotely obtain the set of RPC methods, as well as names, values and attributes of the DM parameters supported on CPEs.

- **Set RPC Methods**

The Set methods enable the ACS to remotely set the values and attributes of the DM parameters supported on CPEs.

- **Inform RPC Methods**

The Inform methods enable CPEs to inform the ACS of their device identifiers, parameter information, and events whenever sessions are established between them.

- **Download RPC Methods**

The Download method enables the ACS to remotely control the file download of CPEs, including firmware management, upgrade, and Web package upgrade.

- **Upload RPC Methods**

The Upload method enables the ACS to remotely control the file upload of CPEs, including upload of firmware and logs.

- **Reboot RPC Methods**

The Reboot method enables the ACS to remotely reboot the CPEs.

↘ Session Management

CWMP sessions or interactions are the basis for CWMP. All CWMP interactions between the ACS and CPEs rely on their sessions. CWMP helps initiate and maintain ACS-CPE sessions to link them up for effective management and monitoring. An ACS-CPE session is a TCP connection, which starts from the Inform negotiation to TCP disconnection. The session is classified into CPE Initiated Session and ACS Initiated Session according to the session poster.

↘ DM Management

CWMP operates based on CWMP Data Model (DM). CWMP manages all functional modules by a set of operations performed on DM. Each functional module registers and implements a respective data model, just like the MIBs implemented by various functional modules of SNMP.

A CWMP data model is represented in the form of a character string. For a clear hierarchy of the data model, a dot (.) is used as a delimiter to distinguish an upper-level data model node from a lower-level data model node. For instance, in the data model **InternetGatewayDevice.LANDevice**, **InternetGatewayDevice** is the parent data model node of **LANDevice**, and **LANDevice** is the child data model node of **InternetGatewayDevice**.

DM nodes are classified into two types: object nodes and parameter nodes. The parameter nodes are also known as leaf nodes. An object node is a node under which there are child nodes, and a parameter node is a leaf node under which there is no any child node. Object nodes are further classified into single-instance object nodes and multi-instance object nodes. A single-instance object node is an object node for which there is only one instance, whereas a multi-instance object node is an object node for which there are multiple instances.

DM nodes can also be classified into readable nodes and readable-and-writable nodes. A readable node is a node whose parameter values can be read but cannot be modified, and a readable-and-writable node is a node whose parameter values can be both read and modified.

A data model node has two attributes. One attribute relates to a notification function; that is, whether to inform the ACS of changes (other than changes caused by CWMP) to parameter values of the data model. The other attribute is an identifier indicating that the parameters of the data model node can be written using other management modes (than the ACS); that is, whether the values of the parameters can be modified using other management modes such as Telnet. The ACS can modify the attributes of the data models using RPC methods.

CWMP manages the data models using corresponding RPC methods.

↘ Event Management

When some events concerned by the ACS occur on the CPE, the CPE will inform the ACS of these events. The ACS monitors these events to monitor the working status of the CPE. The CWMP events are just like Trap messages of SNMP or product logs. Using RPC methods, to the ACS filters out the unconcerned types of events. CWMP events are classified into two types: single or (not cumulative) events and multiple (cumulative) events. A single event means that there is no quantitative change to the same event upon re-occurrence of the event, with the old discarded and the newest kept. A multiple event means that the old are not discarded and the newest event is kept as a complete event when an event re-occurs for multiple times later; that is, the number of this event is incremented by 1.

All events that occur on the CPE are notified to the ACS using the INFORM method.

Features

Feature	Description
Upgrading the Firmware	The ACS controls the upgrade of the firmware of a CPE using the Download method.
Upgrading the Configuration Files	The ACS controls the upgrade of the configuration files of a CPE using the Download method.
Uploading the Configuration Files	The ACS controls the upload of the configuration files of a CPE using the Upload method.
Backing up and Restoring a CPE	When a CPE breaks away from the management center, this feature can remotely restore the CPE to the previous status.

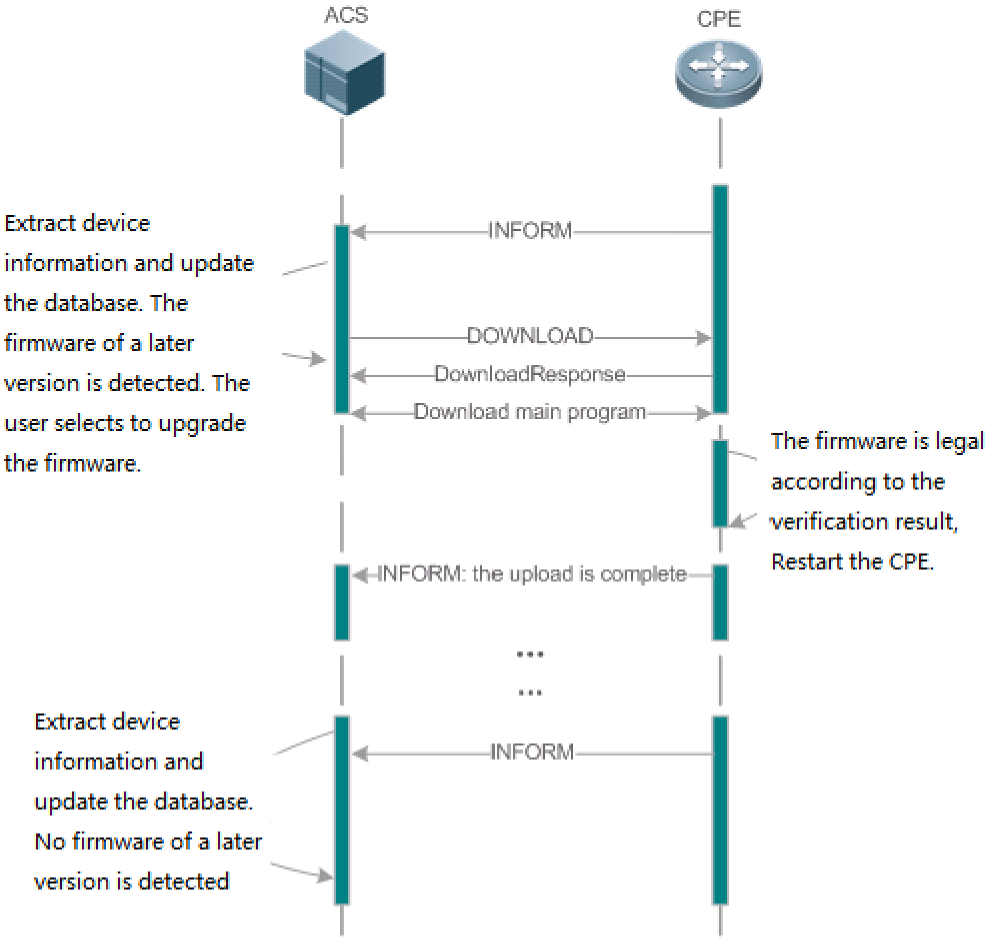
Upgrading the Firmware

Upgrading the Firmware means the firmware of a network element (NE) can be upgraded, so as to implement device version upgrade or replacement.

Working Principle

↘ Sequence Diagram of Upgrading the Firmware

Figure 0-3



ACS
CPE
Extract device information and update the database. The firmware of a later version is detected. The user selects to upgrade the firmware.
INFORM
DOWNLOAD
DownloadResponse
Download main program
The firmware is legal according to the verification result, Restart the CPE.
INFORM: the upload is complete
...
...
Extract device information and update the database. No firmware of a later version is detected
INFORM

Users specify a CPE for the ACS to deliver the Download method for upgrading the firmware. The CPE receives the request and starts to download the latest firmware from the destination file server, upgrade the firmware, and then reboot. After restart, the CPE will indicate the successful or unsuccessful completion of the method application.

Note

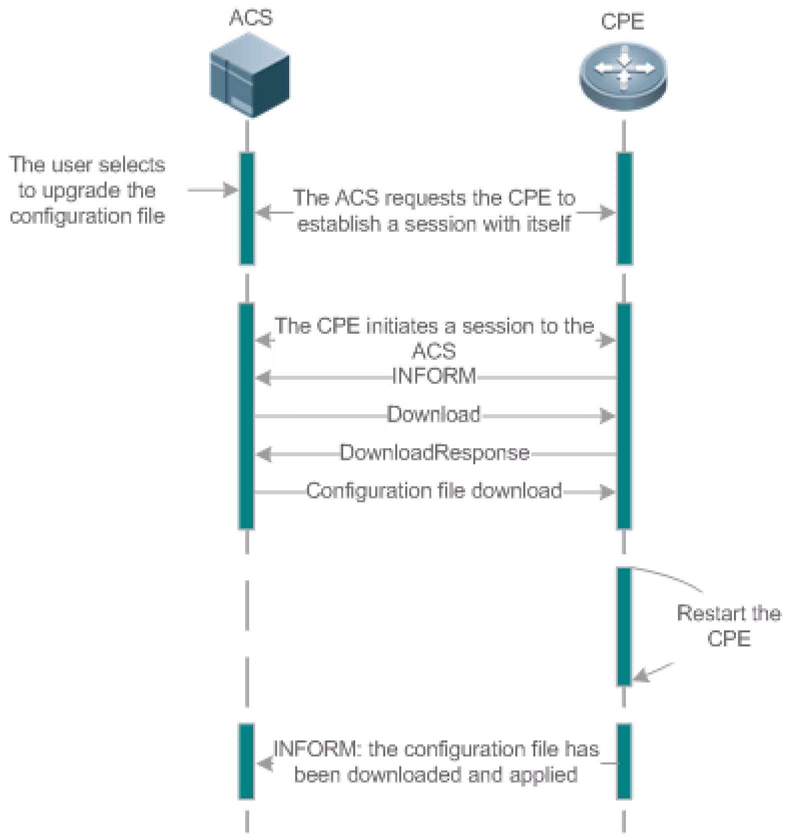
The file server can be ACS or separately deployed.

Upgrading the Configuration Files

Upgrading the Configuration Files means the current configuration files of a CPE can be replaced with specified configuration files, so that the new configuration files act on the CPE after reset.

Working Principle

Figure 0-4



ACS
CPE
The user selects to upgrade the configuration file
The ACS requests the CPE to establish a session with itself
The CPE initiates a session to the ACS
INFORM
Download
DownloadResponse
Configuration file download
Restart the CPE
INFORM: the configuration file has been downloaded and applied

Users specify a CPE for the ACS to deliver the Download methods for upgrading its configuration files. The CPE downloads the configuration files from the specified file server, upgrade configuration files, and then reboot. After that, the CPE will indicate successful or unsuccessful completion of the method application.

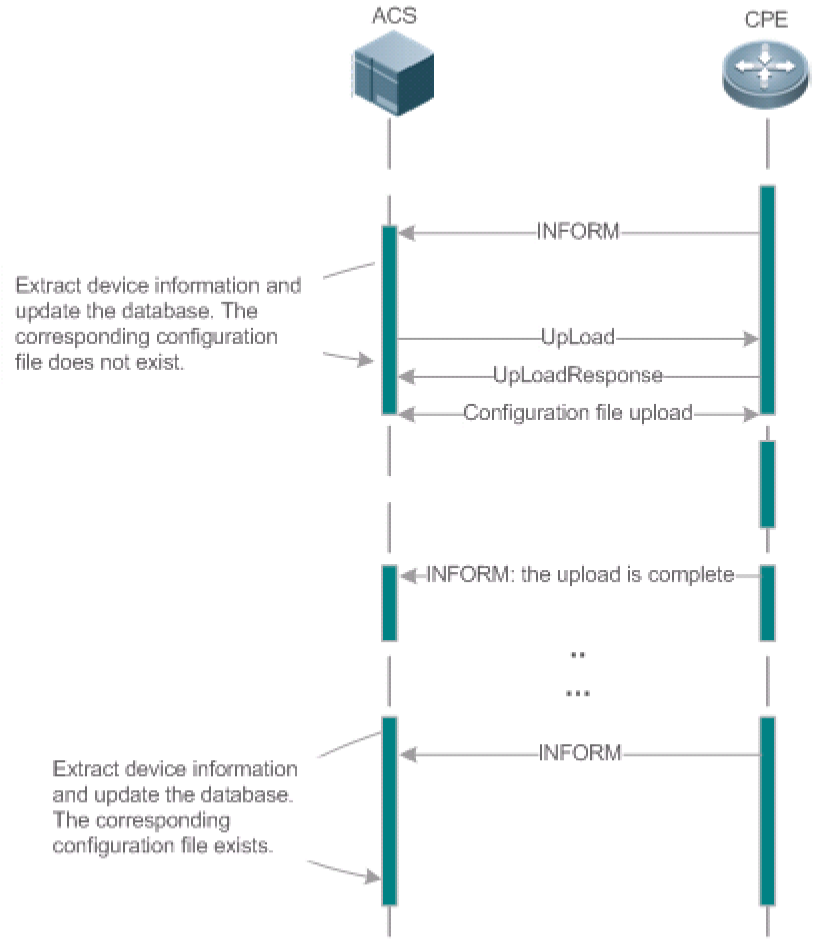
Note The file server can be ACS or separately deployed.

Uploading the Configuration Files

Uploading the Configuration Files means the ACS controls the configuration files of CPEs by using the Upload method.

Working Principle

Figure 0-5



ACS
CPE
INFORM
Extract device information and update the database. The corresponding configuration file does not exist.
UpLoad
UpLoadResponse
Configuration file upload
INFORM: the upload is complete
...
INFORM
Extract device information and update the database. The corresponding configuration file exists.

When a CPE initially accesses the ACS, the ACS attempts to learn the configuration files of the CPE in the following sequence:

- When the ACS initially receives an Inform message from the CPE, it locates the corresponding database information according to device information carried in the message.
- If the database does not contain the configuration files of the CPE, the ACS delivers the Upload method to the CPE for uploading the configuration files.
- The CPE uploads its current configuration files to the ACS.
- The CPE returns a successful or unsuccessful response to the Upload request.

Backing Up and Restoring a CPE

When a remote CPE breaks away from the management center due to abnormal operations, the CPE backup and restoration feature helps restore the CPE to the previous status, so that the management center can resume the supervision of the CPE as necessary.

Working Principle

You can configure the restoration function on a CPE, so that the CPE can restore itself from exceptions of its firmware or configuration files. Then when the CPE fails to connect to the ACS and breaks away from the management center after its firmware or configuration files are upgraded, the previous firmware or configuration files of the CPE can be restored in time for the ACS to manage the CPE. This kind of exception is generally caused by delivery of a wrong version or configuration file.

Before the CPE receives a new firmware or configuration files to upgrade, the CPE will back up its current version and configuration files. In addition, there is a mechanism for determining whether the problem described in the preceding scenario has occurred. If the problem has occurred, the CPE is restored to the previous manageable status.

Configuration

Action	Suggestions and Related Commands	
Establishing a Basic CWMP Connection	⚠ (Mandatory) You can configure the ACS or CPE usernames and passwords to be authenticated for CWMP connection.	
	cwmp	Enables CWMP and enters CWMP configuration mode.
	acs username	Configures the ACS username for CWMP connection.
	acs password	Configures the ACS password for CWMP connection.
	cpe username	Configures the CPE username for CWMP connection.
	cpe password	Configures the CPE password for CWMP connection.
	⚠ (Optional) You can configure the URLs of the CPE and the ACS.	
	acs url	Configures the ACS URL.
	cpe url	Configures the CPE URL.
Configuring CWMP-Related Attributes	⚠ (Optional) You can configure the basic functions of the CPE, such as upload, backup and restoration of firmware, configuration files or logs.	
	cpe inform	Configures the periodic notification function of the CPE.
	cpe back-up	Configures the backup and restoration of the firmware and configuration file of the CPE.
	disable download	Disables the function of downloading firmware and configuration files from the ACS.
	disable upload	Disables the function of uploading configuration and log files to the ACS.

Action	Suggestions and Related Commands	
	timer cpe- timeout	Configures the ACS response timeout on CPEs.

Establishing a Basic CWMP Connection

Configuration Effect

- A session connection is established between the ACS and the CPE.

Precautions

- N/A

Configuration Method

Enabling CWMP and Entering CWMP Configuration Mode

- (Mandatory) The CWMP function is enabled by default.

Command	**cwmp**
Parameter Description	N/A
Defaults	CWMP is enabled by default.
Command Mode	Global configuration guide
Usage Guide	N/A

Configuring the ACS Username for CWMP Connection

- This configuration is mandatory on the ACS.
- Only one username can be configured for the ACS. If multiple are configured, the latest configuration is applied.

Command	**acs username** *username*
Parameter Description	**username** *username*: The ACS username for CWMP connection
Defaults	The ACS username is not configured by default.
Command Mode	CWMP configuration mode
Usage Guide	N/A

Configuring the ACS Password for CWMP Connection

- This configuration is mandatory on the ACS.
- The password of the ACS can be in plaintext or encrypted form. Only one password can be configured for the ACS. If multiple are configured, the latest configuration is applied.

Command	**acs password** {*password* | *encryption-type encrypted-password*}
Parameter Description	*password:* ACS password *encryption-type:* 0 (no encryption) or 7 (simple encryption) *encrypted-password:* Password text
Defaults	*encryption-type*: 0

	encrypted-password: N/A
Command Mode	CWMP configuration mode
Usage Guide	N/A

Configuring the CPE Username for CWMP Connection

- This configuration is mandatory on the CPE.
- Only one username can be configured for the CPE. If multiple are configured, the latest configuration is applied.

Command	**cpe username** *username*
Parameter Description	*username*: CPE username
Defaults	No CPE username is configured by default.
Command Mode	CWMP configuration mode
Usage Guide	N/A

Configuring the CPE Password for CWMP Connection

- This configuration is mandatory on the CPE.
- The password of the CPE can be in plaintext or encrypted form. Only one password can be configured for the CPE. If multiple are configured, the latest configuration is applied.

Command	**cpe password** {*password* | *encryption-type encrypted-password*}
Parameter Description	*password:* CPE password *encryption-type:* 0 (no encryption) or 7 (simple encryption) *encrypted-password:* Password text
Defaults	*encryption-type*: 0 *encrypted-password*: N/A
Command Mode	CWMP configuration mode
Usage Guide	Use this command to configure the CPE user password to be authenticated for the ACS to connect to the CPE. In general, the encryption type does not need to be specified. The encryption type needs to be specified only when copying and pasting the encrypted password of this command. A valid password should meet the following format requirements: ● Contain 1 to 26 characters including letters and figures. ● The leading spaces will be ignored, while the trailing and middle are valid. ● If 7 (simple encryption) is specified, the valid characters only include 0 to 9 and a (A) to f (F).

Configuring the ACS URL for CMWP Connection

- This configuration is optional on the CPE.
- Only one ACS URL can be configured. If multiple are configured, the latest configuration is applied. The ACS URL must be in HTTP format.

Command	**acs url** *url*
Parameter Description	*url*: ACS URL
Defaults	No ACS URL is configured by default.

Command Mode	CWMP configuration mode
Usage Guide	If the ACS URL is not configured but obtained through DHCP, CPEs will use this dynamic URL to initiate connection to the ACS. The ACS URL must: ● Be in format of **http://host[:port]/path**. ● Contain 256 characters at most.

Configuring the CPE URL for CWMP Connection

- This configuration is optional on the CPE.
- Only one CPE URL can be configured. If multiple are configured, the latest configuration is applied. The CPE URL must be in HTTP format instead of domain name format.

Command	**cpe url** *url*
Parameter Description	*url:* CPE URL
Defaults	No CPE URL is configured by default.
Command Mode	CWMP configuration mode
Usage Guide	If CPE URL is not configured, it is obtained through DHCP. The CPE URL must: ● Be in format of **http://ip [: port]/**. ● Contain 256 characters at most.

Verification

- Run the **show cwmp configuration** command.

Command	**show cwmp configuration**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A
Configuration Examples	The following example displays the CWMP configuration.

```
Ruijie(config-cwmp)#show cwmp configuration
CWMP Status                   : enable
ACS URL                      : http://www.ruijie.com.cn/acs
ACS username                  : admin
ACS password                  : ******
CPE URL                      : http://10.10.10.2:7547/
CPE username                  : ruijie
CPE password                  : ******
CPE inform status              : disable
CPE inform interval            : 60s
CPE inform start time          : 0:0:0 0 0 0
CPE wait timeout              : 50s
CPE download status            : enable
CPE upload status              : enable
CPE back up status             : enable
CPE back up delay time          : 60s
```

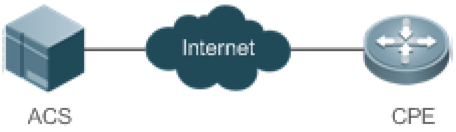
Configuration Examples

The following configuration examples describe CWMP-related configuration only.

Configuring Usernames and Passwords on the CPE

Network Environment

Figure 0-6



Configuration Method

- Enable CWMP.
- On the CPE, configure the ACS username and password to be authenticated for the CPE to connect to the ACS.
- On the CPE, configure the CPE username and password to be authenticated for the ACS to connect to the CPE.

CPE

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# cwmp
Ruijie(config-cwmp)# acs username USERB
Ruijie(config-cwmp)# acs password PASSWORDB
Ruijie(config-cwmp)# cpe username USERB
Ruijie(config-cwmp)# cpe password PASSWORDB
```

Verification

- Run the **show** command on the CPE to check whether the configuration commands have been successfully applied.

CPE

```
Ruijie # show cwmp configuration
CWMP Status                     : enable
ACS URL                         : http://10.10.10.1:7547/acs
ACS username                    : USERA
ACS password                    : ******
CPE URL                         : http://10.10.10.2:7547/
CPE username                    : USERB
CPE password                    : ******
```

Configuring the URLs of the ACS and the CPE

Network Environment

See 错误!未找到引用源。.

Configuration Method

- Configure the ACS URL.
- Configure the CPE URL.

CPE

```
Ruijie# configure terminal
Ruijie(config)# cwmp
Ruijie(config-cwmp)# acs url http://10.10.10.1:7547/acs
Ruijie(config-cwmp)# cpe url http://10.10.10.1:7547/
```

Verification

Run the **show** command on the CPE to check whether the configuration commands have been successfully applied.

CPE

```
Ruijie #show cwmp configuration
CWMP Status                      : enable
ACS URL                          : http://10.10.10.1:7547/acs
ACS username                     : USERA
ACS password                     : ******
CPE URL                          : http://10.10.10.2:7547/
```

Common Errors

- The user-input encrypted password is longer than 254 characters, or the length of the password is not an even number.
- The user-input plaintext password is longer than 100 characters.
- The user-input plaintext password contains illegal characters.
- The user-input encrypted password contains illegal characters (the legitimate characters includes only 0~9, a~f and A~F)
- The URL of the ACS is set to **NULL**.
- The URL of the CPE is set to **NULL**.

Configuring CWMP-Related Attributes

Configuration Effect

- You can configure common functions of the CPE, such as the backup and restoration of its firmware or configuration file, whether to enable the CPE to download firmware and configuration files from the ACS, and whether to enable the CPE to upload its configuration and log files to the ACS.

Configuration Method

Configuring the Periodic Notification Function of the CPE

- (Optional) The value range is from 30 to 3,600 in seconds. The default value is 600 seconds.
- Perform this configuration to reset the periodical notification interval of the CPE.

Command	**cpe inform [interval** *seconds*] **[starttime** *time*]
Parameter Description	*seconds*: Specifies the periodical notification interval of the CPE. The value range is from 30 to 3,600 in seconds. *time*: Specifies the date and time for starting periodical notification in *yyyy-mm-ddThh:mm:ss* format.
Command Mode	CWMP configuration mode
Defaults	The default value is 600 seconds.
Usage Guide	Use this command to configure the periodic notification function of the CPE.

	● If the time for starting periodical notification is not specified, periodical notification starts after the periodical notification function is enabled. The notification is performed once within every notification interval. ● If the time for starting periodical notification is specified, periodical notification starts at the specified start time. For instance, if the periodical notification interval is set to 60 seconds and the start time is 12:00 am next day, periodical notification will start at 12:00 am next day and once every 60 seconds.

↘ Disabling the Function of Downloading Firmware and Configuration Files from the ACS

- (Optional) The CPE can download firmware and configuration files from the ACS by default.
- Perform this configuration if the CPE does not need to download firmware and configuration files from the ACS.

Command	**disable download**
Parameter Description	N/A
Defaults	The CPE can download firmware and configuration files from the ACS by default.
Command Mode	CWMP configuration mode
Usage Guide	Use this command to disable the function of downloading main program and configuration files from the ACS. ● This command does not act on configuration script files. The configuration scripts can still be executed even if this function is disabled.

↘ Disabling the Function of Uploading Configuration and Log Files to the ACS

- (Optional.) The CPE can upload configuration and log files to the ACS by default.
- Perform this configuration if the CPE does not need to upload configuration and log files to the ACS.

Command	**disable upload**
Parameter Description	N/A
Defaults	The CPE can upload configuration and log files to the ACS by default.
Command Mode	CWMP configuration mode
Usage Guide	Use this command to disable the function of uploading configuration and log files to the ACS.

↘ Configuring the Backup and Restoration of the Firmware and Configuration Files of the CPE

- (Optional) The backup and restoration of the firmware and configuration files of the CPE is enabled by default. The value range is from 10 to 600 in seconds. The default value is 30 seconds.
- The longer the delay-time is, the longer the reboot will be complete.
- Perform this configuration to modify the function of backing up and restoring the firmware and configuration files of the CPE.

Command	**cpe back-up [delay-time** *seconds*]
Parameter Description	*seconds*: Specifies the delay for backup and restoration of the firmware and configuration file of the CPE.
Defaults	The default value is 30 seconds.
Command	CWMP configuration mode

Mode	
Usage Guide	N/A

➘ Configuring the ACS Response Timeout

- (Optional) The value range is from 10 to 600 in seconds. The default value is 30 seconds.
- Perform this configuration to modify the ACS response timeout period on the CPE.

Command	**timer cpe- timeout** *seconds*
Parameter Description	*seconds*: Specifies the timeout period in seconds. The value range is from 10 to 600.
Defaults	The default value is 30 seconds.
Command Mode	CWMP configuration mode
Usage Guide	N/A

Verification

- Run the **show cwmp configuration** command.

Command	**show cwmp configuration**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A
Configuration Examples	The following example displays the CWMP configuration.

```
Ruijie(config-cwmp)#show cwmp configuration
CWMP Status                   : enable
ACS URL                      : http://www.ruijie.com.cn/acs
ACS username                  : admin
ACS password                  : ******
CPE URL                      : http://10.10.10.2:7547/
CPE username                  : ruijie
CPE password                  : ******
CPE inform status              : disable
CPE inform interval             : 60s
CPE inform start time           : 0:0:0 0 0 0
CPE wait timeout               : 50s
CPE download status             : enable
CPE upload status              : enable
CPE back up status             : enable
CPE back up delay time          : 60s
```

Configuration Examples

➘ Configuring the Periodical Notification Interval of the CPE

Network Environment

See 错误!未找到引用源。.

Configuration Steps

- Enable the CWMP function and enter CWMP configuration mode.
- Set the periodical notification interval of the CPE to 60 seconds.

CPE

```
Ruijie#config
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#cwmp
Ruijie(config-cwmp)#cpe inform interval 60
```

Verification

Run the **show** command on the CPE to check whether the configuration commands have been successfully applied.

CPE

```
Ruijie #show cwmp configuration
CWMP Status                       : enable
……
CPE inform interval              : 60s
```

Disabling the Function of Downloading Firmware and Configuration Files from the ACS

Network Environment

See 错误!未找到引用源。.

Steps

- Enable the CWMP function and enter CWMP configuration mode.
- Disable the function of downloading firmware and configuration files from the ACS.

CPE

```
Ruijie#config
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#cwmp
Ruijie(config-cwmp)#disable download
```

Verification

Run the **show** command on the CPE to check whether the configuration commands have been successfully applied.

CPE

```
Ruijie #show cwmp configuration
CWMP Status                       : enable
……
CPE download status              : disable
```

Disabling the Function of Uploading Configuration and Log Files to the ACS

Network Environment

See 错误!未找到引用源。.

Configuration Steps

- Enable the CWMP function and enter CWMP configuration mode.
- Disable the CPE's function of uploading configuration and log files to the ACS.

CPE

```
Ruijie#config
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#cwmp
Ruijie(config-cwmp)# disable upload
```

Verification

Run the **show** command on the CPE to check whether the configuration commands have been successfully applied.

CPE

```
Ruijie #show cwmp configuration
CWMP Status                    : enable
……
CPE upload status              : disable
```

Configuring the Backup and Restoration Delay

Network Environment

See 错误!未找到引用源。.

Configuration Steps

- Enable the CWMP function and enter CWMP configuration mode.
- Set the backup and restoration delay to 100 seconds.

CPE

```
Ruijie#config
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#cwmp
Ruijie(config-cwmp)# cpe back-up Seconds 30
```

Verification

- Run the **show** command on the CPE to check whether the configuration commands have been successfully applied.

CPE

```
Ruijie #show cwmp configuration
CWMP Status                      : enable
……
CPE back up delay time           : 30s
```

Configuring the ACS Response Timeout of the CPE

Network Environment

See 错误!未找到引用源。.

Configuration Steps

- Enable the CWMP function and enter CWMP configuration mode.
- Set the response timeout of the CPE to 100 seconds.

CPE

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# cwmp
Ruijie(config-cwmp)# timer cpe-timeout 100
```

Verification

- Run the **show** command on the CPE to check whether the configuration commands have been successfully applied.

CPE

```
Ruijie#show cwmp configuration
CWMP Status                    : enable
……
CPE wait timeout               : 100s
```

Common Errors

N/A

Monitoring

Displaying

Command	Function
show cwmp configuration	Displays the CWMP configuration.
show cwmp status	Displays the CWMP running status.

Configuring USB/SD

Overview

This document describes usage of USB/SD storage devices (mainly U disk/SD). The system only recognizes the U-disk/SD card partitioned by FAT. Other file systems cannot be identified.

After inserting a U disk/SD, the system prompts that U disk/SD is found. The files in this U disk/SD card can be positioned and accessed through URL, such as **usb0:/abc/1.txt** or **sd0:/abc/1.txt**.

Caution

Version 10.4 (2) and the later versions support the access to U disk/SD by URL. For earlier software, use the mount path of the file system to position and access U disk/SD, such as using /mnt/usb0 to access the USB device on port 0, and using /mnt/sd to access the SD card. The mount path is prompted when the device is inserted, or is displayed when users run the **show usb** command.

The USB mobile disk (USB-HDD) is not supported.

Inserting the Device

Just insert a USB device into the USB slot. Messages as below are displayed if the system finds the device and loads the driver.

```
      *Jan  1 00:03:21: %USB-5-USB_DISK_FOUND: USB Disk<USB DISK Pro>Found!

*Jan  1 00:03:21: %USB-5-USB_DISK_PARTITION: USB_DISK_PARTITION found, /dev/uba/disc0/part4
to /mnt/usb0, size 4007657472B(3822MB)
```

Just insert an SD card into an SD slot. Messages as below are displayed if the system finds the device and loads driver.

```
*Jan  1 00:09:42: %USB-5-USB_DISK_PARTITION_MOUNT: Mount sd (type:FAT32),size :
1050673152B(1002MB)
```

SD: is the first SD partition and **size** is the partition size. This SD card has 1002 MB space.

Using the Device

After loading U disk/SD card to the system, directly run file system commands (dir, copy, del, and others) to operate U disk/SD card. Operations below show how to copy the file of U disk/SD card to flash.

Access the U disk partition.

```
Ruijie# cd usb0:/
Access the SD card partitiom.
Ruijie# cd sd0:/
```

Copy the **a.txt** file in the U disk to root directory of the device.

```
Ruijie# copy usb0:/a.txt  flash:/b.txt
```

Copy the a.txt file in the SD card to device’s the root directory of the device.

```
Ruijie# copy sd0:/a.txt  flash:/b.txt
```

Run the **dir** command. The result shows that the b.txt file has been added to the USB/SD card.

For other operation commands, see the “File System Management” section.

Caution

If there are multiple partitions in U disk/SD card, only the first FAT partition can be accessed through the device.

Note

Only the version 10.4(2) and the later versions allow users to access U disc/SD card by URL. For the earlier versions, use path to position and access the device. For example:
Access the U disk partition:
Ruijie# cd /mnt/usb0
Access the SD card partition:
Ruijie# cd /mnt/sd0

Copy the a.txt file under root directory to U disk.
Ruijie# **copy** flash:/a.txt usb0:/a.txt
Copy the a.txt file under root directory to SD card.
Ruijie# **copy** flash:/a.txt sd0:/a.txt

Showing USB Device/SD Card Information

Command	Function
Ruijie# **show usb**	Shows the USB device information of the system
Ruijie# **show sd**	Shows the SD device information of the system

In CLI command mode, use the **show usb** or the **show sd** command to view the USB / SD device information of the system. The displayed information is as follows:

```
Ruijie# show usb
Device: Mass Storage:
ID: 0
URL prefix: usb0
Disk Partitions:
usb0(type:FAT32)
```

```
Size : 131,072,000B(125MB)
Available size: 1,260,020B (1.2MB)

Ruijie# show sd

Device: Mass Storage:
ID: 1
URL prefix: sd0
Disk Partitions:
SD(type:FAT32)

Size : 131,072,000B(125MB)
Available size: 1,260,020B (1.2MB)
```

USB Mass Storage Device is the name of the device.

URL means which prefix can be used by U disk/SD card to access U disk/SD card.

Size means the available space in U disk/SD card that can be accessed.

Available size means the remaining space in U disk/SD card.

Unplugging USB Device/SD Card

Before pulling out USB device/SD card, run the command on the CLI to uninstall the device in case system is using the USB device/SD card to avoid an error.

Command	**Function**
Ruijie# **usb remove** *Device_ID*	Uninstalls the USB device with ID Device_ID

Command	Function
Ruijie# **sd remove** *Device_ID*	Uninstalls the SD device with ID Device_ID

As shown above, IDO indicates a USB device, and ID1 indicates an SD card. The commands below can uninstall the corresponding USB device and SD card.

```
Ruijie# usb remove 0
After the uninstall command is used, the system will print:
OK, now you can pull out the device 0.
*Jan  1 00:18:16: %USB-5-USB_DISK_REMOVED: USB Disk <Mass Storage> has been removed from USB
port 0!
Ruijie# sd remove 1
After the uninstall command is used, the system will print:
OK, now you can pull out the device 1
Now, you can pull out the USB device/SD card.
```

Sometimes, it may lead to failure to uninstall the device for the device is being used. Wait a while, and then run the uninstall command to pull out the device.

Caution Be sure to uninstall the device first and then unplug the device to prevent the system error.

USB/SD Faults

When the system prints the following message:

```
*Jan 2 00:00:39: %USB-3-OHCI_ERR: USB1.0 controller is not available now.
```

USB/SD 1.0 controller is not available, while USB/SD card 2.0 is still available. In this case, reset the whole system to use corresponding version U disk/SD card.

When the system prints the following message:

```
*Jan 2 00:00:39: %USB-3-EHCI_ERR: USB2.0 controller is not available now.
```

USB/SD 2.0 controller is not available, while U disc/SD card 1.0 is still available. In this case, reset the whole system to use corresponding version U disk/SD card.

Configuring System Management

Basic System Management

Showing CPU Utilization

Use the **show cpu** command to show the total CPU utilization of the system and the CPU utilization of each process:

Command	Function
Ruijie# **show cpu**	Shows CPU utilization.

By default, the device name is **Ruijie**.

The following example shows the output result of this command.

```
Ruijie#show cpu
=======================================
    CPU Using Rate Information
CPU utilization in five seconds: 25%
CPU utilization in one minute: 20%
CPU utilization in five minutes: 10%
  NO  5Sec   1Min  5Min   Process
  0    0%    0%    0%    LISR INT
  1    7%    2%    1%    HISR INT
  2    0%    0%    0%    ktimer
  3    0%    0%    0%    atimer
  4    0%    0%    0%    printk_task

100    4%    2%    1%    datapkt_rcv_thread
101    0%    0%    0%    keepalive_link_notify
102    0%    0%    0%    rerp_msg_recv_thread
103    0%    0%    0%    ip_scan_guard_task
104    0%    0%    0%    ssp_ipmc_hit_task
105    0%    0%    0%    ssp_ipmc_trap_task
106    0%    0%    0%    hw_err_snd_task
107    0%    0%    0%    rerp_packet_send_task
108    0%    0%    0%    idle_vlan_proc_thread
109    0%    0%    0%    cmic_pause_detect
110    1%    1%    1%    stat_get_and_send
111    0%    1%    0%    rl_con
```

```
112   75%   80%   90%   idle
```

As shown in the above list, the first three lines indicate the total CPU utilization in the last 5 seconds, 1 minute, and 5 minutes respectively, including the CPU utilization of LISRs, HISRs and tasks, followed by the CPU utilization of various processes. The parameters in the columns are described as follows:

- **No**: number
- **5Sec**: CPU utilization in the last 5 seconds
- **1Min**: CPU utilization in the last 1 minute
- **5Min**: CPU utilization in the last 5 minutes
- **Process**: process name

The first two lines indicate the CPU utilization of all LISRs and all HISRs respectively. All the lines starting from the third line indicate the CPU utilization of processes. The last line indicates the CPU utilization of idle processes. As with **System Idle Process** in the Windows operating system, it indicates an idle status. The above example shows that the CPU utilization of idle processes in the last 5 seconds is 75%, meaning that 75% of the CPU resources are available.

Configuring CPU Utilization Log Thresholds

Use the following command to configure CPU utilization log thresholds.

Command	Function
cpu-log log-limit *low_num high_num*	Configures the high and low thresholds for triggering CPU utilization logs.

By default, the high threshold is 100% and the low threshold is 90%.

The following example sets the low threshold to 70% and the high threshold to 80%.

```
Ruijie# configure terminal                  // Enter the global configuration mode.
Ruijie(config)# cpu-log log-limit 70 80    // Configure the thresholds for triggering CPU logs.
```

If the CPU utilization is higher than 80%, the following information is displayed:

Oct 20 15:47:01 %SYSCHECK-5-CPU_USING_RATE_LOG: CPU utilization rate in one minute: 95%. rl_con occupied most CPU utilization rate: 94%.

If the CPU utilization is lower than 70%, the following information is displayed:

Oct 20 15:47:01 %SYSCHECK-5-CPU_USING_RATE_LOG: CPU utilization rate in one minute: 68%. rl_con occupied most CPU utilization rate: 60%.

Oct 20 15:47:01 %SYSCHECK-5-CPU_USING_RATE_LOG: The CPU utilization ratio has been decreased.

Configuring System Memory Display

Showing the Usage of System Memory

Use the **show memory** command to show the usage and status of system memory:

Command	Function
Ruijie# **show memory**	Shows the usage of system memory.

The switch name is Ruijie by default.

Below is the result of executing this command:

```
Ruijie#show memory
System Memory Statistic:
  Free pages: 174164
    watermarks : min 2012, lower 4024, low 6036, high 9048
  System Total Memory : 1024MB, Current Free Memory : 740580KB
  Used Rate : 29%
```

The above information includes:

Parameter		Description
Free pages		The total free pages of all areas.
watermarks	min	Memory resources are extremely insufficient. It can only keep the kernel running. All application modules fails to run if the minimum watermark has been reached.
	lower	Memory resources are severely insufficient. One route protocol will auto-exit and release the memory if the lower watermark has been reached. For the details, see the **memory-lack exit-policy** command.
	low	Memory resources are insufficient. The route protocol will be in OVERFLOW state if the low watermark has been reached. In the overflow state, the routers do not learn new routes any more. The commands are not allowed to be executed when the memory lacks.
	high	There is plenty of memory resources. Each route protocol restores the state from OVERFLOW to normal.
System Total Memory		System total memory
System Free Memory		System free memory, including free pages space and all free space in the cache pool
Used Rate		Memory utilization rate

Configuring MIB

MIB Lists

The followings are the supported standard MIBs:

- BRIDGE-MIB (RFC1493)
- EtherLike-MIB(RFC1643)
- IF-MIB(RFC2863)
- RFC1213-MIB
- RMON1-MIB(supports RMON etherStats, etherHistory,alarms, events)
- SNMPv2-MIB
- SNMPv3-MIB(supports USM, VACM)

The followings are the private MIBs:

- RUIJIE-AAA-MIB
- RUIJIE -ENTITY-MIB
- RUIJIE -RIP-MIB
- RUIJIE -MEMORY-MIB

You can use the **show snmp mib** command to view the supported MIBs in the current system:

```
Ruijie# show snmp mib
sysDescr
sysObjectID
sysUpTime
sysContact
sysName
sysLocation
sysServices
sysORLastChange
ifNumber
ifEntry
ifEntry.ifIndex
ifEntry.ifDescr
ifEntry.ifType
ifEntry.ifMtu
ifEntry.ifSpeed
ifEntry.ifPhysAddress
ifEntry.ifAdminStatus
ifEntry.ifOperStatus
ifEntry.ifLastChange
ifEntry.ifInOctets
ifEntry.ifInUcastPkts
ifEntry.ifInNUcastPkts
ifEntry.ifInDiscards
ifEntry.ifInErrors
ifEntry.ifInUnknownProtos

ifEntry.ifOutOctets

ifEntry.ifOutUcastPkts

ifEntry.ifOutNUcastPkts

ifEntry.ifOutDiscards

ifEntry.ifOutErrors

ifEntry.ifOutQLen

ifEntry.ifSpecific

......
```

Obtaining the MIB Files

You can obtain the standard MIB information on the http://ietf.org/rfc.html.
You can obtain the private MIB information on the website.

Configuring One-click Upgrade

Understanding One-click Upgrade

Basic Concepts

One-click upgrade means that a user presses the **FUNC** key on the device panel to reset the system. Before the system reset, the user can individually upgrade the software version or configuration file by using the files stored in an SD card or USB drive or upgrade the software version and configuration file at the same time. Specifically, one-click upgrade provides the following functions:

- One-click system reset
- One-click upgrade of software version and configuration file

One-click System Reset

When no SD card or USB drive is inserted into the device or when an SD card or a USB drive is inserted but no appropriate software version or configuration file is available in the SD card or USB drive for upgrade, the user resets the system by pressing the **FUNC** key to the original software version.

One-click Upgrade of Software Version and Configuration File

When an SD card or a USB drive is inserted into the device and the user presses the **FUNC** key, the system scans for the installation package and configuration file in turn in the root directory of the SD card or USB drive. After finding the installation package and configuration file, the system first performs a validity check and then upgrades the device by using the installation package and configuration file if the installation package and configuration file are valid. After the upgrade is complete, the system resets by using the new software version and configuration file.

Though old line cards do not provide the **FUNC** key, so long as the corresponding software is available, one-click upgrade of the software version and configuration file can be triggered through a configuration command. The upgrade triggered by using a configuration command is the same as that by pressing the **FUNC** key. The system scans for the installation package and configuration file in turn in the root directory of the SD card or USB drive. After finding the installation package and configuration file, the system first performs a validity check and then upgrades the device by using the installation package and configuration file if the installation package and configuration file are valid. After the upgrade is successful, the system resets.

Note

When scanning the inserted storage media, the system scans the SD card in preference. If no SD card is inserted or the SD card does not store an appropriate installation package or configuration file, the system scans the USB drive. If the inserted SD card and USB drive do not store an appropriate installation package or configuration file, the software version and configuration file of the device are not upgraded and only the system resets. The system still starts by using the original software version and configuration file.

Caution

- The installation package supports the following four filename formats:
  - *rgos.bin*
  - *Product name_project name_serial number_install.bin*

    Caution For example: RSR77_10.4(3b21)_R166400_install.bin
  - *P product name V1_project name_serial number_install.bin*

    Caution For example: PRSR77V1_10.4(3b21)_R166400_install.bin
  - *P product name v1-version number-install.bin*

    Caution For example: prsr77v1-101939-install.bin
- A product name consists of digits, uppercase, lowercase, and '-'; a version number consists of digits; a project name consist of digits, lowercase, '(', and ')'; a serial number consists of "R" and the version number. The product name in an old installation package is case-insensitive; in a new installation package, the product name is case-sensitive and the configuration file is provided in the form of an encrypted file, for example, **config.des**.
- If a **rgos.bin** file exists, the system uses the file in preference; otherwise, the system uses the first scanned installation package that meets the naming rules in preference.
- The system scans only for the installation package and configuration file in the root directory of the SD card or USB drive and always scans the SD card in preference.
- It is recommended that only one installation package be stored in the root directory of the SD card of USB drive. If multiple installation packages are stored, the system randomly scans for the installation package and takes the first scanned installation package for upgrade, which cannot ensure the correct sequence of searching for the software version.
- The installation package and configuration file must be stored on the same storage medium. If the installation package and configuration file are located in the SD card and USB drive respectively, only the file in the SD card is upgraded.
- Before upgrading the configuration file, you must ensure that the flash memory has sufficient space for storing the configuration file to be upgraded. The size of the configuration file depends on the configuration and is generally not smaller than 1 MB.
- Before upgrading the installation package, you must ensure that the flash memory has sufficient space for storing the installation package to be upgraded. The size of the installation package is generally not smaller than 30 MB.
- Before performing the **FUNC** key triggered one-click upgrade, you must ensure that all line cards are started, that is, the **SYS** indicators of boards become green. For specific positions of **SYS** indicators, see the *Hardware Installation Manual*.
- When using one-click upgrade based on the **FUNC** key, you must ensure that an SD card or USB drive is inserted and the device detects the SD card or USB drive, that is, the indicator of the SD card or USB drive becomes green. For the specific position of the indicator, see the *Hardware Installation Manual*.

- After one-click upgrade is complete, the device resets automatically. If one-click upgrade fails, the indicator of the SD card or USB drive is off and the status indicator becomes red for three seconds. No matter whether the device is upgraded successfully or not, if the SD card or USB drive stores a file that can be used for upgrade, the system generates a Syslog file whose format is “product name-update.log” in the root directory of the SD card or USB drive.
- The function of triggering one-click upgrade through a configuration command requires the software version to be 10.4(3b21) or later.

When scanning the inserted storage media, the system scans the SD card in preference. If no SD card is inserted or the inserted SD card does not store an appropriate installation package or configuration file, the system scans the USB drive. If the inserted SD card and USB drive do not have an appropriate installation package or complete configuration file, the software version and configuration file of the device are not upgraded and only the system resets. The system still starts by using the original software version and configuration file.

Encryption of Configuration File

The configuration file contains confidential information of the user. Therefore, security protection measures must be taken to avoid disclosure of the information. Ruijie’s one-click upgrade function provides a tool on the PC side to realize file encryption. That is, the configuration file is encrypted during transmission. When the device performs one-click upgrade, the device reads the encrypted configuration file in the SD card or USB drive and decrypts the configuration file. After successfully decrypting the configuration file, the device upgrades the configuration file; when the device fails to decrypt the configuration file, the configuration file is used incorrectly or the file is damaged during transmission. In this case, the device does not upgrade the configuration file.

For instructions on the encryption tool on the PC side for Ruijie’s one-click upgrade function, see the *PC Client Configuration for One-click Upgrade*.

Backup of Configuration File

Upgrading the configuration file is an irreversible operation. If you find an error in upgrading the configuration file and want to restore to the previous configuration, you must upgrade the configuration file again. To help the user obtain the configuration file before upgrade, before one-click upgrade is performed, the configuration file is encrypted and stored in an SD card or USB drive as follows: root directory/update_backup/date_time_config.des (if the same file is found in the directory, the file is overwritten). The configuration file of the device is backed up only when the SD card or USB drive stores the available installation package or configuration file. If the SD card or USB drive does not store any installation package or configuration file for upgrade, the configuration file of the device is not backed up. Before using this function, ensure that the SD card has enough space to store the configuration file. The required storage space depends on the configuration and is generally not smaller than 1 MB.

When you find that the configuration file is upgraded incorrectly, copy the **date_time_config.des** file in **/update_backup** under the root directory of the device to the root directory of the SD card or USB drive, rename it **config.des**, and perform one-click upgrade once again to restore the previous configuration.

The configuration file that is backed up can be used by only the device that generates the configuration file to ensure that the backed up configuration file is not incorrectly used on other devices.

Synchronization of Configuration File

The configuration file running on the device must be the same as the configuration file stored in the SD card or USB drive so that the device is replaced directly and the network is restored quickly for the user by using one-click upgrade when the device is faulty. To meet this requirement, when you modify and save the configuration, the device automatically encrypts the configuration file and synchronizes it to the **config.des** file in the root directory of the SD card. If the file already exists in the root directory, the file is overwritten. Before applying this function, ensure that the SD card has enough space to store the configuration file. The required storage space depends on the configuration and is generally not smaller than 1 MB.

The configuration file is synchronized only when you save the configuration. When you modify the device configuration in other modes (for example, rename the existing configuration file and copy other configuration files to the flash memory), the device does not synchronize the configuration file.

The synchronized configuration file can be used on any device that supports one-click upgrade, but you need to ensure that the configuration is applicable to the device.

Synchronization of Installation Package

The configuration file running on the device must be consistent with the configuration file stored in the SD card or USB drive so that the device can be replaced directly and the network can be restored quickly by using one-click upgrade when the device is faulty. To meet this requirement, when you upgrade the installation package, the device automatically synchronizes the installation package to the **rgos.bin** file in the root directory of the SD card. If the file already exists in the root directory, the file is overwritten. Before using this function, ensure that the SD card has enough space to store the installation package. The required storage space depends on the size of the installation package and is generally not smaller than 50 MB.

The installation package is synchronized only when you run the **copy tftp** command. When you upgrade the installation package in other modes (for example, rename the existing installation package and copy files in other SD cards or USB drives to the flash memory), the device does not synchronize the installation package.

Working Principle

The **FUNC** key is available on the device panel. If you press the **FUNC** key, the system interrupts the current task and executes the corresponding task. During execution of the task triggered by the **FUNC** key, the system checks whether an SD card or a USB drive is inserted into the current device. If not, the system resets directly. Otherwise, the system first checks whether an SD card is inserted prior to a USB drive. Each time when the system scans a storage medium (SD card or USB drive), the system checks whether an installation package matching the specified file format exists in the root directory of the storage medium and whether the **config.des** file exists in the root directory. If the file exists, the system decrypts the file and performs a validity check on the file. If the check on the installation package and configuration file is successful, the system upgrades the software version and configuration file of the device and then resets by using the new software version and configuration file after the upgrade is complete. If no applicable installation package or configuration file exists or the installation package and configuration file do not pass the validity check, the system does not upgrade the installation package or configuration file and directly resets by using the original software version and configuration file.

According to the preceding description, in addition to the default one-click system reset based on the **FUNC** key, the one-click upgrade function also supports upgrading the software version and configuration file of a device by using a new software version and configuration file stored in an SD card or a USB drive. This provides another convenient means for the user to reset the system and upgrade the software version.

Different from the traditional mode in which the user logs in to the device through the console port or telnet to perform reset and upgrade, one-key upgrade enables users to reset the device and upgrade the software version and configuration file, without knowing fundamental knowledge about the device. Therefore, users in remote areas without any technical basis can operate and use access routers. When the original software version and configuration file need to be upgraded, only an SD card or a USB drive storing the installation package and configuration file of the new software version needs to be delivered. The customer even without knowing fundamental knowledge about the device can perform the operation and technical personnel do not need to operate on site. This greatly saves the cost of maintenance and the time of technical personnel.

Protocols and Standards

None

Default Configuration

None

Configuring One-click Upgrade

Triggering One-click Upgrade by Using a Command

Command	Function
Ruijie#**onekey**	Enables one-click upgrade.

☑ RSR77 series of version 10.4(3b21) and later support this function.

Displaying Configuration

None

Configuration Example 1

One-click system reset

Networking Requirements

None

Networking Topology

None

Configuration Tips

None

Configuration Steps

Press the **FUNC** key to reset the system when all the **SYS** indicators of boards are green.

Verification

After the system resets, run the **show version** command to check whether the software version of the system is the same as that before the system resets.

Configuration Example 2

One-click upgrade of software version and configuration file

Networking Requirements

None

Networking Topology

None

Configuration Tips

None

Configuration Steps

1) Insert the SD card or USB drive storing the installation package of the new software version into the device (pay attention to the file format. For details, see "One-click Upgrade of Software Version and Configuration File").

Press the **FUNC** key when the **SYS** indicators of all boards are green. The system performs software upgrade and then resets.

Verification

If the SD card or USB drive stores an appropriate configuration file or installation package and the upgrade is successful, the device resets automatically after the upgrade is complete.

If the SD card or USB drive does not store an appropriate configuration file or installation package, as a result of which the upgrade fails, the **SYS** indicators of the device become red for three seconds and then the device resets. For specific positions of **SYS** indicators, see the *Hardware Installation and Reference Guide*.

After the system resets, run the **show version** command to check whether the software version of the system is updated.

Configuring Debugging Improvement

Overview

Debugging information of devices, including output information of syslog, show commands and debug commands, can help post-sales or R&D engineers fast locate problems. However, it is inconvenient to use debugging information at present. For example, syslog information is buffered only in the memory. Once upon exception restart, previously saved syslog information will be lost, which is unfavorable to troubleshooting. In addition, a command for collecting all fault information is unavailable. This document describes how to configure debugging improvement based on the preceding problems.

One-key Collection

One-key collection comprises two parts:

The CLI **show tech-support** command can be used to display platform information in all scenarios.

The **show tech-support** <*module name*> command can be used to display module information in certain scenarios.

One-key Collection of Platform Information

Run the following command for one-key collection of platform information:

Command	Description
Ruijie# **show tech-support**	Collects platform information using the one-key mode.

At present, the show command for one-key collection of platform information integrates the following commands:

1. System platform

```
------------------ show version ------------------

------------------ show running-config ------------------

------------------ show user ------------------

------------------ dir ------------------

------------------ show memory------------------

------------------ show cpu ------------------

------------------ show task statistic------------------

------------------ show timer statistic------------------

------------------ show queue statistic-----------------

------------------ show skbuffer statistic--------------

------------------ show environment----------------------
```

------------------ show version slot----------------------

------------------ show clock----------------------

------------------ show exception----------------------

2. Express forwarding platform

------------------ show core ------------------

------------------ show efb ----------------------

------------------ show core interface all----------------------

3. Flow platform

------------------ show ip fpm statistics ----------------------

------------------ show ip fpm counters----------------------

------------------ show ipv6 fpm statistics----------------------

4. Routing module

------------------ show ip route summary all----------------------

------------------ Show ip route count----------------------

------------------ show ip ref route statistic----------------------

------------------ show ip ref adjacency statistic------------------

------------------ show ipv6 ref route statistic ----------------------

------------------ show ipv6 route summary all------------------

------------------ show ipv6 ref adjacency statistic------------------

5. Interface

------------------ show interfaces ------------------

------------------ show ip interface brief ------------------

------------------ show ef-interfaces ------------------

------------------ show controllers e1 ------------------

In addition, the show command for platform information integrates the show commands for all modules. For the collection of module information, see the next section.

One-key Collection of Module Information

Run the following command for one-key collection of module information:

Command	Description
Ruijie# **show tech-support** <*module name*>	Collects information of modules using the one-key mode.

At present, the command can be used to collect information of the following modules:

3G/CE1/MLP/PPP/NAT/IPSEC/L2TP/BFD/QOS/RIP/OSPF/BGP/ETHERNET/MSTP/FR/PPPOE/CA/DLDP/MPLS

The show commands to be integrated for the modules are as follows:

3G:

show cell info

show plmn backup

show dialer

CE1:

show interface

show controller e1

MLP:

show ppp mul

show ref ppp mul

NAT:

show ip nat translations

show ip nat statistics rule nouse/syn

IPSec:

show crypto isakmp policy

show crypto ipsec sa

show crypto ipsec transform-set

show crypto map

show crypto acl

show crypto detail

show crypto state

L2TP:

show vpdn

show vpdn tunnel

show vpdn session

BFD:

show bfd neighbor details

QoS:

show rate-limit

show policy-map

show queue cq/pq/rtpq/wfq

show traffic-shape queue

show traffic-shape statistics

RIP:

show ip protocol

show ip route

show ip rip

show ip rip database

show ip rip interface

show ip rip peer

show ip rip external

show ip route summary

OSPF:

show ip protocol

show ip route

show ip ospf neighbor detail

show ip ospf interface

show ip ospf database

show ip ospf sham-links

show ip ospf virtual-links

show ip ospf spf

show ip ospf topo

show ip ospf border-routers

show ip ospf summary-address

show ip ospf route

show ip ospf route summary

BGP:

show ip protocol

show ip route

show ip bgp neighbor

show ip bgp summary

show ip bpg all summary

show bgp all summary

Ethernet/MSTP:

show arp

FR:

show fr map

show fr lmi

show fr pvc

PPPoE:

show pppoe session

CA:

show crypto pki trustpoints

show crypto pki certificates

DLDP:

show dldp interface

MPLS:

show ip vrf interfaces

show ip ref adjacency

show ip ref mpls packet debug-buf

show mpls forwarding-table

Configuring Flow Platform

Understanding the Flow Platform

Overview

The flow platform achieves a perfect combination of services and performance, because services (such as QoS, ACL, NAT, and PBR) enabled on a service processing board have nearly no impact on forwarding performance.

Basic Concepts

Service packets based on Layer 3 usually can be abstracted as flows. A flow identifies a sequence of packets from a specific source to a specific destination. Generally, a flow is indentified by a sextuplet, which includes a source address, a destination address, a source port ID, a destination port ID, a transport layer protocol, and VRF.

Working Principle

When the first packet is forwarded through an entire routing process and service processing, the sextuplet of the packet identifies a flow. If a packet received later matches the sextuplet, it is forwarded in the same way as the first packet. The sextuplet and an outbound interface of the packet compose a flow entry. Packets that match the flow entry are forwarded directly without experiencing the entire routing process or service processing any longer. Therefore, enabled services (such as QoS, ACL, NAT, and PBR) have nearly no impact on forwarding performance.

Protocols and Standards

None.

Typical Application

When services (such as QoS, ACL, NAT, and PBR) are enabled, the flow platform is automatically enabled to accelerate service processing.

Configuring the IPv4 Function of the Flow Platform

Default Configuration

The following table describes the default configuration of the flow platform.

Feature	Default Setting
Flow platform	Disabled

Flow overflow alarm interval of the flow platform	5 seconds
Flow overflow alarm threshold of the flow platform	95%
Maximum number of flow entries in the IPv4 flow table	180,223

Prerequisites

When service modules (such as QoS, ACL, NAT, and PBR service modules) that rely on the flow platform are configured, the flow platform is automatically enabled.

Configuration Steps

Step	Configuration Task	Description
Step 1	Configure service modules.	(Mandatory) You can configure service modules such as QoS, ACL, NAT, and PBR.
Step 2	Configure the maximum number of flow entries in the IPv4 flow table.	(Optional) This step is performed if you need to change the memory occupied by the flow table.
Step 3	Configure the IPv4 flow overflow alarm interval of the flow platform.	(Optional) This step is performed if you need to change the flow overflow alarm interval.
Step 4	Configure the IPv4 flow overflow alarm threshold of the flow platform	(Optional) This step is performed if you need to change the flow overflow alarm threshold.

Configuring ACL to Enable the Flow Platform

Command	Function

Ruijie(config)# **access-list** *id* { **deny | permit** } { src *src-wildcard* | **host** *src* | **any** } [**time-range** *tm-rng-nam e*] [**log**]	Defines an ACL.
Ruijie(config)# **interface** *interface*	Specifies the interface to which the ACL is applied.
Ruijie(config-if)# **ip access-group** *id* { in | out } [**unreflect**]	Applies the ACL to the specific interface.

The following example enables the ACL function on the port GigabitEthernet 0/1.

```
Ruijie# configure terminal

Enter configuration commands, one per line. End with CNTL/Z.

Ruijie(config)# access-list 101 permit tcp 192.168.12.0 0.0.0.255 any

Ruijie(config)# interface GigabitEthernet 0/1

Ruijie(config-if)# ip address 192.168.12.1 255.255.255.0

Ruijie(config-if)# ip access-group 101 in
```

Configuring the Maximum Number of Flow Entries in the IPv4 Flow Table

Command	**Function**
Ruijie(config)# **ip fpm flow max-entries** *flow-number*	Configures the maximum number of flow entries in the IPv4 flow table.

The following example configures the maximum number of IPv4 flow entries as 120,000.

```
Ruijie# configure terminal

Enter configuration commands, one per line.  End with CNTL/Z.

Ruijie(config)# ip fpm flow max-entries 120000

FPM subsystem is reinitializing...

Ruijie(config)#*Oct  6 17:35:21: %FPM-5-RESTARTED: The device IPv4 flow max-entries changed.
```

Configuring the IPv4 Flow Overflow Alarm Interval of the Flow Platform

Command	Function
Ruijie(config)# **ip fpm flow alert interval** *seconds*	Configures the IPv4 flow overflow alarm interval of the flow platform.

The following example configures the IPv4 flow overflow alarm interval of the flow platform as 120s.

```
Ruijie# configure terminal

Enter configuration commands, one per line. End with CNTL/Z.

Ruijie(config)# ip fpm flow alert interval 120
```

Configuring the IPv4 Flow Overflow Alarm Threshold of the Flow Platform

Command	Function
Ruijie(config)# **ip fpm flow alert threshold** *percent-value*	Configures the IPv4 flow overflow alarm threshold of the flow platform.

The following example configures the IPv4 flow overflow alarm threshold of the flow platform as 80%.

```
Ruijie# configure terminal

Enter configuration commands, one per line. End with CNTL/Z.

Ruijie(config)# ip fpm flow alert threshold 80
```

Configuring the IPv6 Function of the Flow Platform

Default Configuration

The following table describes the default configuration of the flow platform.

Feature	Default Setting
Flow platform	Disabled

Flow overflow alarm interval of the flow platform	5 seconds
Flow overflow alarm threshold of the flow platform	95%
Maximum number of flow entries in the IPv6 flow table	81,920

Prerequisites

When service modules (such as QoS v6, ACLv6, NAT64, and PBRv6 service modules) that rely on the flow platform are configured, the flow platform is automatically enabled.

Configuration Steps

Step	Configuration Task	Description
Step 1	Configure service modules.	(Mandatory) You can configure service modules such as QoS v6, ACLv6, NAT64, and PBRv6.
Step 2	Configure the maximum number of flow entries in the IPv6 flow table.	(Optional) This step is performed if you need to change the memory occupied by the flow table.
Step 3	Configure the IPv6 flow overflow alarm interval of the flow platform.	(Optional) This step is performed if you need to change the flow overflow alarm interval.
Step 4	Configure the IPv6 flow overflow alarm threshold of the flow platform.	(Optional) This step is performed if you need to change the flow overflow alarm threshold.

Configuring ACLv6 to Enable the Flow Platform

Command	Function
Ruijie(config)# **ipv6 access-list** *name*	Enters ACL configuration mode.

Ruijie (config-ipv6-nacl)#[*sn*] {**permit** | **deny** } *port* { *src-ipv6-prefix/prefix-len* | **host** *src-ipv6-addr* | **any** } { *dst-ipv6-pfix/pfix-len* | **any** | **host** *dst-ipv6-addr* } [**dscp** *dscp*] [**flow-label** *flow-label*] [**fragments**] [**range** lower upper] [**time-range***tm-rng-name*]	Adds an entry to the ACL. For details about the command, see the Command Reference.
Ruijie(config-exp-nacl)# **exit**	Exits ACL configuration mode.
Ruijie(config)# **interface** *interface*	Specifies the interface to which the ACL is applied.
Ruijie(config-if)# **ipv6 traffic-filter** *name* { **in** | **out** }	Applies the ACL to the specific interface.

The following example enables the ACL function on the port GigabitEthernet 0/1.

```
Ruijie# configure terminal

Enter configuration commands, one per line. End with CNTL/Z.

Ruijie(config)# ipv6 access-list v6-list

Ruijie(config-ipv6-acl)# permit ipv6 2001:db8:1::1/64 any

Ruijie(config-ipv6-acl)# deny ipv6 any any

Ruijie(config-ipv6-acl)# exit

Ruijie(config)# interface GigabitEthernet 0/1

Ruijie(config-if)# ipv6 traffic-filter v6-list in
```

Configuring the Maximum Number of Flow Entries in the IPv6 Flow Table

Command	**Function**
Ruijie(config)# **ipv6 fpm flow max-entries** *flow-number*	Configures the maximum number of flow entries in the IPv6 flow table.

The following example configures the maximum number of flow entries in the IPv6 flow table as 70,000.

```
Ruijie# configure terminal
```

```
Enter configuration commands, one per line. End with CNTL/Z.

Ruijie(config)# ipv6 fpm flow max-entries 70000

FPM subsystem is reinitializing...

Ruijie(config)#*Oct  6 17:35:21: %FPM-5-RESTARTED: The device IPv6 flow max-entries changed.
```

Configuring the IPv6 Flow Overflow Alarm Interval of the Flow Platform

Command	**Function**
Ruijie(config)#**ipv6 fpm flow alert interval** *seconds*	Configures the IPv6 flow overflow alarm interval of the flow platform.

The following example configures the IPv6 flow overflow alarm interval of the flow platform as 120s.

```
Ruijie# configure terminal

Enter configuration commands, one per line. End with CNTL/Z.

Ruijie(config)#ipv6 fpm flow alert interval 120
```

Configuring the IPv6 Flow Overflow Alarm Threshold of the Flow Platform

Command	**Function**
Ruijie(config)# **ipv6 fpm flow alert threshold** *percent-value*	Configures the IPv6 flow overflow alarm threshold of the flow platform.

The following example configures the IPv6 flow overflow alarm threshold of the flow platform as 80%.

```
Ruijie# configure terminal

Enter configuration commands, one per line. End with CNTL/Z.

Ruijie(config)# ipv6 fpm flow alert threshold 80
```

Monitoring and Maintaining the Flow Platform

Command	Function
Ruijie#**clear ip fpm counters**	Clears IPv4 packet statistics of the flow platform.
Ruijie#**clear ip fpm flows**	Clears the IPv4 flow table of the flow platform.
Ruijie(config)# **ip fpm flow alert interval** *seconds*	Configures the IPv4 flow overflow alarm interval of the flow platform.
Ruijie(config)# **ip fpm flow alert threshold** *percent-value*	Configures the IPv4 flow overflow alarm threshold of the flow platform.
Ruijie(config)#**ip fpm flow max-entries** *flow-number*	Configures the maximum number of flow entries in the IPv4 flow table.
Ruijie(config)#**ip fpm frq** *queue-number*	Configures the number of concurrent IPv4 fragment reassembly queues.
Ruijie(config)**ip fpm session filter** *acl-number*	Protects the IPv4 flow table against attacks.
Ruijie#**show ip fpm counters**	Displays IPv4 packet counters of the flow platform.
Ruijie#**show ip fpm flows** [**filter** *protocol-number src-ip src-mask dst-ip dst-mask*]	Displays the IPv4 flow table.
Ruijie#**show ip fpm statistics**	Displays IPv4 statistics of the flow platform.
Ruijie#**show ip fpm users**	Displays the number of IPv4 user connections of the flow platform.
Ruijie#**clear ipv6 fpm flows**	Clears the IPv6 flow table of the flow platform.
Ruijie#**clear ipv6 fpm statistics**	Clears IPv6 statistics of the flow platform.

Ruijie(config)**ipv6 fpm flow alert interval** *seconds*	Configures the IPv6 flow overflow alarm interval of the flow platform.
Ruijie(config)**ipv6 fpm flow alert threshold** *percent-value*	Configures the IPv6 flow overflow alarm threshold of the flow platform.
Ruijie(config)**ipv6 fpm flow max-entries** *flow-number*	Configures the maximum number of flow entries in the IPv6 flow table.
Ruijie(config)**ipv6 fpm frq** *queue-number*	Configures the number of concurrent IPv6 fragment reassembly queues.
Ruijie(config)**ipv6 fpm session filter** *acl-name*	Protects the IPv6 flow table against attacks.
Ruijie#**show ipv6 fpm statistics**	Displays IPv6 statistics of the flow platform.
Ruijie#**show ipv6 fpm statistics fragment**	Displays IPv6 fragment reassembly statistics of the flow platform.
Ruijie#**show ipv6 fpm flows** [**filter** *protocol-number src-ip dst-ip*]	Displays the IPv6 flow table.

Configuration Examples

Example of IPv4 Configuration of the Flow Platform

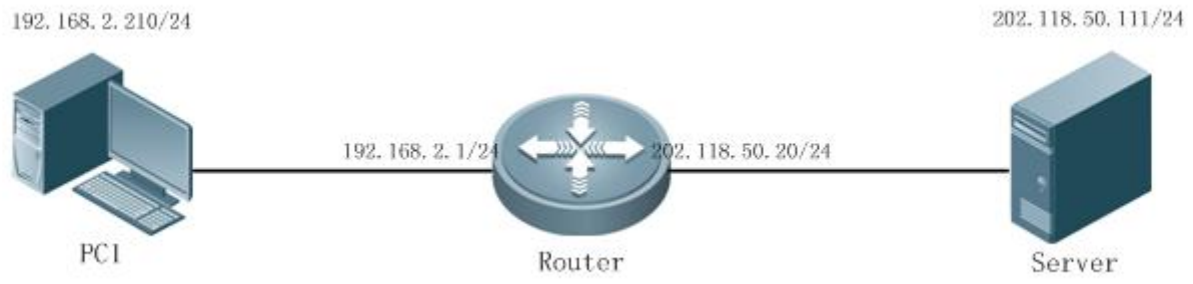
Networking Requirements

As shown in Figure 1-1, a router is connected to a PC and a server. Configure the ACL function on the router to implement the following functions:

- Enable the flow platform on the router.
- Adjust the maximum number of flow entries in the IPv4 flow table of the flow platform on the router.
- Protect the IPv4 flow table on the router by allowing flow establishment for only IP packets from the network segment 192.168.2.0/24 instead of packets from other network segments.
- Configure the IPv4 flow overflow alarm interval as 30s and the IPv4 flow overflow alarm threshold as 80% on the router.

Networking Topology

Figure 1-1 Example of IPv4 Configuration of the Flow Platform



Configuration Tips

None.

Configuration Steps

- Apply the ACL function to the loopback interface on the router to enable the flow platform.

```
Ruijie # configure terminal

Ruijie(config)# ip access-list standard 1

Ruijie(config-std-nacl)# permit any

Ruijie(config-std-nacl)# exit

Ruijie(config)# interface Loopback 0

Ruijie(config-if-Loopback 0)# ip access-group 1 in

Ruijie(config-if-Loopback 0)# exit
```

- Configure the maximum number of flow entries in the IPv4 flow table as 100,000.

```
Ruijie(config)#  ip fpm flow max-entries 100000

FPM subsystem is reinitializing...

Ruijie(config)#*Oct  6 17:35:21: %FPM-5-RESTARTED: The device IPv4 flow max-entries changed.
```

- Configure an ACL numbered 2 on the router so as to protect the IPv4 flow table against attacks.

```
Ruijie(config)#  ip access-list standard 2

Ruijie(config-std-nacl)# permit 192.168.2.0 0.0.0.255
Ruijie(config-std-nacl)# exit

Ruijie(config)# ip fpm session filter 2
```

- Configure the IPv4 flow overflow alarm interval as 30s and the IPv4 flow overflow alarm threshold as 80% on the router.

```
Ruijie(config)# ip fpm flow alert interval 30

Ruijie(config)# ip fpm flow alert threshold 80
```

Verification

Run the **ping 202.118.50.111 ntimes 1** command on PC 1.

```
C:\>ping 192.168.50.1 -n 1

Pinging 202.118.50.111 with 32 bytes of data:

Reply from 202.118.50.111: bytes=32 time=1ms TTL=64

Ping statistics for 202.118.50.111:

   Packets: Sent = 1, Received = 1, Lost = 0 (0% loss),

Approximate round trip times in milli-seconds:

   Minimum = 1ms, Maximum = 1ms, Average = 1ms
```

Run the **show ip fpm flows** command on the router. A flow entry is generated during the ping operation.

Construct a packet with a source IP address in another network segment on PC 1, and send the packet to 202.118.50.111. No corresponding flow entry can be seen in the flow table on the router.

Example of IPv6 Configuration of the Flow Platform

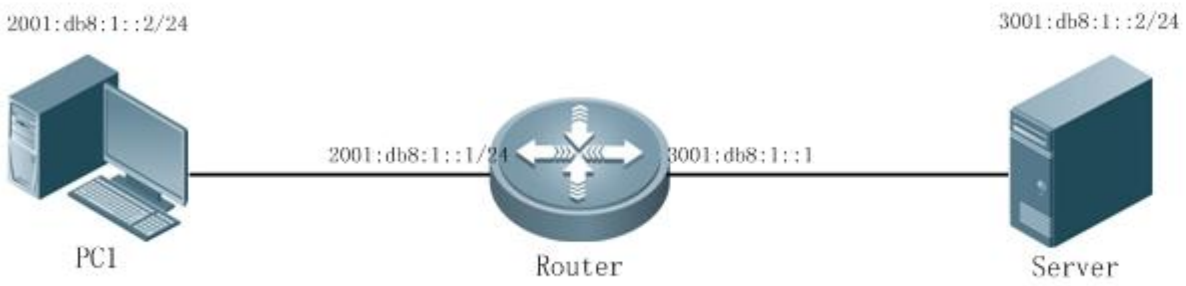
Networking Requirements

As shown in Figure 1-2, a router is connected to a PC and a server. Configure the ACL function on the router to implement the following functions:

- Enable the flow platform on the router.
- Adjust the maximum number of flow entries in the IPv6 flow table of the flow platform on the router.
- Protect the IPv6 flow table on the router by allowing flow establishment for only IP packets from the network segment 2001:db8:1::2/64 instead of packets from other network segments.
- Configure the IPv6 flow overflow alarm interval as 30s and the IPv6 flow overflow alarm threshold as 80% on the router.

Networking Topology

Figure 2-1 Example of IPv6 Configuration of the Flow Platform



Configuration Tips

None

Configuration Steps

2) Apply the ACL function to the loopback interface on the router to enable the flow platform.

```
Ruijie # configure terminal

Ruijie(config)# ip access-list standard 1

Ruijie(config-std-nacl)# permit any

Ruijie(config-std-nacl)# exit

Ruijie(config)# interface Loopback 0

Ruijie(config-if-Loopback 0)# ip access-group 1 in

Ruijie(config-if-Loopback 0)# exit
```

aa. Configure the maximum number of flow entries in the IPv6 flow table as 100,000.

```
Ruijie(config)# ipv6 fpm flow max-entries 100000

FPM subsystem is reinitializing...

Ruijie(config)#*Oct  6 17:35:21: %FPM-5-RESTARTED: The device IPv6 flow max-entries changed.
```

bb. Configure an IPv6 ACL named "virus_filter" on the router to protect the IPv6 flow table against attacks.

```
Ruijie(config)# ipv6 access-list virus_filter
Ruijie(config-ipv6-acl)# permit ipv6 2001:db8:1::/64 any

Ruijie(config-ipv6-acl)# permit icmp 2001:db8:1::/64 any

Ruijie(config)# ipv6 fpm session filter virus_filter
```

cc. Configure the IPv6 flow overflow alarm interval as 30s and the IPv6 flow overflow alarm threshold as 80% on the router.

```
Ruijie(config)# ipv6 fpm flow alert interval 30

Ruijie(config)# ipv6 fpm flow alert threshold 80
```

Verification

Run the **ping 3001:db8:1::2 ntimes 1** command on PC 1.

```
Ruijie#ping 3001:db8:1::2 ntimes 1

Sending 1, 100-byte ICMP Echoes to 3001:db8:1::2, timeout is 2 seconds:

  < press Ctrl+C to break >

!

Success rate is 100 percent (1/1), round-trip min/avg/max = 10/10/10 ms
```

Run the **show ipv6 fpm flows** command on the router. A flow entry is generated during the ping operation.

Construct a packet with a source IP address in another network segment on PC 1, and send the packet to 3001:db8:1::2. No corresponding flow entry can be seen in the flow table on the router.

Interface Configuration

Configuring Interfaces

Interface Overview

RSR series devices supports two types of interfaces: physical interfaces and logical interfaces. A physical interface is an interface that has a corresponding physical hardware port on the device.

A logical interface is an interface that has no corresponding physical hardware port on the device. A logical interface can be associated with a physical interface or independent of a physical interface. For example, dialer interfaces, Null interfaces, loopback interfaces, and sub-interfaces are logical interfaces. For network protocols, physical interfaces and logical interfaces are treated in the same way.

Ruijie series devices support the following types of interfaces:

Interface Type	Interface Configuration Name	Standard Compliance
Fast Ethernet interface	GigabitEthernet Aggregateport	IEEE802.3, RFC894
E1/CE1 port	E1	G.775, G.704, G.706, G.732
Dialer interface	dialer	—
Loopback interface	Loopback	—
NULL interface	NULL	—
Sub-interface	Serial0.1 (example)	—

Configuring Common Interfaces

Entering Interface Configuration Mode

Before you configure an interface, use the following commands to first enter global configuration mode and then enter interface configuration mode.

Command	Function
Ruijie(config)# **interface** *interface-type interface-number*	Creates an interface and enters interface configuration mode.
Ruijie(config)# **no interface** *interface-type interface-number*	Deletes the specified interface.

For example, to enter port 0 of slot 0 of the Fast Ethernet, perform the following steps:

```
Ruijie# config terminal
Ruijie(config)# interface FastEthernet 0/0
```

Note For the names of various interface types, see the interface type table above.

Note For a Ethernet port, the interface number consists of a slot number and a port number.

Note For E1/CE1 interfaces, the interface number consists of a slot number, port number and a channel number. For example, the first channel group of the third port of the E1/CE1 module in slot 2 is represented as serial 2/3:1.

Note Some interfaces have features. When you create and enter such an interface, you can specify its features. For example, to enter the frame relay point-to-point sub-interface, use the interface serial 1/0.1 point-to-point command.

Configuring IP Addresses

Except the NULL interface, every interface has its own IP address. Therefore, you must configure an IP address for an interface before you use the interface.

Use the following commands to configure or delete the IP address of an interface.

Command	**Function**
Ruijie(config-if)# **ip address** *ip-address ip-mask*	Configures the IP address of an interface.
Ruijie(config-if)# **no ip address**	Deletes the IP address of the interface.

For the details about IP address configuration, see the related chapter in the *IP Address and Service Configuration Guide*.

Configuring Interface Descriptions

Interface descriptions are used to identify interfaces.

Use the following commands to configure an interface description in interface configuration mode.

Command	**Function**
Ruijie(config-if)# description *interface-description*	Describes the purpose of the specified interface, which is a string of up to 80 characters.
Ruijie(config-if)# no description	Deletes the description of the interface.

Setting the Maximum Transmit Unit (MTU)

The MTU is a feature of IP packets. It ranges from 64 to 65535 bytes depending on the interface type. Use the following commands to set the MTU.

Command	Function
Ruijie(config-if)# **mtu** *bytes*	Configures the MTU size.
Ruijie(config-if)# **no mtu**	Restores the default value of the MTU.

Configuring Bandwidth

The bandwidth is used for some routing protocols such as OSPF to calculate the route metric and for RSVP to calculate the reserved bandwidth. Modifying the interface bandwidth will not affect the data transmission rate of the physical interface.

Use the following commands to configure the bandwidth of an interface in interface configuration mode.

Command	Function
Ruijie(config-if)# **bandwidth** *kilobits*	Configures the bandwidth
Ruijie(config-if)# **no bandwidth**	Removes the settings of the bandwidth.

Configuring the Queue Size on an Interface

The Hold-Queue allows you to modify the size of the incoming and outgoing queues of each interface. This parameter can adjust the ability of the interface to process burst data.

Use the following commands to configure the size of the incoming and outgoing queues of an interface in interface configuration mode.

Command	Function
Ruijie(config-if)# **Hold-Queue l***ength* {**in** | **out**}	Configures the size of the incoming and outgoing queues of an interface.
Ruijie(config-if)# **no Hold-Queue**	Removes the settings.

However, adjusting the size of the incoming and outgoing queues of the interface will increase network delay, which may affect real-time interactive applications. Unless necessary, it is not recommended that you modify the sizes of queues on an interface.

Monitoring and Maintaining Interfaces

Monitoring the Status of the Interface and Controller

Command	Function
Ruijie# **show interface** [**FastEthernet** | …]	Shows the transmission feature and protocol feature of the interface.

The states of the interfaces encapsulated with different link layer protocols may have some different contents when shown. See the *WAN Protocol Configuration Guide* for the monitoring and maintaining commands of various WAN protocols. For example, when the interface is encapsulated with frame relay, the **show interface serial** *2/0* command will show interface information about frame relay.

Clearing and Resetting Interface Counters

The statistics on the interface vary with the change of communication. Sometimes, to avoid the interference of communication statistics, you need to clear the statistics of the interface, so that the current statistics can faithfully reflect the current communication state of the interface.

Command	Function
Ruijie# Clear counters [**FastEthernet**] | …	Clears the communication statistics counter of the interface shown by using the show interface command to 0.
Ruijie# **Clear interface** [**FastEthernet**] | …	Clears all state values of an interface.

For example, before you use the **clear counter** command, use the **show interface serial *1/0*** command to show information about the interface:

```
Ruijie# show interface serial 1/0
serial 1/0 is DOWN  , line protocol is DOWN
Hardware is Infineon DSCC4 PEB20534 H-10 serial
Interface address is: 192.168.10.10/24
MTU 1500 bytes, BW 2000 Kbit
Encapsulation protocol is PPP, loopback not set
Keepalive interval is 10 sec , set
Carrier delay is 2 sec
RXload is 1 ,Txload is 1
LCP Closed
Closed: ipcp
Queueing strategy: WFQ
5 minutes input rate 0 bits/sec, 0 packets/sec
5 minutes output rate 0 bits/sec, 0 packets/sec
1425 packets input, 22800 bytes, 0 no buffer
Received 0 broadcasts, 0 runts, 0 giants
0 input errors, 0 CRC, 0 frame, 0 overrun, 0 abort
1425 packets output, 22800 bytes, 0 underruns
0 output errors, 0 collisions, 2 interface resets
6 carrier transitions
V35 DTE cable
DCD=down  DSR=down  DTR=up  RTS=up  CTS=down
Ruijie# clear counter serial 1/0
```

Then, use the **show interface** command to show information about the interface:

```
Ruijie# show interface serial 1/0
serial 1/0 is DOWN  , line protocol is DOWN
Hardware is Infineon DSCC4 PEB20534 H-10 serial
Interface address is: 192.168.10.10/24
MTU 1500 bytes, BW 2000 Kbit
Encapsulation protocol is PPP, loopback not set
```

```
Keepalive interval is 10 sec , set
Carrier delay is 2 sec
RXload is 1 ,Txload is 1
LCP Closed
Closed: ipcp
Queueing strategy: WFQ
5 minutes input rate 0 bits/sec, 0 packets/sec
5 minutes output rate 0 bits/sec, 0 packets/sec
0 packets input, 0 bytes, 0 no buffer
Received 0 broadcasts, 0 runts, 0 giants
0 input errors, 0 CRC, 0 frame, 0 overrun, 0 abort
0 packets output, 0 bytes, 0 underruns
0 output errors, 0 collisions, 0 interface resets
0 carrier transitions
V35 DTE cable
DCD=down  DSR=down  DTR=up  RTS=up  CTS=down
```

Shutting Down and Restarting the Interface

When necessary, the interface must be shut down, for example, when you replace the cables on the interface and then restart the interface. The **shutdown** command allows you to shut down an interface, while the **no shutdown** command allows you to restart the interface.

Interface Configuration Example

Enabling an Interface

The following example configures a serial port to run PPP.

```
Ruijie(config)# interface serial 1/0
Ruijie(config-if)# encapsulation ppp
```

Configuring an Interface Description

The following example configures the function description of an Ethernet interface.

```
Ruijie(config)# interface FastEthernet 0/0
Ruijie(config-if)# description Gateway_of_translation
Ruijie(config-if)# ip address 192.168.12.1 255.255.255.0
```

Shuting Down an Interface

If an interface is idle, you can shut down it, as shown in the following example.

```
Ruijie(config)# Interface serial 1/0
Ruijie(config-if)# shutdown
```

Configuring Ethernet Interfaces

Configuring Ethernet Interfaces

Entering Ethernet Interface Configuration Mode

Use the following commands to enter Ethernet interface configuration mode in global configuration mode.

Command	Function
Ruijie(Config)# **interface GIgabitethernet** *interface-number*	Enters Gigabit Ethernet interface configuration mode.

Configuring the IP Address

Use the following commands to configure the IP address of an Ethernet interface in interface configuration mode.

Command	Function
Ruijie(Config-if)# **ip address** *ip-address ip-mask* [secondary]	Configures the IP address and its mask.
Ruijie(Config-if)# **no ip address** *ip-address ip-mask* [secondary]	Removes the settings.

Ethernet interfaces support multiple IP addresses, with the Secondary keyword used to identify the other IP addresses.

Configuring the MAC Address

Each Ethernet interface has a globally unique MAC address by default. If necessary, you can modify the MAC address of an Ethernet interface, provided that the MAC address is unique in the same LAN.

Use the following commands to configure the MAC address of an Ethernet interface in interface configuration mode.

Command	Function
Ruijie(Config-if)# **mac-address** *mac-address*	Configures the MAC address.
Ruijie(Config-if)# **no mac-address**	Removes the configured MAC address.

MAC address settings may affect communication inside the LAN. Therefore, it is not recommended that you configure an MAC address on your own unless really necessary.

Monitoring the Ethernet Interface Status

Use the following commands to monitor the Ethernet interface status.

Command	Function

Command	Function
Ruijie# **show interface GigabitEthernet** *interface-number*	Shows the status of a Gigabit Ethernet interface .

The following example shows the status of a Gigabit Ethernet interface:

```
Ruijie# show interface GigabitEthernet 0/0
GigabitEthernet0/0 is up, line protocol is up
Hardware is PQ3 TSEC GIGABIT ETHERNET CONTROLLER GigabitEthernet, address is 0a0b.0c0d.0e0e
(bia 0a0b.0c0d.0e0e)
Internet address is 192.168.200.1/24
MTU 1500 bytes, BW 1000000 Kbit
Encapsulation protocol is Ethernet-II, loopback not set
Keepalive interval is 10 sec, set
Carrier delay is 2 sec
RXload is 1 ,Txload is 1
Queueing strategy: FIFO
Output queue 0/40, 0 RSRps;
Input queue 0/75, 0 RSRps
5 minutes input rate 281 bits/sec, 0 packets/sec
5 minutes output rate 0 bits/sec, 0 packets/sec
82 packets input, 7947 bytes, 0 no buffer
Received 76 broadcasts, 0 runts, 0 giants
0 input errors, 0 CRC, 0 frame, 0 overrun, 0 abort
0 packets output, 0 bytes, 0 underruns
0 output errors, 0 collisions, 3 interface resets
Link Mode: 1000M/Full-Duplex, media-type is twisted-pair.
Output flowcontrol is off;Input flowcontrol is off.
```

Clearing and Resetting the Ethernet Interface

Use the following commands to clear and reset the internal counters of an Ethernet interface.

Command	Function
Ruijie# **clear counters GigabitEthernet** *interface-number*	Clears and resets the internal counters of a Gigabit interface.

Ethernet Interface Configuration Example

The Ethernet interface configuration is very simple. The basic task is to configure the IP address of the interface. For others, you can often accept the factory defaults. For example:

```
Ruijie# config terminal
Ruijie(config)# interface fastEthernet 0/0
Ruijie(config-if)# ip address 192.168.12.1 255.255.255.0
Ruijie(config-if)# no shutdown
```

Configuring VLANs

The Virtual Local Area Network (VLAN), a logical network subdivided from a physical network, is a Layer 2 network in the ISO model. IEEE published the 802.1Q draft in 1999 to standardize VLAN implementation.

The VLAN technology allows the network administrator to split a physical LAN into different broadcast areas (or called VLANs) logically. Each VLAN consists of a group of computer workstations with the same needs. So they have the same features as the physical LAN. However, since VLANs are defined logically but not physically, the workstations in a VLAN do not need to be configured in the same physical space. In other words, these workstations do not necessarily belong to the same physical LAN network segment. The broadcast and unicast traffic in a VLAN will not be forwarded to other VLANs, which can facilitate flow control, reduce equipment investment, simplify network management, and improve network security.

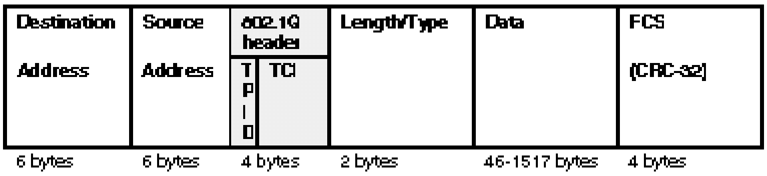
The VLAN is a protocol originated to solve the Ethernet broadcast problem and security. On the basis of Ethernet frames, a VLAN header is added and a VLAN ID is used to assign users into smaller work groups to restrict the mutual access on L2 between different workgroups. Each workgroup is a VLAN. The VLAN allows you to restrict the broadcast range and form a virtual workgroup for dynamic network management.

802.1Q

For details about 802.1Q, see the protocol specification. This section only briefly describes the 802.1Q frame format for your reference.

As shown in 0, when a host supporting 802.1Q sends a packet, it adds a 4-byte 802.1Q frame header before the source address of the old Ethernet frame header, followed by the Length or Type field of the old Ethernet frame.

Figure 2-1 Ethernet Frame with the 802.1Q Tag Header



Destination Address	Source Address	802.1Q header		Length/Type	Data	FCS (CRC-32)
		TPID	TCI			
6 bytes	6 bytes	4 bytes		2 bytes	46-1517 bytes	4 bytes

This 4-byte 802.1Q tag header consists of a 2-byte TPID (Tag Protocol Identifier, with the value of 0x8100) and a 2-byte TCI (Tag Control Information). The TPID is a new type defined by IEEE and it indicates that the packet has been added with the 802.1Q tag. 0 shows details about the 802.1Q tag header.

Figure 2-2 802.1.1Q Tag Header

TPID (Tag Protocol Identifier)		TCI		
0x81	0x00	P	C	VLAN ID

31 23 15 12 0

The information in the tag header is described as below:

VLAN Identified (VLAN ID): This is a 12-bit field, which specifies the ID of the VLAN, totally 4096. Each packet supporting 802.1Q from the host contains this field to indicate that it belongs to which VLAN.

Canonical Format Indicator (C): This bit specifies T-R encapsulation, used for compatibility with the token network, so that the data of the token network can be normally transmitted over the Ethernet without conversion.

Priority (P): It is a 12-bit field that specifies the priority of the frame. There are totally eight priorities, used to select the packets first to be sent when the device is in congestion.

On a network divided with VLANs, devices can forward data, and implement traffic control and broadcast management between VLANs.

Configuring the VLAN Encapsulation Tag

Use the following commands to configure the VLAN encapsulation tag.

Command	Function
Ruijie(config)# **interface FastEthernet** *Sub_interface_number*	Enters or creates an 802.1Q encapsulated sub-interface.
Ruijie((config-subif))# **encapsulation dot1Q** *VlanID*	Encapsulates 802.1Q and specifies a VLAN ID, where the VLANID must be the same as one of the VLAN IDs on the device.

The VLAN ID is in the range from 1 to 4094.

Note Be sure to use the proper port of RSR series routers to connect the VLAN native-enabled devices of other vendors.

Assigning IP Addresses to Interfaces

After you encapsulate the VLAN tag, you must specify the IP address for the Ethernet sub-interface encapsulated with the VLAN tag.

Use the following commands to configure the IP address of an interface in sub-interface configuration mode.

Command	Function
Ruijie((config-subif))# **ip address** *ip-address mask*	Specifies the IP address of an interface.

The IP address of the Ethernet interface encapsulated with 802.1Q is usually the gateway through which the hosts in the VLAN are connected with the hosts in another VLAN.

Debugging and Monitoring VLANs

Use the following commands to debug and monitor the VLAN in privileged user mode.

Command	Function
Ruijie# **debug vlan**	Enables VLAN encapsulation event debugging .

Command	Function
Ruijie# **no debug vlan**	Disables VLAN encapsulation event debugging.
Ruijie# **show vlans** [*VlanID*]	Shows VLAN statistics.
Ruijie# **clear vlan** [*VlanID*]	Clears VLAN statistics.

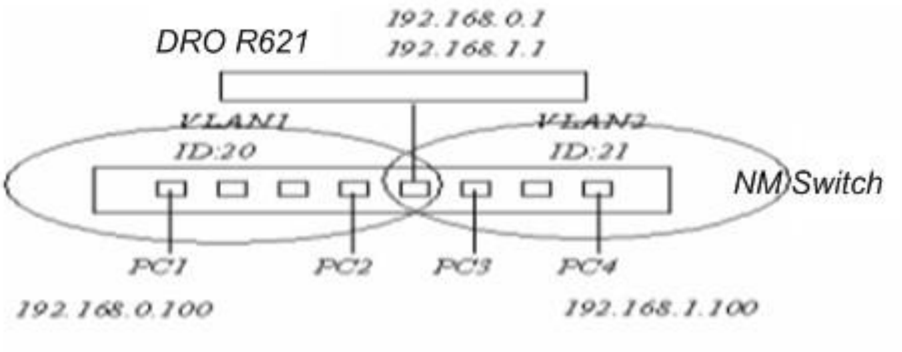
VLAN Configuration Example

Configuration Requirements

Set two VLANs on the VLAN-supported network mangement device:

1. One VLAN is connected to hosts in the 192.168.0.0/24 network segment, and the other VLAN is connected to hosts in the 192.168.1.0/24 network segment.

2. The Ethernet port of the device is encapsulated with 802.1Q to serve as a gateway for mutual communication between hosts in the two VLANs, as shown in the following figure:



Equipment Configuration

Equipment configuration:

```
hostname "Ruijie"
!
interface FastEthernet0/0
no ip address
!
interface FastEthernet0/0.20
encapsulation dot1Q 20                  //Configure 802.1Q encapsulation, with the VlANID as
20
ip addr 192.168.0.1 255.255.255.0       //Configure the IP address of the sub-interface
!
interface FastEthernet0/0.21
encapsulation dot1Q 21                  //Configure 802.1Q encapsulation, with the VlANID as
21
ip addr 192.168.1.1 255.255.255.0       //Configure the IP address of the sub-interface
```

```
!
interface FastEthernet0/1
no ip address
shutdown
!
```

End

Configuring WAN Interfaces

Configuring CE1 Interfaces

CE1 Interface Overview

The CE1 interface works in two modes: E1 and CE1.

E1 working mode: timeslot division does not apply. It is equivalent to an interface whose data bandwidth is 2.048 Mbit/s. In this mode, the CE1 interface supports multiple encapsulation protocols, including PPP, Frame Relay, X.25, HDLC and LAPB.

CE1 working mode: It is the channelized timeslot working mode, where the 2.048 Mbit/s bandwidth is divided into 8K frames per second. Each CE1 frame has 256 bits, and is further divided into 32 timeslots, so each timeslot has 8 bits. The 32 timeslots are identified as 0-31. Among them, timeslot 0 is used to transmit CE1 frame synchronization signals, and timeslots 1-31 are used to transmit data. Accordingly, you can configure up to 31 channel groups, whose numbers are 0-30. Each channel group is effective when one to 31 timeslots are configured. A timeslot may be idle or assigned to a channel group, but cannot be assigned to multiple channel groups. A channel group assigned with timeslots is a logical interface. Its bandwidth is the number of occupied timeslots multiplexed by 64 kbit/s. It supports multiple encapsulation protocols, including PPP, Frame Relay, X.25, HDLC and LAPB.

Configuring CE1 Interfaces

Entering CE1 Interface Configuration Mode

Command	Function
Ruijie(config)# **controller e1** *slot-number / port-number*	Enters CE1 interface configuration mode.

Setting the Timeslot Allocation Mode of the CE1 Interface

Use the **channel-group** command to set the timeslot configuration mode (provided that the interface works in CE1 mode) in CE1 interface configuration mode.

Command	Function
Ruijie(config-controller)# **channel-group** *chan-num* **timeslots** *timeslot-range*	Allocates the specified timeslot range (timeslot numbers within 1-31, not necessarily continuous) to the specified channel group (channel group numbers within 0-30).
Ruijie(config-controller)# **no channel-group** *chan-num*	Removes the configuration.

After you use the above command to allocate the timeslots to a channel group, the system generates a logical interface, for example:

```
Ruijie(config)# controller e1 1/1/0
Ruijie(config-controller)# channel-group 0 timeslots 1-2 4
```

The logical interface serial 1/1/0:0 is generated.

Setting the Channel-Group Working Parameters

Command	Function
Ruijie(config)# **interface serial** *slot-number / port-number:chan-num*	Enters the logical interface configuration mode of the specified channel group.

Setting the Sync Clock Source

When two CE1 interfaces are directly connected, you must specify the synchronous clock source. When one CE1 interface provides the synchronous clock, the other CE1 interface obtains the clock from the data reception line as the synchronous clock for the reception/transmission of the local data. When the CE1 interface is connected with the device, usually the switch provides the synchronous clock.

Command	Function
Ruijie(config-controller)# **clock source** { **line** | **internal** }	Sets the sync clock source of the CE1 interface.
Ruijie(config-controller)# **no clock source**	Restores the default sync clock source of the CE1 interface.

The default sync clock source of the CE1 is *line*.

Setting the Frame Check Mode

When the CE1 interface works in CE1 mode, the 4-bit CRC of the physical frames is supported.

Command	Function
Ruijie(config-controller)#**framing** { **crc4** | **no-crc4** }	Sets the frame check mode of the CE1 interface.
Ruijie(config-controller)#**no framing**	Restores the default frame check mode of the CE1 interface.

The default frame check mode of the CE1 interface is CRC4.

Setting the Line Coding/Decoding Mode

The CE1 interface supports two line coding/decoding modes:

- AMI mode
- HDB3 mode

Command	Function

Command	Function
Ruijie(config-controller)# **linecode** { **ami** | **hdb3** }	Sets the line coding/decoding mode of the CE1 interface.
Ruijie(config-controller)# **no linecode**	Restores the default line coding/decoding mode of the CE1 interface.

The default line coding/decoding mode of the CE1 interface is HDB3.

Enabling or Disabling Local Loopback

Command	Function

Ruijie(config-controller)# **loopback** { **local** }
or
Ruijie(config-controller)# **loopback { local | network** }
	Enables local loopback of the CE1 interface.

Ruijie(config-controller)# **no loopback**	Disables local loopback of the CE1 interface.

By default, the local loopback of the CE1 interface is disabled.

Setting the E1 or CE1 Working Mode

The CE1 interface can work in E1 or CE1 working mode.

Command	Function
Ruijie(config-controller)# **using** { **ce1** | **e1** }	Set sthe CE1 or E1 working mode.
Ruijie(config-controller)# **no using**	Restores the default working mode.

The default working mode is CE1.

Setting the E1 Working Parameters

When the CE1 interface works in E1 mode, the system automatically generates an E1 logical interface *serial slot-number/port-number:0*.

Command	Function
Ruijie(config)# **interface serial** *slot-number/port-number: 0*	Enters the configuration mode of the specified E1 logical interface.

Monitoring and Maintaining CE1 Interfaces

Ruijie products provide the **show controller e1** command for monitoring and maintaining the CE1 interface. The **show interface** command allows you to monitor and maintain the channel group and E1 logical interface.

Command	Function
Ruijie# **show controller e1** [*slot-number/port-number*]	Shows the related status information about the (specified) CE1 interface.

Command	Function
Ruijie# **show interface serial** *slot-number/port-number:chan-num*	Shows the status information about the specified channel-group logical interface.
Ruijie# **show interface serial** *slot-number/port-number:0*	Shows the status information about the specified E1 logical interface.

Example 1: Show the status information about all CE1 interfaces.

```
Ruijie# show controller e1
E1 1/1/0 is down.
Applique type is Channelized E1 - balanced
Receiver has no alarms.
Framing is crc4, Line Code is hdb3, Clock Source is line
Data in current interval (514 seconds elapsed):
0 Line Code Violations, 0 Path Code Violations
0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
Total Data (last 2 fifteen minute intervals):
0 Line Code Violations, 0 Path Code Violations
0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
E1 1/1/1 is down.
Applique type is Channelized E1 - balanced
Receiver has no alarms.
Framing is crc4, Line Code is hdb3, Clock Source is line
Data in current interval (514 seconds elapsed):
0 Line Code Violations, 0 Path Code Violations
0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
Total Data (last 2 fifteen minute intervals):
0 Line Code Violations, 0 Path Code Violations
0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
Applique type is Channelized E1 - balanced
Receiver has no alarms.
Framing is crc4, Line Code is hdb3, Clock Source is line
Data in current interval (514 seconds elapsed):
0 Line Code Violations, 0 Path Code Violations
0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
Total Data (last 2 fifteen minute intervals):
0 Line Code Violations, 0 Path Code Violations
0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
```

```
E1 1/1/3 is down.
Applique type is Channelized E1 - balanced
Receiver has no alarms.
Framing is crc4, Line Code is hdb3, Clock Source is line
Data in current interval (514 seconds elapsed):
0 Line Code Violations, 0 Path Code Violations
0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
Total Data (last 2 fifteen minute intervals):
0 Line Code Violations, 0 Path Code Violations
0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
```

Example 2: Show the status information about the specified CE1 interface.

```
Ruijie# show controller e1 1/0
E1 1/0 is down.
Applique type is Channelized E1 - balanced
Receiver has no alarms.
Framing is crc4, Line Code is hdb3, Clock Source is line
Data in current interval (615 seconds elapsed):
0 Line Code Violations, 0 Path Code Violations
0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
Data in Interval 1:
0 Line Code Violations, 0 Path Code Violations
0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
Data in Interval 2:
0 Line Code Violations, 0 Path Code Violations
0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
Total Data (last 2 fifteen minute intervals):
0 Line Code Violations, 0 Path Code Violations
0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
```

The above infomration includes the physical status, working mode, frame check mode, line coding/decoding mode and sync clock source of the specified CE1 interface. It also includes statistics in the past 24 hours and every 15 minutes, as well as overall statistics.

Example 3: Show the status information about the specified channel-group logical interface.

```
Ruijie# show interface serial 1/1/0:0
serial 1/1/0:0 is DOWN  , line protocol is DOWN
Hardware is  serial
Interface address is: no ip address
```

```
MTU 1500 bytes, BW 192 Kbit
Encapsulation protocol is HDLC, loopback not set
Keepalive interval is 10 sec , set
Carrier delay is 2 sec
RXload is 1 ,Txload is 1
Queueing strategy: WFQ
5 minutes input rate 0 bits/sec, 0 packets/sec
5 minutes output rate 0 bits/sec, 0 packets/sec
0 packets input, 0 bytes, 0 no buffer
Received 0 broadcasts, 0 runts, 0 giants
0 input errors, 0 CRC, 0 frame, 0 overrun, 0 abort
0 packets output, 0 bytes, 0 underruns
0 output errors, 0 collisions, 0 interface resets
Timeslot(s) Used:1-2,4, Transmitter delay is 0 flags
```

Example 4: Show the status information about the specified E1 logical interface.

```
Ruijie# show interface serial 1/1/1:0
serial 1/1/1:0 is DOWN  , line protocol is DOWN
Hardware is  serial
Interface address is: no ip address
MTU 1500 bytes, BW 2000 Kbit
Encapsulation protocol is HDLC, loopback not set
Keepalive interval is 10 sec , set
Carrier delay is 2 sec
RXload is 1 ,Txload is 1
Queueing strategy: WFQ
5 minutes input rate 0 bits/sec, 0 packets/sec
5 minutes output rate 0 bits/sec, 0 packets/sec
0 packets input, 0 bytes, 0 no buffer
Received 0 broadcasts, 0 runts, 0 giants
0 input errors, 0 CRC, 0 frame, 0 overrun, 0 abort
0 packets output, 0 bytes, 0 underruns
0 output errors, 0 collisions, 0 interface resets
Timeslot(s) Used:0-31, Transmitter delay is 0 flags
```

The above information includes the physical status, link status, encapsulation mode, received and sent packet statistics, and timeslot occupation of the channel-group or E1 logical interface.

Configuration Examples

CE1 Configuration Examples

The following example configures the E1 interface as channelized E1 (CE1) and divides two channels: channel 1 and channel 8, where channel 1 occupies timeslots 1, 2, 3, 7, and 19, while channel 8 occupies timeslots 8, 9, 10, 11, 20, and 30. The line clock (default) is used and the line coding mode is HDB3 (default). The specific configuration is shown as follows:

```
Ruijie(config)# controller E1 1/2/0
Ruijie(config)# using ce1          //Default configuration; configured only when using e1 is currently used
Ruijie(config-controller)# channel-group 1 timeslots 1-3,7,19
Ruijie(config-controller)# channel-group 8 timeslots 8-11,20,30
```

After configuration, the following logical interfaces are created:

```
interface serial 1/2/0:1
interface serial 1/2/0:8
```

E1 Configuration Examples

To configure the E1 interface as a pure E1 interface which is not divided into timeslots, first clear the CE1 configuration, that is, clear the 31 timeslots, and then set the interface to the pure E1 working mode. For example, the configuration operations are as below according to 3.3.5.1:

```
Ruijie(config)# controller E1 1/2/0
Ruijie(config-controller)# no channel-group 1
Ruijie(config-controller)# no channel-group 8
Ruijie(config-controller)# using e1
```

If no CE1 channel is configured before, the configuration operation is as below:

```
Ruijie(config)# controller E1 1/2/0
Ruijie(config-controller)# using e1
```

After configuration, the system generates the following logical interface:

```
interface serial 1/2/0:0
```

Troubleshooting CE1 Interfaces

The CE1 interface is often used to provide the service of access to the WAN, and its logical interface is usually encapsulated with the appropriate link layer protocol. After you verify that the physical interface and the line connection are in good connection, if the CE1 logical interface link is still interrupted, you need to debug the configuration of the logical interface and the operation of the link layer protocol. For the specific procedure, see the related link layer protocol configuration section. When the CE1 logical interface is interrupted, you must first check the following Aspects:

1. Make sure that the CE1 interfaces connected have the same working mode, for example, E1 mode or CE1 mode.

2. If both ends work in CE1 mode, ensure that the channel groups at both ends are configured the same.

3. Make sure that the two CE1 interfaces connected have the same line coding/decoding and frame check modes configured.

4. Check the sync clock sources of the CE1 interfaces at both ends. One end must provide the sync clock, and the other end must obtain the sync clock signals from the data line.

5. Make sure the logical interfaces at both ends use the same link encapsulation protocol.

6. Observe if the physical status of the CE1 interface is **UP**. If not, it means that the device at the other end is shut down or the cable connection is abnormal. Please use appropriate substitutes to locate the problem.

Configuring Aggregate Port

This chapter describes how to configure an aggregate port on a Ruijie router.

Overview

Aggregate Port

An aggregate port (AP) is a logical link formed by binding multiple physical links. The AP function provided by Ruijie routers complies with IEEE802.3ad and can be used to expand link bandwidth, thereby improving connection reliability.

The AP function supports load balancing, and therefore load can be evenly distributed to member links. The AP function also implements link backup. When a member link is disconnected, the system automatically distributes load of this link to other available member links. Broadcast or multicast packets received by a member link are not forwarded to other member links.

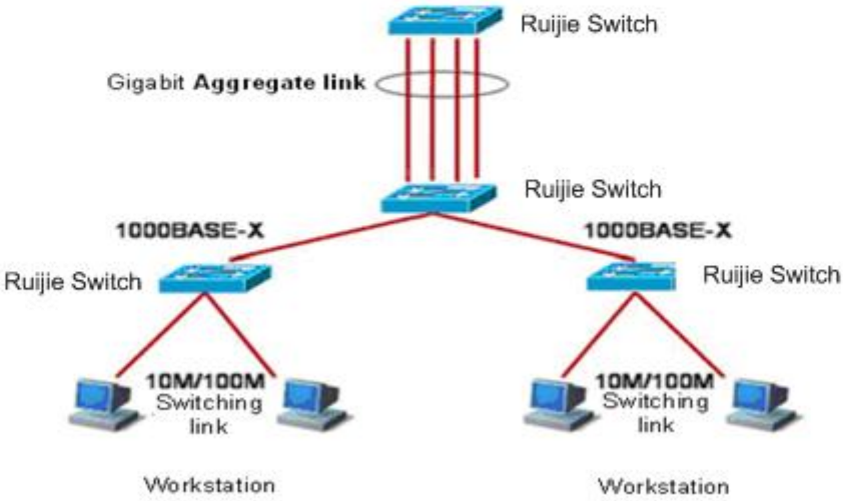


Figure 1 Typical AP configuration on a router

Each AP contains up to 8 members. The following table lists the maximum AP quantity.

Product Series	Maximum AP Quantity
RSR20-X-28	6

Load Balancing

An AP enables even load distribution to its member links based on source IP addresses, the destination IP addresses, a combination of source and destination IP addresses, or a combination of source IP addresses and destination port numbers. You can run the **aggregateport load-balance** command in interface configuration mode to set a load distribution mode.

In the load balancing mode based on source IP addresses, packets are distributed to different member links according to source IP addresses. Packets with different source IP addresses are distributed to different member links; packets with a same source IP address are forwarded along a same member link.

In the load balancing mode based on the destination IP addresses, packets are distributed to different member links according to destination IP addresses. Packets with different destination IP addresses are distributed to different member links; packets with a same destination IP address are forwarded along a same member link.

In the load balancing mode based on source and destination IP addresses, packets are distributed to different member links according to the combination of source and destination IP addresses. Packets with different source and destination IP addresses are distributed to different member links; packets with same source and destination IP addresses are forwarded along a same member link. The Layer-3 AP uses this mode by default.

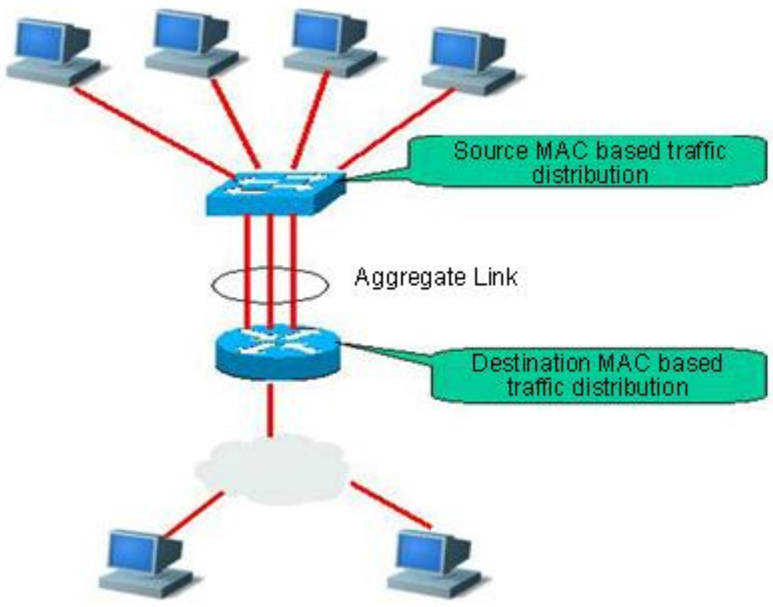
In the load balancing mode based on source IP addresses and destination port numbers, packets are distributed to different member links according to the combination of source IP addresses and destination port numbers. Packets with different source IP addresses and destination port numbers are distributed to different member links; packets with a same source IP address and destination port number are forwarded along a same member link.

All the abovementioned balancing modes are applicable to L2 and L3 APs.

Balancing Mode	**RSR20-X-28**
Source MAC-based	√
Destination MAC-based	√
Source+Destination MAC-based	√
Destination IP-based	×
Source IP-based	×
Source+Destination IP-based	×

A load distribution mode is set based on the network environment, to ensure that load can be evenly distributed to different links, so that network bandwidth can be fully utilized.

In Figure 2, PC1 and PC2 communicate with PC4 to PC6 over the AP. R1 serves as a gateway for all of PC4 to PC6. Packets from an external network (PC1 and PC2) are sent via R2 take the IP addresses of PC1 and PC2 as the source IP addresses. To distribute communication load between R2 and other hosts to other links, perform load balancing based on the source IP addresses. On R1, set the load balancing mode based on destination IP addresses.



Source MAC based traffic distribution
Aggregate Link
Destination MAC based traffic distribution

Figure 2 AP load balancing

Aggregate Port Configuration

Default Configuration

The following table lists the default configuration of the AP.

Feature	Default Value
Layer-3 AP	N/A
Layer-3 AP	N/A ☑ Layer-3 AP is not supported on RSR20-X series routers.
Load balancing	**src-ip**
LinkTrap	Disabled

Configuration Guide

Port rates of AP members must be consistent.

The Layer-3 AP supports Layer-3 ports only, and therefore layer-2 ports cannot be added to the Layer-3 AP.

Do not set a port security function for the AP.

If a port is added to an AP, properties of the port are replaced by those of the AP.

Caution When a port is added to an AP, you cannot perform any configuration on the port before removing the port from the AP.

Configuring Aggregate Port

In interface configuration mode, perform the following step to add a port to an AP.

Command	Description
Ruijie(config-if-range)# **port-group** *port-group-number*	Adds a port to an AP. If the AP does not exist, create the AP at the same time.

Run the **no port-group** command in interface configuration mode to remove a physical port from the AP.

The following example is to configure Layer-2 Ethernet port 0/1 as a member of Layer-2 AP 5.

```
Ruijie# configure terminal
Ruijie(config)# interface range gigabitEthernet 0/1
Ruijie(config-if-range)# port-group 5
Ruijie(config-if-range)# end
```

You can run the Ruijie(config)# **interface aggregateport** *n* command (n indicates the AP number) in global configuration mode to create AP *n* (supposing that AP *n* does not exist).

Caution After adding an ordinary port to an AP, when the port exits from the AP again, the previous configuration of the port will be restored to the default one. Different functions deal with the previous configuration of the AP member port differently. Therefore, it is recommended to view and confirm the port configuration after exiting from the AP.

Configuring Layer-3 Aggregate Port

By default, an AP is a Layer-3 AP.

The following example is to configure a Layer-3 AP (AP 3) and set the IP address of AP 3 to 192.168.1.1.

```
Ruijie# configure terminal
Ruijie(config)# interface aggretegateport 3
Ruijie(config-if)# ip address 192.168.1.1 255.255.255.0
Ruijie(config-if)# end
```

Caution When you run the **port-group** command to add a Layer-3 port to an AP, the operation fails if the AP does not exist. You must create the Layer-3 AP first before adding the Layer-3 port to the AP.

After the Layer-3 AP is created, you can add members to the AP. The following example is to add gigabit Ethernet 0/1-3 ports to Layer-3 AP 2.

```
Ruijie# configure terminal
Ruijie(config)# interface range gigabitEthernet 0/1-3
Ruijie(config-if)# port-group 2
```

Configuring Load Balancing for Aggregate Port

Perform the following step in global configuration mode to configure a load balancing mode for an AP.

Command	Description
Ruijie(config)# **aggregateport load-balance** {**dst-mac | src-mac | src-dst-mac | dst-ip | src-ip | src-dst-ip** }	Selects one of the following load balancing modes for the AP: **src-dst-mac**: Distributes load according to source and destination MAC addresses. **dst-mac**: Distributes load according to destination MAC addresses. **src-mac**: Distributes load according to source MAC addresses. **src-dst-ip**: Distributes load according to source and destination IP addresses. **dst-ip**: Distributes load according to destination IP addresses. **src-ip**: Distributes load according to source IP addresses.

To restore the default load balancing mode of an AP, run the **no aggregateport load-balance** command in global configuration mode.

Configuring LinkTrap for Aggregate Port

Perform the following step in global configuration mode to configure the linktrap function for the AP member port.

Command	Description
Ruijie(config)# **aggregateport member linktrap**	Enables the linktrap function for the AP member port.

To disable the linktrap function, run the **no aggregateport member linktrap** command in global configuration mode.

The following example is to enable the linktrap function for the AP member port.

```
Ruijie# configure terminal
Ruijie(config)# aggregateport member linktrap
```

Displaying Aggregate Port

Perform the following step in privileged EXEC mode to display the AP configuration.

Command	**Description**
Ruijie# **show aggregateport** [*port-number*] {**load-balance | summary**}	Displays AP configuration.

```
Ruijie# show aggregateport load-balance
Load-balance : Source MAC address
Ruijie#show aggregateport 1 summary
AggregatePort MaxPorts SwitchPort Mode   Ports
------------- -------- ---------- ------
Ag1         8       Enabled    ACCESS
```

Configuring Logical Interfaces

Unlike physical interfaces, a logical interface is an interface that can exchange data but does not exist physically or needs to be configured. Ruijie products provide the following types of logical interfaces: Loopback interfaces, NULL interfaces, dialer interfaces and sub-interfaces.

Configuring Loopback Interfaces

A loopback interface is a local interface that is completely simulated by software and is always in UP status. The packets including routing information sent to a loopback interface will be processed at the device locally. The IP address of a loopback interface can be used as the device ID of the OSPF routing protocol and for the Telnet or as the network interface for remote Telnet access. The procedure for configuring a loopback interface is similar to that for configuring an Ethernet interface, and you can take it as a virtual Ethernet interface.

Command	Function
Ruijie(config)# **interface loopback** *loopback-interface-number*	Sets a loopback interface.
Ruijie(config)# **no interface loopback** *loopback-interface-number*	Deletes a loopback interface.

After you create a loopback interface with the specified interface number by using the **interface loopback** *loopback-interface-number* command, you can configure the communication parameters of the loopback interface (such as its IP address) just like an Ethernet interface. For the specific procedure, see the section about Ethernet interface configuration.

Since a loopback interface is a virtual interface and only exists logically, you can delete it by using the **no interface loopback** *loopback-interface-number* when necessary. The system provides the **show interfaces loopback** *loopback-interface-number* command for monitoring and maintaining a loopback interface.

Command	Function
Ruijie# **show interfaces loopback** *loopback-interface-number*	Shows the status of a loopback interface.

The following example shows how to use the **show interfaces loopback** command.

```
Ruijie# show interfaces loopback 0
Loopback 0 is UP  , line protocol is UP
Hardware is  Loopback
Interface address is: no ip address
MTU 1500 bytes, BW 8000000 Kbit
Encapsulation protocol is LOOPBACK, loopback not set
Keepalive interval is 0 sec , no set
Carrier delay is 2 sec
RXload is 1 ,Txload is 1
```

```
Queueing strategy: FIFO
Output queue 0/40, 0 RSRps;
Input queue 0/75, 0 RSRps
5 minutes input rate 0 bits/sec, 0 packets/sec
5 minutes output rate 0 bits/sec, 0 packets/sec
0 packets input, 0 bytes, 0 no buffer
Received 0 broadcasts, 0 runts, 0 giants
0 input errors, 0 CRC, 0 frame, 0 overrun, 0 abort
0 packets output, 0 bytes, 0 underruns
0 output errors, 0 collisions, 0 interface resets
```

From the above information, you can know the settings and working status of the loopback interface, for example, interface and link status, IP address settings, MTU settings, and bandwidth settings.

Configuring Null Interfaces

Ruijie products provide NULL virtual interfaces. This kind of virtual interface is only equivalent to an available system device. The NULL interface is always in UP status and will never send or receive network data unsolicitedly. Any packets sent to the NULL interface will be discarded. Any attempt to encapsulate the link layer protocol on the NULL interface will fail. Not any command can be configured on the NULL interface (excluding the **help** and **exit** commands available for every interface).

The NULL interface is more often used to filter network traffic. You can route the undesired data to the NULL interface without using any ACL, as shown in the following example.

```
Ruijie(config)#ip route 127.0.0.0 255.0.0.0 null 0
```

Use the following command to configure a NULL interface.

Command	Function
Ruijie(config)# **interface nul**l *0*	Enters NULL interface configuration mode.

By functionality, the NULL interface is a null system device, so you cannot delete it by using the **no interface null** command.

Configuring Tunnel Interfaces

Tunnel Interface Overview

Ruijie products provide tunnel interfaces to implement the tunnel function by using transmission protocols like IP to transmit packets of any protocol. As with other logical interfaces, a tunnel interface is also a virtual system interface. Instead of particularly specifying any transmission protocol or load protocol, a tunnel interface provides a standard point-to-point transmission mode. Since a tunnel implements a point-to-point transmission link, a tunnel interface must be set for every individual link.

The tunnel function implementation includes the following parts:

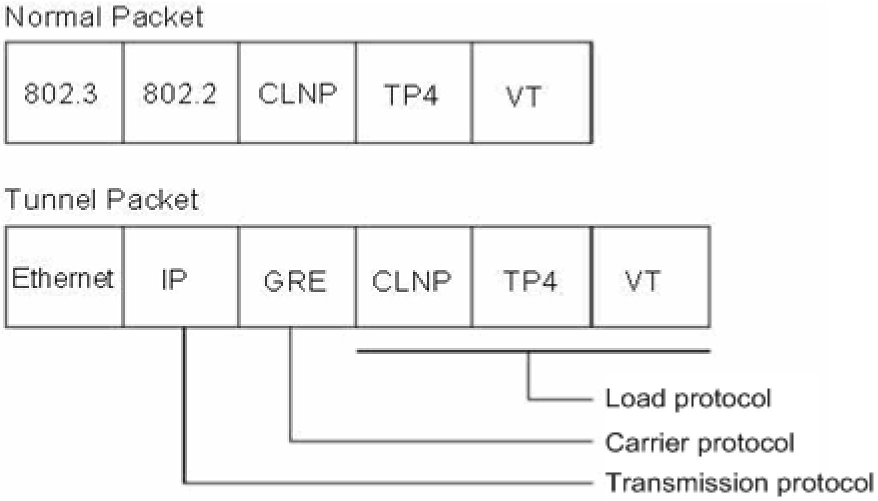
1. Load protocol: the protocol used to encapsulate data over the tunnel. Currently, Ruijie products only support the IP protocol as the load protocol on the tunnel interface.

2. Carrier protocol: the protocol used for secondary encapsulation and identification of the data to be transmitted. Ruijie products support the following encapsulation modes on the tunnel interface: GRE and IPIP.

3. Transmission protocol: network protocol of the load after the secondary encapsulation of the carrier protocol. Ruijie products use the most commonly used IP protocol as the transmission protocol.

0 shows a comparison between packets before and after transmission over the IP tunnel.

Figure 4-1 Comparison Between Packets Before and After Transmission Over the IP Tunnel



As shown in 0, IP tunnel transmission is implemented through GRE encapsulation. In fact, if two private networks running the same protocol need to communicate with each other through a heterogeneous public network, the tunnel mode can be used.

Tunnel transmission is applicable to the following cases:

Allowing the local networks running non-IP protocols to communicate with each other through a single network (IP network), since the tunnel supports multiple different load protocols.

Allowing the protocols that have limit on hops to work in a wider range, since the tunnel uses the transmission protocol (such as IP) for routing.

Allowing discrete subnets to be connected via a single network (IP network).

Allowing the VPN (virtual private network) to be enabled on the WAN.

Since the tunnel transmits data after encapsulation, this makes processing more complicated and in some cases, you need to pay attention to this change:

Since the tunnel is a point-to-point link, it is seen as a next hop in routing. However, actually its route metric may be more than one hop. In using the tunnel, you must note that the route of the tunnel link is different from the actual route.

Data is encapsulated with the transmission protocol. You must bear this in mind when you set firewalls and especially an Access Control List (ACL). At the same time, you must also note that the transmission bandwidth (like MTU) of the load protocol is smaller than the theoretical value.

The following section only describes how to configure the special attributes of the tunnel interface. For other attributes (including the IP address and other parameters, firewall and backup center), see related sections.

Configuring Tunnel Interfaces

Entering Tunnel Interface Configuration Mode

Use the following commands to create a tunnel interface and enter tunnel interface configuration mode in global configuration mode.

Command	Function
Ruijie(config)# **interface tunnel** *tunnel-number*	Enters tullel interface configuration mode.
Ruijie(config)# **no interface tunnel** *tunnel-number*	Deletes the created tunnel interface.

Same as other logical interfaces, one tunnel interface is created at the first time you enter the specified tunnel interface.

Setting the Source Address of the Tunnel Interface

For a tunnel interface, you need to configure the source address and destination address of the tunnel. To ensure the stability of the tunnel interface, the loopback address is usually used as the source address and destination address of the tunnel. Before the tunnel interface is normally working, you must verify the connectivity between the source address and the destination address.

Use the following commands to configure the source address of a tunnel interface in tunnel interface configuration mode.

Command	Function
Ruijie(config-if)# **tunnel source** { *ip-address* | *interface-name* *interface-number* }	Set sthe source address of a tunnel interface.
Ruijie(config-if)# **no tunnel source**	Cancels the source address of the tunnel interface.

The **tunnel source** command sets the source address of a tunnel interface and this source address is also the local end of the tunnel.

Setting the Destination Address of the Tunnel Interface

Use the following commands to configure the destination address of a tunnel interface in tunnel interface configuration mode.

Command	Function
Ruijie(config-if)# **tunnel destination** { *ip-address* }	Sets the destination address of a tunnel interface.
Ruijie(config-if)# **no tunnel destination**	Cancels the destination address of the tunnel interface.

The **tunnel destination** command sets the destination address of a tunnel interface and this destination address is also the remote end of the tunnel.

Caution You should not use the same source address and destination address on a device to create two or more tunnel interfaces with the same encapsulation mode.

Setting the Encapsulation Format of the Tunnel

The tunnel encapsulation format is the carrier protocol of the tunnel. By default, the tunnel interface uses the encapsulation format GRE. You can also determine the encapsulation format of the tunnel interface according to actual needs.

Command	Function
Ruijie(config-if)# **tunnel mode** { **gre ip** | **ipip** | **ipv6ip** }	Set sthe encapsulation format of the tunnel.
Ruijie(config-if)# **no tunnel mode**	Cancels the encapsulation format of the tunnel interface and restores it to the default.

Setting the Tunnel Check

In some cases, you need to enable tunnel check to ensure data integrity.

Command	Function
Ruijie(config-if)# **tunnel checksum**	Enables tunnel check.
Ruijie(config-if)# **no tunnel checksum**	Disables tunnel check.

By default, the tunnel interface does not perform check.

Setting the Key of the Tunnel Interface

By setting the key of a tunnel interface, you can ensure the security of the settings at both ends of the tunnel to some extent, and also prevent malicious external sniffing or attacks.

Command	Function
Ruijie(config-if)# **tunnel key** *key-value*	Sets the key of the tunnel interface.
Ruijie(config-if)# **no tunnel key**	Cancels the key of the tunnel interface.

The key of the tunnel interface takes effect only when the tunnel encapsulation format is GRE, so every GRE packet includes the set key of the tunnel interface.

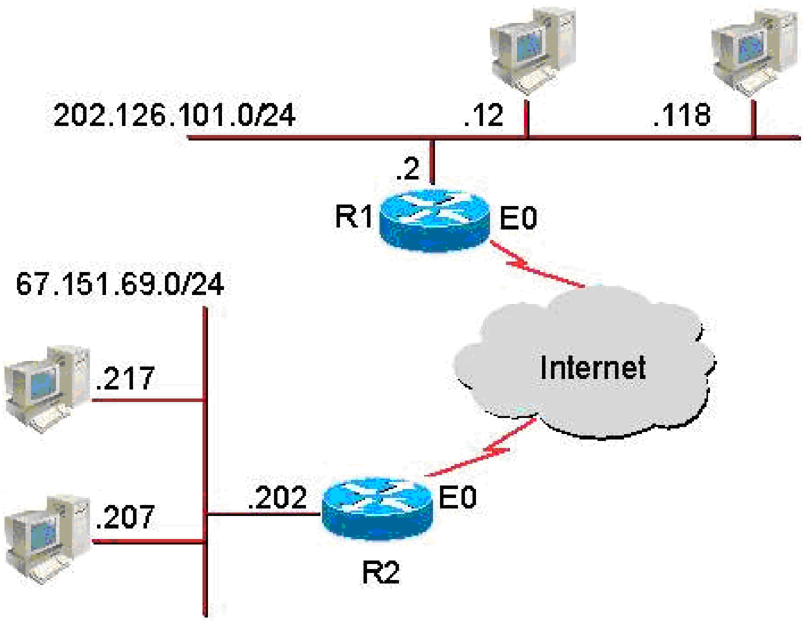
Caution The two ends of the tunnel must use the same key to communicate normally.

Caution Although every GRE packet includes this key when the encapsulation format is GRE, offering security on the basis of this key is not practicable.

Tunnel Interface Configuration Example

0 shows a network connection diagram.

Figure 4-2 Network Connection Diagram of the Tunnel Interface Configuration Example



In this configuration example, a tunnel is established between R1 and R2. The 202.126.101.0/24 subnet behind device R1 and the 67.151.69.0/24 subnet behind device R2 communicate with each other through the tunnel. The connection between R1 and R2 is transparent and invisible to external networks, that is, it is implemented through a VPN. The following example provides the related configuration of the tunnel between R1 and R2.

Related configuration on R1:

```
interface Tunnel0
ip address 21.21.21.3 255.255.255.0
tunnel source 179.208.12.221
tunnel destination 179.208.12.55
!
interface FastEthernet0/0
ip address 179.208.12.221 255.255.255.0
!
interface FastEthernet0/1
ip address 202.106.101.2 255.255.255.0
!
```

Related configuration on R2:

```
interface Tunnel0
ip address 21.21.21.5 255.255.255.0
tunnel source 179.208.12.55
tunnel destination 179.208.12.221
!
interface FastEthernet0/0
ip address 179.208.12.55 255.255.255.0
!
interface FastEthernet0/1
ip address 67.151.69.202 255.255.255.0
!
```

As shown in the above configuration, R1 and R2 both use the f0/0 Ethernet interface to establish a tunnel and use the f0/1 Ethernet interface to connect with external networks and serve as the gateway of the internal network.

Troubleshooting Tunnel Interfaces

If the two ends of a tunnel cannot communicate with each other normally, you can check the following aspects:

1. Ensure the two ends of the tunnel have connectable physical channels, that is, there is connectivity between them when no tunnel is used. In other words, the source address (local address) and the destination address (peer address) of the tunnel can normally communicate with each other.

2. Ensure that the source and destination addresses of the tunnel correspond with each other. In other words, the source address of the tunnel must match with the destination address of the tunnel.

3. Ensure that the tunnel has used the correct encapsulation format (defaulted to GRE) and the same encapsulation format is applied at both ends.

In addition, after the GRE is used as the encapsulation format of the tunnel, you must ensure that the two ends have the same check settings, key settings and reception rule settings.

Configuring Dialer Interfaces

Dialer Interface Overview

Ruijie products support physical dialer interfaces such as sync serial ports and async serial ports. The following section describes how to set the dialer interface. For other parameter settings, monitoring & maintenance, typical configuration example, and troubleshooting, see the dial-up configuration guide in this manual.

Configuring Dialer Interfaces

Ruijie products provide the **interface dialer** command to enter dialer interface configuration mode. Same as other logical interfaces, the first time you enter dialer interface configuration mode, you can create a dialer interface. Use the **no interface dialer** command to delete an existing dialer interface if necessary. For the parameter settings of the dialer interface, see the dial-up configuration section.

Command	Function
Ruijie(config)# **interface dialer** *dialer-number*	Enters dialer interface configuration mode.
Ruijie(config)# **no interface diale**r *dialer-number*	Deletes an existing dialer interface.

Monitoring and Maintaining Dialer Interfaces

Ruijie products provide the **show interfaces dialer** command for monitoring and maintaining dialer interfaces. If the link layer protocol is encapsulated on a dialer interface, use the **debug** command of the appropriate protocol to view the communication status of the dialer inteface.

Command	Function
R2501+# **show interfaces dialer** *dialer-number*	Shows the status of a dialer interface.

The following example shows how to use the **show interfaces dialer** command.

```
Ruijie# show interfaces dialer 1
dialer 1 is UP  (spoofing) , line protocol is UP  (spoofing)
Hardware is  dialer
Interface address is: 192.168.20.1/24
MTU 1500 bytes, BW 56 Kbit
Encapsulation protocol is SLIP, loopback not set
Keepalive interval is 0 sec , set
Carrier delay is 2 sec
RXload is 1 ,Txload is 1
Queueing strategy: WFQ
5 minutes input rate 0 bits/sec, 0 packets/sec
5 minutes output rate 0 bits/sec, 0 packets/sec
0 packets input, 0 bytes, 0 no buffer
Received 0 broadcasts, 0 runts, 0 giants
0 input errors, 0 CRC, 0 frame, 0 overrun, 0 abort
0 packets output, 0 bytes, 0 underruns
0 output errors, 0 collisions, 0 interface resets
```

From the above information, you can know the settings and working status of the dialer interface, such as interface and link status, IP address settings, MTU settings, and bandwidth settings.

Configuring Sub-Interfaces

Sub-Interface Overview

A sub-interface is a logical interface deriving from an individual physical interface and depends on the physical interface. One physical interface may be configured with multiple sub-interfaces, providing great flexibility for application. A sub-interface is one of the logical interfaces derived from a physical interface. In other words, multiple logical interfaces are associated with a physical interface. The logical interfaces of a physical interface share the parameters of the physical interface, but they have their respective link layer and network layer configuration parameters.

The following physical interfaces support sub-interfaces:

- Fast Ethernet interfaces
- WAN interfaces encapsulated with Frame Relay
- WAN interfaces encapsulated with X.25

Sub-interface Configuration

Configuring the Sub-Interface of an Ethernet Interface

Ruijie products provide the **interface fastethernet** command to enter sub-interface configuration mode. Same as other logical interfaces, the first time you enter the sub-interface configuration mode, you can create a sub-interface. Use the **no interface fastethernet** command to delete an existing sub-interface if necessary. For the parameter settings of Ethernet sub-interfaces, see the sections about Ethernet interface configuration and IP protocol configuration.

Command	Function
Ruijie(config)# **interface fastethernet** *slot-number/interface-number.subinterface-number*	Enter s Ethernet sub-interface configuration mode.
Ruijie(config)# **no interface fastethernet** *slot-number /interface-number.subinterface-number*	Deletes an existing Ethernet sub-interface.

Where, the *slot-number/interface-number* is the sequence number of the slot or physical interface, and the *subinterface-number* is the sequence number of the sub-interface on the physical interface. Note that they are connected by a dot (**.**).

Configuring the Sub-Interface of a WAN Interface Encapsulated with Frame Relay

After a WAN interface is encapsulated with frame relay, Ruijie products provide the **interface serial** command for entering WAN sub-interface configuration mode. Same as other logical interfaces, the first time you enter the WAN sub-interface configuration mode, you can create a WAN sub-interface. Use the **no interface serial** command to delete an existing WAN sub-interface if necessary.

Command	Function
Ruijie(config)# **interface serial** *slot-number/interface-number. subinterface-number* [**point-to-point** | **multipoint**]	Enters WAN sub-interface configuration mode.
Ruijie(config)# **no interface serial** *slot-number/interface-number. subinterface-number* [**point-to-point** | **multipoint**]	Deletes an existing WAN sub-interface.

Where, the *slot-number/interface-number* is the sequence number of the slot or physical interface, and the *subinterface-number* is the sequence number of the sub-interface on the physical interface. Note that they are connected with a dot (**.**). In addition, the subinterface-number must be greater than 0.

After a sub-interface of the WAN encapsulated with frame relay is created, you can configure its IP address, virtual circuit, and frame relay address mapping. On the sub-interface, you can also configure the frame relay protocol and some other related parameters of its home physical interface. For the parameter settings of the WAN sub-interface, see the section about WAN protocol configuration.

Configuring the Sub-Interface of a WAN Interface Encapsulated with X.25

After a WAN interface is encapsulated with X.25, Ruijie products provide the **interface serial** command for entering WAN sub-interface configuration mode. Same as other logical interfaces, the first time you enter the WAN sub-interface configuration mode, you can create a WAN sub-interface. Use the **no interface serial** command to delete an existing WAN sub-interface if necessary.

Command	Function
Ruijie(config)# **interface serial slot-number/interface-number. subinterface-number** [**point-to-point** | **multipoint**]	Enters WAN sub-interface configuration mode.
Ruijie(config)# **no interface serial slot-number/interface-number. subinterface-number** [**point-to-point** | **multipoint**]	Deletes an existing WAN sub-interface.

Where, the *slot-number/interface-number* is the sequence number of the slot or physical interface, and the *subinterface-number* is the sequence number of the sub-interface on the physical interface. Note that they are connected with a dot (“**.**). In addition, the subinterface-number must be greater than 0.

After a sub-interface of the WAN encapsulated with X.25 is created, you can configure its IP address and X.25 address mapping. On the sub-interface, you can also configure the X.25 protocol and some other related parameters of its home physical interface. For the parameter settings of the WAN sub-interface, see the section about WAN protocol configuration.

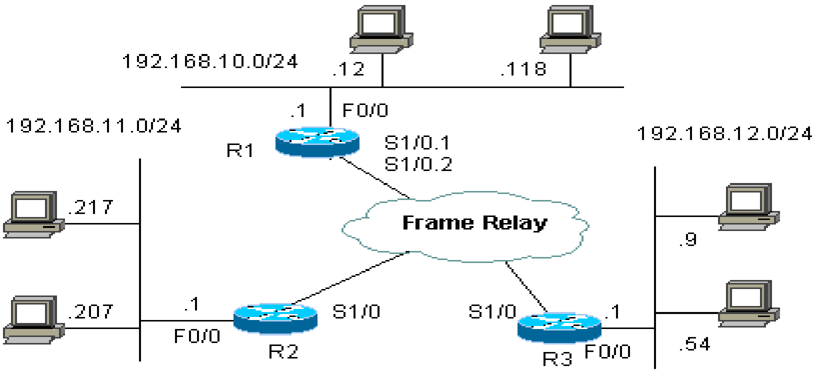
Monitoring and Maintaining Sub-Interfaces

Same as other interfaces, Ruijie products provide the show interfaces command to monitor and maintain sub-interfaces, but with the name of the home physical interface and the sequence number of the sub-interface. For the WAN sub-interfaces, you can use the debug command of the encapsulated protocol to monitor and maintain them. For the sub-interfaces of Ethernet interfaces, you can monitor and maintain them according to the procedure for monitoring and maintaining Ethernet interfaces.

Sub-interface Configuration Example

This configuration example involves a frame relay sub-interface, whose network connections are shown in 0.

Figure 4-3 Network Connections for a Frame Relay Sub-interface Configuration Example



In this configuration example, R1 establishes frame relay links with the S1/0 interface (IP: 101.92.67.2) of R2 and the S1/0 interface (IP: 101.92.68.2) of R3 through the frame relay sub-interfaces S1/0.1 (IP: 101.92.67.1, DLCI: 20) and S1/0.2 (IP: 101.92.68.1, DLCI: 30) respectively. R1, R2 and R3 respectively become the gateways for the network segments connected with their Ethernet interface f0/0. After appropriate routes are configured on devices R1, R2 and R3, the three sub-networks (192.168.10.0/24, 192.168.11.0/24 and 192.168.12.0/24) can communicate with one another. The following example only provides the related configuration of the frame relay subinterface on R1.

```
interface Serial1/0
no ip address
encapsulation frame-relay
frame-relay intf-type dce
!
interface Serial 1/0.1 point-to-point
ip address 101.92.67.1 255.255.255.0
frame-relay interface-dlci 20
!
interface Serial 1/0.2 point-to-point
ip address 101.92.68.1 255.255.255.0
frame-relay interface-dlci 30
            !
```

Troubleshooting Sub-Interfaces

For details about how to troubleshoot a sub-interface, see the section about WAN protocol configuration in this manual if the physical interface of the sub-interface is a WAN interface, or the section about IP protocol configuration in this manual if the physical interface of the sub-interface is an Ethernet interface.

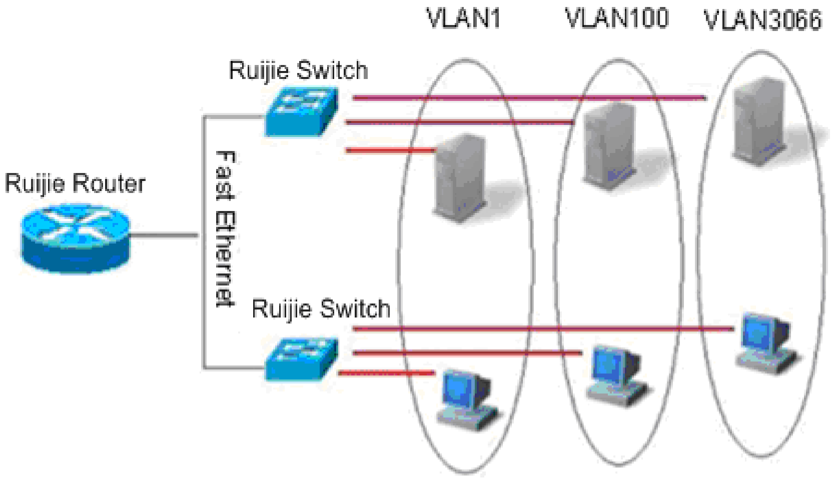
Configuring VLAN

This chapter describes how to configure IEEE802.1q VLAN.

Overview

Virtual Local Area Network (VLAN) is a logical network divided on a physical network. VLAN corresponds to the L2 network in the ISO model. The division of VLAN is not restricted by the physical locations of network ports. A VLAN has the same attributes as a common physical network. Except for no restriction on physical location, unicast, broadcast and multicast frames on layer 2 are forwarded and distributed within a VLAN, not being allowed to directly go to other VLANs.Therefore, when a host in a VLAN wants to communicate with another host in another VLAN, a layer 3 device must be used, as shown in the following diagram.

You can define a port as the member of a VLAN. All the terminals connected to the specified port are part of the VLAN. A network can support multiple VLANs. In this case, when you add, delete, and modify users in the VLANs, you do not need to modify the network configuration physically.



Like a physical network, a VLAN is usually connected to an IP subnet. A typical example is that all the hosts in the same IP subnet belong to the same VLAN. A layer 3 device must be used for communication between VLANs. Ruijie L3 devices can perform IP routing between VLANs through SVI (Switch Virtual Interfaces). For the configuration about SVI, refer to *Interface Management Configuration* and *IP Unicast Routing Configuration*.

Supported VLAN

Complying with IEEE802.1Q Standard, our products support up to 4094 VLANs(VLAN ID 1-4094), in which VLAN 1 is the default VLAN that cannot be deleted.

VLAN Member Type

You can determine the frames that can pass a port and the number of VLANs that the port can belong to by configuring the VLAN member type of the port. For the detailed description about VLAN member type , see the following table:

Member Type	Port Feature
Access	One access port can belong to only one VLAN, which must be specified manually.
Trunk (802.1Q)	By default, one Trunk port belongs to all the VLANs of the device itself, and it can forward the frames of all the VLANs. However, you can impose restriction by setting a list of allowed VLANs.

Configuring a VLAN

A VLAN is identified by its VLAN ID. You can add, remove, and modify the VLANs in the range of 2 to 4094 on a device. VLAN 1 is created by a device automatically and cannot be removed.

You can configure the member type of a port in a VLAN, add a port to a VLAN, and remove a port from a VLAN in the interface configuration mode.

Saving the VLAN Configuration

To save the VLAN configuration in the configuration file, execute the **copy running-config startup-config** command in the privileged EXEC mode. To view VLAN configuration, execute the **show vlan** command.

Default VLAN Configuration

The following table shows the default configuration of a VLAN.

Parameter	Default Value	Range
VLAN ID	1	1 to 4094
VLAN Name	VLAN xxxx, where xxxx is the VLAN ID	None
VLAN State	Active	Two status: active or inactive

Creating/Modifying a VLAN

In the privileged EXEC mode, you can create or modify a VLAN by executing the following commands.

Command	Function
Ruijie(config)# **vlan** *vlan-id*	Enter a VLAN ID. If you enter a new VLAN ID, the device will create it. If you enter an existing VLAN ID, the device modifies the corresponding VLAN.

Command	Function
Ruijie(config)# **name** *vlan-name*	(Optional) Name the VLAN. If you skip this step, the device automatically assigns the VLAN a name of VLAN xxxx, where xxxx is a 4-digit VLAN ID starting with 0. For example, VLAN 0004 is the default name of VLAN 4.

To restore the name of a VLAN to its default, simply enter the **no name** command.

The following example creates VLAN 888, names it test888, and saves its configuration into the configuration file:

```
Ruijie# configure terminal
Ruijie(config)# vlan 888
Ruijie(config-vlan)# name test888
Ruijie(config-vlan)# end
```

Deleting a VLAN

You cannot delete the default VLAN (VLAN 1).

In the privileged EXEC mode, you can delete a VLAN by executing the following command.

Command	Function
Ruijie(config)# **no vlan** *vlan-id*	Enter the VLAN ID that you want to delete.

Adding Existing Access Ports to Specified VLAN

If you assign a port to an inexistent VLAN, the switch will automatically create that VLAN.

In the privileged EXEC mode, you can assign a port to a VLAN by executing the following command.

Command	Function
Ruijie(config-if)# **switchport mode access**	Define the member type of the port in a VLAN (L2 ACCESS port).
Ruijie(config-if)# **switchport access vlan** *vlan-id*	Assign the port to the VLAN.

The following example adds Ethernet 1/10 to VLAN20 as an access port:

```
Ruijie# configure terminal
Ruijie(config)# interface fastethernet 1/10
Ruijie(config-if)# switchport mode access
Ruijie(config-if)# switchport access vlan 20
Ruijie(config-if)# end
```

The following example shows how to verify the configuration:

```
Ruijie(config)#show interfaces gigabitEthernet 3/1
 switchport
Switchport is enabled
Mode is access port
```

```
Acsess vlan is 1,Native vlan is 1
Protected is disabled
Vlan lists is ALL
```

Caution

In the R2700 switching card, although the access vlan can also be configured on the trunk port, the access port configuration does not take effect and the port remains in the trunk port. Only the configuration of native vlan and allowed vlan list takes effect.

Adding Access Ports to the Existing VLAN

In VLAN configuration mode, add the specified Access port to this VLAN. The effect of this command is the same as the command to specify the VLAN to which the interface belongs in interface configuration mode (namely **switchport access vlan** *vlan-id*).

Command	Function
Ruijie(config)# **vlan** *vlan-id*	Type in a VLAN ID. If a new VLAN ID is typed in, the device will create a VLAN. If an existing VLAN ID is typed in, the corresponding VLAN will be modified.
Ruijie(config-vlan)# **add interface** { *interface-id* | **range** *interface-range* }	Add one or a group of Access ports to the existing VLAN. By default, all layer-2 Ethernet ports belong to VLAN1.
Ruijie(config-vlan)# **[no]add interface** { *interface-id* | **range** *interface-range* }	Delete one or a group of Access ports form the existing VLAN.
Ruijie(config-vlan)#**show interface** *interface-id* **switchport**	Display the information about layer-2 interface.

Caution

This command only applies to Access port.

In terms of these two commands to add interface to the VLAN, the later configured command will override the previously configured command.

The following example adds Access port (GigabitEthernet 0/10) to VLAN20:

```
Ruijie# configure terminal
            SwitchA(config)#vlan 20
            SwitchA(config-vlan)#add interface GigabitEthernet 0/10
```

The following example how to verify the configurations:

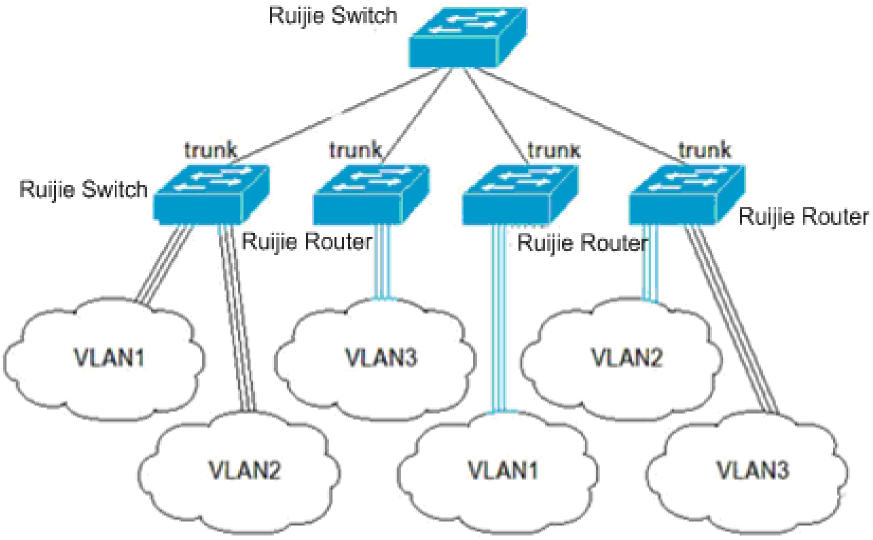
```
Ruijie# show interface GigabitEthernet 0/10 switchport
Interface        Switchport   Mode  Access Native Protected  VLAN lists
----------       --------     -----  ----- ------ ---------- -------
GigabitEthernet 0/10 enabled  ACCESS  20     1    Disabled   ALL
```

Configuring VLAN Trunks

Overview

A trunk is a point-to-point link that connects one or multiple Ethernet switching interfaces to other network devices (for instance, router). A trunk can transmit the traffics of multiple VLANs.

The Trunk encapsulation of Ruijie device is 802.1Q-complied. The following diagram shows a network connected with trunks.



You can set a common Ethernet port or aggregate port to be a trunk port. For the details of aggregate port, refer to *Configuring Aggregate Port*.

In order to switch an interface between the access mode and the trunk mode, use the **switchport mode** command:

Command	Function
Ruijie(config-if)# **switchport mode access**	Set an interface to the access mode
Ruijie(config-if)# **switchport mode trunk**	Set an interface to the Trunk mode

A native VLAN must be defined for a trunk port. The untagged packets received and sent through the port are deemed as the packets of the native VLAN. Obviously, the default VLAN ID of the port (that is, the PVID in the IEEE 802.1Q) is the VLAN ID of the native VLAN. Moreover, you must untag them before sending the packets of the native VLAN through the trunk port. The default native VLAN of a trunk port is VLAN 1.

When you configure a trunk link, be sure that the ports on both ends of the trunk belong to the same native VLAN.

Configuring a Trunk Port

Basic Trunk Port Configuration

In the privileged EXEC mode, you can configure a trunk port by executing the following command.

Command	Function
Ruijie(config-if)# **switchport mode trunk**	Configure the port as a L2 trunk port.
Ruijie(config-if)# **switchport trunk native vlan** *vlan-id*	Specify a native VLAN for the port.

To restore all the trunk-related settings of a trunk port to their defaults, use the **no switchport mode** command in the interface configuration mode.

Defining the Allowed VLAN List of a Trunk Port

By default, the traffic of all VLANs in the range of 1 to 4094 can be transmitted over a trunk port. However, you can restrict the traffic of some VLANs from passing the trunk port by setting its allowed VLAN list.

In the priviledged mode, you can modify the allowed VLAN list of a trunk port by executing the following command.

Command	Function
Ruijie(config-if)# **switchport trunk allowed vlan {all | [add | remove | except] }** *vlan-list*	(Optional) Configure the allowed VLAN list of the trunk port. The vlan-list parameter may be a VLAN or a series of VLANs. It starts with a small VLAN ID and ends with a large VLAN ID. Both IDs are connected with “-”, such as 10–20. All: Add all the allowed VLANs to the allowed VLAN list; add: Add the specified VLAN list to the allowed VLAN list; remove: Remove the specified VLAN list from the allowed VLAN list; except: Add all the VLANs other than the specified VLAN list to the allowed VLAN list.

To restore the allowed VLAN list of the trunk port to its default, execute the **no switchport trunk allowed vlan** command in the interface configuration mode.

The following example removes VLAN 2 from the allowed VLAN list of port 1/15:

```
Ruijie(config)# interface fastethernet 1/15
Ruijie(config-if)# switchport trunk allowed vlan remove 2
Ruijie(config-if)# end
Ruijie# show interfaces fastethernet 1/15 switchport
Interface Switchport Mode  Access Native Protected VLAN lists
--------- ---------- ----  ------ ------ -------- ----------
```

```
Gi0/15    enabled   TRUNK  1     1      Disabled   1,3－4094
```

Configuring a Native VLAN.

Tagged or untagged 802.1Q frames can be received or sent on a trunk port. Untagged frames are used to transmit the traffic of the native VLAN. By default, the native VLAN is VLAN 1.

In the privileged EXEC mode, you can configure a native VLAN for a trunk port by executing the following command.

Command	Function
Ruijie(config-if)# **switchport trunk native vlan** *vlan-id*	Configure a native VLAN.

To restore the native VLAN of a trunk port to its default, execute the **no switchport trunk native vlan** command in the interface configuration command.

If a frame carries the VLAN ID of the native VLAN, it will be automatically untagged when being forwarded through the trunk port.

When you set the native VLAN of a trunk port to an inexistent VLAN, the switch will not automatically create the VLAN. In addition, the native VLAN of a trunk port may be out the allowed VLAN list. In this case, the traffic of the native VLAN cannot pass the trunk port.

Showing VLAN Information

Only in the privileged EXEC mode can you view the VLAN information, including VLAN VID, VLAN status, member ports of the VLAN, and VLAN configuration. The related commands are listed as below:

Command	Function
show vlan [**id** *vlan-id*]	Show the information about all or the specified VLAN.

The following example shows the information about a VLAN:

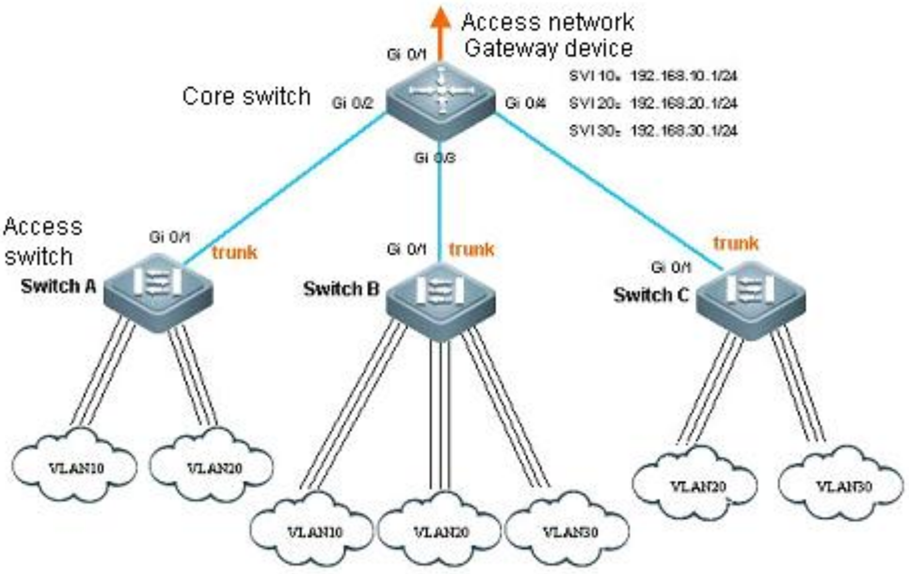
```
Ruijie# show vlan
VLAN  Name      Status            Ports
                ---- --------  --------   ------------------------------
                  1 VLAN0001   STATIC     Gi0/1, Gi0/5, Gi0/6, Gi0/7
                                          Gi0/8, Gi0/9, Gi0/10, Gi0/11
                                          Gi0/12, Gi0/13, Gi0/14, Gi0/15
                                          Gi0/16, Gi0/17, Gi0/18, Gi0/19
                                          Gi0/20, Gi0/21, Gi0/22, Gi0/23
                                          Gi0/24
                 10 VLAN0010  STATIC    Gi0/2, Gi0/3
                 20 VLAN0020  STATIC    Gi0/2, Gi0/3, Gi0/4
                30 VLAN0030  STATIC   Gi0/3, Gi0/4

                Ruijie#show vlan id 20
                VLAN  Name              Status    Ports
                ----  --------         ------   ----------------------
```

```
20  VLAN0020          STATIC    Gi0/2, Gi0/3, Gi0/4
```

Configuration Examples

Network Topology



Networking Requirements

As shown above, an Intranet is divided into VLAN 10, VLAN 20 and VLAN 30 in order to realize laye-2 isolation. The IP subnets corresponding to three VLANs are 192.168.10.0/24, 192.168.20.0/24 and 192.168.30.0/24. The three VLANs are interconnected through the IP forwarding capacity of layer-3 core switch.

Configuration Tips

This example shows to how to configure the core switch and one of the access switches:

- Configure three VLANs on the core switch; configure the port connecting access switch to trunk port and specify the allowed vlan list to realize layer-2 isolation;
- Configure three SVI interfaces on the core switch to serve as the gateway interfaces for IP subnets corresponding to the three VLANs; configure the corresponding IP addresses;
- Create VLANs on three access switches and assign Access port for each VLAN; specify the trunk port for connecting core switch. This example shows the configuration steps on the access switch of Switch A.

Configuration Steps

Configurations on Core Switch

- Create VLAN

# Enter the global configuration mode

```
Ruijie#configure terminal
```

# Create VLAN 10

```
Ruijie(config)#vlan 10
```

# Create VLAN 20

```
Ruijie(config-vlan)#vlan 20
```

# Create VLAN 30

```
Ruijie(config-vlan)#vlan 30
```

# Return to the global configuration mode

```
Ruijie(config-vlan)#exit
```

- Configure respective trunk ports and specify the allowed vlan list

# Enter the interface range of Gi 0/2-4

```
Ruijie(config)#interface range GigabitEthernet 0/2-4
```

# Configure Gi 0/2-4 as trunk ports

```
Ruijie(config-if-range)#switchport mode trunk
```

# Return to the global configuration mode

```
Ruijie(config-if-range)#exit
```

# Enter port Gi 0/2

```
Ruijie(config)#interface GigabitEthernet 0/2
```

# Delete all vlans from the allowed vlan list of this port

```
Ruijie(config-if)#switchport trunk allowed vlan remove 1-4094
```

# Add vlan 10 and vlan 20 into the allowed vlan list of this port

```
Ruijie(config-if)#switchport trunk allowed vlan add 10,20
```

# Enter port Gi 0/3

```
Ruijie(config-if)#interface GigabitEthernet 0/3
```

# Delete all vlans from the allowed vlan list of this port

```
Ruijie(config-if)#switchport trunk allowed vlan remove 1-4094
```

# Add vlan 10, vlan 20 and vlan 30 into the allowed vlan list of this port

```
Ruijie(config-if)#switchport trunk allowed vlan add 10,20,30
```

# Enter port Gi 0/4

```
Ruijie(config-if)#interface GigabitEthernet 0/4
```

# Delete all vlans from the allowed vlan list of this port

```
Ruijie(config-if)#switchport trunk allowed vlan remove 1-4094
```

# Add vlan 20 and vlan 30 into the allowed vlan list of this port

```
Ruijie(config-if)#switchport trunk allowed vlan add 20,30
```

# Return to the global configuration mode

```
Ruijie(config-if)#exit
```

- Display vlan configurations on core switch

# Display vlan information, including vlan id, name, state and member ports

```
Ruijie#show vlan
VLAN  Name      Status             Ports
---- --------  --------   -------------------------------
   1 VLAN0001   STATIC    Gi0/1, Gi0/5, Gi0/6, Gi0/7
                          Gi0/8, Gi0/9, Gi0/10, Gi0/11
                          Gi0/12, Gi0/13, Gi0/14, Gi0/15

# Display the vlan state of port Gi 0/3

```
Ruijie#show interface GigabitEthernet 0/3 switchport
Interface Switchport Mode  Access Native Protected VLAN lists
-------- ---------- -----  ------ ------ --------- ----------
Gi0/3     enabled   TRUNK   1      1     Disabled  10,20,30
```

# Display the vlan state of port Gi 0/4

```
Ruijie#show interface GigabitEthernet 0/4 switchport
Interface Switchport Mode  Access Native Protected VLAN lists
-------- ---------- -----  ------ ------ --------- ----------
Gi0/4     enabled   TRUNK   1      1     Disabled  20,30
```

- Create SVI port and specify the IP address

# Enter the global configuration mode

```
Ruijie#configure terminal
```

# Create SVI 10

```
Ruijie(config)#interface vlan 10
```

# Configure the IP address of SVI 10

```
Ruijie(config-if)#ip address 192.168.10.1 255.255.255.0
```

# Create SVI 20

```
Ruijie(config-if)#interface vlan 20
```

# Configure the IP address of SVI 20

```
Ruijie(config-if)#ip address 192.168.20.1 255.255.255.0
```

# Create SVI 30

```
Ruijie(config-if)#interface vlan 30
```

# Configure the IP address of SVI 30

```
Ruijie(config-if)#ip address 192.168.30.1 255.255.255.0
```

# Return to the global configuration mode

```
Ruijie(config-if)#exit
```

Configurations on the Access Switch of Switch A

- Create VLAN

# Enter the global configuration mode

- Ruijie#configure terminal

# Create VLAN 10

```
Ruijie(config)#vlan 10
```

# Create VLAN 20

```
Ruijie(config-vlan)#vlan 20
```

# Return to the global configuration mode

```
Ruijie(config-vlan)#exit
```

- Assign Access port for each VLAN

# Enter the interface range of Gi 0/2-12

```
Ruijie(config)#interface range GigabitEthernet 0/2-12
```

# Configure Gi 0/2-12 as Access ports

```
Ruijie(config-if)#switchport mode access
```

# Add Gi 0/2-12 to VLAN 10

```
Ruijie(config-if)#switchport access vlan 10
```

# Enter the interface range of Gi 0/13-24

```
Ruijie(config-if)#interface range GigabitEthernet 0/13-24
```

# Configure Gi 0/13-24 as Access ports

```
Ruijie(config-if)#switchport mode access
```

# Add Gi 0/13-24 to VLAN 20

```
Ruijie(config-if)#switchport access vlan 20
```

# Return to the global configuration mode

```
Ruijie(config-if)#exit
```

- Specify the trunk port for connecting core switch

# Enter port Gi 0/1

```
Ruijie(config)#interface GigabitEthernet 0/1
```

# Configure Gi 0/1 as trunk port

```
Ruijie(config-if)#switchport mode trunk
```

# Return to global configuration mode

```
Ruijie(config-if)#exit
```

Configuring RMON

Overview

RMON (Remote Monitoring) is a standard monitoring specification of IETF (Internet Engineering Task Force). It can be used to exchange the network monitoring data among various network monitors and console systems. In the RMON, detectors can be placed on the network nodes, and the NMS determines which information is reported by these detectors, for example, the monitored statistics and the time buckets for collecting history. The network device such as a router acts as a node on the network. The information of current node can be monitored by means of the RMON.

There are three stages in the development of RMON. The first stage is the remote monitoring of Ethernet. The second stage introduces the token ring which is referred to as the token ring remote monitoring module. The third stage is known as RMON2, which develops the RMON to a high level of protocol monitor.

The first stage of RMON (known as RMON1) contains nine groups. All of them are optional (not mandatory), but some groups should be supported by the other groups.

The switch implements the contents of Group 1, 2 , 3 and 9: the statistics, history, alarm and event.

Statistics

Statistics is the first group in RMON. It measures the basic statistics information of each monitored subnet. At present, only the Ethernet interfaces of network devices can be monitored and measured. This group contains a statistics of Ethernet, including the discarded packets, broadcast packets, CRC errors, size block, conflicts and etc.

History

History is the second group in RMON. It collects the network statistics information regularly and keeps them for processing later. This group contains two subgroups:

1. The subgroup History Control is used to set such control information as sampling interval and sampling data source.
2. The subgroup Ethernet History provides history data about the network section traffic, error messages, broadcast packets, utilization, number of collision and other statistics for the administrator.

Alarm

Alarm is the third group in RMON. It monitors a specific management information base (MIB) object at the specified interval. When the value of this MIB object is higher than the predefined upper limit or lower than the predefined lower limit, an alarm will be triggered. The alarm is handled as an event by means of recording the log or sending the SNMP Trap message.

Event

Event is the ninth group in RMON. It determines to generate a log entry or a SNMP Trap message when an event is generated due to alarms.

RMON Configuration Task List

Configuring Statistics

One of these commands can be used to add a statistic entry.

Command	Function
Ruijie(config-if)# **rmon collection stats** *index* [**owner** *ownername*]	Add a statistic entry.
Ruijie(config-if)# **no rmon collection stats** *index*	Remove a statistic entry.

⚠ **Caution**

The current version of Ruijie product supports only the statistics of Ethernet interface. The index value should be an integer between 1 to 65535. At present, at most 100 statistic entries can be configured at the same time.

Configuring History

One of these commands can be used to add a history entry.

Command	Function
Ruijie(config-if)# **rmon collection history** *index* [**owner** *ownername*] [**buckets** *bucket-number*] [**interval** *seconds*]	Add a history entry.
Ruijie(config-if)# **no rmon collection history** *index*	Remove a history entry.

⚠ **Caution**

The current version of Ruijie product supports only the records of Ethernet. The index value should be within 1 to 65535. At most 10 history entries can be configured.

Bucket-number: Specifies the used data source and time interval. Each sampling interval should be sampled once. The sampling results are saved. The Bucket-number specifies the maximum number of sampling. When the maximum is reached for the sampling records, the new one will overwrite the earliest one. The value range of Bucket-number is 1 to 65535. Its default value is 10.

Interval: Sampling interva in the range of 1 to 3600 seconds, 1800 seconds by default.

Configuring Alarm and Event

One of these command can be used to configure the alarm:

Command	Function

Command	Function
Ruijie(config)# **rmon alarm** *number variable interval* {**absolute** | **delta**} **rising-threshold** *value* [*event-number*] **falling-threshold** *value* [*event-number*] [**owner** *ownername*]	Add an alarm entry.
Ruijie(config)# **rmon event** *number* [**log**] [**trap** *community*] [**description** *description-string*] [**owner** *ownername*]	Add an event entry.
Ruijie(config)# **no rmon alarm** *number*	Remove an alarm.
Ruijie(config)# **no rmon event** *number*	Remove an event.

number: Alarm index in the range of 1 to 65535.
variable: Variable to be monitored by the alarm(in integer).
interval: Sampling interval in the range of 1 to 4294967295.
Absolute: each sampling value compared with the upper and lower limits.
Delta: the difference with previous sampling value compared with the upper and lower limits.
value: Upper and lower limits.
Event-number: when the value exceeds the upper or lower limit, the event with the index of Event-number will be triggered.
Log: Record the event.
Trap: Send the Trap message to the NMS when the event is triggered.
Community: Community string used for sending the SNMP Trap message.
Description-string: Description of the event.
Ownername: Owner of the alarm or the event.

Showing RMON status

Command	Function
Ruijie(config)# **show rmon alarms**	Show alarms.
Ruijie(config)# **show rmon events**	Show events.
Ruijie(config)# **show rmon history**	Show history.
Ruijie(config)# **show rmon statistics**	Show statistics.

RMON Configuration Examples

Example of Configuring Statistics

If you want to get the statistics of Ethernet Port 3 , use the following commands:

```
Ruijie(config)# interface gigabitEthernet 0/3
Ruijie(config-if)# rmon collection stats 1 owner aaa1
```

Example of Configuring History

Use the following commands if you want to get the statistics of Ethernet Port 3 every 10 minutes:

```
Ruijie(config)# interface gigabitEthernet 0/3
Ruijie(config-if)# rmon collection history 1 owner aaa1 interval 600
```

Example of Configuring Alarm and Event

If you want to configure the alarm function for a statistical MIB variable, the following example shows you how to set the alarm function to the instance ifInNUcastPkts.6 (number of non-unicast frames received on port 6; the ID of the instance is 1.3.6.1.2.1.2.2.1.12.6) in ***IfEntry*** table of MIB-II. The specific function is as follows: the switch checks the changes to the number of non-unicast frames received on port 6 every 30 seconds. If 20 or more than 20 non-unicast frames are added after last check (30 seconds earlier), or only 10 or less than 10 are added, the alarm will be triggered, and event 1 is triggered to do corresponding operations (record it into the log and send the Trap with “community” name as “rmon”). The “description” of the event is “ifInNUcastPkts is too much”). The “owner” of the alarm and the event entry is “aaa1”.

```
Ruijie(config)#rmon alarm 10 1.3.6.1.2.1.2.2.1.12.6 30 delta rising-threshold 20 1
falling-threshold 10 1 owner aaa1
Ruijie(config)#rmon event 1 log trap rmon description "ifInNUcastPkts is too much " owner aaa1
```

Example of Showing RMON Status

show rmon alarm

```
Ruijie# show rmon alarms
rmon alarm table:
                index: 10,
                interval: 30,
                oid = 1.3.6.1.2.1.2.2.1.12.6
                sampleType: 2,
                alarmValue: 0,
                startupAlarm: 3,
                risingThreshold: 20,
                fallingThreshold: 10,
                risingEventIndex: 1,
                fallingEventIndex: 1,
                owner: zhangesan,
                stats: 1,
```

show rmon event

```
Ruijie# show rmon events
rmon event table:
                index = 1
                description = ifInNUcastPkts
                type = 4
                community = rmon
                lastTimeSent = 0 d:0 h:0 m:0 s
                owner = zhangsan
                status = 1
```

show rmon history

```
Ruijie# show rmon history
rmon history control table:
                index = 1
                interface = FastEthernet 0/1
                bucketsRequested = 10
                bucketsGranted = 10
                interval = 1800
                owner = zhangsan
                stats = 1

rmon history table:
                index = 1
                sampleIndex = 198
                intervalStart = 0d:14h:0m:47s
                dropEvents = 0

                index = 1
                interface = FastEthernet 0/1
                owner = zhangsan
                status = 0
                dropEvents = 0
                octets = 1884085
                pkts = 3096
                broadcastPkts = 161
                multiPkts = 97
                crcAllignErrors = 0
                underSizePkts = 0
                overSizePkts = 1200
                fragments = 0
                jabbers = 0
                collisions = 0
                packets64Octets = 128
                packets65To127Octets = 336
                packets128To255Octets = 229
                packets256To511Octets = 3
                packets512To1023Octets = 0
                packets1024To1518Octets = 1200
```

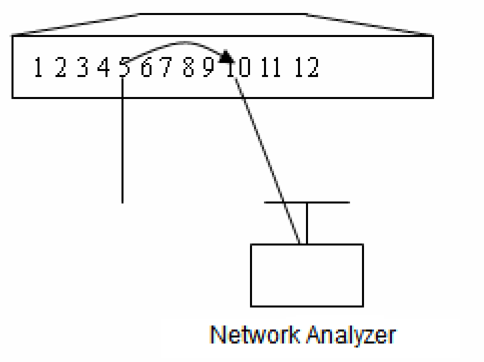
Configuring SPAN

Overview

With SPAN, you can analyze the communications between ports by copying a frame from one port to another port connected with a network analysis device or RMON analyzer. The SPAN mirrors all the packets sent/received at a port to a physical port for analysis.

For example, all the frames on the GigabitEhternet port 5 are mirrored to the GigabitEhternet port 10, as shown in the following figure. Although the network analyzer connected to port 10 is not directly connected to port 5, it can receive all the frames from port 5.

Figure 1-1 SPAN Configuration Example



SPAN does not affect the exchange of packets between the source and destination ports. Instead, it copies the frames incoming/outgoing the source port to the destination port. However, the frames may be discarded on an overflowed destination port, for example, when an 100Mbps port monitors an 1000Mbps port.

SPAN Concepts and Terms

SPAN Session

A SPAN session is a frame between a mirrored source port and destination port. It can monitor received, transmitted and bi-directional packets on one or multiple ports. Switched ports, Routed ports and AP ports can be configured as source and destination ports of SPAN sessions. Adding a port into a SPAN session will not affect the functioning of the switch.

You can configure a SPAN session on a disabled port, but the SPAN session is inactive. Only when the port is enabled, the SPAN session will become active. Moreover, the SPAN session will not take effect immediately after the switch is powered on. Only when the destination port becomes operable, the SPAN session will become active. You can use the **show monitor** [**session** *session_num*] command to view the status of a SPAN session.

Mirror Frame

Frame Direction

The SPAN session includes the following frame types:

- Received frames

Received frames include all known unicast frames and routing frames, and each received frame is copied to the destination port. In one SPAN session, you can monitor the the frames inputted from one or multiple source ports. Although a frame inputted from the source port is dropped due to some reasons, for example, port security, it is still sent to the destination port. This does not affect the function of the SPAN.

- Transmitted frames

All the frames sent from the source port are copied to the destination port. In one SPAN session, you can monitor the frames input from one or multiple source ports. If a frame from a port to the source port is dropped due to some reasons, the frame will not be sent to the destination port as well. Moreover, the format of the frames destined to the source port may change, for example, routed frames, source MAC address, destination MAC address, VLAN ID and TTL. Similarly, the format of the frames copied to the destination port will change.

- Bi-directional frames

Bi-directional frames include the above mentioned two frames. In one SPAN session, you can monitor the frames received and transmitted from/to one or multiple source ports.

SPAN Traffic

You can use the SPAN to monitor all network communications, including multicast frames and BPDU frames.

Source Port

The source port is also called the monitored port. In a SPAN session, frames on the source port are monitored for network analysis or troubleshooting. In a SPAN session, you can monitor received, transmitted and bi-directional frames and the maximum number of source ports is not limited.

A source port has the following features:

- It can be a switched port, routed port or AP.
- It cannot be a destination port at the same time.
- The source port and the destination port can reside in the same VLAN or different VLANs.

Destination Port

The SPAN session has a destination port (also known as the monitoring port) used to receive the frames copied from the source port.

The destination port has the following features:

- It can be a Switched Port , Routed Port or AP.
- The destination port can not be the source port at the same time.

Interaction between the SPAN and Other Functions

The SPAN interacts with the following functions.

- Spanning Tree Protocol (STP)
- The destination port of SPAN participates in the STP.

Configuring SPAN

Default SPAN Configuration

Function	Default Configuration
SPAN status	Disabled

Creating a SPAN Session and Specifying the Monitoring Port and Monitored Port

To set up a SPAN session and sepcify the destination port and the source port, execute the following commands.

Command	Function
Ruijie(config)# **monitor session** *session_number* **source interface** *interface-id* **[,| -] {both | rx | tx**}	Specify the source port. *interface-id*: Specify corresponding interface id.
Ruijie(config)# **monitor session** *session_num* **destination interface** *interface-id* {**encapsulation** | **switch**}	Specify the destination port. *interface-id*: Specify corresponding interface id. Add the encapsulation parameter to support the mirrored port encapsulation function, and add the switch parameter to support the mirrored destination port exchanging function.

To delete a SPAN session, use the **no monitor session** *session_number* command in the global configuration mode. To delete all the SPAN sessions, use the **no monitor session all** command in the global configuration mode. You can use the **no monitor session** *session_number* **source interface** *interface-id* command or the **no monitor session** *session_number* **destination interface** *interface-id* command to delete the source port or destination port in the global configuration mode.

The following example shows how to create session 1. First, clear the configuration of session 1, and then mirror the frames from port 1 to port 8. The **show monitor session** command allows you to verify your configuration.

```
Ruijie(config)# no monitor session 1
Ruijie(config)# monitor session 1 source interface gigabitEthernet 3/1 both
Ruijie(config)# monitor session 1 destination interface gigabitEthernet 3/8
Ruijie(config)# end
Ruijie# show monitor session 1
sess-num: 1
src-intf:
GigabitEthernet 3/1 frame-type Both

dest-intf:
```

```
GigabitEthernet 3/8
```

Caution Session 1 is used to support ther global cross-linecard port mirror.

Deleting a Port from the SPAN Session

To delete a port from a SPAN session, execute the following commands:

Command	Function
Ruijie(config)# **no monitor session** *session_number* **source interface** *interface-id* [,| **-] [both | rx | tx**]	Specify the source port to delete. *interface-id*: Specify corresponding interface id.

You can use the **no monitor session** *session_number* **source interface** *interface-id* command to delete the source port from a SPAN session in the global configuration mode. The following example shows how to delete gigabitEthernet 1/1 port from session 1 and check the configuration.

```
Ruijie(config)# no monitor session 1 source interface gigabitethernet 1/1 both
Ruijie(config)# end
Ruijie# show monitor session 1
sess-num: 1
dest-intf:
GigabitEthernet 3/8
```

Specifying the Source/Destination MAC for the Mirrored Frame

To specify the source and destination MAC addresses for the mirrored frames, execute the following commands:

Command	Function
Ruijie(config)# [**no**] **monitor session** *session_number* [**source interface** *interface-id* [**both** | **rx** | tx] | **destination interface** *interface-id*] | **mac** {**source** *mac-addr*| **destination** *mac-addr* } [**both** | **rx** | **tx**] {**source | destination**} *mac-address* [**both** | **rx** | **tx**]	Specify the source and destination MAC addresses for the mirrored frames.

You can use the **no monitor session** *session_number* **mac** {**source** \| **destionation**} [**both** \| **rx** \| **tx**] command to delete the source and destination MAC addresses for the mirrored frames.

Other Precautions

1) Connect the network analyzer to the monitoring port.
2) When the SPAN is enabled, the configuration change has the following result.

- If you change the VLAN configuration of the source port, the configuration takes effect immediately.
- If you change the VLAN configuration of the destination port, the configuration takes effect immediately.
- If you have disabled the source port or destination port, the SPAN does not take effect.

- If you add the source or destination port to an AP, this will remove the source port or destination port from the SPAN.

Displaying SPAN Configuration

The **show monitor** command shows the current SPAN status. The following example illustrates how to show the current status of SPAN session 1.

```
Ruijie# show monitor session 1
sess-num: 1
src-intf:
GigabitEthernet 3/1 frame-type Both
dest-intf:
GigabitEthernet 3/8
```

IP Address and Service Configuration

Configuring IP Address and Service

Understanding IP Address Configuration

Overview

An IP address is made up of 32 binary bits and expressed in dotted decimal format for the convenience of writing and description. In dotted decimal format, the 32 binary bits form four octets (1 octet equals to 8 bits). Each octet is separated by a period (dot) in the range from 0 to 255. For example, 192.168.1.1 is an IP address in dotted decimal format.

An IP address is an address that IP uses for interconnection. A 32-bit IP address consists of two parts: network address and local address. According to the first several bits of the network address of an IP address, IP addresses are divided into four categories.

Class A: There are totally 128 Class A IP addresses. The most significant bit is 0, followed by seven bits representing a network ID and 24 bits representing a host ID.

Figure 1-1

8 16 24 32

Class A IP address	0	Network ID	Host ID

Class B: There are totally 16,384 Class B IP addresses. The two most significant bits are 10, followed by 14 bits representing a network ID and 16 bits representing a host ID.

Figure 1-2

8 16 24 32

Class B IP address	1	0	Network ID	Host ID

Class C: There are totally 2,097,152 Class C IP addresses. The three most significant bits are 110, followed by 21 bits representing a network ID and 8 bits representing a host ID.

Figure 1-3

8 16 24 32

Class C IP address	1	1	0	Network ID	Host ID

Class D: The four most significant bits are 1110 and the other bits are a multicast IP address.

Figure 1-4

8 16 24 32

Class D IP address	1	1	1	0	Multicast address

Note

An IP address whose four most significant bits are 1111 is prohibited. This type of IP addresses, also called Class E IP addresses, is reserved.

When you build up a network, plan IP addresses according to the real network environment. To make the network connect to the Internet, you need to apply for IP addresses from a central authority, for example, China Internet Network Information Center (CNNIC) in China. Internet Corporation for Assigned Names and Numbers (ICANN) is the ultimate authority responsible for IP address allocation. However, for a private network, you do not need to apply for IP addresses. It is recommended that you assign private IP addresses for hosts in a private network.

The following table lists reserved and available addresses.

Class	Address Space	Status
Class A	0.0.0.0	Reserved
	1.0.0.0 to 126.0.0.0	Available
	127.0.0.0	Reserved
Class B	128.0.0.0 to 191.254.0.0	Available
	191.255.0.0	Reserved
Class C	192.0.0.0	Reserved
	192.0.1.0 to 223.255.254.0	Available
	223.255.255.0	Reserved
Class D	224.0.0.0 to 239.255.255.255	Multicast
Class E	240.0.0.0 to 255.255.255.254	Reserved
	255.255.255.255	Broadcast

Three blocks of IP addresses are reserved for private networks and are not used on the Internet. Address translation is required for a private network using one of these IP addresses to access the Internet. The following table lists these addresses, which are defined in RFC 1918.

Class	Address Space	Status
Class A	10.0.0.0 to 10.255.255.255	1
Class B	172.16.0.0 to 172.31.255.255	16
Class C	192.168.0.0 to 192.168.255.255	256

For information on the assignment of IP addresses, TCP/UDP ports and other codes, refer to RFC 1166.

IP Address Configuration Task List

The IP address configuration task list includes the following tasks. Only the first one is required, and the others are optional depending on your network requirements.

Assigning IP Addresses to Interfaces

Only hosts configured with IP addresses can receive and send IP packets. If an interface is configured with an IP address, this means that the interface supports the IP protocol.

Use the following commands to assign an IP address to an interface in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip address** *ip-address mask*	Assigns an IP address to an interface.
Ruijie(config-if)# **no ip address**	Removes the IP address configured for the interface.

A 32-bit mask identifies the network part of an IP address. In a mask, the IP address bit corresponding to 1 represents the network ID and the IP address bit corresponding to 0 represents the host ID. For example, the mask corresponding to a Class A IP address is 255.0.0.0. You can subdivide a network into multiple segments by using the mask. The goal of subnet definition is to use some bits of the host address of an IP address as the network address to reduce the number of hosts and increase the number of networks. At this point, the mask is called a subnet mask.

Note

Theoretically, any bit of the host address of an IP address can be used as a subnet mask.

☑ Ruijie products only support continuous subnet masks from left to right starting from the network ID.

You can configure the following features related to IP addresses in a task list. These tasks are optional depending on your actual needs.

Assigning Multiple IP Addresses to an Interface

Ruijie products support assigning multiple IP addresses to an interface. Of the assigned IP addresses, one is the primary IP address and the others are secondary IP addresses. Theoretically, you can configure secondary addresses as many as you wish. A secondary IP address, however, must reside in different networks from the primary IP address or the other secondary IP addresses. The secondary IP address will be used frequently during the building of a network, for example, in the following cases:

- There are not enough host addresses for a network. For example, a LAN requires a Class C IP address to support up to 254 hosts. However, when there are more than 254 hosts in the LAN, another Class C IP address is necessary. Therefore, a host needs to connect two networks and thus needs configuring multiple IP addresses.
- Many older networks were built based on Layer 2 bridges without subnet definition. The use of secondary IP addresses makes it easy to upgrade such a network to an IP-based routing network. An IP address is assigned for every device in a subnet.
- Two subnets of a network might be separated by another network. By creating a subnet in each separated subnets, you can connect the two separated subnets together by assigning secondary IP addresses. One subnet cannot appear on two or more interfaces in a device.

Caution

Before configuring a secondary IP address, you need to confirm that the primary IP address has been configured. If a secondary IP address is configured on one device of the network, the secondary IP addresses configured for other devices of the network must be located in the same network. If an IP address is not assigned to other devices, you can configure the IP address as the primary IP address for a device.

Use the following command to assign a secondary IP address to an interface in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip address** *ip-address mask* **secondary**	Assigns a secondary IP address to the interface.
Ruijie(config-if)# **no ip address** *ip-address mask* **secondary**	Removes the secondary IP address configured for the interface.

Configuring the Management IP Address and the Gateway Together

Ruijie Layer-2 switches allow you to configure the management IP address and the gateway by using the same command. Generally, Layer-2 switches provide the **ip default-gateway** command to configure a default gateway. Sometimes, the Layer-2 switch supports remote management via Telnet, and the management IP address and default gateway of the Layer-2 switch must be modified. In such a case, configuring either the **IP address** command or the **IP default-gateway** command will prevent you from configuring the other command (because the configuration has changed and this device can no longer be accessed via the network). Therefore, use the **gateway** keyword of the **IP address** command to modify the management IP address and default gateway.

Caution This command is only supported on Layer-2 devices.

Use the following commands to configure the management IP address and the gateway at the same time in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip address** *ip-address mask* **gateway** *ip-address*	Configures the management IP address and gateway.
Ruijie(config-if)# **no ip address** *ip-address mask* **gateway**	Removes the configured management IP address and gateway.

Configuring the Address Resolution Protocol (ARP)

Every device in a LAN has two addresses: a local address and a network address. The local address is contained in the header of a frame at the data link layer. More exactly, it is a data link layer address. Since this local address is handled in the MAC sub-layer of the data link layer, it is normally called an MAC address representing an IP network device on a network. The network address represents a device on the Internet and indicates the network to which the device belongs.

For mutual communication, a device in a LAN must know the 48-bit MAC address of the other device. It can obtain the MAC address according to an IP address. This process is called ARP. The reversed ARP (RARP) can resolve the IP address based on a MAC address. You can resolve an address in two ways: ARP and proxy ARP. For more information on ARP, proxy ARP and RARP, refer to RFC 826, RFC 1027, and RFC 903.

ARP binds an IP to an MAC address. It can resolve the MAC address according to an IP address. Then, the relationship between the IP address and the MAC address is stored in the ARP cache. With the MAC address, a device can encapsulate the frames of the data link layer and send them to the LAN in the Ethernet II-type by default. However, the frames can also be encapsulated into other types of Ethernet frames, such as SNAP.

The principle of RARP is similar to ARP. RARP resolves the IP address according to an MAC address. RARP is applied on diskless workstations in general.

Normally, a device can work without any special address resolution configuration. Ruijie products can manage address resolution by the following configuration:

Configuring ARP Statically

ARP offers dynamic IP-to-MAC address mapping. It is not necessary to configure ARP statically in most cases. By configuring ARP Statically, Ruijie products can respond to ARP requests from other IP addresses.

Use the following commands to configure static ARP in global configuration mode.

Command	Function
Ruijie(config)# **arp** *ip-address mac-address arp-type*	Defines static ARP. Currently, Only *arp-type* can be set to **arpa** only.
Ruijie(config)# **no arp** *ip-address*	Removes static ARP.

Setting ARP Encapsulation

Currently Ruijie products only support Ethernet II ARP encapsulation, which also known as the **ARPA** keyword.

Setting ARP Timeout

ARP timeout takes effect for only the dynamically-learned IP-to-MAC address mapping. The shorter the timeout, the truer the mapping table saved in the ARP cache, but the more network bandwidth the ARP occupies. Hence the advantages and disadvantages should be weighted. Generally it is not necessary to configure the ARP timeout period unless otherwise stated.

Use the following commands to configure the ARP timeout period in interface configuration mode.

Command	Function
Ruijie(config-if)# **arp timeout** *seconds*	Configures the ARP timeout period in the range from 0 to 2147483, where 0 indicates no aging.
Ruijie(config-if)# **no arp timeout**	Removes the configuration.

By default, the timeout period is 3600 seconds.

Disabling IP Routing

IP routing is enabled by default. Do not execute this command unless you are sure that IP routing is not needed. Disabling IP routing will make the device lose all routes and the route forwarding function.

Run the following commands to disable IP routing in global configuration mode.

Command	Function
Ruijie(config)# **no ip routing**	Disables IP routing.

Command	Function
Ruijie(config)# **ip routing**	Enables IP routing

Configuring Broadcast Packet Processing

A broadcast packet is destined to all hosts in a physical network. Ruijie products support two kinds of broadcast packets: directed broadcast and flooding. A directed broadcast packet is sent to all the hosts in a specific network, with the host ID of the destination IP addresses set to all-1s. While a flooding broadcast packet is sent to all the hosts in all networks, with all 32 bits of the destination IP address set to 1s. Broadcast packets are currently misused by some protocols, including the Internet protocol. Therefore, it is a basic responsibility for a network administrator to manage and control broadcast packets.

Forwarding flooding broadcast packets may make the network overburden and thus affect network operation. This is known as broadcast storm. There are some ways to suppress and restrict broadcast storm in the local network. However, Layer 2 network devices like bridges and switches will forward and spread broadcast packets.

The best solution to solve broadcast storm is to specify a broadcast address for each network, that is, to implement directed broadcast. This requires the IP protocol to use directed broadcast instead of flooding broadcast as much as possible.

For details about broadcast, refer to RFC 919 and RFC 922.

You can configure the following features in a task list to process broadcast packets. These tasks are optional depending on actual network needs.

Enabling Directed Broadcast-to-Physical Broadcast Conversion

A directed broadcast IP packet is one destined to the broadcast address of an IP subnet. For instance, the packet destined to 172.16.16.255 is a directed broadcast packet. However, the node that generates this packet is not a member of the destination subnet.

Upon receipt of a directed broadcast IP packet, the device indirectly connecting the destination subnet will forward the packet in the same way as forwarding a unicast packet. After the directed broadcast IP packet arrives at a device directly connecting the subnet, the device transforms the packet into a flooding broadcast IP packet (whose destination address is all-1s in general), and then send it to all the hosts within the destination subnet by means of broadcast at the link layer.

Enabling the conversion from directed broadcast to physical broadcast on an interface allows the interface to forward directed broadcast IP packets to the directly connected network. This command only affects the transmission of the directed broadcast IP packets to the final destination subnet, but not other directed broadcast packets.

You can control the forwarding of directed broadcast IP packets as required on an interface by defining ACLs. Only those IP packets matching the ACLs will experience the conversion from directed broadcast to physical broadcast.

Use the following commands to configure directed broadcast-to-physical broadcast conversion in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip directed-broadcast** [*access-list-number*]	Enables directed broadcast to physical broadcast conversion on the interface.

Command	Function
Ruijie(config-if)# **no ip directed-broadcast**	Disables the conversion.

Establishing an IP Broadcast Address

Currently, the most popular way is the destination address consisting of all 1s (255.255.255.255). Ruijie products can be configured to generate other IP broadcast addresses and receive all types of IP broadcast packets.

Use the following commands to set a broadcast IP address other than 255.255.255.255 in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip broadcast-address** *ip-address*	Creates a broadcast address.
Ruijie(config-if)# **no ip broadcast-address**	Removes the configuration.

Monitoring and Maintaining IP Addresses

You can monitor and maintain networks according to the following task list. These tasks are optional depending on your actual needs.

Clearing Caches and Table Contents

You can remove all contents of a particular cache, table, or database, including

- Clearing the ARP cache
- Clearing the table of mapping between host names and IP addresses
- Clearing the routing table

Command	Function
Ruijie# **clear arp-cache**	Clears the ARP cache.
Ruijie# **clear ip route** {*network* [*mask*] | *}	Clears the IP routing table.

Displaying System and Network Status

You can show the contents of the IP routing table, cache, and database. Such information is very helpful in network troubleshooting. You also can display information about network reachability of a local device and determine the routing path that the packets of your device are taking after leaving the device.

Use the following commands to display system and network status information in privileged user mode.

Command	Function
Ruijie# **show arp** [[*ip* [*mask*] | *mac-address*] | **static** | **complete** | **incomplete**]	Shows the ARP cache table. The **complete** keyword is used to show resolved entries of dynamic ARP, and the **incomplete** keyword is used to show unresolved entries of dynamic ARP.
Ruijie# **show ip arp**	Shows the IP ARP cache table.
Ruijie# **show ip interface** [*interface-type interface-number*]	Shows interface IP address information.
Ruijie# **show ip route** [*network* [*mask*]]	Shows the routing table.
Ruijie#**show ip route**	Shows brief information about the routing table.

Command	Function
Ruijie# **ping** *ip-address* [**length** *bytes*] [**ntimes** *times*] [**timeout** *seconds*]	Tests network reachability.

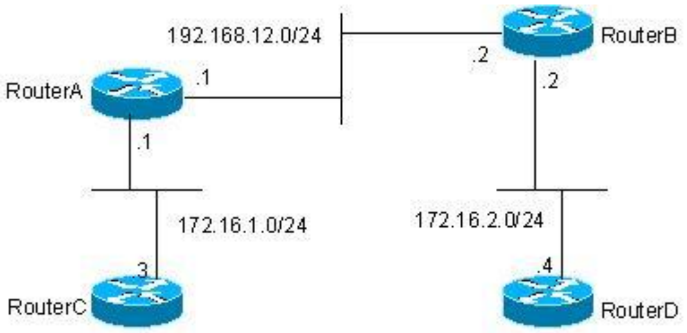
IP Address Configuration Examples

Example of Configuring Secondary IP Addresses

Configuration Requirements

The following figure shows IP address assignment and network device connections.

Figure 1-5 Examples of configuring secondary IP addresses.



Configure RIP. You can set the version to RIPv1 only. You can see the routes of 172.16.2.0/24 on router C and the routes of 172.16.1.0/24 on router D.

Configuration of the Routers

RIPv1 does not support classless routes. This means masks are not carried in route advertisements. 172.16.1.0/24 and 172.16.2.0/24 that belong to the same network are separated by the Class C network 192.168.12.0/24. Generally, router C and router D cannot learn detailed routes from each other. According to a feature of RIP, the mask of the route to be received should be set to the same value as that of the interface network if the route and the interface network belong to the same network. By configuring routers A and B, you can build a secondary network 172.16.3.0/24 on the network 192.168.12.0/24 to link the two separated subnets. The following presents a configuration description of routers A and B only.

Router A:

```
interface FastEthernet 0/0
ip address 172.16.3.1 255.255.255.0 secondary
ip address 192.168.12.1 255.255.255.0
!
interface FastEthernet 0/1
ip address 172.16.1.1 255.255.255.0
!
router rip
network 172.16.0.0
network 192.168.12.0
```

Router B:

```
interface FastEthernet 0/0
ip address 172.16.3.2 255.255.255.0 secondary
ip address 192.168.12.2 255.255.255.0
!
interface FastEthernet 0/1
ip address 172.16.2.1 255.255.255.0
!
router rip
network 172.16.0.0
network 192.168.12.0
```

Configuring the IP Service

IP Configuration Task List

IP service configuration covers the following configuration tasks. These tasks are optional depending on your actual needs.

Configuring the Default Gateway

☑ Run the command only on L2 devices.

If no destination IP address to which a packet will be sent is specified, the packet will be sent to the default gateway by default. Use the **show ip redirects** command to view the settings.

Use the following command to set the default gateway in global configuration mode. Use the **no** form of this command to remove the default gateway.

Command	Function
ip default-gateway *ip-address*	Sets the default gateway.

Use the following command to view the configured default gateway.

Command	Function
show ip redirects	Displays the default gateway.

Managing IP Connections

The IP protocol stack offers a number of services to control and manage IP connections. The Internet Control Message Protocol (ICMP) provides many of these services. Once a network problem occurs, a device or access server will send an ICMP message to the host or other devices. For detailed information on ICMP, see RFC 792.

Enabling the ICMP Destination Unreachable Message

When a router receives a non-broadcast packet destined to it and this packet uses an IP protocol that it cannot handle, it will return an ICMP destination unreachable message to the source address. Similarly, if the router is unable to forward the packet because it knows of no route to the destination address, it sends an ICMP host unreachable message. This feature is enabled by default.

Use the following command to enable or disable ICMP host unreachable messages in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip unreachables**	Enables ICMP protocol unreachable and host unreachable messages.
Ruijie(config-if)# **no ip unreachables**	Disables ICMP protocol unreachable and host unreachable messages.

Enabling the ICMP Redirect Message

Routes are sometimes less than optimal. For example, it is possible for the device to be forced to resend a packet through the same interface on which the packet was received. If the device resends a packet through the receiving interface, it sends an ICMP redirect message to the originator of the packet, telling the originator that the gateway to this destination address is another device in the same subnet. Therefore, the originator will transmit subsequent packets based on the optimized path. This feature is enabled by default.

Use the following commands to enable or disable the ICMP redirect message in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip redirects**	Enables the ICMP redirect message. It is enabled by default.
Ruijie(config-if)# **no ip redirects**	Disables the ICMP redirect message.

Enabling the ICMP Mask Reply Message

Occasionally, a network device needs to know the mask of a subnet on the Internet. To obtain this information, the device can send an ICMP mask request message. The device receiving the request will return an ICMP mask reply message. Ruijie products can respond to the ICMP mask request message. This function is enabled by default.

Use the following commands to enable or disable the ICMP mask reply message in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip mask-reply**	Enables the ICMP mask reply message.
Ruijie(config-if)# **no ip mask-reply**	Disables the ICMP mask reply message.

Setting the IP MTU

All interfaces have a default MTU value. All packets which are larger than the MTU have to be fragmented before they are sent on an interface. Otherwise the packets cannot be forwarded on the interface.

Ruijie products allow you to adjust the MTU on an interface. Changing the MTU value can affect the IP MTU value, and the IP MTU value will be modified automatically to match the new MTU. However, changing the IP MTU value has no influence on the MTU value of the interface.

The interfaces of a device in a physical network should have the same MTU for the same protocol.

Use the following commands to set the IP MTU in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip mtu** *bytes*	Sets the MTU in the range from 68 to 1500 bytes.
Ruijie(config-if)# **no ip mtu**	Restores the default MTU settings.

Configuring IP Source Routing

Ruijie products support IP source routing. Upon receiving an IP packet, the device will check its IP header like strict source route, loose source route and recorded route, which are defined in RFC 791. If one of these options is enabled, the device performs an appropriate action. Otherwise, it sends an ICMP error message to the source and then discards the packet. Ruijie products support IP source routing by default.

Use the following commands to enable or disable IP source routing in interface configuration mode.

Command	**Function**
Ruijie(config)# **ip source-route**	Enables IP source routing.
Ruijie(config)# **no ip source-route**	Disables IP source routing.

Configuring VRF

VRF Overview

Virtual Private Networks (VPNs) provide a secure way to share bandwidths in the backbone networks of ISPs. One VPN is the collection of the sites sharing routes. The sites connect to the service provider’s network through one or multiple interface links, with one VPN routing table associated with one interface. The VPN routing table is also referred to as a VPN routing or forwarding (VRF) table.

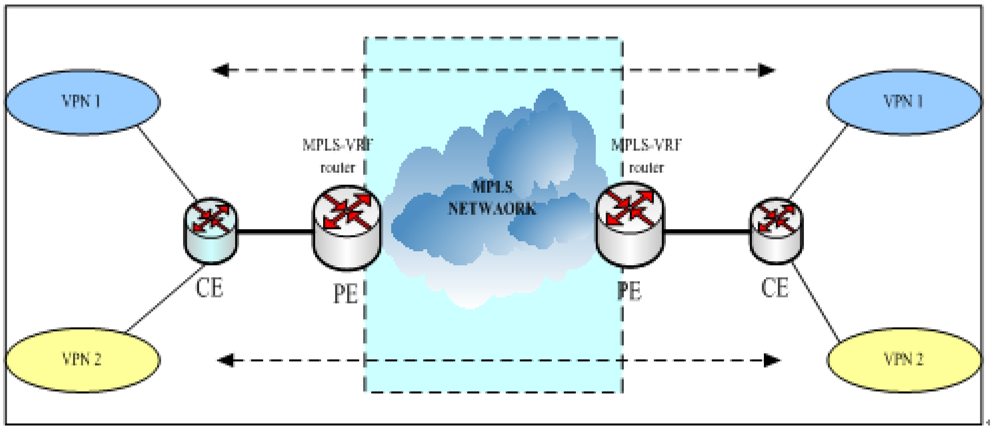
Caution

Ruijie RSRs support the VRF-lite feature, which is also known as the multi-VRF CE or multi-VRF Customer Edge Device, and can implement multiple VPN route forwarding instances when serving as CEs.

Working Principles of VRF-Lite

The working principles of VRF-lite are as follows:

- CEs provide multiple access channels to PEs to support user access. CEs advertise local routes to PEs, and learns VPN remote routes from PEs.
- PEs exchange routing information with CEs via static routing and dynamic routing protocols, such as BGP, RIP, and OSPF.
- PEs may have multiple interfaces that belong to one VPN. PEs exchange VPN routing information with each other via BGP.
- PEs do not rely on the functions of CEs.
- P devices do not process VPN information. That is, VPN information is transparent to P devices.



Typical Application Model of VRF-Lite

The packet processing flow is as follows when VRF-lite is enabled on a network:

- When a CE receives a packet from a VPN, it checks interface information to query the related VRF table. If a route is successfully found in the VRF table, the CE sends the packet to a PE.
- When the ingress PE receives a packet from a CE, it queries the VRF table. If a route is successfully found in the VRF table, the ingress PE adds an MPLS label to the route and sends the packet to the MPLS network.
- When the egress PE receives an MPLS packet from the MPLS network, it removes the MPLS label and finds the related VPN routing table. The egress PE searches for a common route. If a route is successfully found, the egress PE sends the packet to the related adjacency.
- When a CE receives a packet from the egress PE, it checks the inbound interface of the packet to obtain the related VPN routing table and then searches for a route. If a route is successfully found, the packet is sent to the VPN.

Multi-Protocol VRF

You can create only single-protocol VRF supporting IPv4 in version earlier than 10.4(3). Use the **ip vrf** command to create a single-protocol IPv4 VRF. To enable single-protocol IPv4 VRF on a network interface, use the **ip vrf forwarding** command in interface configuration mode.

To support IPv6 VPNs, the 10.4(3) version has introduced multi-address-family VRFs. A multi-address-family VRF enables you to define multiple address families under the same VRF. You can apply a multi-address-family VRF to both IPv4 VPNs and IPv6 VPNs. A multi-address-family VRF is also called a multi-protocol VRF. You can use the **vrf definition** command to create a multi-protocol VRF. To enable a multi-protocol VRF on a network interface, use the **vrf forwarding** command in interface configuration mode.

It is not allowed to use the commands for configuring a single-protocol IPv4 VRF to configure a multi-protocol VRF, and vice versa.

For example, you can use the configuration command of a multi-protocol VRF to create a multi-protocol VRF named "vrf1".

```
Ruijie(config)#vrf definition vrf1
```

If you try to use a configuration command of a single-protocol VRF to edit vrf1, the following prompting message will be displayed:

```
Ruijie(config)#ip vrf vrf1
% Use ‘vrf definition vrf1’ command.
```

If you try to use a multi-protocol VRF command to edit the single-protocol VRF named "vrf2" which only supports IPv4, the following prompting message will be displayed:

```
Ruijie(config)# vrf definition vrf2
% Use ‘ip vrf vrf2’ command.
```

The configuration commands (ip vrf and ip vrf forwarding) of single-protocol IPv4 VRFs will be reserved for a period of time until they are abandoned.

Configuring VRF-Lite

You can configure VRF-Lite as follows:

- A CE supports multiple users via VRF-Lite. Each user has its own routing table on the CE.
- Since each user has its own routing table, they may use the same IP address. This function is temporarily not supported.
- Multiple users share the physical line between a CE and a PE, and there are multiple logical interfaces on the physical line. The physical line can be implemented by multiple means.
- VRF-lite does not support functions related to MPLS-VRF. It mostly acts on CEs.
- For a PE, connecting it to multiple CEs does not differ from using VRF-lite on it.
- EBGP is recommended for route exchange between a PE and a CE. Of course, OSPF, RIP, and static routing protocols may also be used for route exchange, but that would be more complex. If the OSPF protocol is used for route exchange, you need to exercise caution during configuration. It is recommended that you enable the capability VRF-lite function when using the OSPF protocol for route exchange.

Creating VRF

Use the following commands to create a single-protocol IPv4 VRF.

Command	Function
Ruijie(config)# **ip vrf** *vrf-name*	Creates a VRF. vrf-name shall not exceed 31 characters.
Ruijie(config)# **no ip vrf** *vrf-name*	Deletes the VRF.

Use the following commands to create a multiprotocol VRF.

Command	Function
Ruijie(config)# **vrf definition** *vrf-name*	Creates a multi-protocol VRF. *vrf-name* shall not exceed 31 characters.
Ruijie(config-vrf)# **address-family ipv4**	Configures an IPv4 address family, namely to enable the IPv4 protocol of VRFs. No IPv4 address family is configured by default.
Ruijie(config-vrf-af)# **exit-address-family**	Exits VRF address-family configuration sub-mode.
Ruijie(config-vrf)# **address-family ipv6**	Configures an IPv6 address family, namely to enable the IPv6 protocol of VRFs. No IPv6 address family is configured by default.
Ruijie(config-vrf-af)# **exit-address-family**	Exits VRF address-family configuration sub-mode.

Configuring a VRF Descriptor

Command	Function
Ruijie(config-vrf)# **description** *string*	Configures a VRF descriptor, which contains at most 244 characters.

The following example configures a VRF descriptor named “vpn-a” for a single-protocol IPv4 VRF named “vrf1”.

```
Ruijie(config)#ip vrf vrf1
Ruijie(config-vrf)#description vpn-a
```

The following example configures a VRF descriptor named “vpn-b” for a multiprotocol VRF named “vrf2”.

```
Ruijie(config)#vrf definition vrf2
Ruijie(config-vrf)#description vpn-b
```

Enabling VRF on Interfaces

Command	Function
Ruijie(config-if)# **ip vrf forwarding** *vrf-name*	Binds an interface to a single-protocol IPv4 VRF. Note that *vrf-name* cannot be a multiprotocol VRF. If the IPv6 function does not need to be enabled on an interface, you can bind the interface to a single-protocol IPv4 VRF. If the IPv6 function needs to be enabled on an interface, it is not recommended that you use this command to bind the interface to a single-protocol IPv4 VRF.
Ruijie(config-if)# **no ip vrf forwarding** *vrf-name*	Cancels the binding between an interface and a single-protocol IPv4 VRF.
Ruijie(config-if)# **vrf forwarding** *vrf-name*	Binds an interface to a multiprotocol VRF. Note that *vrf-name* cannot be a single-protocol IPv4 VRF. If the IPv6 function needs to be enabled on an interface, it is recommended that you bind the interface to a multiprotocol VRF instead of a single-protocol IPv4 VRF.
Ruijie(config-if)# **no vrf forwarding** *vrf-name*	Cancels the binding between an interface and a multiprotocol VRF.

An interface does not belong to any VRF by default. That is, global routing applies.

Caution

After you bind an interface to a single-protocol IPv4 VRF, the IPv4 address originally configured for the interface will be invalid. The binding does not affect the IPv6 address configured for the interface. In general, enable VRF first on the interface and then configure an IPv4 address.

Caution

If you bind an interface to a single-protocol IPv4 VRF and enables the IPv6 protocol on the interface, the switch cannot forward IPv6 packets received on the interface. Therefore, it is recommended that you use the multiprotocol VRF if you want to bind the interface to a VRF and enable the IPv6 protocol on the interface at the same time.

Caution

You cannot bind an interface to a multiprotocol VRF not configured with any address family.

Caution

If you bind an interface to a multiprotocol VRF, all existing IPv4, IPv6, VRRP IPv4, and VRRP IP6 addresses configured for the interface will be deleted. In addition, the IPv6 protocol will be disabled on the interface.

Caution

If you bind an interface to a multiprotocol VRF not configured with any IPv4 address family, you cannot configure any IPv4 or VRRP IPv4 address for the interface. Before configuring an IPv4 or VRRP IPv4 address for the interface, you needs to configure an IPv4 address family for the multiprotocol VRF.

Caution

If you bind an interface to a multiprotocol VRF not configured with any IPv6 address family, you cannot configure any IPv6 or VRRP IPv6 address for the interface. Before configuring an IPv6 or VRRP IPv6 address for the interface, you needs to configure an IPv6 address family for the multiprotocol VRF.

Caution

If you delete the IPv4 address family configured for a multiprotocol VRF, all IPv4 and VRRP IPv4 addresses of all network interfaces bound to this VRF will be deleted, so will the static IPv4 routes whose routing VRF or next-hop VRF is this VRF. If you delete the IPv6 address family configured for a multiprotocol VRF, all IPv6 and VRRP IPv6 addresses of all network interfaces bound to this VRF will be deleted, the IPv6 protocol will be disabled on the interfaces, and all the static IPv6 routes whose routing VRF or next-hop VRF is this VRF will be deleted.

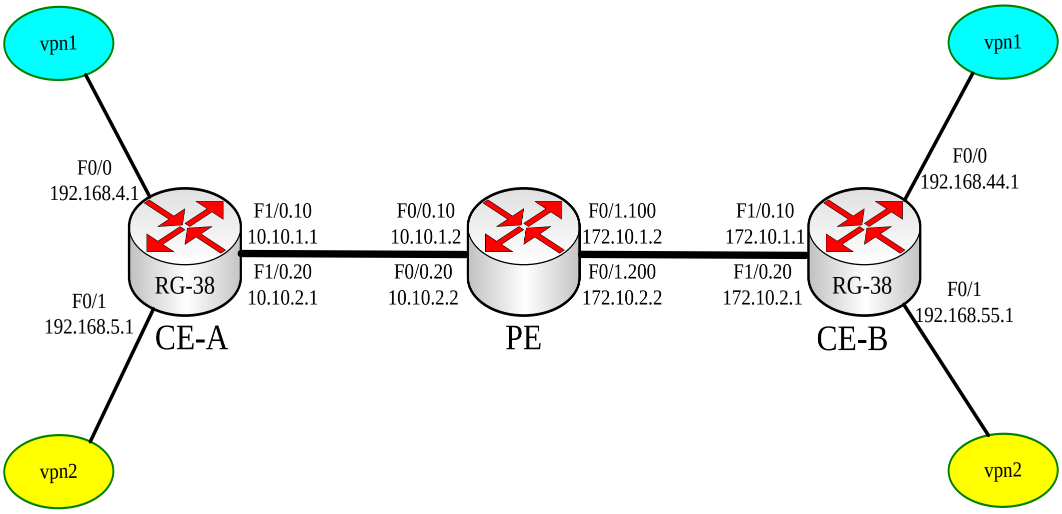
Configuring VRF Routes

Command	Function
Ruijie(config)# **ip route vrf** *vrf-name network mask interface nexthop*	Adds a route.
Ruijie(config)# **no ip route vrf** *vrf-name network mask*	Deletes a route.

You can also use routing protocols to configure routes.

VRF-Lite Configuration Examples

Example 1: As shown in the following figure, Ruijie devices serve as CEs and PEs. The CEs access two VPNs named “vpn1” and “vpn2”.



```
Ruijie# hostname CE-A
# Name the router.
CE-A# configure terminal
# Enter global configuration mode.
CE-A(config)# ip vrf vpn1
# Create a VRF named “vpn1”.
CE-A(config)# ip vrf vpn2
# Create a VRF named “vpn2”.
CE-A(config)# interface f0/0
# Enter interface configuration mode.
CE-A(config-if)#description  connecting-to-vpn1
# Link to vpn1.
CE-A(config-if)# ip vrf forwarding vpn1
# Enable VRF on the interface.
CE-A(config-if)# ip address 192.168.4.1 255.255.255.0
# Configure an IP address.
CE-A(config)# interface f0/1
# Enter interface configuration mode.
CE-A(config-if)# ip vrf forwarding vpn2
# Enable VRF on the interface.

Ruijie(config-if-VLAN 1)#ipv6 address 1000::1/64
Ruijie(config-if-VLAN 1)#exit
# Configure a static IPv4 or IPv6 route of the multiprotocol VRF.
Ruijie(config)#ip route vrf multi-af-vrf-example 0.0.0.0 0.0.0.0 1.1.1.2
Ruijie(config)#ipv6 route vrf multi-af-vrf-example ::/0 1000::2
```

VRF-Lite Debugging

Use the following command to check the routing table of a VRF.

Command	Function
show ip route vrf *vrf-name*	Displays the routes of the specified VRF.

For details about the command syntax, see the *VRF Command Reference*.

Use the following command to clear the routing table of a VRF.

Command	Function

clear ip route vrf *vrf-name* *	Clears the routes of the specified VRF.

For details about the command syntax, see the *VRF Command Reference*.

Use the following commands to check information about a VRF in the system.

Command	Function
show ip vrf [*vrf-name*]	Displays information about an IPv4 VRF.
show vrf [brief] [vrf-name]	Displays brief information about a VRF.
show vrf ipv4 [*vrf-name*]	Displays brief information about an IPv4 VRF.
show vrf ipv6 [*vrf-name*]	Displays brief information about an IPv6 VRF.
show vrf detail [*vrf-name*]	Displays details about a VRF.

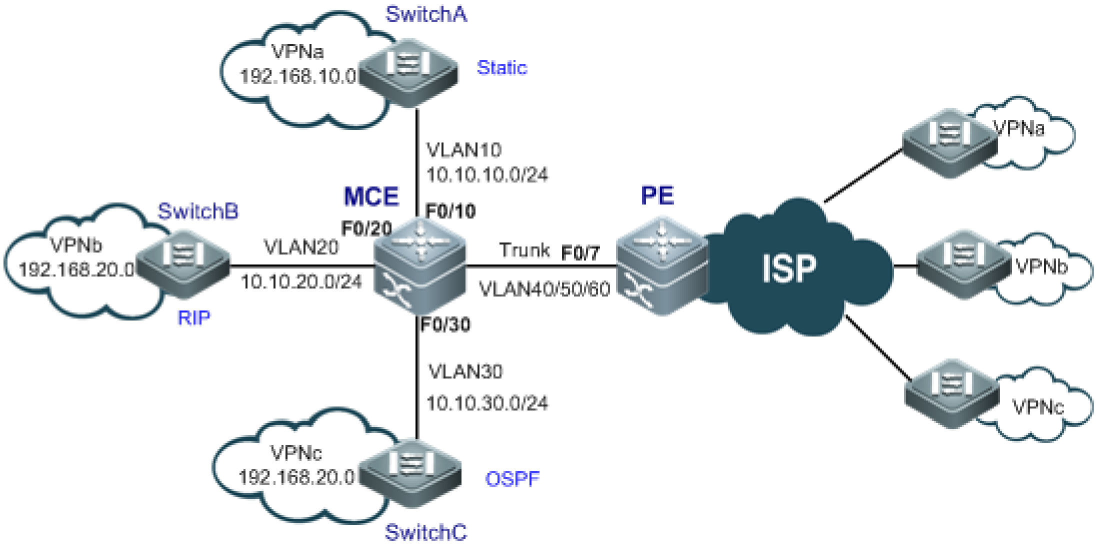
For details about the command syntax, see the *VRF Command Reference*.

MCE Configuration Example

Networking Topology

As shown in the following figure, VPNa, VPNb, and VPNc are located at different sites and exchange information across the backbone network.

- VPN sites access a PE via a MCE.
- Static routes are configured between the MCE and VPNa. RIP is configured between the MCE and VPNb to exchange routing information. The OSPF protocol is configured between the MCE and VPNc to exchange routing information.



Typical Topology of MCE Application

Networking Requirements

The MCE needs to isolate the routes of one VPN from the routes of the other VPNs. It advertises the routes of various VPNs to the PE via the static routing protocol, RIP, and the OSPF protocol respectively.

Duplicate addresses in a VPN must be supported.

Configuration Tips

Create multiple VRF instances on the MCE and the PE, so that the routes of different VPN services are isolated from one another. Perform the following two steps:

Configure VRF instances and bind them to various interfaces.

Interface	Bound VRF	Interface IP Address
Interface of the MCE that connects to VPNa (SVI 10)	VPNa	10.10.10.3
Logical interface of the MCE that connects to the PE (SVI 40)	VPNa	10.10.40.1
Logical interface of the PE that connects to the MCE (SVI 40)	VPNa	10.10.40.2
Interface of the MCE that connects to VPNb (SVI 20)	VPNb	10.10.20.3
Logical interface of the MCE that connects to the PE (SVI 50)	VPNb	10.10.50.1
Logical interface of the PE that connects to the MCE (SVI 50)	VPNb	10.10.50.2
Interface of the MCE that connects to VPNc (SVI 30)	VPNc	10.10.30.3
Logical interface of the MCE that connects to the PE (SVI 60)	VPNc	10.10.60.1
Logical interface of the PE that connects to the MCE (SVI 60)	VPNc	10.10.60.2

Configure route exchange between the MCE, VPN sites, and the PE.

VRF instances on the MCE cooperate with VRF instances on the PE to advertise VPN routes to the PE via the routing protocol between the MCE and the PE. Then the PE advertises the routes to other PEs on the network, so that each VPN site interworks with remote VPN sites on the network.

Note

In this example, VRF instances on the MCE exchange routes with VPN sites and the PE via the same routing protocol.

Note

If VRF instances on the MCE exchange routes with VPN sites and the PE via different routing protocols, to guarantee complete exchange of VPN routes, the routing protocols of VRF instances on the MCE must be redistributed, so that the MCE can advertise VPN routes to VRF instances on the PE and that the routes advertised by the PE to VRF instances on the MCE can be further advertised to VPN sites.

Configuration Steps

Configure VRF instances on the MCE and the PE, and bind VRF instances to interfaces.

Create VRF instances on the MCE.

Step 1: Create VRF instances named “VPNa”, “VPNb”, and “VPNc” on the MCE.

```
MCE(config)#ip vrf vpna
MCE(config-vrf)#exit
MCE(config)#ip vrf vpnb
MCE(config-vrf)#exit
MCE(config)#ip vrf vpnc
MCE(config-vrf)#exit
```

Step 2: Create VLAN 10, and add the FE interface 0/10 of the MCE that connects to Switch A to VLAN 10.

```
MCE(config)#interface fastEthernet 0/10
MCE(config-if-FastEthernet 0/10)#switchport access vlan 10
MCE(config-if-FastEthernet 0/10)#exit
```

Step 3: Bind the interface SVI 10 of VLAN 10 to VPNa, and set the IP address of the interface SVI 10 to 10.10.10.3/24.

```
MCE(config)#interface vlan 10
MCE(config-if-VLAN 10)#ip vrf forwarding vpna
MCE(config-if-VLAN 10)#ip address 10.10.10.3 255.255.255.0
MCE(config-if-VLAN 10)#exit
```

Step 4: Similarly, create VLAN 20 and VLAN 30 (see the previous two steps), bind the interface SVI 20 of the MCE that connects to Switch B to VPNb, and bind the interface SVI 30 of the MCE that connects to Switch C to VPNc. Set the IP address of the interface SVI 20 to 10.10.20.3, and the IP address of the interface SVI 30 to 10.10.30.3.

Step 5: Create VLAN 40, VLAN 50, and VLAN 60, and add the FE interface 0/7 of the MCE that connects to the PE to the three VLANs. Bind SVI 40 to VPNa, SVI 50 to VPNb, and SVI 60 to VPNc. Set the IP address of the interface SVI 40 to 10.10.40.1, the IP address of the interface SVI 50 to 10.10.50.1, and the IP address of the interface SVI 60 to 10.10.60.1.

```
MCE(config)#vlan 40
MCE(config-vlan)#exit
MCE(config)#vlan 50
MCE(config-vlan)#exit
MCE(config)#vlan 60
MCE(config-vlan)#exit
MCE(config)#interface fastEthernet 0/7
MCE(config-if-FastEthernet 0/7)#switchport mode trunk
MCE(config-if-FastEthernet 0/7)#exit
MCE(config)#interface vlan 40
MCE(config-if-VLAN 40)#ip vrf forwarding vpna
MCE(config-if-VLAN 40)#ip address 10.10.40.1 255.255.255.0
MCE(config-if-VLAN 40)#exit
MCE(config)#interface vlan 50
MCE(config-if-VLAN 50)#ip vrf forwarding vpnb
MCE(config-if-VLAN 50)#ip address 10.10.50.1 255.255.255.0
MCE(config-if-VLAN 50)#exit
MCE(config)#interface vlan 60
MCE(config-if-VLAN 60)#ip vrf forwarding vpnc
MCE(config-if-VLAN 60)#ip address 10.10.60.1 255.255.255.0
```

After the above steps are performed, VRF instances are created on the MCE.

Create VRF instances on the PE.

Step 1: Create VRF instances named “VPNa”, “VPNb”, and “VPNc” on the PE.

```
PE(config)#ip vrf vpna
PE(config-vrf)#exit
PE(config)#ip vrf vpnb
PE(config-vrf)#exit
PE(config)#ip vrf vpnc
PE(config-vrf)# exit
```

Step 2: Create VLAN 40, VLAN 50, and VLAN 60, and add the FE interface 0/7 of the PE that connects to the MCE to the three VLANs. Bind SVI 40 to VPNa, SVI 50 to VPNb, and SVI 60 to VPNc. Here, the operations for creating VLANs and adding interfaces to VLANs are omitted.

```
PE (config)#interface vlan 40
PE(config-if-VLAN 40)#ip vrf forwarding vpna
PE(config-if-VLAN 40)#ip address 10.10.40.2 255.255.255.0
PE(config-if-VLAN 40)#exit
PE(config)#interface vlan 50
PE(config-if-VLAN 50)#ip vrf forwarding vpnb
PE(config-if-VLAN 50)#ip address 10.10.50.2 255.255.255.0
PE(config-if-VLAN 50)#exit
PE(config)#interface vlan 60
PE(config-if-VLAN 60)#ip vrf forwarding vpnc
PE(config-if-VLAN 60)#ip address 10.10.60.2 255.255.255.0
```

After the above steps are performed, VRF instances are created on the PE.

Configure static routes between the MCE and VPNa, and between the MCE and the PE.

Configure a static route on Switch A (access switch for the site VPNa).

Set the IP address of the interface of Switch A that connects to the MCE to 10.10.10.2/24, and that of the interface of Switch A that connects to the site VPNa to 192.168.10.1/24. Here, the operations for adding ports to VLANs and setting interface IP addresses are omitted.

# Configure a default route on Switch A, with the next hop of the outbound packet pointing to 10.10.10.3.

```
SwitchA(config)#ip route 0.0.0.0 0.0.0.0 10.10.10.3
```

Configure a static route on the MCE.

# Configure a static route on the MCE for packets destined to the network segment 192.168.10.0, with the next hop pointing to 10.10.10.2, and binds the route to the instance VPNa.

```
MCE(config)#ip route vrf vpna 192.168.10.0 255.255.255.0 10.10.10.2
```

Configure static routes on the PE.

# Configure two static routes on the PE, and bind them to the instance VPNa. One is for packets destined to the network segment 192.168.10.0, with the next hop pointing to 10.10.40.1. The other is for packets destined to the network segment 10.10.10.0, with the next hop also pointing to 10.10.40.1.

```
PE (config)#ip route vrf vpna 192.168.10.0 255.255.255.0 10.10.40.1
PE (config)#ip route vrf vpna 10.10.10.0 255.255.255.0 10.10.40.1
```

Configure RIP route exchange between the MCE and VPNb, and between the MCE and the PE.

Configure RIP on Switch B (access switch for the site VPNb).

# Set the IP address of the interface of Switch B that connects to the MCE to 10.10.20.2/24, and that of the interface of Switch B that connects to the site VPNb to 192.168.20.1/24. Here, the operations for adding ports to VLANs and setting interface IP addresses are omitted.

```
SwitchB(config)#router rip
SwitchB(config-router)#version 2
SwitchB(config-router)#no auto-summary
SwitchB(config-router)#network 10.10.20.0 0.0.0.255
SwitchB(config-router)#network 192.168.20.0 0.0.0.255
```

Configure RIP on the MCE.

```
MCE(config)#router rip
MCE(config-router)#address-family ipv4 vrf vpnb
MCE(config-router-af)# version 2
MCE(config-router-af)# no auto-summary
MCE(config-router-af)#network 10.10.20.0 0.0.0.255
MCE(config-router-af)#network 10.10.50.0 0.0.0.255
```

Configure RIP on the PE.

```
PE(config)#router rip
PE(config-router)#address-family ipv4 vrf vpnb
PE(config-router-af)# version 2
PE(config-router-af)# no auto-summary
```

PE(config-router-af)#network 10.10.50.0 0.0.0.255 Configure OSPF route exchange between the MCE and VPNc, and between the MCE and the PE.

Configure the OSPF protocol on Switch C (access switch for the site VPNc).

# Set the IP address of the interface of Switch C that connects to the MCE to 10.10.30.2/24, and that of the interface of Switch C that connects to the site VPNc to 192.168.20.1/24. Here, the operations for adding ports to VLANs and setting interface IP addresses are omitted.

```
SwitchC(config)#router ospf 1
SwitchC(config-router)#network 10.10.30.0 0.0.0.255 area 0
SwitchC(config-router)#network 192.168.20.0 0.0.0.255 area 0
```

Configure the OSPF protocol on the MCE.

```
MCE(config)#router ospf 1 vrf vpnc
MCE(config-router)#network 10.10.30.0 0.0.0.255 area 0
MCE(config-router)#network 10.10.60.0 0.0.0.255 area 0
```

Configure the OSPF protocol on the PE.

```
PE(config)#router ospf 1 vrf vpnc
PE(config-router)#network 10.10.60.0 0.0.0.255 area 0
```

Verification

Check routing information about the instance VPNa.

Check routing information on Switch A (access switch for the site VPNa).

```
SwitchA (config)#show ip route
Gateway of last resort is 10.10.10.3 to network 0.0.0.0
S*  0.0.0.0/0 [1/0] via 10.10.10.3
C   10.10.10.0/24 is directly connected, VLAN 10
C   10.10.10.2/32 is local host.
C   192.168.10.0/24 is directly connected, FastEthernet 0/23
C   192.168.10.1/32 is local host.
```

Check routing information about the instance VPNa on the MCE.

```
MCE#show ip route vrf vpna
Routing Table: vpna
C   10.10.10.0/24 is directly connected, VLAN 10
C   10.10.10.3/32 is local host.
C   10.10.40.0/24 is directly connected, VLAN 40
C   10.10.40.1/32 is local host.
S   192.168.10.0/24 [1/0] via 10.10.10.2
```

Check routing information about the instance VPNa on the PE.

PE#show ip route vrf vpna

```
Routing Table: vpna
S   10.10.10.0/24 [1/0] via 10.10.40.1
C   10.10.40.0/24 is directly connected, VLAN 40
C   10.10.40.2/32 is local host.
S   192.168.10.0/24 [1/0] via 10.10.40.1
```

Check routing information about the instance VPNb.

Check routing information on Switch B (access switch for the site VPNb).

SwitchB#show ip route vrf vpnb

```
Routing Table: vpnb
C   10.10.20.0/24 is directly connected, VLAN 20
C   10.10.20.2/32 is local host.
R   10.10.50.0/24 [120/1] via 10.10.20.3, 00:01:20, VLAN 20
C   192.168.20.0/24 is directly connected, FastEthernet 0/23
C   192.168.20.1/32 is local host.
```

Check routing information about the instance VPNb on the MCE.

```
MCE#show ip route vrf vpnb
Routing Table: vpnb
C   10.10.20.0/24 is directly connected, VLAN 20
```

```
C    10.10.20.3/32 is local host.
C    10.10.50.0/24 is directly connected, VLAN 50
C    10.10.50.1/32 is local host.
R    192.168.20.0/24 [120/1] via 10.10.20.2, 00:22:01, VLAN 20
```

According to the above information, the MCE has learned the private network routes of VPNb via RIP. These routes and the routes of VPNa and VPNc are separately maintained in three routing tables, thus effectively isolating the VPNs from each other and supporting address duplication inside each VPN.

Check routing information about the instance VPNb on the PE.

```
PE#show ip route vrf vpnb
Routing Table: vpnb
R    10.10.20.0/24 [120/1] via 10.10.50.1, 00:04:48, VLAN 50
C    10.10.50.0/24 is directly connected, VLAN 50
C    10.10.50.2/32 is local host.
R    192.168.20.0/24 [120/2] via 10.10.50.1, 00:02:15, VLAN 50
```

The above information shows that all the routes of the instance VPNb have been advertised to the PE.

Check routing information about the instance VPNc.

Check routing information on Switch C (access switch for the site VPNc).

```
SwitchC (config-router)#show ip route

C    10.10.30.0/24 is directly connected, VLAN 30
C    10.10.30.2/32 is local host.
O    10.10.60.0/24 [110/2] via 10.10.30.3, 00:02:42, VLAN 30
C    192.168.20.0/24 is directly connected, FastEthernet 0/23
C    192.168.20.1/32 is local host.
```

Check routing information about the instance VPNc on the MCE.

```
MCE#show ip route vrf vpnc

Routing Table: vpnc
C    10.10.30.0/24 is directly connected, VLAN 30
C    10.10.30.3/32 is local host.
C    10.10.60.0/24 is directly connected, VLAN 60
C    10.10.60.1/32 is local host.
O    192.168.20.0/24 [110/2] via 10.10.30.2, 00:01:36, VLAN 30
```

According to the above information, the MCE has learned the private network routes of VPNc via OSPF. These routes and the routes of VPNa and VPNb are separately maintained in three routing tables, thus effectively isolating the VPNs from each other and supporting address duplication inside each VPN.

Check routing information about the instance VPNc on the PE.

```
PE#show ip route vrf vpnc

```

```
Routing Table: vpnc
O    10.10.30.0/24 [110/2] via 10.10.60.1, 00:00:00, VLAN 60
C    10.10.60.0/24 is directly connected, VLAN 60
C    10.10.60.2/32 is local host.
O    192.168.20.0/24 [110/3] via 10.10.60.1, 00:00:00, VLAN 60
```

The above information shows that all the routes of the instance VPNc have been advertised to the PE.

PE	Provider Edge Device
MCE	Multi-CE
VPN	Virtual Private Network
VRF	VPN Routing and Forwarding Table

Configuring IPv4 Express Forwarding

Understanding IPv4 Express Forwarding

Overview

To meet the needs of higher-end devices, we use a Prefix Tree+Adjacency Ruijie Express Forwarding (REF) model to enable express forwarding. REF constitutes the mirroring of the whole core routing table instead of buffering some information in the core routing table. Therefore, the cache does no longer need to be added to the CPU in the case of a cache failure, thus reducing the impact on the CPU and guaranteeing routing stability.

REF constructs the routing table mirroring by using the following two parts:

- Prefix Tree

The Prefix Tree is an IP prefix tree organized according to the maximum matching rule for retrieving adjacent nodes. In general, the data structure for constructing the Prefix Tree is different from the Radix Tree of the core routing table. Instead, a data structure called the M-Tries Tree is used to enable more rapid multi-step search. Using the M-Tries Tree to construct the Prefix Tree will take up more memory than using the Radix Tree. Although updating prefix and node information relatively consumes time, high retrieval performance can be obtained.

- Adjacency

Adjacency refers to an adjacent node, which contains the interface information output by routed packets, such as next-hop list, next processing part, and link-layer output encapsulation. When packets match with such an adjacent node, packets are directly encapsulated, and then the send function of this node is called to enable forwarding. To facilitate retrieval and update, the tables made up of adjacent nodes are generally organized into a hash table. To support load balancing of routes, the next list information on adjacent nodes is organized in load-balancing table form.

REF routing consists of three steps:

- REF de-encapsulates packets.
- Use the Prefix Tree to retrieve the adjacent nodes according to the routes of packets.
- After the adjacent nodes are matched, the final output interface of packets is determined according to adjacent nodes, and then packets are encapsulated according to the output interface type.

Configuring Load Balancing Policy for Express Forwarding

Express forwarding supports load balancing of packets. At present, three load balancing policies are supported. In the REF model, when the route prefix IP/MASK is associated with multiple next hops, namely, a multi-path route, the route will be associated with one load-balancing table and load is balanced according to route weights. When IP packets match with the load balancing table according to the longest prefix, express forwarding hashes the IP addresses of packets, and then one path is selected for packet forwarding. There arethree routing policies:

- Load is balanced according to destination addresses of IP packets. The destination IP addresses of packets are hashed. The route with a greater weight is more likely to be selected. By default, this policy is selected.
- Load is balanced according to destination and source IP addresses of IP packets. Destination and source IP addresses of packets are hashed and the route with a greater weight is more likely to be selected.
- Load is balanced according to packets polling. Each packet takes turn to select the path and all paths can be selected.

Use the following commands to configure the load balancing policy in global configuration mode:

Command	Function
Ruijie(config)# ip ref load-sharing algorithm original	Sets the load balancing algorithm based on source and destination IP addresses.
Ruijie(config)# **ip ref load-sharing packet**	Performs the load balancing according to packet polling
Ruijie(config)# no ip ref load-sharing algorithm	Load is balanced according to destination addresses of packets.

Note These commands are unique to routers.

Maintaining and Monitoring the Express Forwarding Table

The express forwarding module passively receives and maintains external routing information instead of actively adding or deleting any route information. As a result, the express forwarding table provides current statistical information on routes.

Statistical information on Express Forwarding Packets

Statistical information on express forwarding packets refers to the statistical information on the packets processed by the express forwarding REF, including the number of forwarded packets and the number of packets dropped due to various reasons.

Command	Function
Ruijie# show ip ref packet-statistic [clear]	Displays or clears the current statistical information on packets in REF.

Adjacency Table Information

In the express forwarding table, one type of important data table is the adjacency table. Use the following command to check current adjacency information.

Command	Function

Ruijie# show ip ref adjacency [glean | local | *ip* | (interface *interface_type* *interface_number*) | statistic]	Displays the specified gleaned adjacency, local adjacency, adjacency corresponding to the specified IP address, adjacency associated with the specified interface, and information on all adjacency nodes.

Information on Packet Forwarding Path

Packets are forwarded according to IP addresses of packets. Therefore, if source IP addresses and destination IP addresses of packets are specified, the path for forwarding packets will be determined. Use the following command and specify source IP addresses and destination IP addresses of packets. The actual path for forwarding packets will be displayed. For example, you can learn whether packets are dropped, submitted to the CPU, or forwarded. Furthermore, you can know about the interface through which packets are forwarded.

Command	**Function**
Ruijie# show ip ref exact-route [vrf *vrf_name*] *source-ipaddress dest_ipaddress*	Displays the actual forwarding path of a specified packet.

Note This command is unique to routers.

Routing information in the Express Forwarding Table

Express forwarding receives external route advertisements and maintains an express forwarding table, which is a mirroring of the core routing table. Use the following commands to display routing information in the express forwarding table.

Command	**Function**
Ruijie# show ip ref route [vrf vrf_name] [default | (ip mask) | statistic]	Displays current default routing information in the express forwarding table. If the default route is not specified, all routing information in the express forwarding table is displayed, including the 0 route, default route, and common gateway route.

Configuring TCP

Overview

The TCP module provides a reliable and connection-oriented IP-based transmission layer protocol for the application layer.

The application layer sends data streams represented in 8-bit bytes for Internet transmission to the TCP layer, which separates the data streams into packet segments with proper sizes. The maximum segment size (MSS) is generally limited by the maximum transmission unit (MTU) of the data link layer of the network to which the computer is connected. After that, TCP transmits the result packets to the IP layer, which will then transmit the said packets through the network to the TCP layer of receiving terminal.

To ensure no packet loss, TCP assigns a sequence number to each byte, and the sequence number also ensures that packets transmitted to the receiving terminal are received in sequence. The receiving terminal will then reply with an ACK to confirm the receipt of each byte. If no ACK is received within the reasonable Round Trip Time (RTT), then the corresponding byte (assumed lost) will be retransmitted by the sender.

- With regard to data accuracy and validity, TCP uses a checksum function to verify the data. The checksum must be calculated while the date is sent or received. In the meantime, MD5 authentication can also be utilized to encrypt the data.
- To ensure reliability, TCP applies the mechanisms of timeout retransmission and piggybacking.
- The sliding window protocol is applied to implement flow control. According to the protocol, all unconfirmed packets within the window will be retransmitted.
- The widely recognized TCP congestion control algorithm (also called the AIMD algorithm) is applied to implement congestion control. This algorithm mainly involves: 1) additive increase and multiplicative decrease; 2) slow start; 3) response to timeouts.

Configuring TCP

Changing the Timeout for Establishing a TCP Connection

Establishing a TCP connection requires a three-way handshake: The local end sends a SYN packet, the remote end responds with a SYN+ACK packet, and then the local end responds with an ACK.

- After the local end sends SYN, if the remote end does not respond with SYN+ACK, the local end will continuously retransmit SYN packets until the specified number of retransmissions is reached or until the timeout timer expires.
- After the local end sends SYN and the remote end responds with SYN+ACK, if the local end no longer responds with ACK, the remote end will keep retransmission until the specified number of retransmissions is reached or until the timeout timer expires (Such as SYN attacks).

Use the following command to configure the timeout value for SYN packets (the maximum time from SYN transmission to successful three-way handshake), namely the timeout for establishing a TCP connection.

Command	Function
Ruijie(config)# ip tcp syntime-out *seconds*	Changes the timeout value for establishing a TCP connection. Range: 5 to 300 seconds; default: 20

Use the **no ip tcp syntime-out** command to restore the default value.

Note This command only applies to IPv4 TCP.

Changing the Buffer Size

The TCP receiving buffer is utilized to buffer the data received from the peer end. These data will be subsequently read by application programs. Generally, the window size of TCP packets implies the size of the free space in the receiving buffer. For connections involving a greater bandwidth and mass data, increasing the size of the receiving buffer will remarkably improve TCP transmission performance. The sending buffer is utilized to buffer the data of application programs. Each byte in the buffer has a sequence number, and bytes with sequence numbers acknowledged will be removed from the sending buffer. Increasing the sending buffer will improve the interaction between TCP and application programs, thus enhancing the performance. However, increasing the receiving buffer and sending buffer will result in more memory consumption of TCP.

Command	Function
Ruijie(config)# ip tcp window-size *size*	Changes the size of receiving buffer and sending buffer for TCP connections. Range: 0 to 65535 bytes; default: 4096.

Use the **no ip tcp window-size** command to restore the default value.

Note This command only applies to IPv4 TCP.

Note This command does not apply to existing TCP connections. It only applies to subsequent TCP connections.

Note This command will apply to both the receiving buffer and sending buffer.

Prohibiting the Reset Packet When the Port is Unreachable

When the TCP module distributes TCP packets, if the TCP connection to which such packets belong cannot be found, a reset packet will be replied to the peer end to terminate the TCP connection. The attacker may initiate attacks by sending excessive port-unreachable TCP packets.

Run the following commands to prohibit or restore the reset packet sent when the port-unreachable TCP packet is received.

Command	Function
Ruijie(config)# ip tcp not-send-rst	Prohibits sending a reset packet when the port-unreachable TCP packet is received.

Use the **no ip tcp not-send-rst** command to restore the default settings.

Note

This command only applies to IPv4 TCP.

Limiting the MSS of TCP Connections

The MSS refers to the maximum size of the payload of a TCP packet, excluding TCP options.

During the three-way handshake for establishing a TCP connection, one important job is to carry out MSS negotiation. Both sides will insert an MSS option into the SYN packet to indicate the maximum size of the segment that can be received by the local end, namely the maximum size of the segment that can be sent by the remote end. Both sides will take the smaller of the MSS value sent locally and that received from the remote end as the maximum segment size of this connection.

The methods for calculating the value of the MSS option while sending SYN packets are shown below:

Non-directly connected network: MSS = Default value 536

Directly connected network: mss = egress interface MTU corresponding to the peer IP address – 20-byte IP header – 20-byte TCP header

Generally speaking, if the MTU is affected by certain applications configured on the egress interface, such applications will configure the MTU accordingly, such as the MTUs of the tunnel port and VPN port.

Note

In release 10.4(3), in the SYN+ACK packet replied by the remote end of a directly connected network, the MSS option is not calculated through MTU. Instead, the default value 536 is used.

Note

The MSS calculated cannot exceed the size of the receiving buffer or the IP TCP MSS configured by the user. Otherwise, the smaller of them will be used.

Note

If certain options are supported by this connection, then the size obtained after 4-byte alignment of the option must be subtracted from the MSS. For example, if the size of the MD5 option is 18 bytes, 20 bytes will be obtained after alignment.

The RMSS value obtained here is the value of the MSS option in the SYN packet sent. For example, BGP adjacency is generally established in the directly connected network, and the MSS of such a connection is 1500 – 20 – 20 – 20 = 1440.

The function of IP TCP MSS is to limit the MSS of the pending TCP connection. The negotiated MSS cannot exceed the value configured.

Command	Function
Ruijie(config)# **ip tcp mss** *max-segment-size*	Limits the maximum segment size of TCP connections. Range: 68 to 10000 bytes.

Use the **no ip tcp mss** command to disable such limit.

Note This command only applies to IPv4 TCP.

Enabling PMTU Discovery

The TCP Path MTU (PMTU) is implemented as per RFC1191. This feature can improve the network bandwidth utilization ratio. When the user uses TCP to transmit mass data, this feature can substantially enhance the transmission performance.

Command	Function
Ruijie(config)# **ip tcp path-mtu-discovery** [**age-timer** *minutes* | **age-timer infinite**]	Enables PMTU discovery. **age-timer** *minutes*: The time interval for further discovery after discovering PMTU in the range from 10 to 30 minutes. The default value is 10. **age-timer infinite**: No further discovery after discovering PMTU.

According to RFC1191, after discovering PMTU, TCP can use a greater MSS to discover a new PMTU, and the time interval thereof is specified by the parameter **age-timer**. When the PMTU discovered by the device is smaller than the MSS negotiated, the device will try to discover a greater PMTU as per the aforementioned time interval. Such a discovery process will not end until PMTU reaches the value of MSS or until the user stops this timer. To turn off the timer, use the parameter **age-timer infinite**.

Use the **no ip tcp path-mtu-discovery** command to disable PMTU discovery.

Note This command applies to both IPv4 TCP and IPv6 TCP.

Note This command does not apply to existing TCP connections. It only applies to subsequent TCP connections.

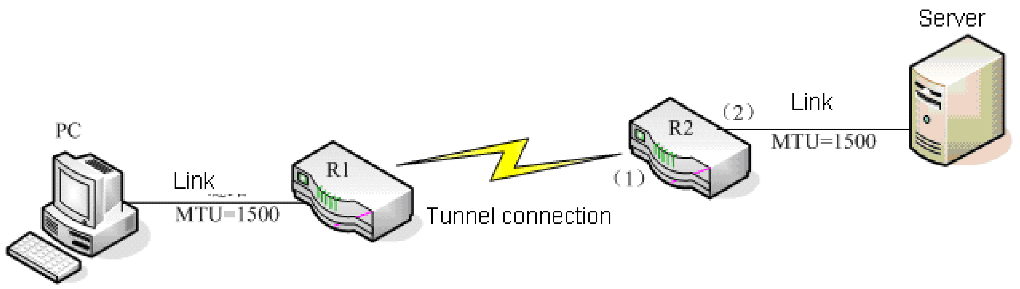
Configuring the MSS Option of SYN Packets Sent and Received on the Interface

The TCP Path MTU (PMTU) is implemented as per RFC1191. This feature can improve the network bandwidth utilization ratio. When the user uses TCP to transmit mass data, this feature can substantially enhance the transmission performance.

When the client initiates a TCP connection, it negotiates the maximum payload of TCP packets through the MSS Option field of the TCP SYN packet. The MSS value of client's SYN packet implies the maximum payload of TCP packets sent by the server, and vice versa.

As shown in the following figure, a PC may fail to access the server through HTTP, because the MSS of 1460 will be negotiated between the PC and the server, but such MSS cannot pass R1 and R2 (R1 and R2 are connected through a tunnel, with an MTU smaller than 1500).

Figure 1-1



In such a case, we can configure the following command on port (1) and port (2) of R2 to change the MSS Option value of the SYN packet, so as to change the MSS value negotiated for the TCP connection going through port (1) and port (2).

Command	Function
Ruijie(config-if)# **ip tcp adjust-mss** *max-segment-size*	Configures the MSS Option value of SYN packets sent and received on the interface. Range: 500 to 1460 bytes.

Use the **no ip tcp adjust-mss** command to remove the configuration. In such a case, the MSS Option value of packets will not be changed when the interface sends and receives SYN packets.

Configuring this command on the interface will change the MSS option of SYN packets received or sent on the interface to the MSS value configured on the interface. It is suggested that you configure the same value on the ingress interface and egress interface, or else the MSS option of SYN packets going through the device will be changed to the smaller of the two values configured.

Note

This command only applies to IPv4 TCP and is only supported by routers.

Note

In release 10.4(3), the MSS value of SYN+ACK packets will not be changed.

Monitoring and Maintenance

Command	Function
Ruijie# show tcp connect	Displays basic information about the current TCP connection.
Ruijie# show tcp pmtu	Displays information about TCP PMTU.
Ruijie# show tcp port	Displays information about the current TCP port.

Application Protocol Configuration

Configuring DNS

Overview

Due to the Domain Name System (DNS), each IP address can present a host name consisting of one or more strings separated by the decimal. Then, you only need to remember the host name rather than IP address.

There are two methods of mapping the host name to the IP address: 1) Static mapping: A device maintains its host name to IP address mapping table and uses it only by itself. 2) Dynamic mapping: The host name to IP address mapping table is maintained on the DNS server. In order for a device to communicate with others by its host name, the corresponding IP address needs to be searched on the DNS server.

The domain name resolution (or host name resolution) is the process that the device obtains an IP address corresponding to the host name by the host name. Ruijie switches support the host name resolution locally or by the DNS. During domain name resolution, you can firstly adopt the static method. If it fails, use the dynamic method. Some frequently used domain names can be put into the resolution list of static domain names. In this way, the efficiency of domain name resolution can be increased considerably.

Configuring Domain Name Resolution

Default DNS Configuration

The following table describes default configurations of DNS.

Attribute	**Default value**
Enable/disable the DNS resolution service	Enable
IP address of DNS server	None
Status Host List	None
Maximum number of DNS servers	Six

Enabling DNS Resolution Service

The following table describes how to enable the DNS resolution service.

Command	**Function**
Ruijie(config)# **ip domain**-lookup	Enables DNS.

To disable DNS, use the **no ip domain-lookup** command.

```
Ruijie(config)# ip domain-lookup
```

Configuring the DNS Server

This section describes how to configure the DNS server. The dynamic domain name resolution can be carried out only when the DNS Server is configured.

Use the **no ip name-server** [*ip-address*] command to remove the DNS server. In the command, the *ip-address* parameter indicates the specified DNS server to be removed. If this parameter is omitted, all the DNS servers will be removed.

Command	Function
Ruijie(config)**# ip name-server** *ip-address*	Adds the IP address of the DNS Server. The switch will add a DNS Server every time this command is executed. If the domain name can't be obtained from the first DNS Server, the switch will send the DNS request to the subsequent several servers until the correct response is received. The system can support six DNS servers at most.

Configuring the Host Name to IP/IPv6 Address Mapping Statically

This section describes how to configure the host name to IP/IPv6 address mapping. The switch maintains a host name to IP/IPv6 address corresponding table, which is also referred to as the host name to IP/IPv6 address mapping table. You can obtain the mapping table in two ways: manual configuration and dynamic learning. Manual configuration is required when dynamic learning is impossible.

Command	Function
Ruijie(config)# **ip host** *host-name ip-address*	Configures the host name to IP address mapping manually.
Ruijie(config)# **ipv6 host** *host-name ip-address*	Configures the host name to IPv6 address mapping manually.

To remove the mapping between the host name and IP/IPv6 address, use the **no** form of this command.

Clearing the Dynamic Buffer Table of Host Names

This section describes how to clear the dynamic buffer table of host names. If the **clear host** or **clear host** * command is entered, the dynamic buffer table will be cleared. Otherwise, only the entries of specified domain names will be cleared.

The following table describes related command.

Command	Function
Ruijie# **clear host** [*word*]	Clears the dynamic buffer table of host names. The host names configured statically will not be removed.

Showing Domain Name Resolution Information

This section describes how to display the DNS configuration.

Command	Function

Command	Function
Ruijie# **show hosts** [*host-name*]	Show parameters related to DNS.

```
Ruijie# show hosts
Name servers are:
192.168.5.134  static
Host                 type      Address          TTL(sec)
www.163.com          static    192.168.5.243    ---
```

Typical DNS Configuration Examples

Example of Static DNS Configuration

Topological Diagram

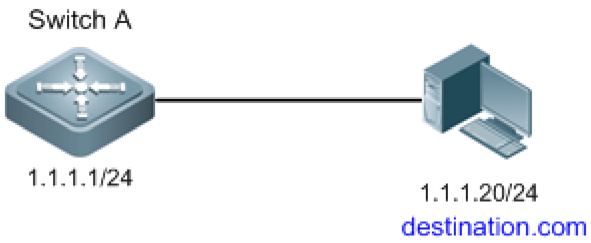


Figure1 Networking topology for static DNS configuration

Application Requirements

Since Switch A will frequently access the host of destination.com, you can use static DNS to access the host of IP 1.1.1.20 through the domain name of destination.com for domain resolution efficiency.

Configuration Tips

- Ensure that the route between device and host is reachable.
- The mapping between host name and IP address is correct.

Configuration Steps

Manually configure the mapping between host name and IP address. In this example, configure the host name to "destination.com" and the corresponding IP address to 1.1.1.20.

```
SwitchA(config)#ip host destination.com 1.1.1.20
```

Verification

Step 1: Show DNS information. Key points: the mapping between host and IP address shall be correct.

```
Ruijie-A# show host
```

```
Name servers are:
Host               type    Address                   TTL(sec)
destination.com    static  1.1.1.20                   ---
```

Step 2: Use the **ping destination.com** command to verify the result.

```
Ruijie-A# ping destination.com
Translating "destination.com"...[OK]
Sending 5, 100-byte ICMP Echoes to 1.1.1.20, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms
```

The output shows that Ruijie-A has successfully accessed the host with IP address being 1.1.1.20 through the host name of destination.com by means of static DNS.

Example of Dynamic DNS Configuration

Topological Diagram

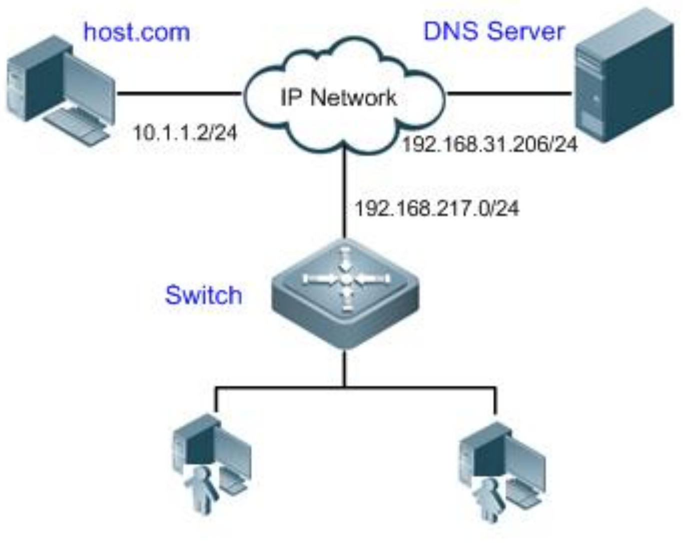

Figure2 Networking topology for dynamic DNS configuration

Application Requirements

- The IP address of DNS server is 192.168.31.206/24.
- The switch is the DNS client that can access the host of 10.1.1.2 through the host name of host.com by means of dynamic DNS.

Configuration Tips

- The route between DNS client, DNS server, and access PC shall be reachable.
- DNS shall be enabled. DNS is enabled by default.
- The IP address of the DNS server has been correctly configured.

Configuration Steps

Step 1: Configure the DNS server

Configure different DNS servers according to the actual conditions.

Configure the mapping between host and IP address on DNS server. This example configures the host name as "host.com" and the IP address as 10.1.1.2/24.

Step 2: Configure the DNS client

The route between DNS client, DNS server, and access PC shall be reachable. The interface IP configurations are shown in the topological diagram.

! DNS shall be enabled. The DNS feature is enabled by default.

```
Ruijie(config)#ip domain-lookup
```

! Configure the IP address of DNS server as 192.168.31.206

```
Ruijie(config)#ip name-server 192.168.31.206
```

Verification

Step 1: Use the **ping host.com** command to verify the result.

```
Ruijie#ping host.com

Translating " host.com "...[OK]
Sending 5, 100-byte ICMP Echoes to 10.1.1.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms
```

The preceding information shows that the client can ping the host, and the destination IP is 10.1.1.2. Through dynamic DNS, the host with the IP address 10.1.1.2 can be accessed through the host name of host.com.

Step 2: Show DNS information. Key points: the host name and IP address.

```
Ruijie#show host
Name servers are:
192.168.31.206 static

Host               type      Address         TTL(sec)
host.com          dynamic    10.1.1.2         3503
```

The output shows that the mapping between host name and host IP is correct.

Configuring DHCP

Understanding DHCP

The Dynamic Host Configuration Protocol (DHCP), as specified in RFC 2131, provides configuration parameters for hosts over the Internet. DHCP works in client/server mode. The DHCP server assigns IP addresses for the hosts dynamically and provides configuration parameters.

DHCP assigns IP address in three ways:

- Assigning IP addresses automatically. The DHCP server assigns permanent IP addresses to the clients;
- Assigning IP addresses dynamically. The DHCP server assigns temporary IP addresses to the clients (or the clients can release the addresses by themselves);
- Configuring IP addresses manually. Network administrators specify IP addresses and send the specified IP addresses to the clients through DHCP.

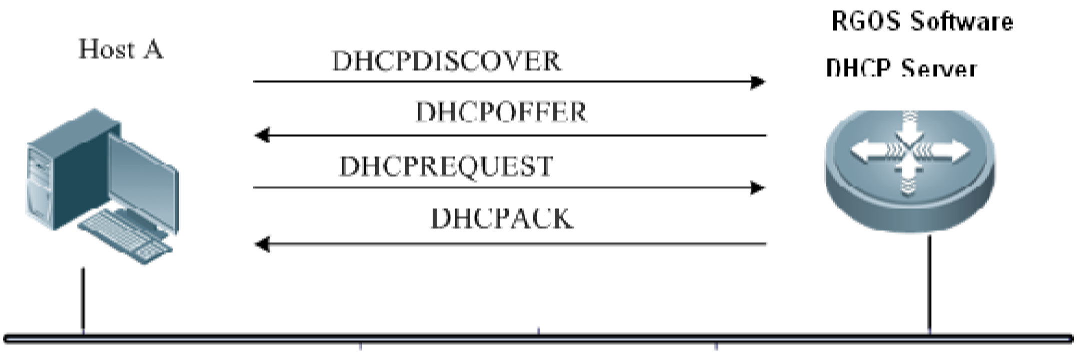
Among the mentioned three methods, only dynamic assignment allows reuse of the IP address that the client does not need any more.

The format of a DHCP message is based on that of a Bootstrap Protocol (BOOTP) message. Hence, the device must act as the BOOTP relay agent and interact with the BOOTP client and the DHCP server. The BOOTP relay agent eliminates the need of deploying a DHCP server in every physical network. DHCP is detailed in RFC 2131 and RFC 2132.

Understanding the DHCP Server

As specified in RFC2131, the DHCP server of Ruijie Networks is implemented to assign and manage IP addresses for the DHCP clients. The DHCP operation process is shown in the following figure.

Fig 1-1 DHCP process



Process of requesting an IP address:

The host broadcasts a DHCPDISCOVER packet in the network to locate the DHCP server;
The DHCP server sends a DHCPOFFER packet in unicast form to the host, including IP address, MAC address, domain name and address lease period;
The host sends a DHCPREQUEST packet in broadcast form to formally request the server to assign the provided IP address;

The DHCP server sends a DHCPACK packet in unicast form to the host to confirm the request.

Note

The DHCP client may receive the DHCPOFFER packets from multiple DHCP servers, and accept all received DHCPOFFER packet. However, the DHCP client usually accepts the first received DHCPOFFER packet only.

Note

The address specified in the DHCPOFFER packet from the DHCP server is unnecessarily the finally assigned address. Generally, the DHCP server reserves this address until the client sends a formal request.

The DHCPREQUEST that requests the DHCP server to assign an address is a broadcast packet with the server address to enable all other DHCP servers that send DHCPOFFER response packets to receive the packet. Other DHCP servers are unable to find that the client has received the DHCPOFFER packet from just the DHCPREQUEST packet, so they will not release the IP addresses provided (pre-assigned) to the clients and will enable the IP addresses corresponding to the unaccepted OFFER lease to be reused through the timing mechanism.

If the DHCPOFFER packet sent to the DHCP client contains invalid parameters, the DHCP client sends the DHCPDECLINE packet to refuse the assigned configuration.

The following are advantages of using the DHCP server of Ruijie Networks for network construction:

- Decreases network access cost. Generally, dynamic address assignment costs less than static address assignment.
- Simplifies configuration tasks and reduce network construction cost. Dynamic address assignment significantly simplifies equipment configuration, and even reduces deployment cost if devices are deployed in the places where there are no professionals.
- Centralizes management. During configuration management on several subnets, each configuration parameter can be changed simply by modifying and updating configurations in the DHCP server.

Understanding the DHCP Client

The DHCP client can obtain IP addresses and other configuration parameters from the DHCP server automatically. The DHCP client brings the following advantages:

- Saves device configuration and deployment time.
- Reduces the possibility of configuration errors.
- Centrally manages IP address assignment.

☑ The DHCP client is supported on the Ethernet interface, FR, PPP, and HDLC interfaces.

Understanding the DHCP Relay Agent

The DHCP relay agent forwards DHCP packets between the DHCP server and the DHCP clients. When the DHCP clients and the server are not located in the same subnet, the DHCP relay agent must be available for forwarding the DHCP request and response messages. Data forwarded by the DHCP relay agent is different from general forwarding. In general forwarding, IP packets are unaltered and the transmission is transparent. However, upon receiving a DHCP message, the DHCP relay agent regenerates a DHCP message before forwarding it.

For the DHCP client, the DHCP relay agent works like a DHCP server. For the DHCP server, the DHCP relay agent works like a DHCP client.

Configuring DHCP

To configure DHCP, perform the following tasks, of which the first three tasks are mandatory.

Enabling the DHCP Server and Relay Agent

Use the following commands to enable the DHCP server and relay agent in global configuration mode.

Command	Function
Ruijie(config)# **service dhcp**	Enables the DHCP server and the DHCP relay agent.
Ruijie(config)# **no service dhcp**	Disables the DHCP server and the DHCP relay agent.

☑ By default, in v10.1 and later, the **service dhcp** command can be used for both the DHCP server and DHCP relay, which are two mutually-exclusive functions. The switchover of those two functions depends on whether the DHCP address pool is configured.

☑ However, for the product in the version earlier than v10.1 (excluding v10.1), the **service dhcp** command is not supported by both DHCP server and DHCP relay. You can use the **service dhcp** command to enable the DHCP service or the DHCP server.

☑ For some products in v10.1 and later, DHCP may conflict with some functions. For more information, see the prompting message of a specific product.

Configuring DHCP Excluded Addresses

Unless configured particularly, the DHCP server tries to assign all the subnet addresses defined in the address pool to the DHCP clients. To reserve some addresses, such as those addresses that have been assigned, you must define those addresses as excluded.

Use the following commands to configure the excluded addresses in global configuration mode.

Command	Function
Ruijie(config)# **ip dhcp excluded-address** *low-ip-address [high-ip-address]*	Defines excluded addresses.
Ruijie(config)# **no ip dhcp excluded-address** *low-ip-address [high-ip-address]*	Removes the configuration.

Note

A good practice in configuring the DHCP server is to prohibit the DHCP server from assigning any address that has been assigned specifically. This provides two advantages: 1) No address conflict will occur; 2) When DHCP assigns addresses, the time for detection is shortened and DHCP will perform assignment more efficiently.

Configuring DHCP Address Pool

DHCP Address assignment and DHCP parameters sent to the client should be defined in the DHCP address pool. If no DHCP address pool is configured, addresses cannot be assigned to the DHCP clients even though the DHCP server has been enabled. However, if the DHCP server has been enabled, the DHCP relay agent is always working regardless of the DHCP address pool.

You can give a meaningful name that can be memorized easily to the DHCP address pool. The name of address pool contains characters and digits. Ruijie product allows you to define multiple address pools. The IP address of the DHCP relay agent in the DHCP request packet is used to determine which address pool is used for address assignment.

- If a DHCP request packet contains no IP address of the relay agent, the address will be assigned according to the segment range of the interface receiving request packets. The logic of assignment is that, if an address pool of a large segment scope is configured, addresses can be assigned for the request packets received by the small segment interfaces within the large address pool segment scope. For example, if the large address pool configured is 192.168.0.0/16, it can be used to assign addresses to the DHCP requests arriving at the small segment interfaces 192.168.1.0/24, 192.168.2.0/24 and 192.168.4.0/24. If multiple address pools of small segments are configured, these pools can assign addresses to the request packets arriving at the large segment interface covering the small segments. For example, the two small address pools 192.168.1.0/24 and 192.168.3.0/24 can assign addresses to the DHCP requests arriving at the interface of 192.168.0.0/16. If the minimum match between the segment range of the interface receiving request packets and the segment range of the address pool is unsuccessful, the address assignment fails.
- If the DHCP request packet contains the IP address of the DHCP relay agent, the address that is in the same subnet or network as this address is assigned to the DHCP client. If no address pool is defined for this network segment, address assignment fails.

To configure a DHCP address pool, perform the following tasks as appropriate, of which the first three tasks are mandatory:

-

Configuring an Address Pool Name and Enter Configuration Mode

Use the following command to configure an address pool name and enter address pool configuration mode in global configuration mode.

Command	Function
Ruijie(config)# **ip dhcp pool** *dhcp-pool*	Configures an address pool name and enter address pool configuration mode.

To display address pool configuration mode, use the **Ruijie(dhcp-config)** command.

Configuring the Address Pool Network Number and Mask

To configure dynamic address binding, the subnet and its mask of the new address pool must be configured to provide the DHCP server with an address space that can be assigned to clients. Unless there is address exclusion configuration, the addresses in all the address pools can be assigned to clients. DHCP assigns addresses in the address pool in order. If an address exists in the DHCP binding table or is detected to have existed in the segment, the next address will be checked until a valid address is assigned.

Use the following command to configure the subnet and mask of an address pool in address pool configuration mode.

Command	Function
Ruijie(dhcp-config)# **network** *network-number mask*	Configures the network number and mask of a DHCP address pool

Configuring the Client Boot File

The client boot file is the boot mapping file required when the client boots up. The boot mapping file is usually the operating system to be downloaded to the DHCP client.

Use the following commands to configure the client boot file in address pool configuration mode.

Command	Function
Ruijie (dhcp-config)# **bootfile** *filename*	Configures the client boot file.

Configures the Default Gateway of the Client

The default gateway of the client is configured to function as the default gateway parameter that the server assigns to the client. The IP address of the default gateway must be in the same network as the IP address of the DHCP client.

Use the following commands to configure the default gateway of the client in address pool configuration mode.

Command	Function
Ruijie(dhcp-config)# **default-router** *address* [*address2…address8*]	Configures the default gateway.

Configuring the Default Gateway for the DHCP Client

When Ruijie devices assign DHCP addresses, default gateways to be assigned to clients can be either specified manually or assigned dynamically.

- If the default gateway of the address pool is specified manually, the gateway address manually specified is the default gateway of the client when a lease is obtained from the corresponding address pool.
- If no default gateway is configured, the default address type dynamically assigned is determined based on whether the VRRP address is configured to the interface that receives packets. If the VRRP address has been configured, the gateway is selected based on whether the request packets carry the field “relay”. If the request packet is forwarded by the relay, the segment of the field “relay” is used as the default gateway to issue; otherwise, the interface address selected by the longest match principle is the gateway to be issued.

Use the following command to configure the default gateway for the DHCP client in address pool configuration mode.

Command	Function
Ruijie(dhcp-config)# **default-router** *address* [*address2…address8*]	Configures the default gateway.

Configuring the Address Lease Period

The lease period of the addresses assigned to clients by the DHCP server is infinite for static address pools, and 1 day for other address pools, by default. The client should request to update when the lease period is going to expire. Otherwise, it cannot use this address when the lease period expires.

Use the following command to configure the address lease period in address pool configuration mode.

Command	Function
Ruijie(dhcp-config)# **lease** {*days* [*hours*] [*minutes*] | **infinite**}	Configures the address lease period.

Configure the startup server and boot file of the client. The client startup file is the boot image file that is used for client startup. Usually, after obtaining an IP address from the DHCP server, the DHCP client will download the boot image file from the startup server (usually the TFTP server) and initialize the device using the obtained configuration file. If no configuration file information is obtained, the device will be started up with the empty configuration.

Use the following commands to configure the download server and boot file of a client in address pool configuration mode.

Command	Function
Ruijie (dhcp-config)# **next-server** *address* [*address2…address8*]	Configures the download server address for client startup
Ruijie (dhcp-config)# **bootfile** *filename*	Configures the client boot file name

Configuring the Domain Name of the DHCP Client

The domain name of the DHCP client can be specified. In this way, the domain name suffix will be automatically added to the incomplete host name to form a complete host name when the DHCP client accesses the network resources using the host name.

Use the following command to configure the domain name of the DHCP client in address pool configuration mode.

Command	Function
Ruijie(dhcp-config)# **domain-name** *domain*	Configures the domain name.

Configuring the Domain Name Server

A domain name server (DNS) should be specified for domain name resolution when the DHCP client accesses the network resources using a host name.

Use the following command to configure a domain name server for the DHCP client in address pool configuration mode.

Command	Function
Ruijie(dhcp-config)# **dns-server** *address* [*address2…address8*]	Configures a DNS server.

Configuring the NetBIOS WINS Server

Windows Internet Naming Server (WINS) is a domain name resolution service from Microsoft used by the TCP/IP network to resolve a NetNBIOS name to an IP address. The WINS server runs in Windows NT. After started, the WINS server will receive a registration request from the WINS client. When the WINS client is being shut down, it will send a name release message to the WINS server to guarantee the consistency of available computers between the WINS database and the network.

Use the following command to configure a NetBIOS WINS server for the DHCP client in address pool configuration mode.

Command	Function
Ruijie(dhcp-config)# **netbios-name-server** *address* [*address2…address8*]	Configures a DNS server.

Configuring the NetBIOS Node Type for the DHCP Client

There are four types of NetBIOS nodes for Microsoft DHCP client: 1) Broadcast. The NetBIOS name is resolved in broadcast mode; 2) Peer-to-peer. The WINS server is asked directly to resolve the NetBIOS name; 3) Mixed. First, the name is resolved in broadcast mode, and then the WINS server is connected to resolve the name; 4) Hybrid. First the WINS server is asked directly to resolve the NetBIOS name. If there is no response, the NetBIOS name is resolved in broadcast mode.

By default, the Windows operation systems support the broadcast or hybrid type NetBIOS nodes. If no WINS server is configured, the node is of the broadcast type. If a WINS server is configured, the node is of the hybrid type.

Use the following command to configure the NetBIOS node type for the DHCP client in address pool configuration mode.

Command	Function
Ruijie(dhcp-config)# **netbios-node-type** *type*	Configures the NetBIOS node type.

Configuring the 6RD Parameters

The IPv6 rapid development (6RD) parameter includes the generic IPv4 prefix and suffix length, 6RD prefix length, 6RD prefix, and IPv4 address of the 6RD border relay (BR) for a given 6RD domain. If the DHCP client wants to create a 6RD tunnel, it can obtain the 6RD parameter via DHCP option 212.

Use the following command in DHCP address pool configuration mode to configure the 6RD parameter available for the DHCP client.

Command	Function
Ruijie(dhcp-config)# **option 6rd ipv4masklen** <*mask-length*> **ipv6prefixlen** <*prefix-length*> **ipv6prefix** <*ipv6-prefix*> **br-addr** <*ipv4-address*>	Configures the 6RD parameter.

Configuring the Network ID and Mask of the DHCP Address Pool

You must configure the subnet and its mask to provide the DHCP server with a client address assignment range when binding dynamic addresses. All address in this range can be allocated to clients if no excluded address is configured. DHCP assigns addresses in the range one by one. If an address exists in the DHCP binding table or is detected in the network segment, the DHCP proceeds to the next address until finding an effective allocable address.

Use the following commands to configure the subnet and its mask of the address pool in address configuration mode.

Command	Function
Ruijie(dhcp-config)# **network** *network-number mask*	Configures the network ID and mask of the DHCP address pool.

Caution

Address assignment is indexed by the physical address and ID of the client in the DHCP dynamic address pool of Ruijie products. In this case, the DHCP address pool cannot have two leases of the same client. Then, address assignment of the server becomes faulty and may result in failure to assign addresses if path redundancy occurs in the network topology between the server and the client (the client can connect to the server through both the direct path and the relay path).

Caution

To avoid the preceding problem, the network administrator can avoid path redundancy between the server and the client using methods such as adjusting the physical link or network link.

Configuring DHCP Address Pool to Allocate Address as per Option82

Generally, the DHCP relay agent will insert Option 82 to carry relevant information about the client during the process of packet forwarding (such as the VLAN to which the client belongs, slot number, port number or user's 1X class). Upon receipt of such packets, the DHCP server will allocate addresses according to the specific information about clients by analyzing Option 82 information. For example, Option 82 can be used to allocate an IP address range to clients belonging to a VLAN or user class. This feature can be used when required to allocate a specific range of IP addresses according to user's network allocation information (such as VLAN, slot number or port number) or user's priority.

Each DHCP address pool can allocate addresses using Option 82 information. Option 82 information will be matched and classified, and we can specify the allocable address range for the corresponding class. One DHCP address pool can be associated with multiple classes, and different network segment ranges can be specified for each class.

During the process of address allocation, we can first determine the allocable address pool according to the network segment to which the client belongs, and then further determine its CLASS according to Option 82 information, so as to allocate IP address from the network segment range corresponding to the CLASS. When a request packet matches multiple classes in the address pool, address will be assigned from the address ranges corresponding to these classes so that the classes are configured in the address pool. If the class has no allocable address, the network segment range for the next matching class will be used, and the like. Each class corresponds to one address range, and the addresses must be assigned from low to high. Multiple classes can be configured with the same address range. If the CLASS associated with the address pool is specified, but the segment range of the CLASS is not configured, the DHCP clients of this CLASS cannot be assigned addresses.

Use the following commands to configure the CLASS associated with address pool and the address range corresponding to the class in address pool configuration mode.

Command	Function
Ruijie(dhcp-config)# **class** *class-name*	Configures the name of associated class, and enter class configuration mode of address pool.

Command	Function
Ruijie(config-dhcp-pool-class)# **address range** *low-ip-address high-ip-address*	Configures the corresponding network segment range.

Note

1. When the global class cannot be found, it will be created automatically.
2. The associated class configured in the address pool may conflict with the static manual binding, and therefore they cannot be configured at the same time.
3. Up to five classes can be configured for each address pool

Configuring Class

Configuring Option82 Matching Information for the CLASS

The specific Option82 matching information corresponding to each CLASS can be configured after entering CLASS configuration mode in global mode. One CLASS can match multiple pieces of Option 82 information, and it is considered matched if the packet matches any information. If no matching information is configured for CLASS, then this CLASS can match any request packets carrying Option 82 information. The address can only be assigned from the corresponding address pool after the request packet matches a specific CLASS.

Use the following commands to configure global CLASS and the Option 82 information corresponding to the CLASS in global configuration mode.

Command	Function
Ruijie(config)# **ip dhcp class** *class-name*	Configures CLASS name and enters global CLASS configuration mode.
Ruijie(config-dhcp-class)# **relay agent information**	Enters Option 82 matching information configuration mode.
Ruijie(config-dhcp-class-relayinfo)# **relay-information hex** *aabb.ccdd.eeff…* [*****]	Configures specific Option 82 matching information: 1. The parameter *aabb.ccdd.eeff..* is a hexadecimal number. The asterisk (*) indicates imperfect matching mode. It is considered matched if the information before * is matched.

Note

The Global CLASS can have up to 20 matches.

Configuring Remark Information for the CLASS

Use the following commands to configure remark information to describe the meaning of CLASS in global configuration mode.

Command	Function
Ruijie(config)# **ip dhcp class** *class-name*	Configures CLASS name and enters CLASS configuration mode.
Ruijie(config-dhcp-class)#**remark** *used in #1 building*	Configures remark information.

Configuring whether to Use CLASS Allocation

Use the following command to configure address allocation using CLASS in global configuration mode.

Command	Function
Ruijie(config)# **ip dhcp use class**	Configures address allocation using CLASS.

Caution

This command is enabled by default. Execute NO command to disable address allocation using CLASS.

Configuring Binding Database Storage

Configuring to Periodically Save Binding Database into FLASH

To avoid the loss of binding database (lease information) on DHCP server due to power failure or reboot of the device, you can configure the delay time to write the database into FLASH. The time is **0** by default, namely the database will be written into FLASH at variable intervals.

Use the following command to periodically write the binding database into the FLASH in global configuration mode.

Command	Function
Ruijie(config)# [**no**] **ip dhcp database write-delay** [*time*]	Configures DHCP delay time to write into FLASH. *The range of the time* parameter is from 600—to 86400 in seconds. The default is 0.

Caution

Since frequent FLASH reading and writing will shorten the service life of FLASH, we shall pay attention to the delay time configured. Short delay will enable efficient storage of device information, while long delay can reduce the frequency of FLASH reading and writing, thus prolonging the service life.

Configuring to Manually Save the Binding Database into FLASH

To avoid the loss of DHCP binding database (lease information) due to power failure or reboot of the device, you can also manually write the existing binding database information into the FLASH as needed besides configuring the delay time for FLASH writing.

Use the following command to manually write the binding database into the FLASH in global configuration mode.

Command	Function
Ruijie(config)# **ip dhcp database write-to-flash**	Writes DHCP binding database information into the FLASH

Manual Address Binding

Address binding refers to mapping the IP address to the MAC address for the DHCP clients. You can bind addresses in two ways. 1) Manual binding: Configure the static IP address to MAC address mapping for the DHCP client on the DHCP server manually. Manual binding actually offers a special address pool; 2) Dynamic binding: Upon receiving a DHCP request from the DHCP client, the DHCP server dynamically assigns an IP address from the DHCP address pool to the DHCP client, and thus mapping the IP address to the MAC address for the DHCP client.

To define manual address binding, you first need to define a host address pool for each manual binding, and then define the IP address and hardware address (MAC address) or ID for the DHCP client. Generally, a client ID, instead of a MAC address, is defined for the Microsoft clients. The client ID contains media type and MAC address. For the codes of media types, see the section "Address Resolution Protocol Parameters" in RFC 1700. The code of Ethernet type is “01”.

Use the following commands to configure the manual address binding in address pool configuration mode.

Command	Function
Ruijie(config)# **ip dhcp pool** *name*	Defines the name of the DHCP address pool and enters DHCP configuration mode.
Ruijie(dhcp-config)# **host** *address* [*netmask*]	Defines an IP address for the DHCP client.
Ruijie(dhcp-config)# **hardware-address** *hardware-address type* *or:* Ruijie(dhcp-config)# **client-identifier** unique-identifier	Defines a hardware address for the DHCP client, such as aabb.bbbb.bb88. Defines an ID for the DHCP client, such as 01aa.bbbb.bbbb.88.
Ruijie(dhcp-config)# **client-name** *name*	(Optional) Defines the client name using standard characters of American Standard Code for Information Interchange (ASCII). Exclude the domain name in the client name. For example, if you define the host name as *mary*, do not define the client name as *mary.rg.com*.

Configuring Ping Times

By default, when trying to assign an IP address from the DHCP address pool to a DHCP client, the DHCP server will ping the IP address twice (one packet for each time). If there is no response, the DHCP server considers this address an idle address and assigns it to the DHCP client. If there is a response, the DHCP server considers that this address is in use and tries to assign another address to the DHCP client until an address is assigned successfully.

Use the following command to configure the number of Ping packets in global configuration mode.

Command	Function
Ruijie(config)# **ip dhcp ping** *packets number*	Configures the number of Ping packets before the DHCP server assigns an address. If it is set to **0**, the Ping operation is not performed. The default value is **2**.

Configuring Ping Packet Timeout

By default, the DHCP server considers an IP address nonexistent if no response is received within 500 milliseconds after pinging the IP address. You can adjust the Ping packet timeout.

Use the following command to configure the Ping packet timeout in global configuration mode.

Command	Function

Command	Function
Ruijie(config)# **ip dhcp ping timeout** *milliseconds*	Configures the Ping packet timeout for the DHCP server. The default value is 500ms.

Configuring the DHCP Client on the Ethernet Interface

☑ Ruijie products support the function of dynamically obtaining the IP address that is assigned by the DHCP server on an Ethernet interface.

Use the following command to configure the DHCP client on the Ethernet port, execute the following command in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip address dhcp** [**6rd**]	Obtains an IP address through DHCP. The **6rd** parameter indicates that the device applies for the 6RD parameter configuration while requesting the IP address.

Configuring the DHCP Client in the PPP Encapsulation Link

Ruijie products support the function of dynamically obtaining the IP addresses that is assigned by the DHCP server on a PPP encapsulation interface.

Use the following command to configure the DHCP client, execute the following command in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip address dhcp**	Obtains an IP address through DHCP.

Configuring the DHCP Client in the FR Encapsulation Link

☑ Ruijie products support obtaining the IP addresses dynamically assigned by the DHCP server on an FR encapsulation interface.

Use the following command to configure the DHCP client, execute the following command in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip address dhcp**	Obtains an IP address through DHCP.

Configuring the DHCP Client in the HDLC Encapsulation Link

☑ Ruijie products support obtaining the IP address dynamically assigned by the DHCP server on an HDLC encapsulation interface.

Use the following command to configure the DHCP client, execute the following command in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip address dhcp**	Obtains an IP address through DHCP.

☑ For some product of v10.1 and later versions, DHCP client supports obtaining the IP address assigned by the DHCP server in the point-to-point link of PPP, HDLC, and FR encapsulation.

Monitoring and Maintaining Information

Monitoring and Maintaining the DHCP Server

Three types of commands are available for monitoring and maintaining the DHCP server:

Clear commands, used to clear such information as DHCP address binding, address conflict and server statistics;
Debug commands, used to output necessary debugging information. Such commands are mainly used to diagnose and fix faults;
Show commands, used to show information about DHCP.

Ruijie products provide three clear commands. Use the following commands to clear information in command execution mode.

Command	Function
Ruijie# **clear ip dhcp binding** { *address* | *****}	Clears the DHCP address binding information.
Ruijie# **clear ip dhcp conflict** { *address* | *}	Clears the DHCP address conflict information.
Ruijie# **clear ip dhcp server statistics**	Clears the DHCP server statistics.

Use the following command to debug the DHCP server in command execution mode.

Command	Function
Ruijie# **debug ip dhcp server** [**events | packet**]	Debugs the DHCP server.

Use the following commands to show the working status of the DHCP server in command execution mode.

Command	Function
Ruijie# **show ip dhcp binding** [*address*]	Shows the DHCP address binding information.
Ruijie# **show ip dhcp conflict**	Shows the DHCP address conflict information.
Ruijie# **show ip dhcp server statistics**	Shows the DHCP server statistics.

Monitoring and Maintaining the DHCP Client

There are two types of commands for monitoring and maintaining the DHCP client. The following operations can be performed on the DHCP client:

Debug commands, used to output necessary debugging information. Such commands are mainly used to diagnose and clear faults.
Show commands, used to show information about DHCP.

Use the following command to debug the DHCP client, execute the following command in command execution mode.

Command	Function
Ruijie# **debug ip dhcp client**	Debugs the DHCP client.

Use the following command to show information about the lease of the DHCP client in command execution mode.

Command	Function
show dhcp lease	Shows the information about DHCP lease.

Example of Configuring the Address Pool to Support Option82

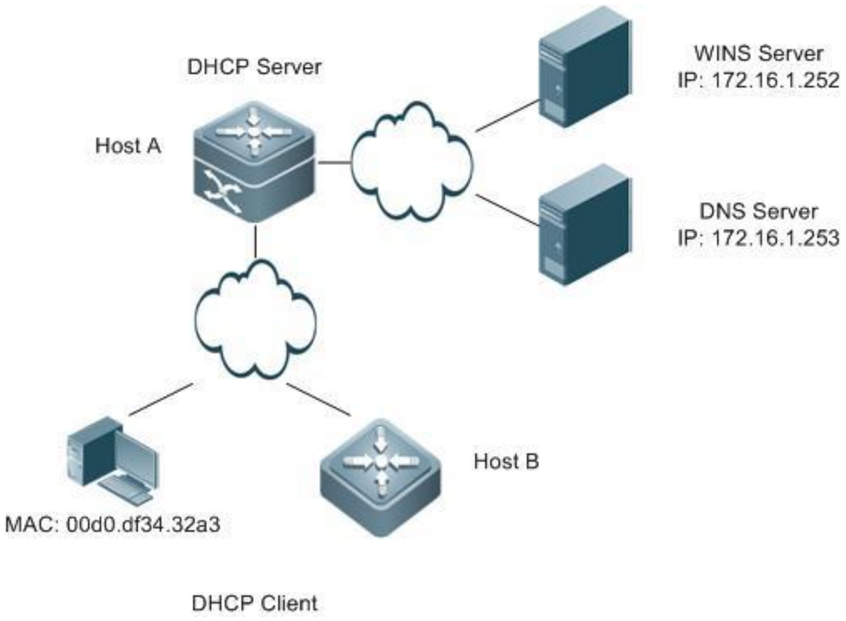
In the following example, an address pool of "net82" is defined; the address pool is in the network segment of 172.16.1.0/24, and the associated classes include class1, class2, class3 and class4. Class1 will allocate addresses from the range of 172.16.1.1-172.16.1.8; class2 will allocate addresses from the range of 172.16.1.9-172.16.1.18; class3 will allocate addresses from the range of 172.16.1.19-172.16.1.28; class4 has no defined address range, and will allocate addresses from the range of entire network segment. Configure class1 to match Option 82 information of 0100002120, class2 to match 0106020145, class3 to match 06020506*, and class4 to match any information.

```
!
ip dhcp class class1
 relay agent information
   relay-information hex 0100002120
!
ip dhcp class class2
 relay agent information
   relay-information hex 0106020145
!
ip dhcp class class3
 relay agent information
   relay-information hex 06020506*
!
ip dhcp class class4
!
ip dhcp pool net82
network 172.16.1.0 255.255.255.0
class class1
address range 172.16.1.1 172.16.1.8
class class2
address range 172.16.1.9 172.16.1.18
class class3
address range 172.16.1.19 172.16.1.28
class class4
```

Typical DHCP Configuration Examples

Topological Diagram

Fig 1-6 Diagram of DHCP example



Application Requirements

- Host A can serve as the DHCP server to assign dynamic IP addresses to some client users. The network segment for IP address assignment is 172.16.1.0/24; the default gateway is 172.16.1.254; the domain name is ruijie.com; the domain name server is 172.16.1.253; the WINS server is 172.16.1.252; the NetBIOS node type is compound; and the address lease period is 1 day. Except the addresses from 172.16.1.2 to 172.16.1.100 in the address segment, all the other addresses can be assigned.
- Host A assigns fixed IP addresses to some client users. The IP address assigned to the fit AP (DHCP client) with the MAC address 00d0.df34.32a3 is 172.16.1.101; the mask is 255.255.255.0; the domain name is admin; the default gateway is 172.16.1.254; the domain name server is 172.16.1.253; the WINS server is 172.16.1.252; and the NetBIOS node type is compound.
- Host B configures the DHCO automatically assigned address to the device interface FastEthernet 0/0.

Configuration Tips

- Enable the function of DHCP server on Host A and create an address pool to dynamically assign IP addresses. And create another address pool to manually bind IP addresses. Specify the address of the domain name server in the corresponding address pool (in this example, the addresses of the DNS server and WINS server) and the domain name of the client.
- Enable the function of the DHCP client on Host B to obtain the IP address automatically.

Configuration Steps

Step 1: Create a new DHCP address pool and configure dynamic IP address allocation on the Host A.

! Configure the name of address pool as "dynamic" and enter DHCP configuration mode.

```
HostA# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
HostA(config)# ip dhcp pool dynamic
```

! In DHCP configuration mode, configure an IP address network allocable to clients, configure the default gateway of this network segment, and set the lease period to 1 day.

```
HostA(dhcp-config)# network 172.16.1.0 255.255.255.0
HostA(dhcp-config)# default-router 172.16.1.254
HostA(dhcp-config)# lease 1
```

Step 2: Specify the DNS Server of "dynamic" address pool and configure the domain name of client.

! Assuming that the IP address of DNS Server is 172.16.1.253, configure Domain Name Server in the address pool and configure the domain name of client as ruijie.com.

```
HostA(dhcp-config)# dns-server 172.16.1.253
HostA(dhcp-config)# domain-name ruijie.com
```

Step 3: Specify the WINS Server of "dynamic" address pool and configure the NetBIOS node type of client.

! Assuming that the IP address of WIN Server is 172.16.1.252, configure NetBIOS WINS server in the address pool and configure the NetBIOS node type as Hybrid.

```
HostA(dhcp-config)# netbios-name-server 172.16.1.252
HostA(dhcp-config)# netbios-node-type h-node
```

Step 4: Configure excluded addresses in global mode.

! As shown in the preceding information, IP addresses of 172.16.1.254, 172.16.1.253 and 172.16.1.252 have been assigned to the gateway, the DNS server and the WINS server, and the addresses from 172.16.1.2 to 172.16.1.100 are excluded addresses. The excluded addresses won't be assigned to clients.

```
HostA(dhcp-config)# exit
HostA(config)# ip dhcp excluded-address 172.16.1.252 172.16.1.254
HostA(config)# ip dhcp excluded-address 172.16.1.2 172.16.1.100
```

Step 5: Create another address pool and manually bind the IP address.

! Configure the name of address pool as "static" and enter DHCP configuration mode.

```
HostA(config)# ip dhcp pool static
```

! Manually bind the IP address of 172.16.1.101/24 to the MAC address of 00d0.df34.32a3, with client name being "admin". Note: The identifier for identifying the client shall indicate the network media type ("01" for Ethernet), namely the identifier of the client corresponding to the manually bound MAC address shall be 00d0.df34.32a3.14.

```
HostA(dhcp-config)# host 172.16.1.101 255.255.255.0
HostA(dhcp-config)# client-identifier 00d0.df34.32a3.14
HostA(dhcp-config)# client-name admin
```

Step 6: Specify the gateway address corresponding to the "static" address pool.

! Configure gateway address as 172.16.1.254.

```
HostA(dhcp-config)# default-router 172.16.1.254
```

Step 7: Specify the DNS Server of "static" address pool and configure the domain name of client.

! Assuming that the IP address of the DNS server is 172.16.1.253,configure the DNS in the address pool and configure the domain name of client as ruijie.com.

```
HostA(dhcp-config)# dns-server 172.16.1.253
```

HostA(dhcp-config)# domain-name ruijie.com Step 8: Specify the WINS Server of "static" address pool and configure the NetBIOS node type of client.

! Assuming that the IP address of WIN Server is 172.16.1.252, configure NetBIOS WINS server in the address pool and configure the NetBIOS node type as Hybrid.

```
HostA(dhcp-config)# netbios-name-server 172.16.1.252
HostA(dhcp-config)# netbios-node-type h-node
```

HostA(dhcp-config)# exit Step 9: Enable the DHCP server on HOST A.

```
HostA(dhcp-config)# exit
```

HostA(config)# service dhcp Step 10: Enable the DHCP client on Host B.

！The following example shows how to enable the DHCP client, assuming that the client uses a layer 3 interface by default.

```
HostB(config)# interface fastEthernet 0/1
HostB(config-if-fastEthernet 0/1)# ip address dhcp
```

Verification

Step 1: View the configuration information on Host A.

```
HostA# show running-config
!
service dhcp
!
ip dhcp excluded-address 172.16.1.252 172.16.1.254
ip dhcp excluded-address 172.16.1.2 172.16.1.100
!
!
ip dhcp pool dynamic
 netbios-node-type n-node
 netbios-name-server 172.16.1.252
 domain-name ruijie.com
 lease 1 0 0
 network 172.16.1.0 255.255.255.0
 dns-server 172.16.1.253

Configuring DHCP Relay

Overview

Understanding DHCP

The Dynamic Host Configuration Protocol (DHCP) is widely used to dynamically allocate reusable network resources such as IP addresses.

The DHCP client sends the DHCP DISCOVER broadcast packet to the DHCP server. After receiving the DHCP DISCOVER broadcast packet, the DHCP server allocates resources such as IP addresses to the DHCP client according to the appropriate policy, and sends the DHCP OFFER packet. After receiving the DHCP OFFER packet, the DHCP client checks if the resources are available. If yes, the DHCP client sends the DHCP REQUEST packet. If no, the DHCP client sends the DHCP DISCOVER packet. After receiving the DHCP REQUEST packet, the DHCP server checks if the IP addresses (or other limited resources) can be allocated. If yes, the DHCP server sends the DHCP ACK packet. If no, the DHCP server sends the DHCP NAK packet. After receiving the DHCP ACK packet, the DHCP client starts to use the resources allocated by the DHCP server. Upon receiving the DHCP NAK packet, the DHCP client may re-send the DHCP DISCOVER packet to request another IP address.

Understanding DHCP Relay

The destination IP address of DHCP REQUEST packet is 255.255.255.255. Such packets are only forwarded inside a subnet. To allocate IP addresses dynamically across network segments, the DHCP relay agent comes into being. It encapsulates the received DHCP REQUEST packet into unicast IP packets and forwards it to the DHCP server. Meanwhile, it forwards the received DHCP response packet to the DHCP client. In this way, the DHCP Relay Agent works as a transit station responsible for communicating with the DHCP clients and the DHCP server on different network segments. In this case, one DHCP server in a LAN can implement the dynamic IP management for all network segments, that is, a dynamic DHCP IP management in Client - Relay Agent - Server mode, as shown in Figure 1.

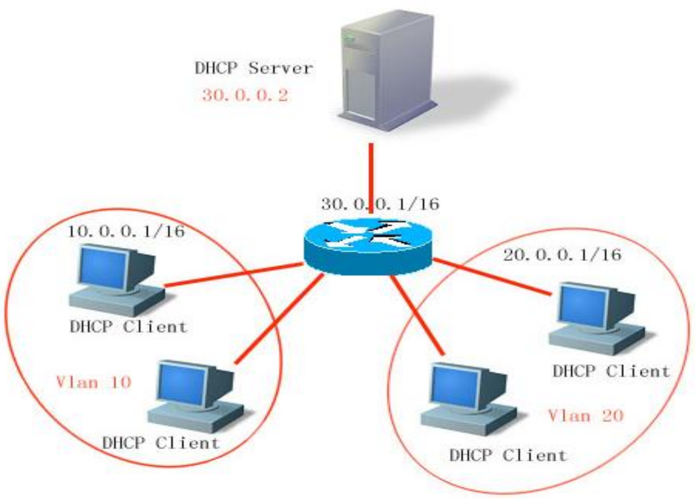

Figure 1

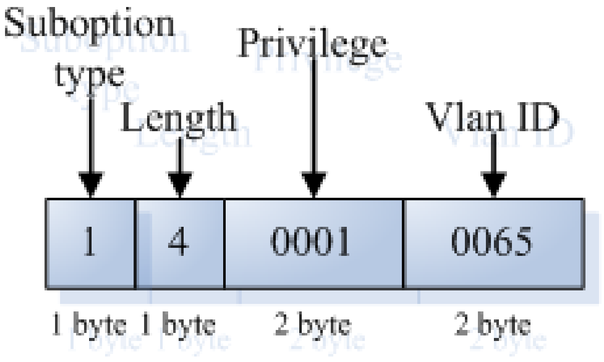
VLAN 10 and VLAN 20 correspond with the 10.0.0.1/16 and 20.0.0.1/16 networks respectively, while the DHCP server is located on the 30.0.0.1/16 network. To have a dynamic IP management on the 10.0.0.1/16 and 20.0.0.1/16 networks through the DHCP server at 30.0.0.2, just enable the DHCP Relay Agent on the device that functions as the gateway, and specify the IP address of the DHCP server to 30.0.0.2.

Understanding DHCP Relay Agent Information (option82)

As specified in RFC3046, when a relay device performs DHCP relay, an option can be added to identify the network information of the DHCP client, so that the DHCP server can assign users with IP addresses of different privileges. RFC3046 specifies that the option is numbered 82, so it is also called option82. This option can be divided into several sub-options. Currently, the sub-options frequently used are Circuit ID and Remote ID. Ruijie Networks provides threetwo schemes for relay agent information, which are described as follows.

relay agent information option dot1x: This requires the combination of 802.1x authentication and Ruijie RG-SAM.

DHCP relay forms the Circuit ID sub-option by combining the IP priority assigned to RG-SAM in 802.1x authentication with VID of the DHCP client. Figure 2 shows the option format.



relay agent information option82: This can be used without running other protocol modules. During DHCP relay, the device forms option82 information according to the port that receives the DHCP request message and the physical IP address of the device, and uploads the option82 information to the DHCP server.

Figure 3 and Figure 4 show the option formats.

Agent Circuit ID

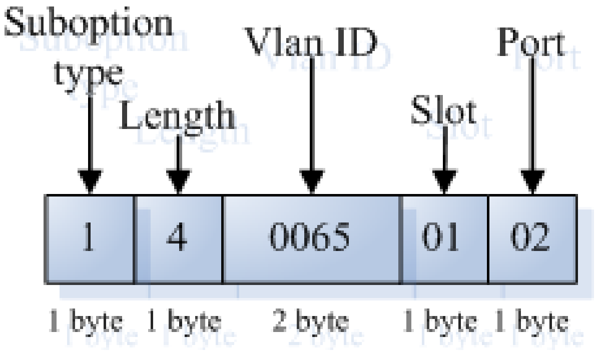


Figure 3

Agent Remote ID

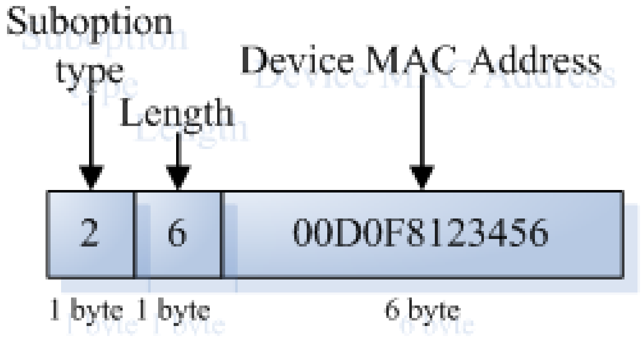

Figure 4

Understanding the DHCP Relay Check Server-id Function

This section describes the DHCP relay check server-id function. When DHCP is used, multiple DHCP servers are configured for a network for backup, so that the network will continue to work even if a server fails. During the four interaction processes of DHCP acquisition, a DHCP server has been selected when the DHCP client sends the DHCP request message. The DHCP request message includes the optional server-id. In particular application circumstances, you need to enable this option for relay to reduce loads on the network server. In this way, the DHCP request message is only sent to the specified DHCP server.

Configuring DHCP

Configuring the DHCP Relay Agent

Use the following commands to configure the DHCP relay agent in global configuration mode.

Command	Function
Ruijie (config)# **service dhcp**	Enables the DHCP agent.
Ruijie(config)# **no service dhcp**	Disables the DHCP agent.

Configuring the IP Address of the DHCP Server

After you have configured the IP address of the DHCP server, the DHCP request message received by the device will be forwarded to the DHCP server. Meanwhile, the DHCP response message from the DHCP server will be forwarded to the DHCP client.

The IP address of the DHCP server can either be configured globally or on the layer 3 interface. Up to 20 IP addresses can be configured for the DHCP server in each mode. When the DHCP request message is received from an interface, the DHCP server list on the interface is at first. If no DHCP server list is configured on the interface, the DHCP server list globally configured will be used.

DHCP supports vrf-based relay by adding the *vrf* parameter to the IP address of the DHCP server.

Use the following commands to configure the IP address of the DHCP server in global configuration mode.

Command	Function
Ruijie(config)# **ip helper-address** [**vrf** { *vrf-name*} **|** **global**] *A.B.C.D*	Adds the IP address of the DHCP server globally. The VPN or global space of the specified server can be displayed.
Ruijie(config-if)# **ip helper-address** [**vrf** {*vrf-name*} **|** **global**] *A.B.C.D*	Adds the IP address of the DHCP server on the interface. This command must be set on the layer 3 interface. The VPN or global space of the specified server can be displayed. The server is of the same VPN or global space as the current interface by default.
Ruijie(config)# **no IP helper-address** [**vrf** { *vrf-name*} **|** **global**] *A.B.C.D*	Deletes the globally configured IP address of the DHCP server.
Ruijie(config-if)# **no IP helper-address** [**vrf** { *vrf-name* } **| global**] *A.B.C.D*	Deletes the IP address of the DHCP server configured on the interface.

Configuring DHCP option dot1x

The section "Understanding the DHCP Relay Agent Information" shows that you can configure the **ip dhcp relay information option dot1x** command to enable the **option dot1x** function of DHCP relay when you need to assign the IP addresses with different privileges to the users of different privileges. When this function is enabled, the device will work with 802.1x to add corresponding option information to the DHCP server when it relays. This function should be used with the dot1x function.

Use the following commands to configure DHCP option dot1x in global configuration mode.

Command	Function
Ruijie(config)# **ip dhcp relay information option dot1x**	Enables the DHCP option dot1x function.
Ruijie(config)# **no ip dhcp relay information option dot1x**	Disables the DHCP option dot1x function.

Configuring DHCP option dot1x access-group

In the option dot1x application scheme, the device needs to restrict the unauthorized IP address or the IP address with low privilege to access certain IP addresses, and restrict the access between users with low privileges. To do so, configure the **ip dhcp relay information option dot1x access-group** *acl-name* command. The Access Control List (ACL) defined by *acl-name* must be configured in advance. It is used to filter some contents and prohibit unauthorized users from accessing each other. In addition, the ACL associated here is applied to all the ports on the device. This ACL has no default Access Control Entry (ACE) and does not conflict with ACLs associated with other interfaces. For example:

Assign a type of IP addresses for all the unauthorized users, namely 192.168.3.2-192.168.3.254, 192.168.4.2-192.168.4.254, and 192.168.5.2-192.168.5.254. Do not assign gateway addresses 192.168.3.1, 192.168.4.1, and 192.168.5.1 to users. In this way, an unauthorized user uses one of the 192.168.3.x-5.x addresses to access the web portal for downloading the client software. The device should be configured as follows:

```
Ruijie# configure terminal
Ruijie(config)# ip access-list extended DenyAccessEachOtherOfUnauthrize
Ruijie(config-ext-nacl)# permit ip any host 192.168.3.1
```

//Permit the packet to be transmitted to the gateway.

```
Ruijie(config-ext-nacl)# permit ip any host 192.168.4.1
Ruijie(config-ext-nacl)# permit ip any host 192.168.5.1
Ruijie(config-ext-nacl)# permit ip host 192.168.3.1 any
```

//Permit the packet communication with the source IP address being the gateway.

```
Ruijie(config-ext-nacl)# permit ip host 192.168.4.1 any
Ruijie(config-ext-nacl)# permit ip host 192.168.5.1 any
Ruijie(config-ext-nacl)# deny ip 192.168.3.0 0.0.0.255 192.168.3.0 0.0.0.255
```

//Prohibit mutual accesses of unauthorized users.

```
Ruijie(config-ext-nacl)# deny ip 192.168.3.0 0.0.0.255 192.168.4.0  0.0.0.255
Ruijie(config-ext-nacl)# deny ip 192.168.3.0 0.0.0.255 192.168.5.0  0.0.0.255
Ruijie(config-ext-nacl)# deny ip 192.168.4.0 0.0.0.255 192.168.4.0  0.0.0.255
Ruijie(config-ext-nacl)# deny ip 192.168.4.0 0.0.0.255 192.168.5.0  0.0.0.255
Ruijie(config-ext-nacl)# deny ip 192.168.5.0 0.0.0.255 192.168.5.0  0.0.0.255
Ruijie(config-ext-nacl)# deny ip 192.168.5.0 0.0.0.255 192.168.3.0  0.0.0.255
Ruijie(config-ext-nacl)# deny ip 192.168.5.0 0.0.0.255 192.168.4.0  0.0.0.255
Ruijie(config-ext-nacl)# exit
```

Then, apply the command to the global interfaces using the **ip dhcp relay information option dot1x access-group** *DenyAccessEachOtherOfUnauthrize* command.

Use the following commands to configure **DHCP option dot1x access-group** in global configuration mode.

Command	Function
Ruijie(config)# **ip dhcp relay information option dot1x access-group** *acl-name*	Enables DHCP option dot1x acl.
Ruijie(config)# **no ip dhcp relay information option dot1x access-group** *acl-name*	Disables DHCP option dot1x acl.

Configuring DHCP option82

When the **ip dhcp relay information option82** command is configured, the device, as DHCP relay, adds option information in the DHCP request packet to the DHCP server during forwarding the request packet.

Use the following commands to configure DHCP option82 in global configuration mode:

Command	Function
Ruijie(config)# ip dhcp relay information option82	Enables the DHCP option82 function.
Ruijie(config)# no ip dhcp relay information option82	Disables the DHCP option82 function.

Configuring DHCP relay check server-id

After the **ip dhcp relay check** *server-id* command is configured, the device resolves the *dhcp server-id* option upon receiving DHCP relay. If this option is set, the DHCP request message is sent to this server only.

Use the following commands to configure **DHCP relay check** *server-id* function in global configuration mode.

Command	Function
Ruijie(config)# **ip dhcp relay check** *server-id*	Enables the DHCP relay check server-di function.
Ruijie(config)# **no ip dhcp relay check** *server-id*	Disables the DHCP relay check server-id function.

Configuring DHCP Relay Suppression

After the **ip dhcp relay suppression** command is configured, the port will not relay the DHCP request broadcast packet by transforming it into the unicast form. However, it will not suppress the normal forwarding of broadcast packets received.

Use the following commands to configure DHCP relay suppression in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip dhcp relay Suppression**	Enables the DHCP relay suppression function.
Ruijie(config-if)# **no ip dhcp relay Suppression**	Disables the DHCP relay suppression function.

DHCP Relay Configuration Example

The following commands enable the DHCP relay function and add two groups of IP addresses of the DHCP server:

```
Ruijie# configure  terminal
Ruijie(config)# service dhcp       //Enable the dhcp relay function
Ruijie(config)# service dhcp             //Enable the DHCP option vpn function.
Ruijie(config)# ip helper-address 192.18.100.1
Ruijie(config)# ip helper-address 192.18.100.2
  //Add the IP address of the server at the interface.
Ruijie(config)# interface gigabitEthernet 0/3
Ruijie(config-if-gigabitEthernet 0/3)# ip helper-address 192.18.200.1
Ruijie(config-if-gigabitEthernet 0/3)# ip helper-address 192.18.200.2
Ruijie(config-if-gigabitEthernet 0/3)# end
```

Other Precausions on DHCP Relay Configuration

For layer 2 network devices, you must enable at least one of the option dot1x, dynamic address binding, and option82 functions when the cross network segment management vlan relay function is required. Otherwise, only the relay function of management VLAN can be enabled for the layer 2 device.

Precautions on DHCP option dot1x Configuration

This command works only when the configuration related to AAA/802.1x is correct.

When this scheme is adopted, the IP authorization of the DHCP mode of 802.1x should be enabled.

This command cannot be used together with the **dhcp option82** command because they are conflicted.

When the IP authorization of the DHCP mode of 802.1x is enabled, the MAC address and the IP address will also be bound. Therefore, IP authorization and DHCP dynamic binding function cannot be enabled at the same time.

Precautions on DHCP option82 Configuration

The DHCP option82 function and the **dhcp option dot1x** function cannot be used at the same time because they are conflicted.

Showing the DHCP Configuration

Use the **show running-config** command to show the DHCP configuration in privileged mode.

```
Ruijie# show running-config

Typical DHCP Relay Configuration Examples (for Switches)

Topological Diagram

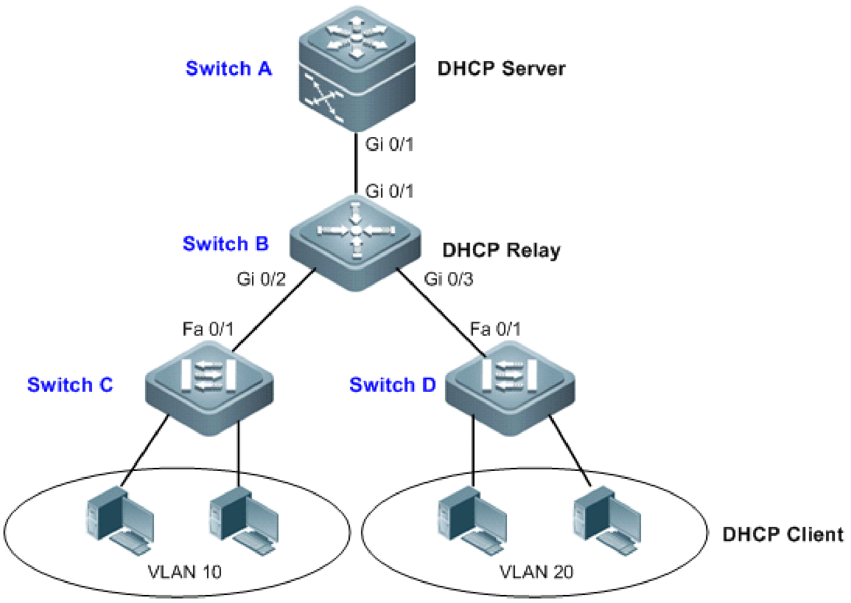

Diagram for DHCP relay configuration

Application Requirements

As shown in the preceding diagram, Switch C and Switch D are access devices connecting with PC users belonging to VLAN 10 and VLAN 20. Switch B is the gateway device, while Switch A is the core routing device. The following requirements must be met:

- Switch A can serve as DHCP server allocating dynamic IP addresses to VLAN users.
- The users connecting to Switch C and Switch D can acquire dynamic IP addresses across the network segment.

Configuration Tips

- **Configuring the DHCP server:** On Switch A, create DHCP address pools for users from VLAN 10 and VLAN 20 respectively, and enable the DHCP server (relevant configurations of the DHCP server can be found in the section "DHCP Configuration").
- **Configuring DHCP Relay:** On Switch B, configure the address of the DHCP server (configure the address of the DHCP server as 10.1.1.2/24) and enable the DHCP server.

Note

On Switch C and Switch D, configure the VLAN to which the corresponding ports belong, and the access PC can dynamically acquire IP address once connected.

Configuration Steps

Configure the DHCP server.

! In global mode, create a DHCP address pool named "vlan10" on Switch A, with corresponding IP network segment being 192.168.1.0/24 and the address of network gateway being 192.168.1.1.

```
SwitchA(config)#ip dhcp pool vlan10
SwitchA(dhcp-config)#network 192.168.1.0 255.255.255.0
SwitchA(dhcp-config)#default-router 192.168.1.1
SwitchA(dhcp-config)#exit
```

! Create an address pool named "vlan20", with IP network segment being 192.168.2.0/24 and gateway address being 192.168.2.1.

```
SwitchA(config)#ip dhcp pool vlan20
SwitchA(dhcp-config)#network 192.168.2.0 255.255.255.0
SwitchA(dhcp-config)#default-router 192.168.2.1
SwitchA(dhcp-config)#exit
```

! In global configuration mode, configure 192.168.1.1 and 192.168.2.1 as the excluded addresses, so as to avoid the conflict between allocated IP address and gateway address.

```
SwitchA(config)#ip dhcp excluded-address 192.168.1.1
SwitchA(config)#ip dhcp excluded-address 192.168.2.1
```

! Enable the DHCP server.

```
SwitchA(config)#service dhcp
```

Step 2: Configure layer-3 communication between Switch A and Switch B.

! On Switch A, configure port Gi 0/1 as the Route Port, with the corresponding IP address being 10.1.1.2/24.

```
SwitchA(config)#interface gigabitEthernet 0/1
SwitchA(config-if-GigabitEthernet 0/1)#no switchport
SwitchA(config-if-GigabitEthernet 0/1)#ip address 10.1.1.2 255.255.255.0
SwitchA(config-if-GigabitEthernet 0/1)#exit
```

! On Switch B, configure port Gi 0/1 as the Route Port, with the corresponding IP address being 10.1.1.3/24.

```
SwitchB(config)#interface gigabitEthernet 0/1
SwitchB(config-if)#no switchport
SwitchB(config-if)#ip address 10.1.1.3 255.255.255.0
SwitchB(config-if)#exit
```

! Configure default route on Switch A

```
SwitchA(config)#ip route 0.0.0.0 0.0.0.0 10.1.1.3
```

Step 3: Configure the gateway for access users.

! On Switch B, configure the Switch Virtual Interface (SVI) of VLAN 10 to 192.168.1.1/24.

```
SwitchB(config)#vlan 10
SwitchB(config-vlan)#exit
SwitchB(config)#interface vlan 10
SwitchB(config-if)#ip address 192.168.1.1 255.255.255.0
SwitchB(config-if)#exit
```

! Configure the SVI of VLAN 20 to 192.168.2.1/24.

```
SwitchB(config)#vlan 20
SwitchB(config-vlan)#exit
SwitchB(config)#interface vlan 20
SwitchB(config-if)#ip address 192.168.2.1 255.255.255.0
SwitchB(config-if)#exit
```

Step 4: Configure DHCP Relay.

! On Switch B, globally configure the address of DHCP server as 10.1.1.2 and enable the DHCP server.

```
SwitchB(config)#ip helper-address 10.1.1.2
SwitchB(config)#service dhcp
```

Step 5: Configure layer-2 communication between Switch B and Switch C/D.

! On Switch B, configure ports Gi 0/2 and Gi 0/3 as the Trunk Port.

```
SwitchB(config)#interface range gigabitEthernet 0/2-3
SwitchB(config-if-range)#switchport mode trunk
```

! Configure port Fa 0/1 of Switch C and Switch D as the Trunk Port.

Verification

Step 1: Show configurations of devices.

! Configurations of Switch A

```
SwitchA#show running-config
!
service dhcp
!
ip dhcp excluded-address 192.168.1.1
ip dhcp excluded-address 192.168.2.1
!
ip dhcp pool vlan10
 network 192.168.1.0 255.255.255.0
 default-router 192.168.1.1
!
ip dhcp pool vlan20
 network 192.168.2.0 255.255.255.0
 default-router 192.168.2.1
!
```

```
interface GigabitEthernet 0/1
 no switchport
 no ip proxy-arp
 ip address 10.1.1.2 255.255.255.0
!
ip route 0.0.0.0 0.0.0.0 10.1.1.3
!
! Configurations of Switch B
SwitchB#show running-config
!
vlan 10
!
vlan 20
!
service dhcp
ip helper-address 10.1.1.2
!
interface GigabitEthernet 0/1
 no switchport
 no ip proxy-arp
 ip address 10.1.1.3 255.255.255.0
!
interface GigabitEthernet 0/2
 switchport mode trunk
!
interface GigabitEthernet 0/3
 switchport mode trunk
!
interface VLAN 10
 no ip proxy-arp
 ip address 192.168.1.1 255.255.255.0
!
interface VLAN 20
 no ip proxy-arp
 ip address 192.168.2.1 255.255.255.0
!
```

Step 2: Connect two PCs with the ports belonging to VLAN 10 and VLAN 20 and verify dynamic IP address allocation.

```
SwitchA#show ip dhcp binding
IP address Client-Identifier/ Lease expiration  Type Hardware address
192.168.1.2 0100.1320.4990.14 000 days 23 hours 59 mins  Automatic
192.168.2.2 0100.e04c.70b7.e2 000 days 23 hours 59 mins  Automatic
```

Typical DHCP Relay Configuration Examples (for Routers)

Topological Diagram

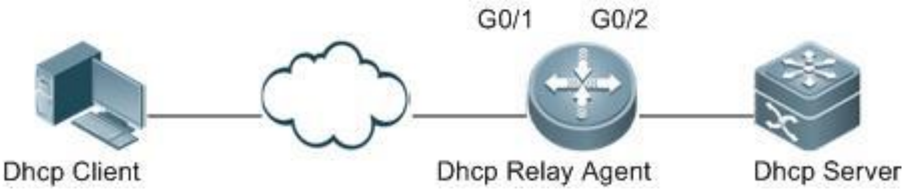

Diagram for DHCP Relay configuration

Application Requirements

As shown in the preceding diagram, obtaining the IP address and surfing the Internet by the user in different network segment shall be implemented when the DHCP Relay function is enabled.

Configuration Tips

- Enable the function of acquiring IP addresses through DHCP.
- Enable the DHCP Relay function on the DHCP Relay Agent.
- Configure the DHCP server.

Configuration Steps

Enable DHCP to acquire IP addresses.

Configure DHCP Relay:

# Enable the DHCP Relay Agent.

```
Ruijie(config)# server dhcp
```

# Add an IP address of DHCP server globally.

```
Ruijie(config)# ip helper-address 172.2.2.1
```

# Configure an IP address of the port connecting the user device.

```
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# ip address 192.1.1.1 255.255.255.0
```

# Configure an IP address for the port connecting the user device.

```
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# ip address 192.1.1.1 255.255.255.0
```

# Configure an IP address for the port connecting the Server device.

```
Ruijie(config)# interface gigabitEthernet 0/2
Ruijie(config-if-gigabitEthernet 0/2)# ip address 172.2.2.2 255.255.255.0
```

Configure the DHCP server.

Verification

Verify configurations of the DHCP Relay Agent device.

# Log in to the DHCP Relay Agent device, and use the **show running-config** command in privileged mode to show the DHCP Relay configuration.

```
Ruijie# show running-config
service dhcp
ip helper-address 172.2.2.1
!
interface GigabitEthernet 0/1
ip address 192.1.1.1 255.255.255.0
!
interface GigabitEthernet 0/2
ip address 172.2.2.2 255.255.255.0
!
```

Typical Option dot1x Configuration Example (for Switches)

Topological Diagram

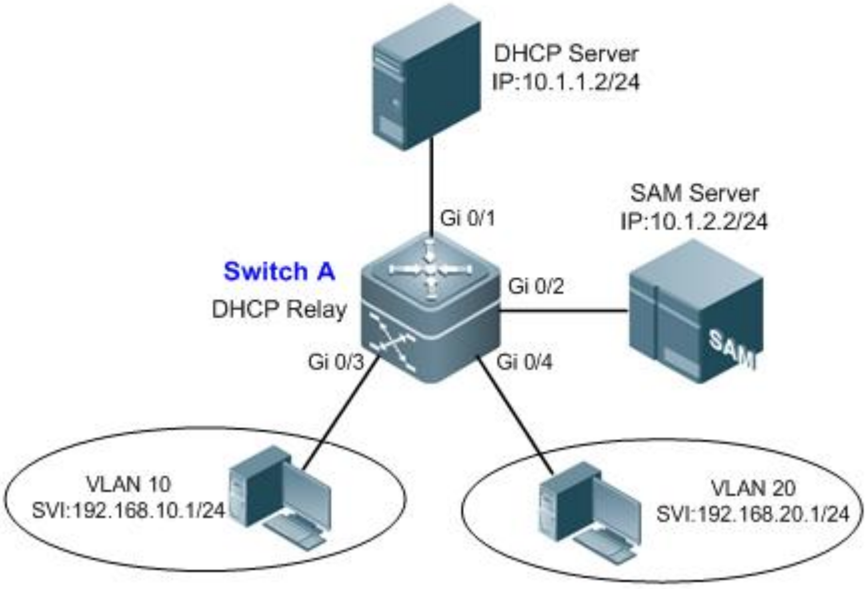

Diagram for DHCP Option Dot1x

Application Requirements

- Switch A is a layer 3 device allowing route communication cross different network segments.

- Access users belonging to different VLANs access Internet after Dot1x authentication, and SAM Server assigns different access privileges to different users.
- The DHCP server can allocate IP addresses to users according to the privilege of an authenticated user.

Configuration Tips

- **Configure basic DHCP Relay:** On Switch A, configure the address of the DHCP server (10.1.1.2/24) and enable the DHCP server. After configuration, the user can acquire dynamic IP address across the network segment.
- **Configure 802.1X authentication:** On Switch A, enable 802.1X authentication and set the user ports to controlled ports (Gi 0/3 and Gi 0/4). After configuration, the user will need to pass Dot1x authentication before accessing the Internet.
- **Configure the assignment of privilege-based IP address:** On Switch A, enable DHCP Option dot1x and configure IP authorization mode as DHCP server mode. After configuration, the DHCP server can allocate IP addresses according to user's privilege.

Note

1. Relevant configurations of 802.1X are detailed in the *802.1X Configuration*.

Note

2. The implementation of this example also needs the configuration of SAM Server and the DHCP server. For relevant details, see the relevant documents.

Configuration Steps

Configuring Switch A

Configure the address of the user gateway and the address of server interface.

! Configure the VLANs corresponding to Gi 0/3 and Gi 0/4 and configure the SVI corresponding to each VLAN.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface gigabitEthernet 0/3
Ruijie(config-if-GigabitEthernet 0/3)#switchport access vlan 10
Ruijie(config-if-GigabitEthernet 0/3)#exit
Ruijie(config)#interface gigabitEthernet 0/4
Ruijie(config-if-GigabitEthernet 0/4)#switchport access vlan 20
Ruijie(config-if-GigabitEthernet 0/4)#exit
Ruijie(config)#interface vlan 10
Ruijie(config-if-VLAN 10)#ip address 192.168.10.1 255.255.255.0
Ruijie(config-if-VLAN 10)#exit
Ruijie(config)#interface vlan 20

Configuring NTP

Understanding NTP

Network Time Protocol (NTP) is designed for time synchronization on network devices. With its clock source or the server. Moreover, NTP can provide time correction (the time difference is less than one millisecond on the LAN and dozens of milliseconds on the WAN, compared with the standard time) and prevent attacks using encryption and confirmation.

To provide accurate Coordinated Universal Time (UTC), NTP needs an accurate clock source from the atom clock, observatory, satellite or Internet.

To prevent the time server from malicious attacks, NTP uses an authentication mechanism is used to check whether the time synchronization request really comes from the declared server, and check the return path, thus providing the protection of anti-interference.

Ruijie switches support the NTP client and server. That is, the switch can synchronize the time from the time server and work as the time server (only in unicast server mode) to synchronize the time of other switches.

Configuring NTP

This chapter describes how to configure the NTP client and server.

Configuring the Global NTP Authentication Mechanism

Ruijie NTP client supports encrypted communication with the NTP server using key encryption.

Configure the encrypted communication between the NTP client and the NTP server as follows: Step 1, Authenticate the NTP client and configure the key globally; Step 2, Configure the trusted key for the NTP server. To initiate the encrypted communication with the NTP server, you need to set the authentication key for the NTP server in addition to performing Step 1.

By default, the NTP client does not use the global security authentication mechanism and the communication will not be encrypted. To enable encrypted communication, you need to enable the global security authentication, configure other global keys and set an encryption key for the server.

Use the following commands in global configuration mode to configure the global security authentication mechanism.

Command	Function
ntp authenticate	Configures the global NTP security authentication mechanism.
no ntp authenticate	Disables the global NTP security authentication mechanism.

To verify the packet, use the trusted key specified by the **ntp authentication-key** or **ntp trusted-key** command.

Configuring the Global NTP Authentication Key

The next step to configure the global security authentication for the NTP is to set the global authentication key.

Each key is identified by a globally unique key-id. You can use the **ntp trusted-key** command to set the key corresponding to the key-id as a global trusted key.

Use the following commands in global configuration mode to specify a global authentication key.

Command	Function
ntp authentication-key *key-id* **md5** *key-string* [*enc-type*]	Specifies a global authentication key. *key-id*: sets the parameter in the range 1 to 4294967295. *key-string*: sets the parameter to any values. *enc-type*: sets the parameter to **0** or **7**.
no ntp authentication-key *key-id* **md5** *key-string* [*enc-type*]	Removes a global authentication key.

The global authentication key takes effect after being configured as a global trusted key.

Caution Ruijie's current NTP version supports up to 1024 authentication keys, but only one key can be set for each server for encrypted communication.

Configuring the Global NTP Trusted key ID

The last step is to set a global authentication key as a global trusted key. Only by this trusted key you can send encrypted data and check the validity of the packet.

Use the following commands to specify a global trusted key in global configuration mode.

Command	Function
ntp trusted-key *key-id*	Specifies a global trusted key ID.
no ntp trusted-key *key-id*	Removes a global trusted key ID.

The three steps are the basis of implementing the security authentication mechanism. To initiate encrypted communication between the NTP client and the NTP server, a trusted key must be set for the corresponding server.

Caution When a global authentication key is removed, its trusted information is also removed.

Configuring the NTP Server

No NTP server is configured by default. Ruijie’s client can simultaneously interact with up to 20 NTP servers, and one authentication key can be set for each server to initiate encrypted communication with the NTP server after relevant settings of global authentication and keys are completed.

NTP version 3 is used in communication with the NTP server by default. NTP version 3 enables you to specify the source interface for sending the NTP packet and configure that the NTP packet from the relevant server can only be received on the sending interface at the same time.

Use the following commands to configure the NTP server in global configuration mode.

Command	Function
ntp server ip-addr [**version** *version*] [**source** *if-name number*] [**key** *keyid*] [**prefer**]	Configures the NTP server. version (NTP version number): sets the parameter in the range 1 to 3 if-name (interface type): sets the parameter to **Aggregateport, Dialer GigabitEthernet**, **Loopback, Multilink, Null, Tunnel, Virtual-ppp, Virtual-template,** or **VLAN.** keyid: sets the parameter in the range 1 to 4294967295.
no ntp server *ip-addr*	Removes the NTP server.

The NTP client can initiate the encrypted communication with the NTP server only when the global security authentication and key setting mechanisms are completed and the trusted key for communicating with the server is set. To this end, the NTP server should have the same trusted key.

Disabling the Function of Receiving the NTP Packet on the Interface

Use this command to disable the function of receiving the NTP packet on the interface for time synchronization, which is available to the NTP client by default.

Caution

This command takes effect only for the interface whose IP address can be configured to receive and send packets.

Use the following commands to disable the interface to receive the NTP packet in interface configuration mode.

Command	Function
interface interface-type number	Enters interface configuration mode.
ntp disable	Disables the function of receiving NTP packets on the interface.

To enable the function of receiving NTP packets on the interface, use the **no ntp disable** command in interface configuration mode.

Enabling or Disabling NTP

Use the **no ntp** command to disable the NTP synchronization service, stop the time synchronization, and clear relevant information of NTP configuration.

The NTP function is disabled by default, but may be enabled as long as the NTP server is configured.

Use the following commands to disable or enable the NTP in global configuration mode:

Command	Function
ntp authenticate or ntp server *ip-addr* [version *version*] [source *if-name number*] [*key keyid*] [*prefer*]	Enables NTP.
no ntp	Disables NTP.

Configuring the NTP Real-time Synchronization

To improve accuracy, eight consecutive packets are synchronized for the first synchronization between the client and the server. Follow-up NTP synchronization occurs automatically every one minute. To manually implement real-time synchronization during the auto-synchronization interval, you can use this command.

Use the following commands to configure the NTP real-time synchronization in global configuration mode.

Command	Function
ntp synchronization	Enables the NTP real-time synchronization.
no ntp synchronization	Disables the NTP real-time synchronization.

The synchronization is set to be implemented every 30 minutes on Ruijie's client system. New servers will trigger the real-time synchronization, which is also be implemented when this command is used during the synchronization interval. However, the command is invalid during the auto-synchronization.

The command of disabling the real-time synchronization and the one that disables NTP can be used to end the time synchronization (during the synchronization) or disable the synchronization function (between the synchronization interval). The difference lies in that the NTP-disabling command disables the NTP synchronization as well as clears related NTP configuration.

Note

The NTP real-time synchronization is supported only by some products. The **ntp synchronize** command cannot be executed on products that do not support this function.

Configuring the NTP Update-Calendar

Use this command to enable the NTP client to update the calendar using the clock time synchronized from an external clock source.

Use the following commands to configure the NTP update-calendar in global configuration mode.

Command	Function
ntp update-calendar	Configures the update-calendar.
no ntp update-calendar	Disables the update-calendar.

The update-calendar is not configured by default. After configuration, the NTP client updates the calendar when the time synchronization of external clock source is successful. It is recommended to enable this function for keeping the accurate calendar.

Setting the NTP Master

Use this command to set the local clock as the NTP master (the reference source of the local clock is reliable), providing the synchronized time for other devices.

Generally, the local system synchronizes the time from the external clock source directly or indirectly. However, if the time synchronization of the local system fails for the network connection trouble, use the command to set the reliable reference source of the local time, providing the synchronized time for other devices.

Once set, the system time can not be synchronized to the clock source with higher stratum.

Note

NTP uses stratum to describe the hops between the device and the authorization clock. A time server with 1 stratum shall have a directly connected atomic clock or radio wave clock. A time server with the 2 stratums obtains time from the stratum 1 server and a time server with 3 stratums obtains time from the stratum 2 server and so on. Therefore, the clock source with the lowest stratum value is more precise than others.

Use the following commands to configure the NTP master in global configuration mode:

Command	Function
ntp master [*stratum*]	Sets the local time as the NTP master and specifies the corresponding stratum. The time stratum is in the range 1 to 15. The default value is 8.
no ntp master	Cancels the NTP master setting.

The following example shows how to set the reliable reference source of the local time and set the time stratum to 12:

```
Ruijie(config)# ntp master 12
```

Caution

Be careful when using this command. Using this command to set the local time as the master (in particular, specify a lower stratum value), is likely to cover the effective clock source. If multiple devices in the same network use this command, time synchronization instability may occur due to time difference between the devices.

Caution

In addition, before using this command, if the system has never been synchronized with an external clock source, it is necessary to manually calibrate the system clock to prevent too much bias. (For more information, see the section about system time configuration in the *Basic Host management Configuration Guide*.)

Configuring the Access Control Privilege of NTP Service

The NTP service access control function provides a minimal security measure (a more secure way is to use the NTP authentication mechanism). By default, no NTP access control rules are configured in the system.

Use the following commands to set the NTP services access control privilege in global configuration mode.

Command	Function
ntp access-group { **peer** | **serve** | **serve-only** | **query-only** } *access-list-number* | *access-list-name*	Sets the access control privilege of the local service.
no ntp access-group { **peer** | **serve** | **serve-only** | **query-only** } *access-list-number* | *access-list-name*	Cancels the settings of access control privilege of the local service.

peer: allows the time requests and control queries for the local NTP service as well as the time synchronization between the local device and the remote system (full access privilege).

serve: allows the time requests and control queries for the local NTP service, not the time synchronization between the local device and the remote system.

serve-only: allows the time requests for the local NTP service.

query-only: allows the control queries for the local NTP service.

access-list-number: indicates the IP access control list label in the range of 1 to 99 and 1300 to 1999. For how to create IP access control list, see the *Access Control List Configuration Guide*.

access-list-name: indicates the IP access control list name. For how to create IP access control list , see the *Access Control List Configuration Guide*.

When an access request arrives, the NTP service matches the rules from the smallest to the largest access restriction, and the first matched rule shall prevail. The matching order is *peer*, *serve*, *serve-only*, and *query-only*.

⚠ Caution

The control query function (used by the network management device to control the NTP server, such as setting the leap second mark or monitoring the working state) is not supported in the current system. Although it matches with the order in accordance with the preceding rules, requests related to the control query function are not supported.

If you do not configure any access control rules, all accesses are allowed. Once the access control rules are configured, only the rule that allows access can be carried out.

The following example shows how to allow the peer device in acl1 to control the query, request for and synchronize the time with the local device; and limit the peer device in acl2 to request the time for the local device.

```
Ruijie(config)# ntp access-group peer 1
Ruijie(config)# ntp access-group serve-only 2
```

Showing NTP Information

Debugging NTP

Use this command to debug NTP for diagnosis and troubleshooting,.

Use the following commands to enable or disable the function of debugging NTP in privilege mode.

Command	Function
debug ntp	Enables the debugging function.
no debug ntp	Disables the debugging function.

Showing NTP Information

Use the **show ntp status** command in privilege mode to show the current NTP information.

Use the following command to show the NTP status information in privilege mode.

Command	Function
show ntp status	Shows the current NTP information.

This command be used to print the shown information only when the relevant communication server is configured.

```
Ruijie# show ntp status
Clock is synchronized, stratum 9, reference is 192.168.217.100
nominal freq is 250.0000 Hz, actual freq is 250.0000 Hz, precision is 2**18
reference time is AF3CF6AE.3BF8CB56 (20:55:10.000 UTC Mon Mar 1 1993)
clock offset is 32.97540 sec, root delay is 0.00000 sec
root dispersion is 0.00003 msec, peer dispersion is 0.00003 msec
```

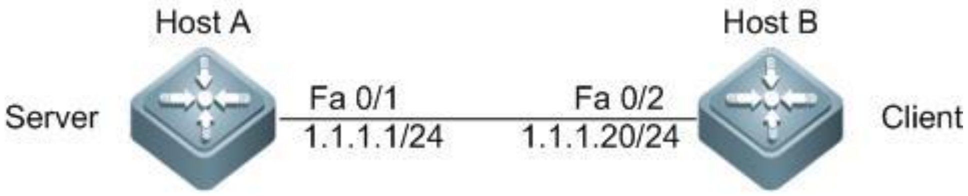
Note

stratum indicates the level of current clock;
reference indicates the address of the server used for synchronization;
freq indicates the clock frequency of current system;
precision indicates the precision of current system clock;
reference time indicates the UTC time of reference clock on the synchronization server;
clock offset indicates the offset of current clock;
root delay indicates the delay of current clock,
root dispersion indicates the precision of top server;
peer dispersion indicates the precision of synchronization server.

Typical NTP Configuration Examples

Configuring NTP Client or Server Mode

Topological Diagram



NTP client or server model

Application Requirements

On Host A, the local clock is configured as the NTP master clock, with the clock stratum being 12;
Host B is configured as the NTP client and Host A is specified as the NTP server;
The hardware clock of Host B shall be synchronized as well.

Configuration Tips

NTP server

Generally, the local system will directly or indirectly synchronize with the external clock sources. However, the local system may not be able to synchronize with the external clock sources due to the network connection failure. In this case, you can use the **ntp master** command to configure the local clock as NPT master to synchronize time to other devices.

NTP client

Configure the NTP server

By configuring the NTP update-calendar, the NTP client can use the clock value synchronized from external clock sources to update its calendar for accuracy.

Configuration Steps

Configuration of the NTP server

! Configure the NTP master. Configure local clock as the trusted reference clock source, with the clock stratum being 12.

```
HostA(config)# ntp master 12
```

Configuration of the NTP client

! Configure Host A as the NTP server.

```
HostB(config)#ntp server 1.1.1.1
```

! Configure NTP hardware clock update

```
HostB(config)# ntp update-calendar
```

Verification

Verify the time before configuring NTP synchronization.

! Verify the time of reference clock source.

```
HostA#show clock
17:12:48 UTC Tue, Sep 8, 2009
```

! Verify the time of client before synchronization.

```
HostB#show clock
12:01:10 UTC Sat, Jan 1, 2000
```

! Verify the NTP status of client before synchronization.

```
HostB(config)#show ntp status
Clock is unsynchronized, stratum 16, no reference clock
nominal freq is 250.0000 Hz, actual freq is 250.0000 Hz, precision is 2**0
reference time is 0.0 (00:00:00.000 UTC Thu, Jan 1, 1970)
clock offset is 0.00000 sec, root delay is 0.00000 sec
root dispersion is 0.00000 msec, peer dispersion is 0.00000 msec
```

The output shows that the time hasn't been synchronized.

After configuring NTP synchronization, show NTP configurations. Key points: the NTP server address and stratum.

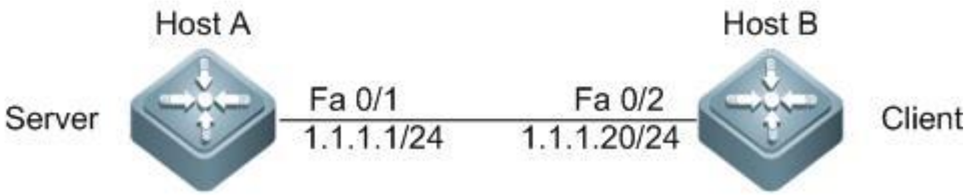
The following log information will be displayed on CLI interface:

```
*Sep  8 18:10:37: %SYS-6-CLOCKUPDATE: System clock has been updated to 18:10:37 UTC Tue Sep
8 2009.
HostB#show ntp status
Clock is synchronized, stratum 13, reference is 1.1.1.1
nominal freq is 250.0000 Hz, actual freq is 250.0000 Hz, precision is 2**24
reference time is CE511CC9.37EB5B2D (18:11:21.000 UTC Tue, Sep 8, 2009)
clock offset is -0.00107 sec, root delay is 0.00000 sec
root dispersion is 0.00002 msec, peer dispersion is 0.00002 msec
```

The output shows that the NTP client has connected to the server and the time of Host B has been synchronized with the time of Host A, with the stratum level being higher than that of Host A by 1 (i.e., 13).

Configuring NTP Client or Server Mode with Authentication

Topological Diagram



NTP client/server model

Application Requirements

On Host A, the local clock is confiugred as the NTP master clock, with the clock stratum being 12;
Host B is configured as the NTP client and Host A is specified as the NTP server;
The authentication mechanism is enabled to prevent illegal users from maliciously attacking the clock server.

Configuration Tips

Configuring NTP server/client authentication will involve the following steps:

Enable NTP global authentication.
Configure the key for NTP global authentication and the corresponding key ID.
Specify NTP global trusted key ID.

The authentication key used by NTP client to communicate with NTP server must be consistent with the corresponding Key ID.

Configuration Steps

Configuration of the NTP server

Step 1: Configure the NTP master. Configure the local clock as the trusted reference clock source, with the clock stratum being 12;

```
HostA(config)#ntp master 12
```

Step 2: Configure NTP authentication;

! Enable NTP global authentication.

```
HostA(config)# ntp authenticate
```

! Configure the NTP global authentication key as **helloworld** and the corresponding key ID as **6**.

```
HostA(config)# ntp authentication-key 6 md5 helloworld
```

! Specify **6** as the NTP global trusted key ID

```
HostA(config)# ntp trusted-key 6
```

Configuration of the NTP client

Step 1: Configure NTP authentication;

! Enable NTP global authentication.

```
HostB(config)# ntp authenticate
```

! Configure NTP global authentication key as **helloworld** and the corresponding key ID as **6**.

```
HostB(config)# ntp authentication-key 6 md5 helloworld
```

! Specify **6** as the NTP global trusted key ID.

```
HostB(config)# ntp trusted-key 6
```

! Configure Host A as the NTP server and set the key ID for communicating with this server as **6**.

```
HostB(config)# ntp server 1.1.1.1 key 6
```

Verification

Verify the configurations of NTP server. Key points: the NTP master clock configuration, NTP server's IP address, and authentication related configurations.

```
HostA#show run
!
interface fastEthernet 0/1
ip address 1.1.1.1 255.255.255.0
!
ntp authentication-key 6 md5 07360623191d300a004609 7
ntp authenticate
ntp trusted-key 6
ntp master 12
!
```

Verify the configurations of NTP client. Key points: the IP address and key ID of NTP server, and authentication related configurations.

```
HostB #show run
!
interface fastEthernet 0/2
 ip address 1.1.1.20 255.255.255.0
!
ntp authentication-key 6 md5 141a4f012d1d3c23174905 7
ntp authenticate
ntp trusted-key 6
ntp server 1.1.1.1 key 6
!
```

After proper configurations, the following log information will be displayed on the CLI:

```
*Sep  9 11:31:29: %SYS-6-CLOCKUPDATE: System clock has been updated to 11:31:29 UTC Wed Sep 9 2009.
```

The log information indicates that the clock of HostB (NTP client) has been updated.

Verify NTP server status.

```
HostA #show ntp status
Clock is synchronized, stratum 12, reference is 127.127.1.1
nominal freq is 250.0000 Hz, actual freq is 250.0000 Hz, precision is 2**24
reference time is CE521261.E52DECA2 (11:39:13.000 UTC Wed, Sep 9, 2009)
clock offset is 0.00000 sec, root delay is 0.00000 sec
root dispersion is 0.00002 msec, peer dispersion is 0.00002 msec
```

Verify NTP client status. Key points: the NTP server address and stratum.

```
HostB# show ntp status
Clock is synchronized, stratum 13, reference is 1.1.1.1
nominal freq is 250.0000 Hz, actual freq is 250.0000 Hz, precision is 2**24
reference time is CE5212A1.E5D712A0 (11:40:17.000 UTC Wed, Sep 9, 2009)
clock offset is -0.00005 sec, root delay is 0.00000 sec
root dispersion is 0.00002 msec, peer dispersion is 0.00002 msec
```

The output shows that the NTP client has successfully connected to the server and the time of Host B has been synchronized with that of Host A, with the stratum level being higher than that of Host A by 1 level (i.e., 13).

Configuring SNTP

Overview

Network Time Protocol (NTP) is designed for time synchronization on network devices. Another protocol, the Simple Network Time Protocol (SNTP) can also be used to synchronize the network time.

NTP can be used across various platforms and operating systems, provide precise time calculation (1-50 ms precision), and prevent from latency and jitter in the network. NTP also provides the authentication mechanism with a high security level. However, the NTP algorithm is complicated and demands delicate systems.

As a simplified version of NTP, SNTP simplifies the algorithm of time calculation while maintains great performance, with the precision about 1s.

The SNTP client is totally compatible with the NTP server due to the consistency between the SNTP and NTP packets.

Understanding SNTP

SNTP works in client/server mode. The standard server system time is set by receiving the GPS signal or the atomic clock. The client obtains its accurate time from the service time accessing the server regularly, and adjusts its system clock to synchronize the time.

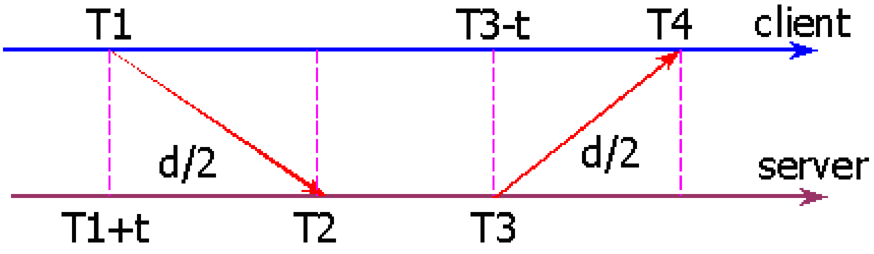


Figure-1

Originate Timestamp	T1	Time request sent by client
Receive Timestamp	T2	Time request received at server
Transmit Timestamp	T3	Time reply sent by server
Destination Timestamp	T4	Time reply received at client

T1: Time request sent by client (refer to the client time) with the mark “Originate Timestamp”;

T2: Time request received at server (refer to the server time) with the mark “Receive Timestamp”;

T3: Time reply by server (refer to the server time) with the mark “Transmit Timestamp”;

T4: Time reply received at client (refer to the client time) with the mark “Destination Timestamp”.

T: Time offset between the server and the client d: Round-tour time between the server and the client

The following formula calculates the time:

```
∵ T2 = T1 + t + d / 2;

∴ T2 - T1 = t + d / 2;

∵ T4 = T3 - t + d / 2;

∴ T3 - T4 = t - d / 2;

∴ d = (T4 - T1) - (T3 - T2);

t = ((T2 - T1) + (T3 - T4)) / 2;
```

Then, according to the value of *t* and *d*, the SNTP client gets the current time: T4 + t.

Configuring SNTP

This chapter describes how to configure SNTP.

Default Configuration

The following table describes the default SNTP configurations.

Function	Default
SNTP state	Disabled
IP address for the NTP server	0
SNTP Sync Interval	1800 seconds
Local Time-zone	GMT + 8

Enabling SNTP

Enter privileged mode and perform the following steps to enable the SNTP:

Enter global configuration mode:

```
Ruijie# config
```

Enable the SNTP and synchronize the time once immediately. The time will be immediately synchronized if this command is entered and regular synchronization is unnecessary. (in order to prevent frequent time synchronization, the sync-interval must not be less than 5 seconds)

```
Ruijie(config)# sntp enable
Return to privileged mode:
Ruijie(config)# End
```

Show the current configuration:

```
Ruijie# show running-config
```

Save the configuration:

```
Ruijie# copy running-config startup-config
```

To disable the SNTP, use the **no sntp enable** command.

Configuring the IP address of the SNTP Server

The SNTPclient is totally compatible with the NTP server due to the consistency between SNTP and NTP packets. There are many NTP servers in the network, and you can choose one with less latency.

For the detailed NTP server ip addresses, please log on to http://www.time.edu.cn/ or http://www.ntp.org/. For example, 192.43.244.18 (time.nist.gov).

Enter privileged mode and perform the following steps to specify an IP address for the SNTP server:

Enter global configuration mode:

```
Ruijie# config
```

Specify the IP address for the SNTP server.

```
Ruijie(config)# sntp server <ip-addr>
```

Return to privileged mode:

```
Ruijie(config)# End
```

Show the current configuration:

```
Ruijie# show running-config
```

Save the configuration:

```
Ruijie# copy running-config startup-config
```

Configuring the SNTP Synchronization Interval

To adjust the time regularly, you need to set the synchronization interval for SNTP client to access the NTP server SNTP client regularly. Perform the following steps to set the sync interval for the device and the NTP server:

Enter global configuration mode:

```
Ruijie# config
```

Configure the SNTP sync interval, in second.

Interval range: 60-65535s; Default value: 1800s.

```
Ruijie(config)# sntp interval <seconds>
```

Return to privileged mode:

```
Ruijie(config)# End
```

Show the current configuration:

```
Ruijie# show running-config
```

Save the configuration:

```
Ruijie# copy running-config startup-config
```

Caution

The synchronization interval configuration cannot take effect immediately unless you execute the **sntp enable** command immediately after configuring the synchronization interval.

Configuring the Local Time Zone

Greenwich Mean Time (GMT) is obtained through the SNTP communication. To obtain the accurate local time, you need to set the local time to adjust the mean time.

Enter global configuration mode:

```
Ruijie# config
```

Configure the time-zone, ranging from GMT-23 to GMT+23, wherein “-” indicates western area, “+” indicates eastern area. For example "8" indicates the 8th eastern time zone, "-8" indicates the 8th western time zone and “0” indicates Greenwich mean time. Universal Time Coordinated (UTC) is the default time zone name and the default value is **0**.

```
Ruijie(config)# clock timezone <time-zone>
```

Return to privileged mode:

```
Ruijie(config)# end
```

Show the current configuration:

```
Ruijie# show running-config
```

Save the configuration:

```
Ruijie# copy running-config startup-config
```

To restore the local time-zone to the default, use the command **no clock time-zone**.

Showing SNTP Information

The procedure is as follows:

Show related SNTP parameters:

```
Ruijie# show sntp
```

Use the **show sntp** command to show configured SNTP parameters:

```
Ruijie# show sntp
SNTP state              : ENABLE          //to view whether SNTP is enabled or not
SNTP server             : 192.168.4.12   //NTP Server
SNTP sync interval       : 60           //SNTP sync interval
Time zone             : +8               //Local Time-zone
```

Configuring UDP-Helper

Understanding UDP-Helper

Overview

UDP-Helper relays and forwards User Datagram Protocol (UDP) broadcast packets. As a relay, UDP-Helper can convert the UDP broadcast packets into the unicast packets and then forward them to the specified destination server by configuring the destination server for the UDP broadcast packets to be forwarded.

Once enabled, UDP-Helper checks whether the destination UDP port number of the received packet matches the port number to be forwarded to. If yes, it modifies the destination IP address of packets as the IP address of the specified destination server, and sends the packet to the destination server in unicast form.

When UDP-Helper is enabled, the broadcast packets from Ports 69, 53, 37, 137, 138 and 49 are relayed and forwarded by default.

Note

The BOOTP/DHCP broadcast packet is relayed through the UDP Port 67 and 68 by the DHCP Relay module; therefore, the two ports cannot be configured as the relay port of UDP-Helper.

Configuring UDP-Helper

Default Configuration

The following table describes the default configuration.

Attribute	Default value
Relay and forwarding	Disabled
UDP port for relay and forwarding	Indicates that the UDP broadcast packets from Ports 69, 53, 37, 137, 138 and 49 are relayed and forwarded by default when UDP-Helper is enabled.
Destination server for delay and forward	None

Enable the Relay and Forward Function of UDP-Helper

Command	Function
Ruijie(config)# **udp-helper** **Enable**	Enables the relay and forward function of UDP broadcast packets. This function is disabled by default.

To disable this function ,sue the **no udp-helper enable** command.

Note This function is disabled by default.

Note When UDP-Helper is enabled, the broadcast packets from UDP Ports 69, 53, 37, 137, 138 and 49 are relayed and forwarded by default.

Note When UDP-Helper is disabled, all of the configured UDP ports including the default ports are cancelled.

Configuring the Destination Server for Relay and Forwarding

Command	Function
Ruijie(config-if)# **ip helper-address** *IP-address*	Configures the destination server to which the UDP broadcast packets are relayed and forwarded. By default, it is not configured.

To remove the destination server for relay and forwarding, use the **no ip helper-address** command.

Note At most 20 destination servers can be configured for an interface.

Note If the destination server for relay and forwarding is configured on a specified interface and UDP-Helper is enabled, the broadcast packets of the specified UDP port received from this interface will be sent to the destination server configured for this interface in unicast form.

Configuring the UDP Port for Relay and Forwarding

Command	Function
Ruijie(config)# **ip forward-protocol udp** [*port*]	Configures the UDP port for relay and forwarding. If only the UDP parameter is specified, the default port will be used for relay and forwarding; otherwise, the port can be configured if necessary. When UDP-Helper is enabled, the broadcast packets from Ports 69, 53, 37, 137, 138 and 49 are relayed and forwarded by default.

To disable the UDP port for relay and forwarding, use the **no ip forward-protocol udp** [*port*] command.

Note

The UDP port can be configured for relay and forwarding. Otherwise, the error prompts will appear only when the function of delay and forwarding is enabled for UDP-Helper and the destination server is configured for the relay and forwarding.

Note

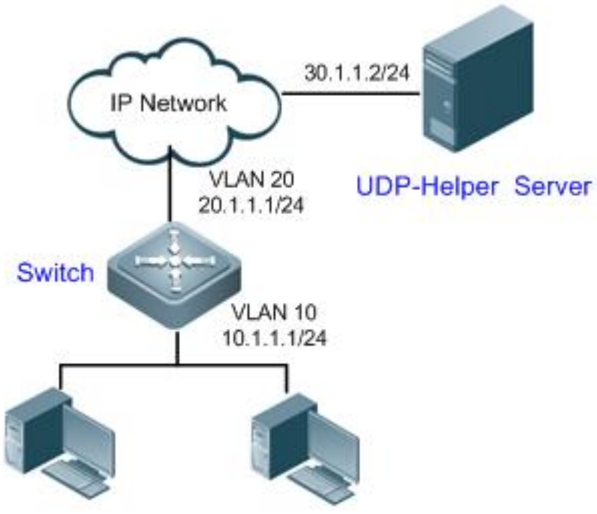
When the relay and forwarding function of UDP-Helper is enabled, the function of forwarding the broadcast UDP packets from the default ports 69, 53, 37, 137, 138 and 49 will be enabled immediately without any configuration.

At most 256 UDP ports are supported for relay and forwarding by the switch.

You can use both the **ip forward-protocol udp domain** and **ip forward-protocol udp** *53* commands to configure default ports.

Configuration Examples

Topology Diagram



Topology diagram for UDP-Helper configuration

Application Requirements

The network device can forward UDP broadcast packets with destination port being 1000 to the specified UDP-Helper server (with server IP being 30.1.1.2/24).

Configuration Tips

Configure UDP-Helper relay and forwarding as follows:

Enable UDP-Helper relay forwarding.

Configure the destination server of UDP-Helper relay forwarding.

Configure the destination port number of UDP broadcast packets for relay forwarding (in this example, UDP broadcast packets with destination port being 1000 are subject to relay forwarding; meanwhile, the device will by default forward UDP broadcast packets containing destination port numbers of 69, 53, 37, 137, 138 and 49).

Note

The UDP port for relay forwarding can only be configured after UDP-Helper relay forwarding is enabled and the destination server is configured; otherwise, error messages will be displayed.

After UDP relay forwarding is enabled, the device will immediately forward UDP broadcast packets containing the default port numbers of 69, 53, 37, 137, 138 and 49 without further configuration.

Configuration Steps

Before configuring relevant features of UDP-Helper, make sure that the route from the switch to the network segment of UDP-Helper server is reachable. The IP addresses configured on respective interfaces are shown in the topological diagram. Here we will introduce how to configure relevant features of UDP-Helper.

Step 1: Enable UDP-Helper relay forwarding on the network device

```
Ruijie(config)#udp-helper enable
```

Step 2: Configure the IP address for the destination server of UDP-Helper relay forwarding as 30.1.1.2 on fastEthernet 1/1.

```
Ruijie(config)# interface fastEthernet 1/1
Ruijie(config-if-VLAN 10)#ip address 10.1.1.1 255.255.255.0
Ruijie(config-if-VLAN 10)# ip helper-address 30.1.1.2
Ruijie(config-if-VLAN 10)#exit
```

Step 3: Configure the Switch to forward UDP broadcast packets carrying the destination port number 1000.

```
Ruijie(config)#ip forward-protocol udp 1000
```

Verification

Verify configurations of the switch. Key points: whether relay forwarding is enabled or not; IP address of relay server; destination port number carried in UPD broadcast packets requiring relay forwarding.

```
Ruijie#show run
!
udp-helper enable
!
ip forward-protocol udp 1000
!
interface fastEthernet 0/1
 ip address 10.1.1.1 255.255.255.0
!
interface fastEthernet 1/1
ip helper-address 30.1.1.2
```

```
 ip address 20.1.1.1 255.255.255.0
!
```

Verify whether relay forwarding has taken effect.

Step 1: Send UDP broadcast packets carrying the destination port number 999.

PC1 sends a UDP broadcast packet of the following format:

```
Src_mac:0000.0000.0001
Dst_mac:0xFFFFFFFFFFFF
Src_ip:1.0.0.3
Dst_ip:255.255.255.255
Dst_port:999
PC2 acts as UDP-Helper server. Such packet is not received on PC2.
Step 2: Send UDP broadcast packets carrying the destination port number of 1000.
PC1 sends a UDP broadcast packet of the following format:
Src_mac:0000.0000.0001
Dst_mac:0xFFFFFFFFFFFF
Src_ip:1.0.0.3
Dst_ip:255.255.255.255
Dst_port:1000
PC2 acts as UDP-Helper server. Such packet is received on PC2. The destination IP address of packet is 30.1.1.2, and the data contained are the same as the packets sent.
```

Step 3: Send UDP broadcast packets with destination port number 69, 53, 37, 137, 138 or 49.

PC1 sends a UDP broadcast packet of the following format (taking destination port number of 69 as the example):

```
Src_mac:0000.0000.0001
Dst_mac:0xFFFFFFFFFFFF
Src_ip:1.0.0.3
Dst_ip:255.255.255.255
Dst_port:69
```

PC2 acts as UDP-Helper. Such packet is received on PC2. The destination IP address of packet is 30.1.1.2, and the data contained are the same as the packets sent.

From the verification output, we can learn that the switch has successfully forwarded UDP broadcast packets with the user-defined destination port number (destination port number 1000 and default numbers of 69, 53, 37, 137, 138, and 49) to the specified UDP-Helper server.

Configuring URPF

Understanding URPF

Overview

Recently, frequent Denial of Service (DOS) attacks caused by forged source address are causing many troubles to Internet Service Providers (ISPs) and network maintenance.

Figure 1 shows a common scenario of using a forged source address to perform DOS attacks.

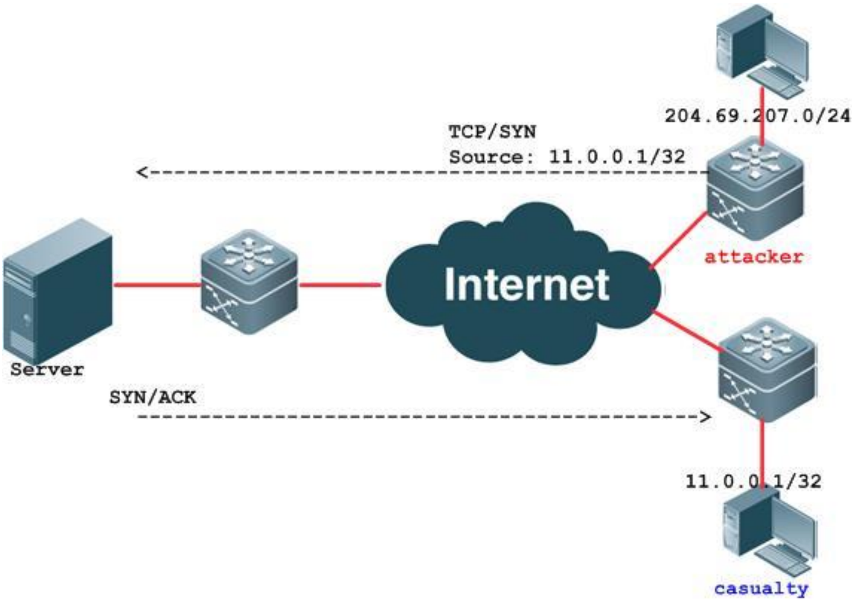


Figure 1 Scenario of source-address-based attacks

The attacker initiates attacks by sending packets with the forged source address 11.0.0.1, making the server send excessive SYN/ACK packets to the host unrelated to this attack, and the host with the real source address is also affected. What's worse, if the network administrator identifies that this address is related to the attack on the network and discards all data streams from this source address; therefore, the denial of service to the source address occurred.

Unicast Reverse Path Forwarding (URPF) well addresses the preceding problem.

It is known that during packet forwarding, the forwarding table is looked up according to the destination address contained in the IP packet received, and the packet is forwarded according to the entry found in the forwarding table. URPF will look up the forwarding table for the forwarding entry according to source address and ingress interface of the incoming packet. If the forwarding entry is not found in the forwarding table, the packet will be discarded; if the egress interface specified in the forwarding table doesn't match with the ingress interface of the packet, the packet will also be discarded. Otherwise, the packet will be forwarded.

URPF can protect the network by intercepting source address spoofing attacks.

Features of URPF

URPF strict mode

Conventional URPF technical requirements: URPF will look up the forwarding table for the forwarding entry according to the source address and ingress interface of the incoming packet. If the forwarding entry is not found in the forwarding table, the packet will be discarded; if the egress interface specified in the forwarding table doesn't match with the ingress interface of the packet, the packet will also be discarded. This requires that the "ingress interface of the packet received must be the egress interface of the route reaching this source address". We call such URPF check mode as URPF strict mode.

Note

URPF strict mode is generally deployed on the point-to-point interface, and the data streams from both directions need to pass this point-to-point interface.

URPF loose mode

URPF strict mode has its limitations, and is particularly not applicable to the asymmetrical routing environment and multi-homed network environment.

To implement the network flow control and routing policy, asymmetrical routing is a common seen network application. In asymmetrical routing, URPF strict mode will result in the loss of data streams. Figure 2 shows an example of asymmetrical routing. If G1/2 on R1 enables URPF strict mode and receives packets from the network segment of 192.168.20.0/24, URPF check will indicate the interface of G1/1 and the packet will not be able to pass URPF check.

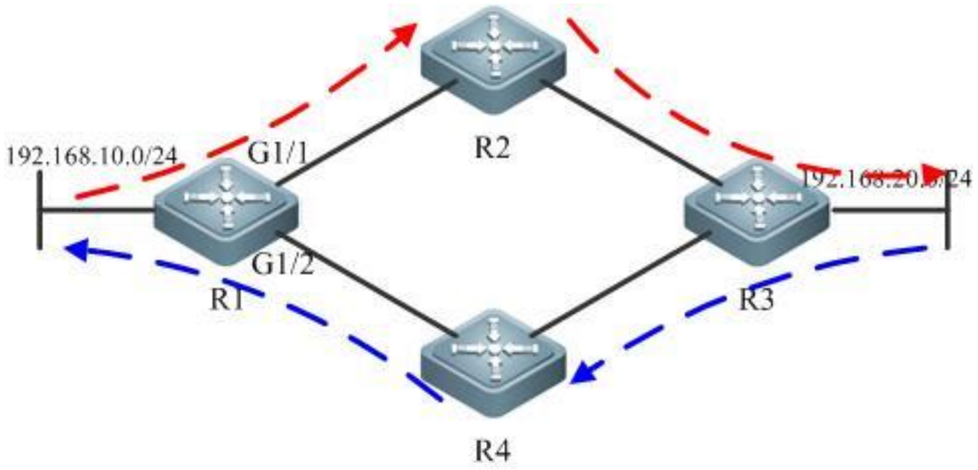

Figure 2 Asymmetrical routing

The multi-homed network is the common network application between a user and the ISP or between ISPs. As shown in Figure 3, user network A is simultaneously connected to multiple ISPs, and the incoming and outgoing streams are always asymmetrical. The figure shows that user network A is visiting user network B.

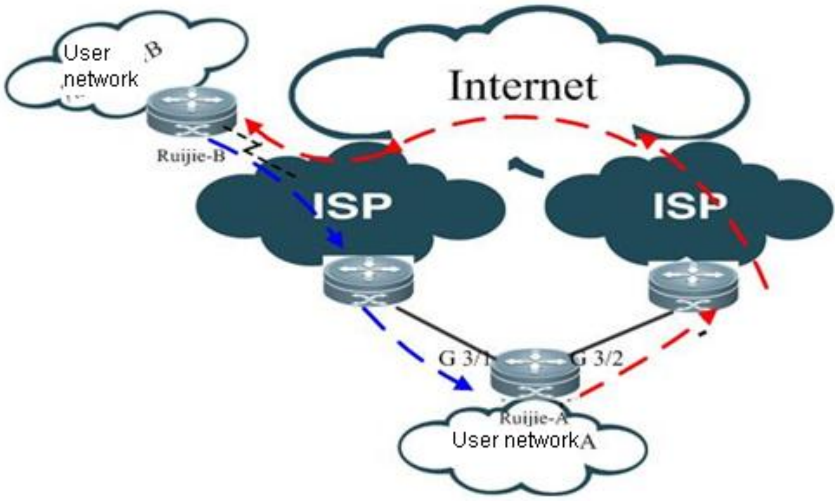

Figure 3 Multi-homed network

In the preceding two application scenarios, valid packets will be filtered if URPF strict mode is enabled. Therefore, URPF loose mode is introduced.

URPF loose mode: Reverse route check is conducted according to the source IP of incoming packet. As long as the route is found, the next-hop egress interface may unnecessarily be the interface that receives the packet. URPF loose mode well addresses the asymmetrical stream problem in the aforementioned asymmetrical routing application and multi-homed network.

URPF monitoring

To conveniently monitor the drop rate of packets after URPF is enabled, Ruijie devices initiatively inform the user of such drop rate via Syslog and Trap. The mechanism will be detailed in this section.

URPF monitoring has introduced the following concepts:

Drop rate: indicates the number of packets discarded due to URPF check within a specific period of time divided by this time. Unit: packets/second (pps).

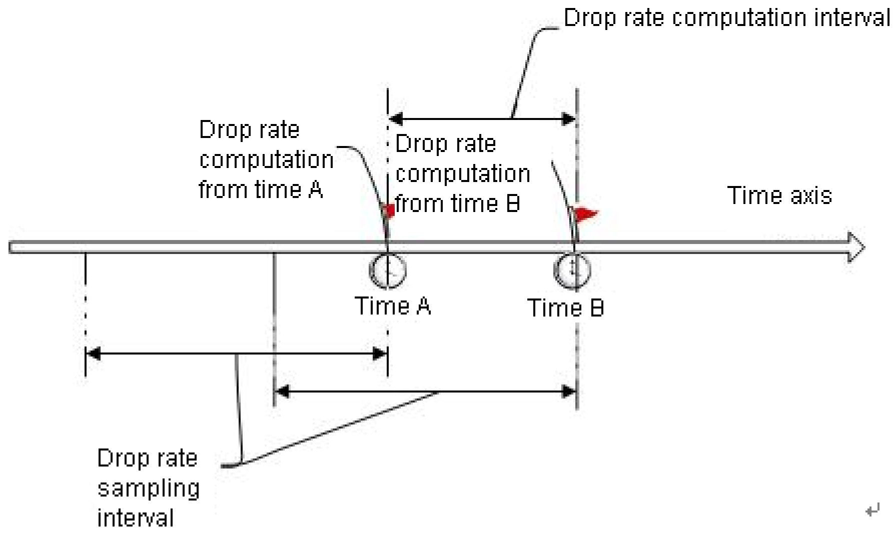
Drop rate computation interval: indicates the time interval from the previous calculation to the recalculation of the drop rate.

Drop rate sampling interval: indicates the time interval for calculating the number of packets dropped. This value must not be smaller than the drop rate computation interval.

Drop rate notification threshold: indicates the maximum drop rate allowed. When the drop rate is higher than this threshold, the user will be notified via Syslog or Trap. The user may also adjust the drop rate notification threshold according to actual situations of the network.

Drop rate notify hold-down time: indicates the time interval between two successive notifications. The user may adjust the value according to actual situations of the network to avoid frequent Log printing or Trap sending.

The following figure shows two successive computations of the drop rate:



Drop rate computation interval
Drop rate computation from time A
Drop rate computation from time B
Time axis
Time A
Time B
Drop rate sampling interval

Figure 4 Two successive computations of drop rate

Main points of URPF monitoring:

Drop rate computation

After URPF function is enabled, within the time interval of "0-drop rate sampling interval (including the sampling time point reaching the drop rate)", the drop rate is computed by dividing the currently computed number of dropped packets by the time of URPF running. The subsequent method for drop rate computation: Computed the number of currently dropped packets at every drop rate computation interval, deduct the number of dropped packets before the drop rate sampling interval, and then divide the difference by drop rate sampling interval to obtain the current drop rate.

URPF allows interface-based and global-based drop rate computation and monitoring.

For configurations related to URPF monitoring, see the *Configuring URPF Drop Rate Notification*.

Working Principle

The working principle of URPF has been described in the section Features of URPF.

URPF functions can be applied to IPv4/IPv6 packets according to configurations. However, note that the following packets will not be subject to URPF check.

Destination addresses being multicast packets. URPF check is only applied to the source address with destination address being IPv4/IPv6 packet.
DHCP/BOOTP packets with source IP address being 0.0.0.0 and destination IP address being 255.255.255.255
IPv6 packets with source IP address being Link local addresses

Application Restrictions

Ruijie products that support URPF include:

1) Router products.
2) Switches that support URPF function:

S5750 V2.x product

Category B and C line cards and the M8600-MPLS line card of the S8600 series products

S12000EA line card

The URPF function supported by our router products has the following application restrictions:

Router products only support the URPF function during progress forwarding. If the fast forwarding is enabled on the interface (interface configuration mode: **ip ref**), the URPF function will be disabled.

Currently, the URPF function on routers cannot be applied to IPv6 packets.

The URPF function also has the following characteristics in switch and router products:

After the URPF function is enabled, a route whose source address is matched with a NULL interface will still be subject to URPF check.

After the URPF function is enabled, URPF enjoys precedence over the Access Control List (ACL, interface configuration mode: **ip access-group in**) during packet check.

If URPF strict mode is enabled, incoming packets with the source address being the address of the ingress interface will be discarded. If URPF loose mode is enabled, such packets will pass the interface.

Protocol Specification

Protocol specifications related to URPF include:

RFC 2827, Network Ingress Filtering: DDOS Attacks which employ IP Source Address Spoofing

RFC 3704, Ingress Filtering for Multi-homed Networks

Default Configurations

The following table describes the default configurations of URPF.

Function	Default setting
URPF global configuration mode	Disabled
URPF interface configuration mode	Disabled
URPF drop rate monitoring	Disabled
URPF drop rate computation interval	30 seconds
URPF drop rate sampling interval	URPF drop rate computation interval x 5
URPF drop rate notification threshold	1000 pps
URPF drop rate notify hold-down time	300 seconds
URPF Trap sent for drop rate notification	Disabled

Configuring URPF Functions

The following sections describe how to configure the basic functions of URPF:

Configuring URPF (Global Configuration Mode)

After the MPLS line card is inserted in the S8600 series switches, packets will be forwarded by the MPLS line card. In this case, you need to enable the URPF function according to the steps described in the following table.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# i**p verify unicast source reachable-via rx**	Enables the URPF function rx: uses strict mode to perform URPF check
Ruijie(config)# **end**	Exits global configuration mode
Ruijie# **show ip urpf**	Shows URPF configurations and statistics

To disable global URPF function, use the **no ip verify** command in global configuration mode.

⚠ Caution

The configuration of the URPF feature in global configuration mode takes effect on the S8600 series switches only after the MPLS line card is inserted. After the URPF function takes effect, it will enable URPF check on IPv4 packets.

⚠ Caution

The URPF function configured in global configuration mode supports only URPF strict mode. When used with equal-cost routing, it will switch to URPF loose mode.

⚠ Caution

URPF function configured in global configuration mode doesn't support URPF check with the default route.

⚠ Caution

The URPF function cannot be configured in global configuration mode and in interface configuration mode at the same time.

⚠ Caution

Note that it is not recommended to configure URPF globally if the S8600 series devices are directly connected to users' network segments. The URPF check fails and the packets are discarded if the S8600 series devices did not learn the Address Resolution Protocol (ARP) entry of a directly-connected user before packet forwarding.

Configuration example:

```
# Enable URPF in global configuration mode:
```

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# ip verify unicast source reachable-via rx
```

Configuring URPF (Interface Configuration Mode)

URPF is not enabled on the interface by default.

Use the following commands to enable the URPF function on the interface.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *interface-name*	Enters interface configuration mode.
Ruijie(config-if)# **ip verify unicast source reachable-via** { **any** | **rx** } [**allow-default** | *acl_name*]	Enables the URPF function. any: uses loose mode to perform URPF check. rx: uses strict mode to perform URPF check. allow-default: allows the use of default route to perform URPF check. *acl-name*: indicates the ACL number, supporting: 1 to 99 (IP standard access list) 100 to 199 (IP extended access list) 1300 to 1999 (IP standard access list, expanded range) 2000 to 2699 (IP extended access list, expanded range)
Ruijie(config-if)# **end**	Exits interface configuration mode and returns to privilege mode.
Ruijie# **show ip urpf interface** *interface-name*	Displays URPF configurations and statistics.

Note

By default, the default route is not used for URPF check; if required, the user can use the keyword *allow-default* to enable this function.

Note

By default, a packet failing in URPF check will be discarded. If the ACL (*acl-name*) is configured, such a packet will undergo ACL check after failing in URPF check. If ACL doesn't exist or the packet points to a deny ACE, such packet will be discarded. If the packet points to a permit ACE, the packet will be forwarded.

Caution

After this command is enabled, the S5700 V2.x switch and the S8600 and S12000 series switches will enable the URPF check on IPv4 and IPv6 packets at the same time, and the routers will enable the URPF check on IPv4 packets.

Caution

For switches, the URPF feature is supported only on the S5700 V2.x switch and the routed port and Layer 3 AP associated with category B line cards of S8600 series. The restrictions are as follows:

- The URPF function doesn't support the function of associating ACL options.
- The URPF function doesn't support the use of IPv6 routes with 65-to-127 bit prefix to perform URPF check.
- After URPF function is enabled, all packets received by the physical port of these interfaces will be subject to URPF check, thus expanding the range of URPF check. A typical application scenario is: If a packet received by Tunnel interface is received from the aforementioned physical port, this packet will also be subject to URPF check. If such an application scenario exists, be cautious when enabling URPF check.
- After URPF function is enabled, the route forwarding capacity of the device will be reduced by 50%.
- After URPF strict mode is enabled, if the packets received by the interface match with equal-cost routing during URPF check, it will switch into loose mode.
- The URPF function cannot take effect on interfaces of the S8600 series switches after the MPLS line card is inserted.

Caution

The URPF function cannot be configured in global configuration mode and in interface configuration mode at the same time.

Configuration example:

```
# Perform strict URPF check for packets received by interface
```

GigabitEthernet 0/21, with no need to use default route for URPF check.

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# interface gigabitEthernet0/21
Ruijie(config-if)# ip verify unicast source reachable-via rx
```

Configuring URPF Drop Rate Notification

To configure URPF drop rate notification, you must enable the URPF function first.

Use the following commands to configure URPF drop rate notification.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **ip verify urpf drop-rate compute interval** *seconds*	Configures URPF drop rate computation interval in seconds. The value range is 30 to 300. The default value is 30 seconds.

Ruijie(config)# ip verify urpf drop-rate notify **hold-down** *seconds*	Configures URPF drop rate notify hold-down time in seconds. The range is 30 to 300. The default value is 300 seconds.
Ruijie(config)# **interface** *interface-name*	Enters interface configuration mode.
Ruijie(config-if)# **ip verify urpf drop-rate notify**	Enables URPF drop rate monitoring.
Ruijie(config-if)# ip verify urpf notification threshold *rate-value*	Configures URPF drop rate notification threshold.in Packets Per Second (pps). The range is 0 to 4294967295. The default value is 1000 pps.
Ruijie(config-if)# **exit**	Exits interface configuration mode and returns to global configuration mode.
Ruijie(config)# **snmp-server enable traps urpf**	Sends Trap packets after the URPF drop rate has exceeded the notification threshold.
Ruijie(config)# **snmp-server host** {*host-addr*| *ipv6 ipv6-addr* } **traps** *word urpf*	Configures the host to receive URPF Trap.
Ruijie(config)# **end**	Exits global configuration mode.
Ruijie# **show ip urpf**	Shows URPF configurations and statistics.

Note

By default, the drop rate notification threshold is 1000 pps. The user may adjust the drop rate notification threshold as required.

Caution

Drop rate monitoring is only effective in interface configuration mode, and is not supported in global configuration mode.

Caution

In interface configuration mode, the drop rate will be computed according to the packets dropped by the interface after URPF check is enabled.

Configuration example:

# Perform strict URPF check for packets received by interface GigabitEthernet 0/21 with no need to use default route for URPF check. Monitor the URPF drop rate via SNMP Trap. Configure the drop rate notification threshold to 500 pps. Configure the SNMP host 192.168.12.219 to receive Trap packets.

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# ip verify urpf notification threshold 500
Ruijie(config)# snmp-server enable traps urpf
Ruijie(config)# snmp-server host 192.168.12.219 public urpf
Ruijie(config)# interface gigabitEthernet0/21
Ruijie(config-if)# ip verify unicast source reachable-via rx
```

Viewing URPF Configurations

Use the following command provided by URPF to show various configurations and statistics.

Command	Function
show ip urpf [**interface** *interface-name*]	Shows URPF configurations and statistics.

Use the following command provided by URPF to clear URPF statistics.

Command	Function
clear ip urpf [**interface** *interface-name*]	Clears the statistics about packets dropped in URPF check.

Typical URPF Configuration Example

Example of Strict Mode Configuration

Networking Requirements

Figure 5 shows the typical hierarchical network architecture.

The packets with forged source addresses may be transmitted from user PCs to the core-layer network. To avoid this, the source address attack packets need to be isolated on the access layer or distribution layer to eliminate invalid data on the aggregation-layer and core-layer network.

The preceding requirement can be satisfied by enabling URPF strict mode on the interface linking aggregation-layer devices and access-layer devices.

Networking Topology

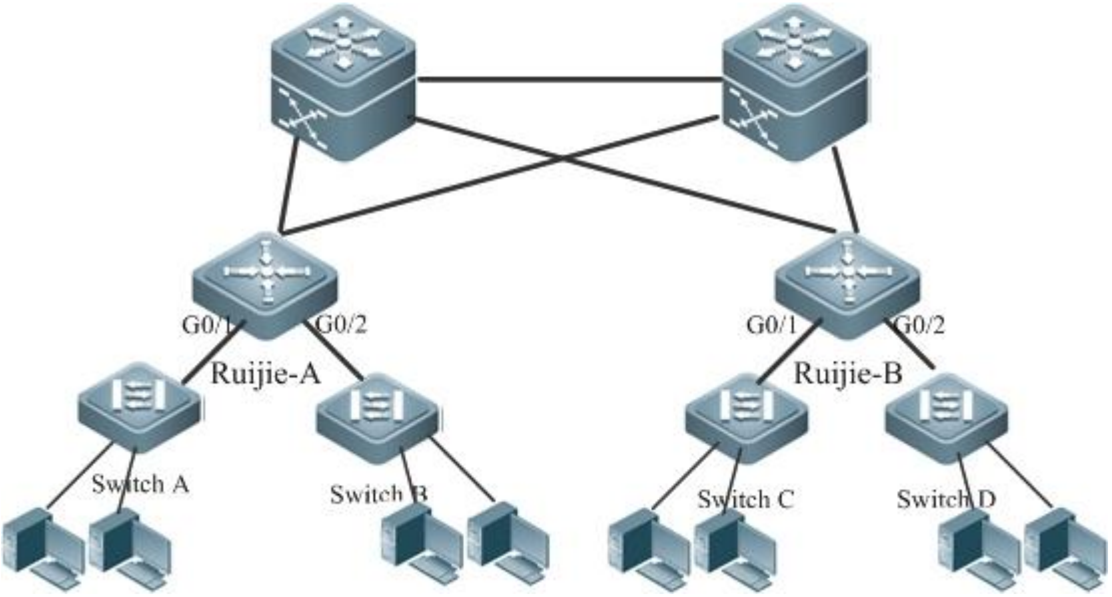


Figure 5 Application of URPF strict mode

Configuration Steps

As shown in Figure 5, enable URPF strict mode on the aggregation-layer device. That is, enable URPF strict mode on Ruijie-A and Ruijie-B.

# Configurations of device Ruijie-A:

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# interface gigabitEthernet0/1
Ruijie(config-if)# ip address 195.52.1.1 255.255.255.0
Ruijie(config-if)# ip verify unicast source reachable-via rx
Ruijie(config-if)# ip verify urpf drop-rate notify
```

The configurations to enable URPF strict mode are the same on interface G0/2 of Ruijie-A and G0/1 and G0/2 of Ruijie-B.

Verification

# Verify URPF configurations of Ruijie-A.

```
Ruijie #show ip urpf interface gigabitEthernet 0/1
IP verify source reachable-via RX
IP verify URPF drop-rate notify enabled
IP verify URPF notification threshold is 1000pps
Number of drop packets in this interface is 124
Number of drop-rate notification counts in this interface is 0
```

Example of Loose Mode Configuration

Networking Requirements

The section describes the common application scenario of URPF loose mode, including asymmetrical routing environment and multi-homed network environment.

This section describes the configurations of outlet device connecting the ISP in the multi-homed network as shown in Figure 3.

Networking Topology

Figure 3 shows the multi-homed network.

Configuration Steps

As shown in Figure 3, URPF loose mode is enabled on G3/1 and G3/2 connecting two ISPs to prevent invalid packets from attacking the interior user network and isolate invalid packets outside the user network on the outlet device Ruijie-A in the user network.

# Configurations of Ruijie-A:

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# interface gigabitEthernet3/1
Ruijie(config-if)# ip address 195.52.1.2 255.255.255.252
Ruijie(config-if)# ip verify unicast source reachable-via any
Ruijie(config-if)# ip verify urpf drop-rate notify
Ruijie(config-if)# exit
Ruijie(config)# interface gigabitEthernet3/2
Ruijie(config-if)# ip address 152.95.1.2 255.255.255.252
Ruijie(config-if)# ip verify unicast source reachable-via any
Ruijie(config-if)# ip verify urpf drop-rate notify
Ruijie(config-if)# end
```

Verification

# Verify URPF configurations of Ruijie-A.

```
Ruijie #show ip urpf
IP verify URPF drop-rate compute interval is 300s
IP verify URPF drop-rate notify hold-down is 300s
Interface gigabitEthernet3/1
IP verify source reachable-via ANY
IP verify URPF drop-rate notify enabled
IP verify URPF notification threshold is 1000pps
Number of drop packets in this interface is 4121
Number of drop-rate notification counts in this interface is 2
Interface gigabitEthernet3/2
IP verify source reachable-via ANY
IP verify URPF drop-rate notify enabled
IP verify URPF notification threshold is 1000pps
Number of drop packets in this interface is 352
Number of drop-rate notification counts in this interface is 0
```

Configuring IPFIX

Overview

IP Flow Information eXport (IPFIX), is a standard protocol published by the Internet Engineering Task Force (IETF) for the netflow measurement. It standardizes the format of the network traffic statistics. IPFIX is applicable to network devices and management system platforms of any manufacturers, and is used to export the flow statistics by network device. On one hand, IPFIX allows an administrator to easily extract and view the important flow information stored in the network device. On the other hand, it is unnecessary for the administrator to upgrade the network device software or management tools if the flow monitoring requirement changes as the export format is extensible.

IP flow information is transmitted from an export device (router, switch, or network sniffer device) to the collector. Different data formats are defined to meet different requirements, because IPFIX is a highly-scalable template-based format for the data export.

To export the complete data, seven key fields are adopted to represent each network flow: source IP address, destination IP address, source port, destination port, Layer-3 protocol type, byte of Type-of-service, and input logical interface. If all those seven key fields of different IP packets are matched, then all the IP packets belong to the same flow. Network optimization, security detection and traffic accounting can be performed according to the current network application information about recorded features of the netflow, such as flow duration, and the average length of the packet in the flow.

Basic Concept

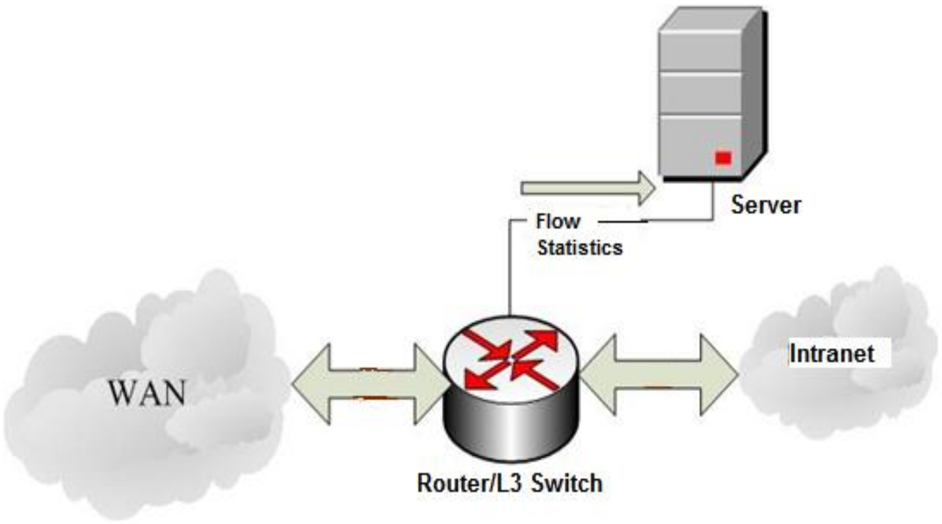
Template: Defines the recorded data format, including a series of data bit domain fields, each of which contains the data type of the data bit domain and the data length. You can parse the recorded data according to the template. If you want to add a data field you are interested in to the data record, you only need to add the corresponding data bit domain field to this template, without modifying the management software.

Collector: Receives the IP flow information generated from the network device. The collector analysis is based on the received data template and data records, and it clearly shows flow information in graphics or tables and saves the information to the database for further use.

IPFIX Application

The router/switch enabled with the IPFIX flow statistics function can collect the statistics on lots of information of packets, including the Layer-3 protocol type, the transport layer port, source/destination address, and service type. The information can be widely used in application scenarios such as user detection, network analysis and planning, security analysis, traffic accounting, and network traffic engineering. Figure-1 shows a typical application topology.

Figure-1



Network Application and User Detection

The IPFIX traffic statistics feature allows you to view detailed, real-time, application-based, and current network usage. It allows you to reasonably allocate and optimize the network resources, and provides the capability of real-time detection of the network capacity. With the IPFIX flow detection function, you can easily understand the network usage and plan to limit the usage combined with other functions such as the Access Control List (ACL). IPFIX can also help effectively and quickly solve some potential security problems.

Network Planning

The IPFIX flow statistics function can detect netflow information over a long period and track network trends. The data enables you to predict network changes and optimize upgrade plans of various networks effectively. It minimizes network costs, but maximizes network performance, capacity and stability. IPFIX can also detect unwanted traffic in Wide Area Network (WAN) and redundant bandwidth and quality of service (QoS) usage. The IPFIX flow statistics function offers valuable information for reducing the cost of operating the network. For example, when the traffic over a WAN link increases, generally you will increase the investment to upgrade the link. However, the traffic increase is possibly attributed to some illegal usage such as BT download. IPFIX enables you to find out the real reason, modify the network usage policy and solve the problem, and thus preventing unnecessary network upgrade.

Security Analysis and Attack Detection

You can use the export flow record of the IPFIX flow statistics to identify denial of service (DoS) attacks, viruses and worms in real-time. Anomalistic changes in network behaviors are clearly reflected in flow records. Take DoS attack for example, its feature is to send a bulk of IP packets (different from the ordinary ones) in the network from untrusted source addresses to the same destination address. Combined with other network control methods (ACL and QoS), the IPFIX flow statistics function can prevent malicious network attack effectively by collecting the source address, destination address, protocol number, port number and size of these packets and sending the information to the collector for network security experts or software analysis.

Flow Accounting

The IPFIX flow statistics function measures the flows in a network in a fine granularity way, including the source/destination IP address, number of packets, total bytes, timestamp, QoS and application ports. Internet Service Providers (ISPs) can utilize the information for accounting based on time, bandwidth, application or network service quality.

IPFIX Function

Note Ruijie IPFIX function is implemented based on the multi-service card only.

Understanding the IP Packet Flow

A packet flow is a series of consecutive packets of the same attributes and pass a same detection point in a period. The packets belong to a same flow have some same attributes, which can be some fields in the head of the IP packets, such as source IP address, Tos field and any combination of those fields. The key fields defining the packet flow are not fixed. For Ruijie switches, a netflow is defined as the unidirectional packet flow with the same source and destination. To be precise, a netflow is determined by the combination of the following key fields:

- Source IP address
- Destination IP address
- Source port number
- Destination port number
- Layer-3 protocol type
- Tos
- Input logical interface
- VRF

Those eight key fields determine a unique flow. If one key field of a packet is different from that of another packet, they belong to different flows. A flow record also includes other statistical fields, such as the packet number, the next-hop IP address, total flow byte number, etc. For each probe packet, ascertain the flow records first, and record the corresponding information stored in the main cache. The flow record cache is used to store the IP flow information, including the main cache and the flow aggregation cache.

Understanding the Main Cache

The main cache is used to store the raw IP flow information, using seven keywords to match the flow statistics. The IPFIX export mechanism records the flow information and sends it to the configured collector. For an IP packet, first search for the corresponding flow record from its keyword in the main cache: if no flow record exists, create a new one; and if the flow record exists, then update the flow statistical information, such as the packet number, flow bytes, etc. The cache capacity is limited; therefore, the aging mechanism of the flow record is set. The following conditions are used to determine whether a flow is aged out or not:

If no packets belong to the flow are detected in a certain period of time (the non-active time), this flow has been aged and shall be exported.

The flow information cannot be recored indefinitely for it persists for a too long time, which exceeds the set active time, then this flow shall be aged.

When it needs to export the aged flow record, the flow information shall be encapsulated as User Datagram Protocol (UDP) packets and sent to the set collector on the server for processing. The collector is the software tool for processing the flow record, and can display the visualized current network status and analyze the netflow according to the received flow record information.

Understanding the Format of the Flow Export Packet

The format of the flow record export packet is the IPFIX standard format. The IPFIX standard format is based on the template, and easy to extend. When encapsulating the data record, first create the format template of the data record, which defines the filed type and length of the data record. For each data record, use the template to identify and explain the analytical format. To add a new field to the date record, you only need to re-create the corresponding data template rather than to upgrade the software, which greatly improves the scalability.

On Ruijie routers, IPFIX supports the exporting of netflow packet formats of version 9 and version 10, and supports the netflow software versions ManageEngine_NetFlowAnalyzer_7001 and ManageEngine_NetFlowAnalyzer_8000. However, the netflow software version ManageEngine_NetFlowAnalyzer_9100 may be problematic on Ruijie routers, because the deployed template is different from Cisco's template.

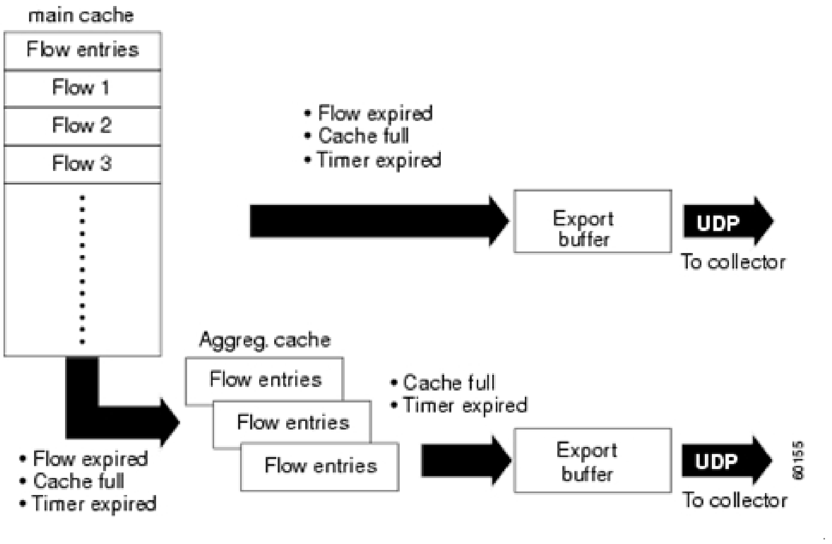
Understanding Flow Aggregation Mode

Similar to main mode, flow aggregation mode also deals with the netflow statistics. The only difference is that the main mode acquires the original packet to generate and export the flow record, while flow aggregation mode reprocesses the flow record to generate and export the new record of the flow aggregation.

Such processing meets requirements of using different key fields to reprocess flow records and generate the required flow records in different flow aggregation modes. As described in the preceding sections, a flow consists of packets of the same attributes, and the attributes can be the combination of any fields in packet headers. In the software, seven keywords differentiate flows, and you can select any seven fields in packet headers to reprocess flow records. For example, to know Layer-3 packet distribution, you can use Layer-3 protocol ID as the key field to aggregate flow records exported in main mode and obtain the required flow information.

Similar to the main mode, flow aggregation mode requires the cache to store the current statistical flow information. The flow aggregation function maps the export flow record in the main cache to the corresponding flow record in the flow aggregation cache, updates the flow aggregation record and regularly checks whether the flow aggregation record expires. Once expired, the flow aggregation record must be exported. Figure-2 shows the principle..

Figure-2:



Configuring the Flow Record Export in Main Mode

When a flow record in the main cache expires, the software uses the export mechanism to encapsulate the expired flow record to a UDP packet and sends the UDP packet to the configured server. Meanwhile, to prevent the loss of the template carrying the flow record because of unrelizable transmission over UDP, it requires for the regular template retransmission to ensure the successful receiving of the data template.

Configuring the Export Destination IP Address and Port

Up to two export servers can be set at the same time to improve the reliability of flow information transmission.

Use the following commands to configure the export server.

Command	Function
Ruijie> **enable**	Enters privileged command mode.
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **ip flow-export destination** *ip-address udp-port* [**vrf** [*vrf-name*]]	Configures the destination IP address and destination port of the flow export, and VRF.
Re-execute the third command	Configures the destination IP addresses and destination ports of multiple flow exports.
Ruijie(config)# **end**	Returns to privileged command mode.
Ruijie# copy running-config startup-config	Saves the configuration.

To remove the flow export, use the **no ip flow-export destination** *ip-address udp-por*t [**vrf** [*vrf-name*]] command.

Configuration example

```
Ruijie# config terminal
Ruijie(config)#ip flow-export destination 192.168.217.76 1111
Ruijie(config)#ip flow-export destination 192.168.217.76 2222
%Warning: Second destination address is the same as previous address 192.168.217.76
Ruijie(config)#ip flow-export destination 192.168.217.76 3333
%Exceeded maximum export destinations
```

```
Ruijie(config)# end
Ruijie products display error information when the third export destination is configured.
```

Caution By default, no flow export is set in the system. The flow record will be saved in the device for checking instead of being exported.

Configuring the Export Source IP Address

A device can have multiple IP addresses, so the IP address on one port can be specified as the source IP address for the sent packet when exporting the flow record.

Use the following commands to configure the source IP address.

Command	Function
Ruijie> **enable**	Enters privileged command mode.
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **ip flow-export source** *interface-number*	Configures the export source IP address as the IP address for an interface.
Ruijie(config)# **end**	Returns to privileged command mode.
Ruijie# copy running-config startup-config	Saves the configuration.

Configuration example

```
Ruijie# config terminal
Ruijie(config)# ip flow-export source gigabitEthernet 6/2
Ruijie(config)# end
Ruijie#
```

The example uses the IP address of g 6/2 as the source address.

Caution By default, the default system IP address is used as the source IP address when sending the packets in the system.

Caution An IP address must have been configured for the port designated as the source address.

Configuring the Related Parameters of the Export Template

Before exporting the netflow data, the corresponding data template shall be sent to the server. UDP, an unreliable protocol, may result in the template loss and cause that the server fails to analyze the flow data correctly. Therefore, the retransmission mechanism is adopted to send the template. There are two RGOS retransmission mechanisms: 1. In the unit of packets, retransmit the template once each time sending *n* data packets; 2. In the unit of minutes, retransmit the template at every certain interval.

Use the following configuration commands.

Command	Function
Ruijie> **enable**	Enters privileged command mode.
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **ip flow-export template refresh-rate** *packets*	Configures the retransmission packet number. The range is from 1 to 600. The default value is 20.
Ruijie(config)# **ip flow-export template timeout-rate** *minutes*	Configures the retransmission interval, in minutes. The range is from 1 to 1000 minutes. The default value is 30 minutes.
Ruijie(config)# **end**	Returns to privileged command mode.
Ruijie(config)# **copy running-config startup-config**	Saves configurations.

Configuration example

```
Ruijie# config terminal
Ruijie(config)#ip flow-export template refresh-rate 30
Ruijie(config)#ip flow-export template timeout-rate 40
Ruijie(config)# end
Ruijie#
```

In the example, *refresh-rate 30* indicates that the template is retransmitted every 30 packets, and *timeout-rate 40* indicates that the template is retransmitted every 40 minutes.

Caution By default, the retransmission packet refresh rate is 20, the time interval is 10 minutes.

Showing the Export Configurations in Main Mode

Use the **show ip flow export** command to display the current export configurations, including the export enable, export destination, the format of the flow record export packet, etc.

Configuring the Main Cache

The main cache is used to save the raw flow record information, and each flow entry size is fixed. A flow entry is created for each active flow in the system, with the record of flow characteristic and statistical information. All flow entries will be regularly checked for determining whether they have expired based on the following conditions:

1. The cache is full and no available space for the flow entries, so some entries shall expire.

2. A flow is inactive. By default, if a flow is not updated within 15 seconds, it becomes inactive.

3. A flow keeps active for too long time. By default, a flow shall expire if it has been active for 30 minutes.

The following introduces those configurable parameters.

Configuring the Flow Cache Entry Number

With the IPFIX flow statistics function enabled on a port, certain storage space is reserved for saving the flow entry in the main cache, which meets the user network demands generally. By default, 64K flow entries (with each entry size 64 bytes) are reserved, so it needs 4M memory space for the main cache. You can increase or decrease the entry number according to your needs to improve the performance or reduce the memory usage, which depends on your device memory size. Use the **ip flow-cache entries** *number* command to set the entry number in the cache.The range of *number* is from 1024 to 524288. The detailed configuration is described as follows.

Use the following configuration commands.

Command	Function
Ruijie> **enable**	Enters privileged command mode.
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **ip flow-cache entries** *number*	Configures the entry number in the cache. The range is from 1024 to 524288.
Ruijie(config)# **end**	Returns to privileged command mode.
Ruijie# **copy running-config startup-config**	Saves the configuration.

To restore the entry number to the default value, use the **no ip flow-cache entries** command.

Configuration example

```
Ruijie# config terminal
Ruijie(config)#ip flow-cache entries 32768
Ruijie(config)# end
```

Caution

By default, 65536 entries are in the main cache. With IPFIX enabled, the entry number configuration in the cache will take effect only after you re-enabling the IPFIX function. It is not recommended to change the entry number in the cache casually and inappropriately, which may result in abnormal system working.

Configuring the Flow Cache Timeout

Use the following command to set the flow cache timeout parameters.

Command	Function
Ruijie> **enable**	Enters privileged command mode.
Ruijie# **config terminal**	Enters global configuration mode.

Command	Function
Ruijie(config)# **ip flow-cache timeout active** *minutes*	Configures the active aging time in minutes. The range is from 1 to 60 minutes.
Ruijie(config)# **ip flow-cache timeout inactive** *seconds*	Configures the inactive aging time in seconds. The range is from 10 to 600 seconds.
Ruijie(config)# **end**	Returns to privileged command mode.
Ruijie# **copy running-config startup-config**	Saves the configuration.

By default, the active aging time is 30 minutes and the inactive aging time is 15 seconds. To restore the default value, use the **no ip flow-cache timeout active** command and the **no ip flow-cache timeout inactive** command.

Configuration example

```
Ruijie# config terminal
Ruijie(config)#ip flow-cache entries 32768
Ruijie(config)#ip flow-cache timeout active 20
Ruijie(config)#ip flow-cache timeout inactive 20
Ruijie(config)# end
```

Showing Information About the Main Cache

Use the **show ip flow cache** command to show the packet flow statistical information in the current main mode, including the packet size distribution, the cache entry usage, etc.

The output is as follows:

```
Ruijie# sh ip flow cache
Ipfix collect data from CM-CARD
ip flow switching cache, 250000 entries
   10 active, 249990 inactive
   active flows timeout in 1 minutes
   inactive flows timeout in 15 seconds

```

Enabling Flow Statistics

The preceding configurations are performed when the IPFIX flow statistics function is disabled. This section describes how to enable the IPFIX flow statistics function which is to measure the ingress or egress packets. Therefore, to enable the IPFIX flow statics function, you need to set the observation point, flow types, and ports where flows are measured. To enable the IPFIX flow statistics function for ingress or egress flows, you need to enter interface configuration mode.

Use the following configuration commands.

Command	**Function**
Ruijie> **enable**	Enters privileged command mode.
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *interface-type interface-number*	Enters interface configuration mode.
Ruijie(config)# **ip flow { ingress | egress }**	Enables the IPFIX flow statistics function on the interface.
Ruijie(config)# **end**	Returns to privileged command mode.
Ruijie# **copy running-config startup-config**	Saves the configuration.

To disable the IPFIX flow statistics function, use the **no ip flow { ingress | egress }** command interface configuration modein interface configuration mode.

Configuration example

```
Ruijie# config terminal
Ruijie(config)# interface gigabitEthernet 6/2
Ruijie(config-if)# ip flow ingress          //Enable IPFIX on port 6/2 for statistics of ingress
flows.
Ruijie(config-if)# exit
Ruijie(config)# interface gigabitEthernet 6/3
Ruijie(config-if)# ip flow ingress          //Enable IPFIX on port 6/3 for statistics of ingress
flows.
Ruijie(config-if)# exit
Ruijie(config)# interface gigabitEthernet 6/4
Ruijie(config-if)# ip flow ingress          //Enable IPFIX on port 6/4 for statistics of ingress
flows.
Ruijie(config-if)# exit
Ruijie(config)# interface gigabitEthernet 6/5
Ruijie(config-if)# ip flow ingress          //Enable IPFIX on port 6/5 for statistics of ingress
flows.
Ruijie(config-if)# exit
Ruijie(config)#
```

Use the **show ip flow interface** command to show the IPFIX state on the interface.

Configuration example

```
Ruijie# show ip flow interface
interface gigabitEthernet 6/2
Ip flow ingress
interface gigabitEthernet 6/3
Ip flow ingress
interface gigabitEthernet 6/4
Ip flow ingress
interface gigabitEthernet 6/5
Ip flow ingress
```

Caution

By default, IPFIX is disabled on all interfaces. Once the IPFIX flow statistics function is enabled on an interface, the global IPFIX function is enabled, and the corresponding cache and timer are created. The settings of the main cache will take effect when the IPFIX function is re-enabled. Use the **no** form to disable all interface with IPFIX enabled, and then the global IPFIX takes no effect.

The IPFIX captured data flow is sent to the data flow analysis software (Such as NewFlow,RILL) and then be converted into a visible report for the user. Because the IPFIX flow statistics function is enabled on an interface.When the system restarted, the interface index might change and the IPFIX is unable to capture the data flow on the original designated interface. To avoid this consequence, use the command snmp-server if-index persist to bind the function on a interface.

Configuring Flow Aggregation Mode

Flow Aggregation Mode Overview

Flow aggregation mode re-aggregates the main mode flow and generates a new flow through the defined specified key field. The system reserves certain cache, which is similar to the main cache and here called the flow aggregation cache, for aggregation mode. When a flow entry comes out of the main cache, the flow information is used to refresh the flow aggregation record in each enabled flow aggregation cache. You could set the entry number in the aggregation cache, entry aging parameter, export destination IP address and export destination UDP port separately. Meanwhile, the entry aging mechanism in the flow aggregation mode, which supports the forcible aging according to the user requirements, is the same as the one in main mode. By default, the entry number in the flow aggregation cache is 4096.

The following flow aggregation modes are supported:

- Destination Prefix aggregation mode
- Prefix aggregation mode
- Protocol Port aggregation mode
- Source Prefix aggregation mode
- Destination Prefix-ToS aggregation mode
- Prefix-port aggregation mode
- Prefix-ToS aggregation mode
- Protocol-port-ToS aggregation mode
- Source Prefix-ToS aggregation mode

Aggregation Mode	Key Field
destination-prefix	Destination AS number, destination address mask length, destination prefix and egress interface index
prefix	Source AS number, destination AS number, source address mask length, destination address mask length, source prefix, destination prefix and egress interface index.
prefix-port	Source prefix, destination prefix, source port, egress interface index and ToS value.
protocol-port	Protocol number, source port and destination port.
source-prefix	Source AS number, source address mask length, source prefix.
destination-prefix-tos	Destination AS number, destination mask length, destination prefix and egress interface index.
prefix-tos	ToS, source AS number, source prefix, source mask length, destination AS number, destination mask length, destination prefix.
protocol-port-tos	ToS, protocol type, source port and destination port.
source-prefix-tos	ToS, source prefix, source mask length and source interface index.

The nine modes are independent and can be configured concurrently.

Configuring Flow Aggregation Mode

IPv4 Aggregation Mode

Configuration example

```
enable
configure terminal
```

```
ip flow-aggregation cache { destination-prefix | destination-prefix-tos | prefix  | prefix-port
| prefix-tos | protocol-port | protocol-port-tos | source-prefix | source-prefix-tos}
cache entries number
cache timeout active minutes
cache timeout inactive seconds
export destination ip-address udp-port
Repeat the step7, set the second export destination.
enabled
exit
interface interface-type interface-number
ip flow {ingress | egress}
exit
Repeat the step11-13, set the IPFIX function on other interfaces.
end
```

The following table describes the configuration commands in detail.

Command	Function
Ruijie> **enable**	Enters user execution mode.
Ruijie# config terminal	Enters global configuration mode.
Ruijie(config)# ip flow-aggregation cache { destination-prefix | destination-prefix-tos | prefix | **prefix-port | prefix-tos** | **protocol-port** | **protocol-port-tos** | **source-prefix** | **source-prefix-tos** }	Enters corresponding flow aggregation mode. destination-prefix: enters destination-prefix aggregation configuration mode. destination-prefix-tos: enters destination-prefix-tos aggregation configuration mode. prefix: enters prefix aggregation configuration mode. prefix-port: enters prefix-port aggregation configuration mode. prefix-tos: enters prefix-tos aggregation configuration mode. protocol-port: enters protocol-port aggregation configuration mode. protocol-port-tos: enters protocol-port-tos aggregation configuration mode. source-prefix: enters source-prefix aggregation configuration mode. source-prefix-tos: enters source-prefix-tos aggregation configuration mode.
Ruijie(config-flow-cache)# **cache entries number**	Configures the cache entry number. number: indicates the allowed cache entry number in this aggregation mode. The range is from 1024 to 524288. The default value is 4096.

Command	Function
Ruijie(config-flow-cache)# **cache timeout active minutes**	(Optional) Configures the cache entry active timeout time. minutes: indicates the active timeout time. The range is from 1 to 60 minutes. The default value is 30 minutes.
Ruijie(config-flow-cache)# **cache timeout inactive seconds**	(Optional) Configures the cache entry inactive timeout time. seconds: indicates the inactive timeout time. The range is from 10 to 600 seconds. The default value is 15 seconds.
Ruijie(config-flow-cache)# **export destination ip-address udp-port**	(Optional) Configures the flow aggregation export destination. ip-address: indicates the export destination IP address. udp-port: indicates the destination UDP port number.
Repeat the previous step, set the second export destination.	(Optional) Configures up to two export destination for each aggregation mode.
Ruijie(config-flow-cache)# **enabled**	
Ruijie(config-flow-cache)# exit	Exits flow aggregation configuration mode and enters global configuration mode.
Ruijie(config)# **interface ethernet** 0/0	Enters interface configuration mode.
Ruijie(config-if)# ip flowegress	Enables the IPFIX function on the interface. Ingress: detects the ingress flow to the interface; Egress: detects the egress flow from the interface.
Ruijie(config-if)# **end**	Exits interface configuration mode.

Configuration example

```
Ruijie> enable
Ruijie# configure terminal
Ruijie(config)# ip flow-aggregation cache destination-prefix
Ruijie(config-flow-cache)# cache entries 2048
Ruijie(config-flow-cache)# cache timeout active 15
Ruijie(config-flow-cache)# cache timeout inactive 300
Ruijie(config-flow-cache)# export destination 172.30.0.1 991
Ruijie(config-flow-cache)# enabled
Ruijie(config-flow-cache)# exit
Ruijie(config)# interface ethernet 0/0
Ruijie(config-if)# ip flow egress
Ruijie(config-if)# end
```

Showing Flow Aggregation Information

IPv4 configuration commands

show ip flow cache aggregation { **as** | **as-tos** | **destination-prefix** | **destination-prefix-tos** | **prefix** | **prefix-port** | **prefix-tos** | **protocol-port** | **protocol-port-tos** | **source-prefix** | **source-prefix-tos** } [vrf *vrf-name*]

Use this command to show the cache information in each flow aggregation mode, including the cache size, effective flow entry number, idle flow entry number, etc.

Configuration example

```
Ruijie# sh ip flow cache aggregation protocol-port
IP Flow Switching Cache, 278544 bytes
2 active, 4094 inactive, 12523 added
239947 ager polls, 0 flow alloc failures
Active flows timeout in 30 minutes
Inactive flows timeout in 15 seconds
IP Sub Flow Cache, 17160 bytes
0 active, 1024 inactive, 0 added, 0 added to flow
0 alloc failures, 0 force free
1 chunk, 1 chunk added
Protocol  Source Port  Dest Port  Flows  Packets  Bytes/Packet  Active
0x11      0x007B     0x007B     1       1       76
0.0
0x01      0x0000     0x0303     1       5      132
5.0
Ruijie#
```

show ip flow export

Use this command to show the export information in main mode, and the export configuration information about enabled aggregation modes, such as the format of the ouput packet, export destination, etc.

Configuration example

```
Ruijie# sh ip flow export
Ipfix collect data from CM-CARD
cache for main metering process:
       flow export is enabled
       Exporting flows to 55.1.1.55 (99)
       Exporting using source interface Loopback 1
       Template export information:
         Template timeout = 10 minutes
         Template refresh rate = 20 packets
       total 400 packets metering
       total 0 packets dropped for no memory
       total 42 flows exported in 5 udp datagrams
       0 ipfix message export failed

Ipfix export information from device 3
cache for main metering process:
       flow export is enabled
       Exporting flows to 55.1.1.55 (99)
       Exporting using source interface Loopback 1
```

```
Template export information:
  Template timeout = 10 minutes
  Template refresh rate = 20 packets
total 1124 packets metering
total 0 packets dropped for no memory
total 62 flows exported in 9 udp datagrams
0 ipfix message export failed
```

Configuring the Flow Filtering and Sampling Mechanism

With the netflow growth, concurrent netflows set in, affecting the performance of the IPFIX flow measurement. Then the flow filtering and sampling mechanism comes into being. The flow filtering analyzes the flows which the users are interested in, decreasing the IPFIX flow and network device loads sharply. The sampling mechanism analyzes some netflows randomly according to a certain sampling rate, decreasing the IPFIX flow greatly.

Configuring Sampling for the Specified Flow

The sampling for the specified flow uses the ACL to match the packets, and only the matched packet flow is recorded.

Use the following configuration commands.

Command	Function
Ruijie> **enable**	Enters privileged command mode.
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *interface-name*	Enters interface configuration mode.
Ruijie(config-if)# **flow-sample** *packet-num* filter *acl-name*	Applies the ACL to the interface to filter the input flow. *acl-name* is the existed ACL ID or name, it can also be 0, which means all flows are permitted. The matched packets are sampled by the ratio of 1/*packet-num*, and then flow statistics are collected.
Ruijie(config)# **end**	Returns to privileged command mode.
Ruijie# **copy running-config startup-config**	Saves the configuration.

To restore the default configuration of an interface, use the **no** form of this command in interface configuration mode.

All packets of ports are sampled and measured by the ratio 1/255 by default.

⚠ Caution

If the IPFIX flow measurement is disabled on the configured interface, this configuration will be saved. Once IPFIX is enabled on the port, this configuration takes effect. The corresponding ACL must exist when you configure this command. If the ACL is deleted, this configuration will be deleted automatically.

For example:

```
Ruijie# config terminal
Ruijie(config)# interface gi 2/2
Ruijie(config-if)# flow-sample 100 filter acl1
Ruijie(config-if)# end
```

Configuring RLOG

Overview

The device side is responsible for log collection and uploading, while RLOG will send all Internet access information and user connection information to the server. The server-side software will analyze the logs and then write the logs into the database, and the user can then find the corresponding connection records through log query system.

RLOG contains NAT logs and the number of bytes received/sent, as well as connection establishment/deletion and other relevant information.

To enable logging function, you need to complete the following configurations:

- Configure logging service on device side and enable flow log;
- Enable background service program on the service side;
- Configure web server.

Log configuration

Log Server Configuration

Configure log server to enable logging function. If no log server is configured, the device will not send any log to the log server.

When the log server is configured, the device will enable the logging module and send out log information in UDP packets.

To configure log server, execute the following commands in global configuration mode:

Command	Function
Ruijie(config)# **rlog server** *server-ip* [**vrf** *vrf-name*]	Specify the IP address and VRF name of log server and enable log service;
Ruijie(config)# **no rlog server**	Remove log server configuration, disable logging service and clear relevant statistics.

Note

The command to configure log server will only enable log service, and the log output function is not enabled at the same time. Executing this command along will not output any log. The command to enable flow log is "**ip session log-on**", which must be executed separately.

Log Service Parameter Configuration

Log service related parameters include the maximum length of log packets, number of service port.

By executing these commands, the user can modify the configurations of log server and avoid the conflict between log service and other network services.

To configure log service parameters, execute the following commands in global configuration mode:

Command	Function
Ruijie(config)# **rlog mtu** *number* Ruijie(config)# **no rlog mtu**	Configure maximum length of log packets Remove the configuration of maximum length of log packets and restore to the default 1500
Ruijie(config)# **rlog port** *number* Ruijie(config)# **no rlog port**	Specify the log service port number Remove the configuration of log service port number and restore to the default 10000.
Ruijie(config)# **rlog export-rate** *number* Ruijie(config)# **no rlog export-rate**	Specify the log service export rate (maximum number of logs sent per second) Remove the configuration of log service export rate and restore to the default 1000

Note

Any change to the log service parameters will not take effect immediately. You need to restart log service to apply the configurations. You can reconfigure log server to reboot the server.

Note

The default value for log export rate is on the low side. You can configure to the maximum value if the performance of log server allows.

Log Service Testing

You can execute log service testing command to check whether the logging function is normal. This command is used to check free buffer and send test packets to the log server. If the log server receives the test packets and replies with the corresponding prompting messages, we can then determine that whether the log service is properly configured and whether the network is accessible.

To test the log server, execute the following command in global configuration mode:

Command	Function
Ruijie(config)# **rlog test**	Test log server and check free buffer; send test packets to the log server.

Note

Checking free buffer may occupy full log buffer and result in the loss of logs. Please don't use this function unless it is necessary.

Log Service Statistics

Log service statistics also includes the current configuration information, the number of logs received, the number of logs sent, the number of errors sent, and the cause of the latest error.

To display log service statistics, execute the following command in global configuration mode:

Command	Function
Ruijie(config)# **show rlog**	Display log service statistics.

Log Database

The log server supports MySQL, SQLSever, Oracle and etc.

Log data are long-term and continuous records. The storage of long-term data will require sufficient storage space. Different on-site service conditions will have different requirements on database.

The following is a simple example for explaining the size of database required.

Approximate 4,000 users in one school access Internet through router. Assuming that there are averagely 8k new connections and each connection contains 50 bytes of data.

Data per second: 8k*50 = 400k

Daily data: 400k*60*60*24 = 34.5G

Monthly data: 34.5*30 = about 1T

If there are more users or if the storage time is longer, then the storage space shall be increased accordingly.

Caution

The device will only send logs ceaselessly, while the log server will only analyze the logs and write into the database. The user shall be responsible for data maintenance.

Caution

For example, logs to be kept for only 15 days can be deleted by adding a trigger configured to delete data exceeding 15 days at 12:00pm of everyday.

Caution

The logs will keep all connection information, as well as some attack attempts or invalid connections. If these data are considered unnecessary, you can add a trigger configured to periodically records with 0 received byte in order to optimize the data.

Caution

These actions cannot be achieved by programs on the device or log server.

Web pages are directly related to database. Any change to the database (address, username, password and other configuration items) will need to change the corresponding web page.

Log Server

Please refer to the enclosed CD for content and web configurations of the server.

Configuring WAN-TA

Understanding WAN-TA

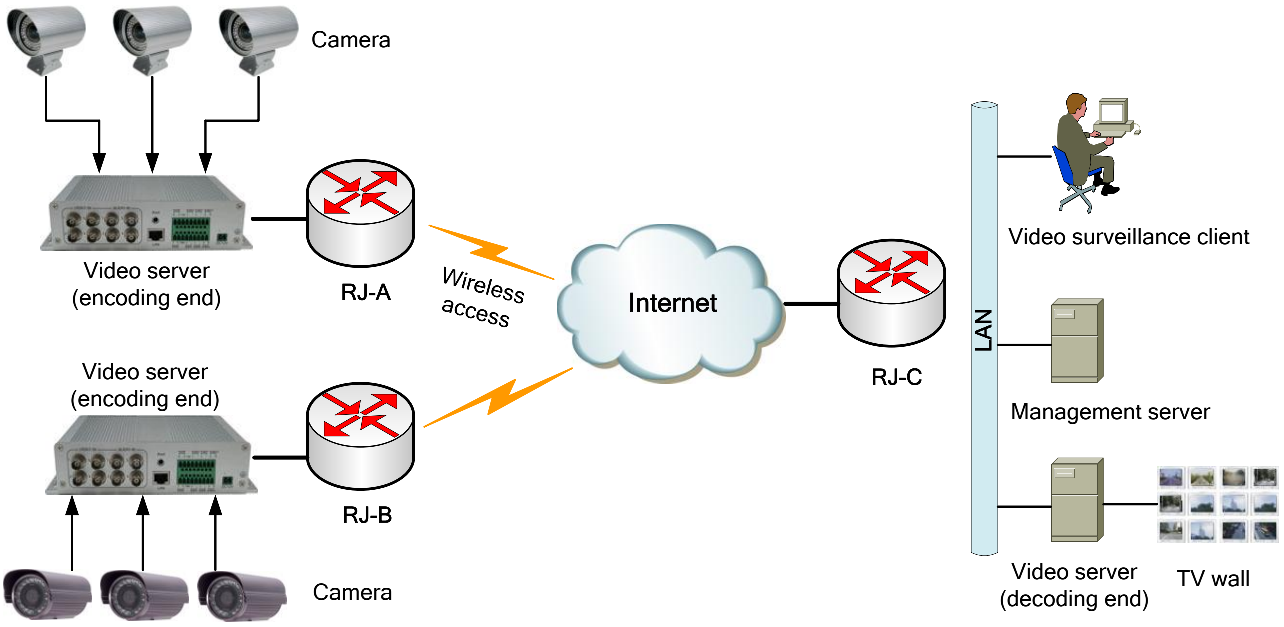
Overview

The video transmission optimization solution is mainly used in network video surveillance scenarios. This document briefly introduces the network video surveillance system and the video transmission optimization solution.

Network Video Surveillance System

The network video surveillance system is generally a real-time remote video surveillance system based on an IP network. It involves the processes of video collection, digital video encoding, data transmission, video decoding, and video playing. A typical video surveillance system consists of front-end surveillance devices (such as a camera, a microphone, and a video server), an IP network, and display devices (video clients). After the camera collects image signals and the microphone collects voice signals, the signals access the video server. The video server performs analog-to-digital conversion, H.264-based video compression and other digital processing, and releases the data to the network. The data reaches the video client after traversing a LAN, a wireless network, and the Internet. Then the video client decodes the data and plays the data on a screen. Figure 0-1 shows the typical structure of the wireless network video surveillance system.

Figure 0-1 Wireless Network Video Video data has two characteristics during transmission:



1) Mass data: A large volume of video data and information is involved.

2) Irregular traffic: The video data volume changes over time.

The characteristics, however, result in many challenges when video data is transmitted on a wireless network. It is well known that the wireless network has poor stability, such as instable bandwidths, high delay, high jitter, and high packet loss rates. The video server at the sending end sends video frames at a fixed interval (a video frame is composed of one or more packets). If video packets are transmitted through an unstable network, the video packets may reach the receiving end after an irregular delay. As a result, video played after being decoded may pause or stutter, or even that the video connection is interrupted and needs to be set up again.

Video Transmission Optimization Solution

The video transmission optimization solution shown in Figure 1-1 is implemented as follows: Firstly, enable WAN-TA on the sending end (RJ-A or RJ-B) to enhance video transmission quality; secondly, enable WAN-TA and RTP shaping on the receiving end (RJ-C) to eliminate video pause and stutter caused by network jitter. This solution enables videos transmitted through networks to be more smoothly played, reduces video pause and stutter, and enhances the video effect.

Basic Concepts

Main Protocols

The network video surveillance system mainly involves the protocols TCP, RTSP, and RTP/RTCP.

The Transmission Control Protocol (TCP) provides a mechanism that allows applications to reliably exchange data on a network. Although TCP provides a connection-oriented and reliable transmission environment, the network where applications are deployed has been greatly changed over the past two decades. In many cases, TCP has become a bottleneck for WAN application performance. The low transmission efficiency of TCP is outstanding on a wireless network (3G/4G), and therefore is urgent to be solved.

The Real Time Streaming Protocol (RTSP) defines a process for one-to-multiple applications to efficiently transmit multimedia data through an IP network, and provides the stop, fast forward, fast backward, and positioning functions for video and audio streams. RTSP is also an application-layer protocol and works with RTP and other lower-layer protocols to provide complete sets of services based on the Internet. Generally, RTSP uses TCP to complete control information transmission and uses RTP to complete media data transmission. The TCP port 554 is used by RTSP.

The Realtime Transport Protocol (RTP) is a protocol for transmitting multimedia data streams on the Internet. RTP is mainly used to transmit real-time streams in network video surveillance applications. It is defined to work in one-to-one or one-to-many transmission scenarios, aiming to provide time information and synchronize streams. RTP only ensures transmission of real-time data, but cannot provide a mechanism for transmitting data packets in order. It does not provide the traffic control or congestion control function, either. RTP provides services based on the Realtime Transport Control Protocol (RTCP).

WAN-TA

WAN Transmission Acceleration (WAN-TA) is a generic name of technologies for enhancing TCP transmission efficiency on WAN links. To enhance the TCP transmission efficiency in a video network transmission environment (in the network video surveillance system, video packets are encapsulated in TCP packets), Ruijie routers have ushered in new TCP features through WAN-TA and applied the features to data streams to be forwarded so as to improve TCP transmission performance on WAN links. WAN-TA splits a TCP connection that is set up through a Ruijie router into two connections, so that the router can serve as a client to participate in TCP sessions, and control TCP data streams through a WAN-TA optimization policy on the router. WAN-TA can eliminate nearly all TCP barriers without changing the client, the server, or network features.

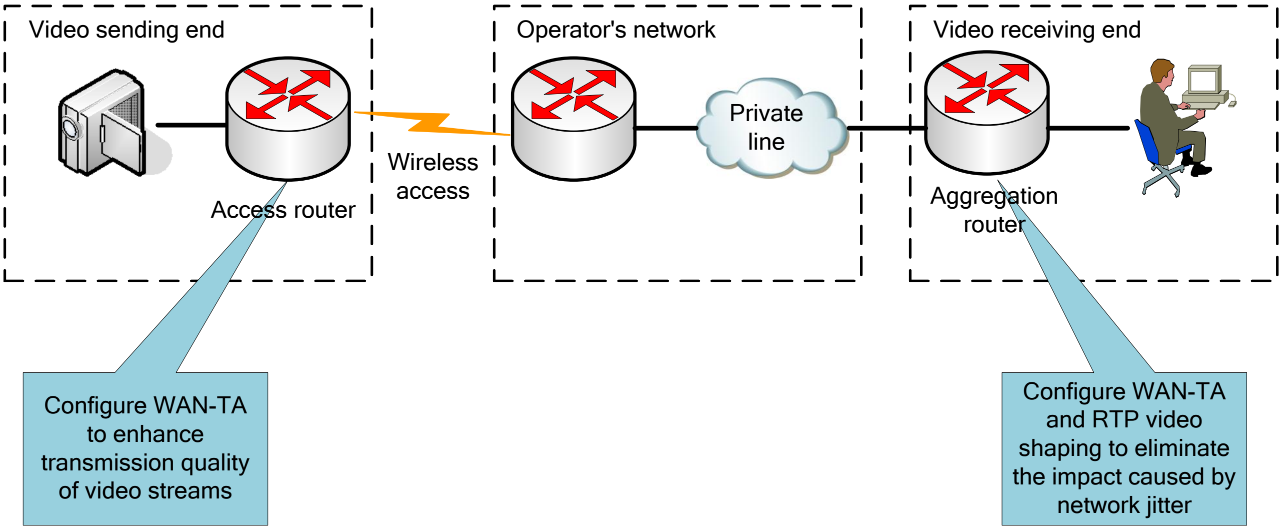
RTP Shaping

RTP shaping mainly uses the delay technology to ensure that RTP service packets reach the peer end at a fixed interval. Based on WAN-TA, RTP shaping fetches packets from a WAN-TA receiving queue, and caches video frames in an RTP queue. After a specific period of time (generally hundreds of milliseconds to several seconds), video frames are sent one after another according to the original time sequence at a fixed interval. This allows the video client to receive stable video streams.

Working Principle

As shown in the wireless network video transmission system in Figure 0-2, the video server is connected with the access router through a wired line, and the access router is connected with the video client through a wireless link. When WAN-TA is configured on the access router, the access router can use the air interface bandwidth to the utmost, thereby accelerating traffic transmission from the server to the client (in the outbound direction). Configured with WAN-TA and RTP shaping, the aggregation router can receive and cache video packets and send them to the video client at a fixed interval, allowing the client to obtain stable video streams. WAN-TA on the receiving router and RTP shaping on the aggregation router work together to ensure the best video effect. If WAN-TA is not configured on the access router to ensure video data transmission, videos played on the client may stutter frequently, or even that the connection is interrupted and needs to be set up again. If RTP shaping is not configured on the aggregation router for caching and shaping video packets, videos played on the client may pause frequently.

Figure 0-2 Deployment Mode of the Video Transmission Optimization Solution



Video sending end
Access router
Wireless access
Operator's network
Private line
Video receiving end
Aggregation router
Configure WAN-TA to enhance transmission quality of video streams
Configure WAN-TA and RTP video shaping to eliminate the impact caused by network jitter

Protocol Specification

The video transmission optimization solution involves the following RFC specifications:

- RFC793: TCP
- RFC2326: RTSP
- RFC3550: RTP

Configuring WAN-TA

Default Configuration

Feature	Default Setting
Globally enabling WAN-TA	WAN-TA is disabled by default.
Configuring a WAN-TA policy	No WAN-TA policy is configured.
Configuring the congestion control algorithm of the WAN-TA policy	The default algorithm is low-bandwidth-delay.
Configuring the WAN-TA policy to support SACK	The SACK option of the WAN-TA policy is enabled.
Configuring whether the WAN-TA policy supports the timestamp option	The timestamp option of the WAN-TA policy is enabled.
Configuring whether the WAN-TA policy supports the window scaling option	The window scaling option of the WAN-TA policy is enabled.
Configuring the send queue depth of the WAN-TA policy	The send queue depth is 1024 by default.
Configuring the window compensation of the WAN-TA policy	The window compensation is 0 by default. That is, no window compensation is added.
Configuring the initial window of the WAN-TA policy	The initial window size is 10 MSS by default.
Configuring the MSS of the WAN-TA policy	The MSS is 1420 by default.
Configuring the keepalive packet sending interval and the maximum number of retries of the WAN-TA policy	The keepalive packet sending interval is 120 minutes, and the maximum number of retries is 9 by default.
Applying the WAN-TA policy to an interface	WAN-TA is disabled on an interface.
Configuring the matching port of the WAN-TA policy	The default matching port number is 554.

Configuration Guide

- The inbound interface and the outbound interface of data flows to which WAN-TA is applied must be express-forwarding interfaces.
- All TCP data flows optimized by WAN-TA are forwarded by the device running WAN-TA.

Globally Enabling WAN-TA

Command	Function
Ruijie(config)# **wan-ta enable**	Globally enables the WAN-TA function. The WAN-TA function takes effect on an interface only when the WAN-TA function is globally enabled and a WAN-TA policy is applied to the interface.

To disable the WAN-TA function, use the **no wan-ta enable** command in global configuration mode.

Configuration example:

The following example enables the global WAN-TA function:

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
```

```
Ruijie(config)# wan-ta enable
```

Note

After the WAN-TA function is enabled, it takes effect for only new flows instead of existing flows. If you hope that the WAN-TA function takes effect for an existing connection, you need to disconnect and then re-create the connection after enabling the WAN-TA function.

Note

After the global WAN-TA function is disabled, the existing TCP sessions to which WAN-TA is applied will continue to be effective.

Creating a WAN-TA Policy

Command	Function
Ruijie(config)# **wan-ta policy { video |** *policy-name* } [**cong-algorithm** *cong-value* | **init-cwnd** *cwnd-value* | **sack { enable | disable} | mss** *mss-value* | **keepalive interval** ***i****nterval-value* **retry** *retry-count* **]**	Creates a WAN-TA policy and specifies the parameters of the WAN-TA policy. This command can be configured in the following two ways: 3) Directly specify parameters behind the command. Then the command does not enter the following WAN-TA policy configuration mode. 4) Do not specify any parameter behind the command. Then the command enters the following WAN-TA policy configuration mode, and you can specify the parameters of the WAN-TA policy one by one.
Ruijie(config-wan-ta-policy)#**cong-algorithm { default | high-delay-1 | high-delay-2 | high-lost | low-bandwidth-delay }**	Configures the congestion algorithm of the WAN-TA policy. This command has the same function as the cong-algorithm *cong-value* parameter of the wan-ta policy command.
Ruijie(config-wan-ta-policy)# **sack { enable | disable }**	Enables or disables the SACK function of the WAN-TA policy. This command has the same function as the sack parameter of the wan-ta policy command.
Ruijie(config-wan-ta-policy)# **init-cwnd** *cwnd-value*	Configures the initial window size of the WAN-TA policy. The value range is 2 to 10. This command has the same function as the init-cwnd *cwnd-value* parameter of the wan-ta policy command.
Ruijie(config-wan-ta-policy)#**mss** *mss-value*	Configures the MSS of the WAN-TA policy. The value range is 68 to 1460. This command has the same function as the mss *mss-value* parameter of the wan-ta policy command.
Ruijie(config-wan-ta-policy)#**keepalive interval** *interval-value* retry *retry-count*	Configures the keepalive packet sending interval of the WAN-TA policy within the range from 2 to 300 minutes and the maximum number of retries of the keepalive

Command	Function
	packet within the range from 1 to 9. This command has the same function as the keepalive interval *interval-value* retry *retry-count* parameter of the wan-ta policy command.
Ruijie(config-wan-ta-policy)#**peer window-compensation** *cmp-value*	Configures the peer window compensation of the WAN-TA policy. The value range is 0 to 655350.
Ruijie(config-wan-ta-policy)#**queue-send-depth** *dep-value*	Configures the send queue depth of the WAN-TA policy. The value range is 8 to 4096.
Ruijie(config-wan-ta-policy)#**timestamp disable**	Disables the timestamp option of the WAN-TA policy. Use the no form of this command to enable the timestamp option.
Ruijie(config-wan-ta-policy)#**window-scale disable**	Disables the window scaling option of the WAN-TA policy. Use the no form of this command to enable the window scaling option.
Ruijie(config-wan-ta-policy)#**match-port** *port-number [port-number…]*	Configures the matching port of the WAN-TA policy. The port number range is 1 to 65535 (554, by default). Use the **no** form of this command to delete all matching ports.

To delete the configured WAN-TA policy, use the **no wan-ta policy video** command in global configuration mode.

Configuration example 1:

The following example creates a system-defined WAN-TA policy named "video":

```
Ruijie(config)#wan-ta policy video
```

Configuration example 2:

The following example creates a user-defined WAN-TA policy named "ftp" and specifies parameters behind the command:

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)# wan-ta policy ftp init-cwnd 8 cong-algorithm low-bandwidth-delay
```

Configuration example 3:

The following example creates a user-defined WAN-TA policy named "ftp" and enters the policy mode to specify parameters:

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#wan-ta policy ftp
Ruijie(config-wan-ta-policy)#init-cwnd 8
Ruijie(config-wan-ta-policy)#cong-algorithm low-bandwidth-delay
```

Caution It is not recommended that you specify parameters when creating a system-defined policy, such as the policy in configuration example 1. The system automatically generates the parameters. It is not recommended that you modify the settings of the parameters.

Caution When creating a user-defined policy, you can directly use the **wan-ta policy** command with parameters or enter the WAN-TA policy configuration mode to specify parameters one by one. For details, see configuration examples 2 and 3.

Caution In WAN-TA policy configuration mode (**wan-ta-policy**), you can configure the peer window compensation and send queue depth, disable the timestamp option, and disable the window scaling option. However, it is recommended that generally you keep the default settings of these parameters instead of manually configuring them.

Caution Before deleting a WAN-TA policy, you need to remove the WAN-TA policy from interfaces on which the WAN-TA policy has been applied. If you modify the configuration after a policy is applied on an interface, the changes do not take effect for the existing connections to which WAN-TA is applied.

Enabling a WAN-TA Policy on an Interface

Command	Function
Ruijie(config-if-gigaethernet0/0)# **wan-ta-policy video list** { *acl-id* | *acl-name*}	Applies a WAN-TA policy to an interface. The *acl-id* or *acl-name* parameter specifies the ACL that matches the flow to be optimized.

To delete the configured WAN-TA policy from an interface, use the **no wan-ta-policy** { *policy-name* | **video** } command in interface configuration mode.

Configuration example:

The following example applies a WAN-TA policy named "video" to an interface, so that all flows matching ACL 101 will be accelerated according to the WAN-TA policy named "video":

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface gigaethernet0/0
Ruijie(config-if-gigaethernet0/0)# wan-ta-policy video  list 101
```

Caution When there is a TCP connection to which a WAN-TA policy is applied on an interface, the WAN-TA function still takes effect on the interface even after the WAN-TA policy is deleted from the interface.

Monitoring and Maintaining WAN-TA

Command	Function
Ruijie# **show wan-ta policy session**	Shows summary information about TCP sessions to which WAN-TA has been applied.
Ruijie# **show wan-ta policy session** *session_id*	Shows statistics about the session with the specified session ID.
Ruijie# **show wan-ta policy video**	Shows configuration information about a WAN-TA policy.

Configuration Examples

Configuration Example of Video Transmission Optimization

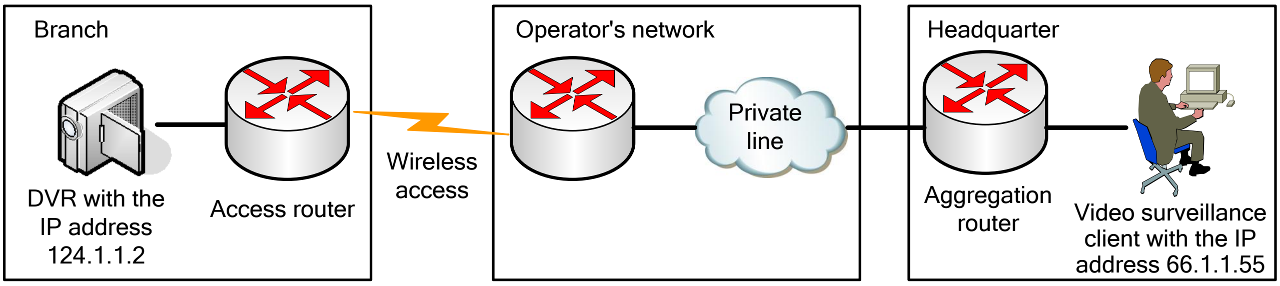
Networking Requirements

As shown in the wireless video surveillance scenario in Figure 0-3, the access router in the branch is connected to the video server (DVR); the aggregation router in the headquarter is connected to the video client.

- The access router is connected to the headquarters through a 3G/4G link.
- The video surveillance connection between the branch and the headquarter is set up based on TCP.
- Before reaching the router to which an optimization policy applies, data streams are not encrypted or encapsulated in other tunnels.

Networking Topology

Figure 0-3 WAN-TA Application Topology



Configuration Tips

On the access router:

- Globally enable WAN-TA.
- Identify the features of data streams to which WAN-TA applies.
- Create a WAN-TA optimization policy.
- Enable the WAN-TA optimization policy on the interfaces that data streams pass through.

On the aggregation router, configure WAN-TA and RTP shaping:

- Identify the features of data streams to which RTP applies.
- Configure RTP shaping.

Configuration Steps

1. Configure and enable WAN-TA on the access router.

5) Configure an ACL for matching data streams that need to be optimized.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#ip access-list extended 101
Ruijie(config-ext-nacl)#10 permit ip any any
```

6) Globally enable WAN-TA.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#wan-ta enable
```

7) Create a WAN-TA optimization policy. For example, create an optimization policy named "video" to optimize the video surveillance connection between the branch and the headquarter. Video surveillance data is generally encapsulated through RTSP on the TCP port 554.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# wan-ta policy video
Ruijie(config-wan-ta-policy)#match-port 554 37777
```

8) Enable the optimization policy on a port. You can enable the WAN-TA optimization policy on either the inbound interface gigaethernet0/1 or the outbound port on the access router.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#int gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)#wan-ta-policy video list 101
```

2. Configure WAN-TA and enable RTP shaping on the aggregation router.

9) Configure and enable WAN-TA on the aggregation router, because RTP shaping is based on WAN-TA.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#ip access-list extended 111
Ruijie(config-ext-nacl)#10 permit ip any any
Ruijie(config-ext-nacl)#exit
Ruijie(config)#wan-ta enable
Ruijie(config)#wan-ta policy video
Ruijie(config-wan-ta-policy)#match-port 554 37777
Ruijie(config-wan-ta-policy)#exit
Ruijie(config)#interface gigabitEthernet 2/1/0
Ruijie(config-if-GigabitEthernet 2/1/1)#wan-ta-policy video list 111
```

10) Configure RTP shaping on either the inbound port or the outbound port on the aggregation router.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#
Ruijie(config)#traffic classifier tc1 or
Ruijie(config-traffic-classifier)# if-match acl 111
Ruijie(config-traffic-classifier)#
Ruijie(config-traffic-classifier)#traffic behavior tb1
Ruijie(config-traffic-behavior)# rtp-shaping delay 1000 clock-rate 90000
Ruijie(config)#traffic policy tp1
Ruijie(config-traffic-policy)# classifier tc1 behavior tb1 precedence 1
Ruijie(config-if-GigabitEthernet 2/1/0)#traffic-policy tp1 inbound
```

Verification

11) Check WAN-TA optimization policy configuration.

```
Ruijie#show wan-ta policy video
wan-ta policy: video
   Congestion Control : low-bandwidth-delay
   SACK Support: TRUE
   Initial Congest Window: 10 MSS
   Maxitum Segment Size: 1460
Keepalvie Interval(retry): 120(9)
Match Port: 554 37777

apply on interfaces:
interface name                      list
GigabitEthernet 2/1/0                 101
```

12) Check the current session.

```
Ruijie#sh wan-ta  policy session  vtty 2/1
session_id  pair    flow                          tcp_state        uptime     service
391        392     [124.1.1.2:554->66.1.1.55:1776]    TCP_ESTABLISHED   0:00:06    RTSP
392        391     [66.1.1.55:1776->124.1.1.2:554]    TCP_ESTABLISHED   0:00:06    RTSP
```

The session proxy with the session ID 392 deals with LAN communication with the off-bank ATM end. The session proxy with the session ID 391 deals with WAN communication with the headquarter end. Ruijie focuses on WAN communication.

13) Check the running status of a session on a link.

```
Ruijie#sh wan-ta  policy session vtty 2/1 391

[124.1.1.2:554->66.1.1.55:1776]
```

```

Queue length:
  recv_queue_len: 0        write_queue_len: 64      ofo_queue_len: 0
```

Major parameters are described as follows:

- **write_queue_len**: Specifies the length of the sending queue. Packets can be sent to a specific link only when the parameter value is not null.
- **out_pkt_num**: Specifies the number of sent packets.
- **snd_cwnd**: Specifies the sending congestion window, which defines the number of packets allowed to be sent to a link. It is an important parameter to control congestion.
- **total retans**: Specifies the number of retransmitted packets.
- **srtt**: Specifies the current delay of the link.

14) Enter line card mode to check RTP shaping statistics.

```
[LC2/1]#show rtp-shaping statistics

```

Configuring HTTP Service

Understanding HTTP

Overview

The Hypertext Transfer Protocol (HTTP) is used to transmit web page information over the Internet. HTTP resides at the application layer of the TCP/IP protocol stack. The transmission layer uses connection-oriented TCP.

Hypertext Transfer Protocol Secure (HTTPS) is the HTTP supporting the Secure Sockets Layer (SSL). HTTPS sets up a secure channel on an insecure network to ensure that information can hardly be intercepted and to defend against man-in-the-middle attacks to some extent. Currently, HTTPS has been widely used among security-sensitive communication services, such as electronic payment.

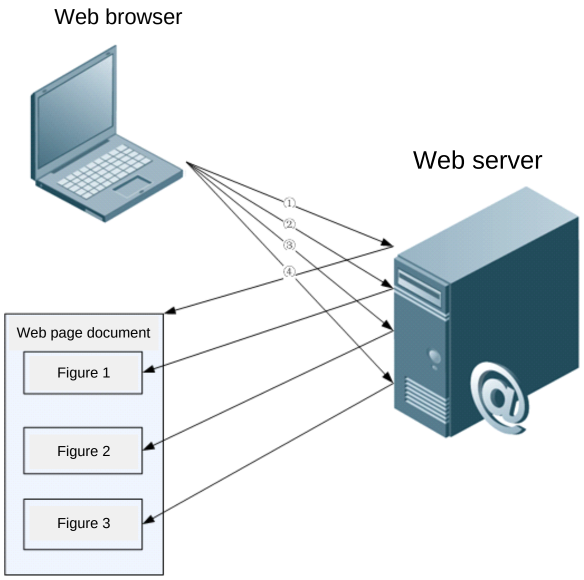
Basic Concept

HTTP Service

The HTTP service facilitates HTTP to transmit web page information over the Internet. HTTP/1.0 is the most popular HTTP version in the industry. HTTP/1.0 uses the short connection mode to simplify connection management, as a web server may be accessed for tens of thousands or even a million times each day. When receiving a connection request, the server sets up a TCP connection and releases it after the request is completed. The server does not record or trace previous requests. Although HTTP/1.0 simplifies connection management, it introduces certain performance defects.

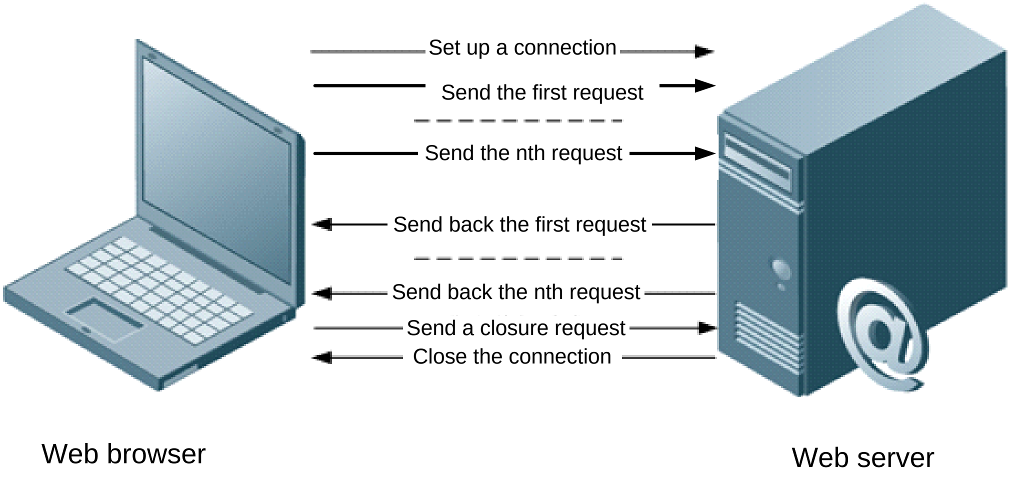
For example, a web page may contain URLs of multiple images, so that the browser sends multiple requests in the access process. When receiving a request, the server sets up an independent connection which is completely isolated from other connections. The process of setting up and releasing a connection consumes plenty of resources, and therefore has serious severe impact on the performance of the client and the server, as shown in Figure 0-1.

Figure 0-1 HTTP/1.0 Protocol Packet Exchange



HTTP/1.1, however, has solved this defect. HTTP/1.1 supports a persistent connection, through which multiple requests and responses can be transmitted. The client can send the next request before the previous request is completed, thereby reducing network delay and enhancing performance, as shown in Figure 0-2.

Figure 0-2 HTTP/1.1 Protocol Packet Exchange



Currently, Ruijiedevices support HTTP/1.0 and HTTP/1.1.

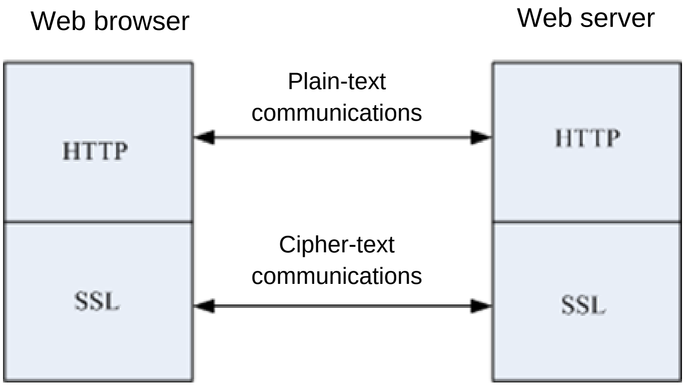
Note The protocol version used by a device depends on the specific web browser.

HTTPS Service

HTTPS adds the security base of SSL to HTTP. To enable HTTPS to run normally, the server must have a Public Key Infrastructure (PKI) certificate, which is not necessary for the client. SSL provides the following services:

- Authenticating users and servers to ensure that data is sent to correct clients and servers
- Encrypting data to prevent data interception during transmission
- Keeping data integrity to ensure that data is not changed during transmission

Figure 0-3 HTTPS Service



HTTP Upgrade Service

The HTTP upgrade service includes local and remote HTTP upgrade services.

- During local upgrade, the device works as an HTTP server. Users can log in to the device through the web browser and upload the upgrade files to the device so as to upgrade files on the device.
- During remote upgrade, the device works as a client connected to a remote HTTP server. It obtains the upgrade files from the server so as to upgrade local files.

Working Principle

HTTP Working Process

HTTP is used for web management. Users log in to the device through the web interface for configuration and management. Web management involves the web client and web server. The HTTP service adopts the client/server mode accordingly. The HTTP client is embedded in the web browser of the web management client and can send HTTP packets, receive HTTP response packets, and handle HTTP response packets. The web server (HTTP server) is embedded in the device. The client and the server exchanges information with each other according to the following process:

- The client sets up a TCP connection with the server. The default HTTP port number is 80, and the default HTTPS port number is 443.
- The client sends a request to the server.
- After processing the request, the server sends a response to the client.
- After processing a request, the HTTP service directly closes the TCP connection between the client and the server; while HTTPS can handle multiple requests until the client sends a TCP connection closure request or until the connection is closed due to server timeout.

The HTTP remote upgrade process is summarized as follows:

- The device connects to the server. In this process, the user-configured server address is preferentially used. If the connection fails, the server address in the local upgrade record file is used to establish the connection.
- The device sends the version numbers of local programs to the server.
- After resolution, the server returns a download file list.
- The device connects to file servers according to the list and downloads the upgrade files as necessary.
- The device can connect to different file servers according to the different files to be downloaded.
- The device upgrades its local files.

Protocol Specification

RFC1945 - Hypertext Transfer Protocol -- HTTP/1.0

RFC2616 - Hypertext Transfer Protocol -- HTTP/1.1

RFC2818 - Hypertext Transfer Protocol Over TLS -- HTTPS

Typical Application

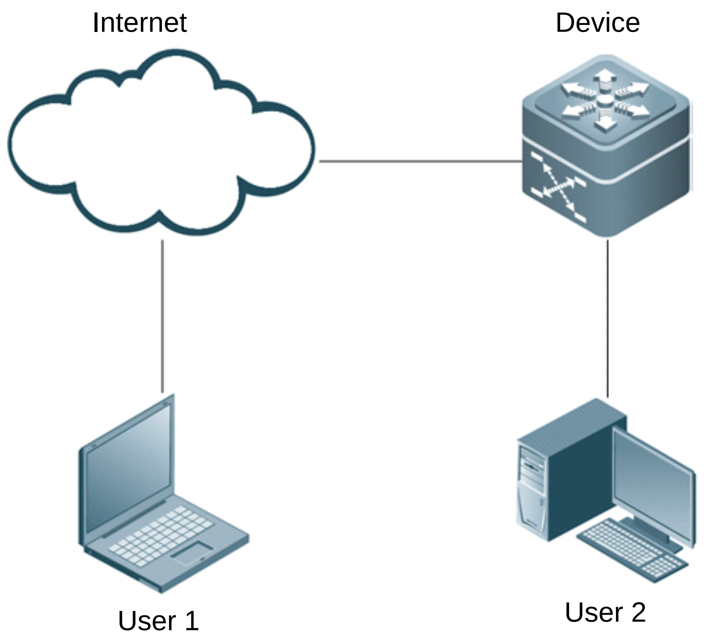
HTTP Application Service

Currently, the web NMS is still a major method for users to maintain and manage devices. Ruijie network devices also provide the web management function. When HTTP is enabled, users can log in to the web management interface after entering "http://+device IP address" on the PC browser and passing the authentication. Through the web interface, users can perform various operations, such as monitoring device states, configuring devices, uploading files, and downloading files.

The common HTTP-based service is actually insecure. For security-sensitive communications, Ruijie devices also provide the more secure HTTPS service, which encrypts the information transmitted between users and the device, so that third-party devices cannot intercept or modify the information. Users can perform web management simply after entering "https://+device IP address" on the web browser and passing the authentication.

Figure 0-4 illustrates a typical web management scenario. Users can remotely access and manage the device through the Internet or log in to the web server through a LAN to perform configuration management for the device. Users can enable either HTTPS or HTTP, or both as necessary on the device.Users can also specify HTTP/1.0 or HTTP/1.1 on the web browser for accessing the HTTP service of the device.

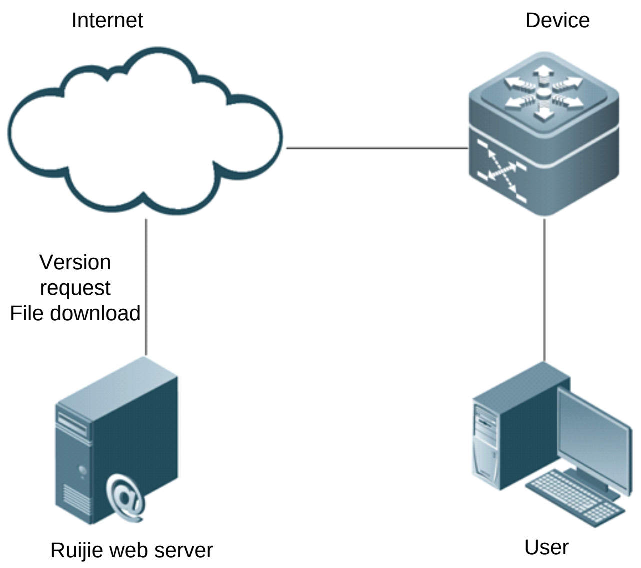
Figure 0-4 HTTP Application Scenario



HTTP Remote Upgrade Service

The HTTP Remote Upgrade Service means that a device serving as a client connects the remote HTTP server and obtains files from the server to upgrade local files. The default domain name of Ruijie web server is "rgos.ruijie.com.cn." Figure 0-5 shows a typical application scenario.

Figure 0-5 HTTP Remote Upgrade



Configuring HTTP

Default Configuration

The following table describes the default configuration of HTTP.

Feature	Default Setting
Enabling the HTTP service	The HTTP service is disabled by default.
HTTP authentication method	Usernames: **admin** and **guest**
HTTP service port	Common HTTP port number: 80 HTTPS port number: 443
HTTP upgrade server	Server address: 0.0.0.0 Port number: 80
HTTP upgrade mode	Manual
HTTP upgrade auto-detection time	Random

Prerequisites

Before configuring the domain name of the HTTP upgrade server, enable the DNS function on the device and configure the address of the DNS server.

Configuration Steps

Step	Configuration Task	Description
1	Enable the HTTP service.	Mandatory
2	Configure HTTP authentication information.	(Optional) This step is performed when authentication information needs to be modified.
3	Configure the HTTP port.	(Optional) This step is performed when the HTTP port needs to be changed.
4	Configure the HTTP upgrade server.	(Optional) This step is performed when the server address needs to be specified.

5	Configure the HTTP upgrade mode.	(Optional) This step is performed when the upgrade mode needs to be changed.
6	Configure HTTP upgrade auto-detection time.	(Optional) This step is performed when the HTTP upgrade auto-detection time needs to be changed.
7	Manually upgrade files with HTTP.	Mandatory

Enabling the HTTP Service

The HTTP service includes the commonly used HTTP service and the HTTPS service. HTTPS adds SSL on the basis of HTTP to enhance information security.

Use the following commands to enable the HTTP service in configuration mode.

Command	**Function**
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)#**enable service web-server http**	(Mandatory) Enables the HTTP service.
Ruijie(config)#**enable service web-server https**	(Mandatory) Enables the HTTPS service.
Ruijie(config)#**enable service web-server [all]**	(Mandatory) Enables both HTTP and HTTPS services.

Configuration example:

The following example enables both HTTP and HTTPS services on a Ruijie device.

```
Ruijie# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)# enable service web-server
```

Configuring HTTP Authentication Information

When HTTP is enabled, users can log in to the web interface only after being authenticated. Use the **webmaster level** command to configure HTTP authentication information.

Command	**Function**
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(confing)# **webmaster level** *privilege-level* **username** *name* **password** { *password* | [**0 | 7**] *encrypted-password* }	(Mandatory) Configures the login authentication mode, which is not configured by default.

Note

Usernames and passwords come with three permission levels, each of which includes at most 20 usernames and passwords.

Configuration example:

The following example uses the username **admin** and plain-text password **ruijie** at level 0 to perform web authentication on a Ruijie device.

```
Ruijie# configure terminal
```

```
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)# webmaster level 0 username admin password ruijie
```

Configuring the HTTP Port

Configuring the HTTP port can reduce attacks from unauthorized users to HTTP. Ruijie devices support the HTTP and HTTPS service modes.

- Use the following commands to configure the HTTP port number.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **ip http port** *port-number*	(Optional) Configures the HTTP port number, which is 80 by default.

Configuration example:

The following example configures the HTTP port number as 8080 on a Ruijie device.

```
Ruijie# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)# ip http port 8080
```

- Use the following commands to configure the HTTPS port.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **ip http secure-port** *port-number*	(Optional) Configures the HTTPS port number, which is 443 by default.

Configuration example:

The following example configures the HTTPS port number as 4430 on a Ruijie device.

```
Ruijie# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)# ip http secure-port 4430
```

Configuring the HTTP Upgrade Server

The address of the HTTP remote upgrade server is 0.0.0.0 and the port number is 80 by default. Use the following commands to change the server address.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **http update server** { *host-name* | *ip-address* } [**port** *port-number*]	(Optional) Configures the address of the HTTP upgrade server.

Note The HTTP upgrade server address does not need to be configured because the local upgrade record file records available upgrade server addresses.

Caution If the server domain needs to be configured, enable the DNS function on the device and configure the DNS server address.

Caution The server address cannot be an IPv6 address.

Configuration example:

The following example configures the domain name of the HTTP upgrade server as **rgos.ruijie.com.cn** and the port number as 85 on a Ruijie device.

```
Ruijie# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)# http update server rgos.ruijie.com.cn port 85
```

Configuring an HTTP Upgrade Mode

The manual upgrade mode applies for HTTP by default. Use the following commands to enter global configuration mode and configure HTTP to automatically detect the files available for upgrade on the server.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **http update mode auto-detect**	(Optional) Configures the HTTP upgrade mode as auto-detection. If this step is not performed or the **no** form of this command is executed, the manual upgrade mode is used by default.

In auto-detection mode, the device detects the files on the server during upgrade. Users can find the web versions to be upgraded through the web interface.

Configuration example:

The following example configures the HTTP upgrade mode as auto-detection on a Ruijie device.

```
Ruijie# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)# http update mode auto-detect
```

Configuring HTTP Upgrade Auto-Detection Time

In auto-detection mode, the remote HTTP auto-detection time is random. Use the following commands to change the auto-detection time in global configuration mode.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **http update time daily** *hh*:*mm*	(Optional) Configures HTTP auto-detection time, which is random by default.

Note

The HTTP auto-detection time is a specific time point with the accuracy of minutes each day.

Caution

This configuration command takes effect only when the HTTP upgrade mode is auto-detection.

Configuration example:

The following example configures the HTTP auto-detection time as 3:00 am on a Ruijie device.

```
Ruijie# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)# http update time daily 03:00
```

Manually Upgrading Files with HTTP

- Remote Upgrade

HTTP provides only the remote auto-detection function by default, and the system does not automatically perform upgrade. Use the following commands to upgrade the system in privileged EXEC mode.

Command	Function
Ruijie# **http check-version**	(Optional) Checks the upgrade version.
Ruijie# **http update web** [**version** *string*]	Updates the web package.

Configuration example:

The following example performs remote file upgrade for a Ruijie device through HTTP.

```
Ruijie# http check-version
app name:web
sn           version               filename
-- ------------------- -------------------------
0        1.2.1(82381)     web1.2.1(145680).upd
1        1.2.1(82380)     web1.2.1(145680).upd
2        1.2.1(82379)     web1.2.1(145680).upd
3        1.2.1(82378)     web1.2.1(145680).upd
```

- Local Upgrade

You can use the **copy tftp** command to download latest web files to a Ruijie device and then use the following command to upgrade the web package.

Command	Function

Ruijie# **http web-file update**	Updates the web package.

Caution To enable the new web package to take effect, log in to the web interface again.

The following example locally upgrades the web package for a Ruijie device.

```
Ruijie#copy tftp://10.10.10.13/web_management_pack.upd flash:web_management_pack.upd
Ruijie#http web-file update
```

Monitoring and Maintaining HTTP

Displaying HTTP Configuration Information

Command	Function
show web-server status	Displays the configuration information and status of the web service.

Configuration example:

The following example displays the HTTP configuration information of a Ruijie device.

```
Ruijie# show web-server status
http server status : enabled
http server port : 80
https server status: enabled
https server port: 443
http(s) use memory block: 768, create task num: 0
```

Configuration Examples

HTTP Configuration Example

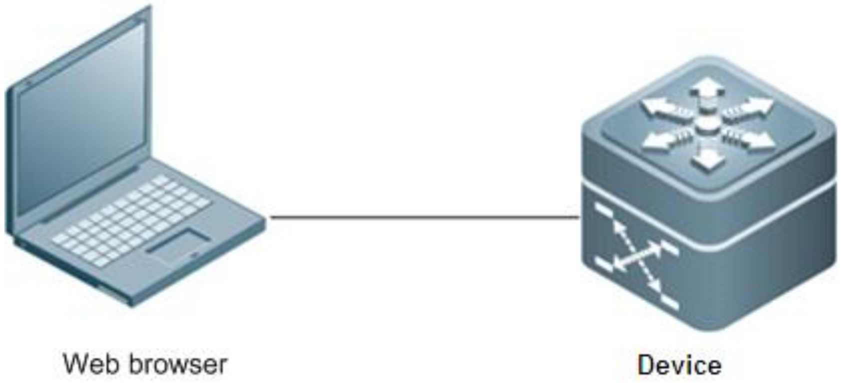
Networking Requirements

Network administrators hope to manage a device through web, and therefore log in to the device through the web browser to configure the switch.

- Log in with the user-configured authentication information.
- Ensure that the web browser can be accessed through HTTP or HTTPS so as to enhance security.
- Configure the HTTP port to reduce attacks from unauthorized users to HTTP.

Networking Topology

Figure 0-6 HTTP Application Topology



Configuration Tips

To meet the customer's requirements, focus on the following points:

- Use the **webmaster level** command to configure authentication information.
- Enable HTTP and HTTPS at the same time to meet the customer's security requirements.
- Configure the HTTP port number as 8080 and the HTTPS port number as 4430.

Configuration Steps

15) Configure the username as admin and the password as ruijie.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)# webmaster level 0 username admin password ruijie
```

16) Enable the HTTP and HTTPS services.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#enable service web-server
```

17) Configure the HTTP port number as 8080.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#ip http port 8080
```

18) Configure the HTTPS port number as 4430.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#ip http secure-port 4430
```

Verification

19) Check HTTP configuration information.

```
Ruijie#show web-server status
http server status : enabled
http server port : 8080
https server status: enabled
https server port: 4430
http(s) use memory block: 768, create task num: 0
```

Configuration Example of HTTP Remote Upgrade

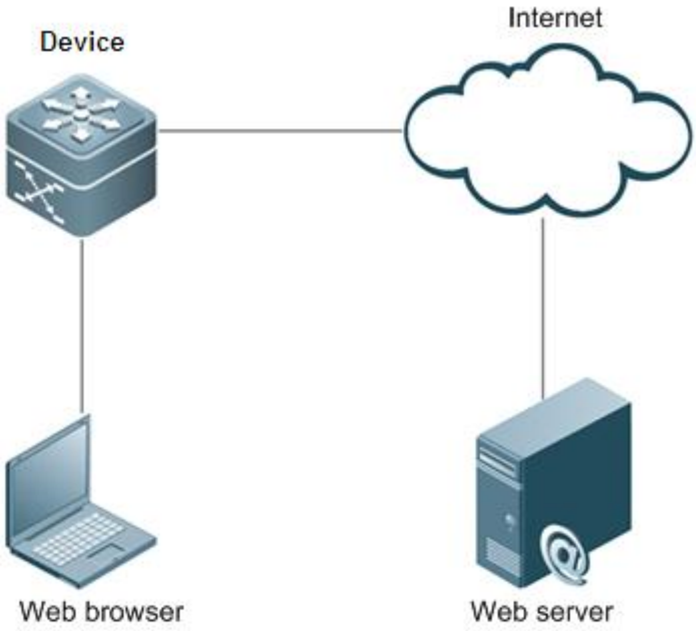
Networking Requirements

An enterprise purchasing a Ruijie device hopes to use the HTTP upgrade function to upgrade files.

- Ensure that the device can periodically and remotely obtain information about the files available for upgrade from a Ruijie server.
- Check the files currently available for upgrade.
- Download the latest files from the Ruijie server and update the device to be upgraded.

Networking Topology

Figure 0-7 Networking Topology of HTTP Remote Upgrade



Configuration Tips

To meet the customer's requirements, focus on the following point:

- Configure the device to remotely obtain information about the latest files at 2:00 am each day.

Configuration Steps

20) Configure DNS information.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

```
Ruijie(config)#ip domain-lookup                            //Enable the DNS function on the
device.
Ruijie(config)#ip name-server 192.168.5.134                   //Configure the IP address of
the DNS server.
```

21) Configure the address of the upgrade server.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)# http update server rgos.ruijie.com.cn
```

22) Enable the auto-detection mode and configure the remote detection time of the device as 2:00 am.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#http update mode auto-detect
Ruijie(config)#http update time daily 02:00
```

23) Obtain information about the files available for upgrade from the remote server.

```
Ruijie#http check-version
app name:web
sn           version               filename
-- ------------------- -------------------------
0       1.2.1(82381)     web1.2.1(145680).upd
1       1.2.1(82380)     web1.2.1(145680).upd
2       1.2.1(82379)     web1.2.1(145680).upd
3       1.2.1(82378)     web1.2.1(145680).upd
```

24) Download the files from the server and update the device.

```
Ruijie#http update web
```

Verification

Check server version information on the online upgrade interface of web.

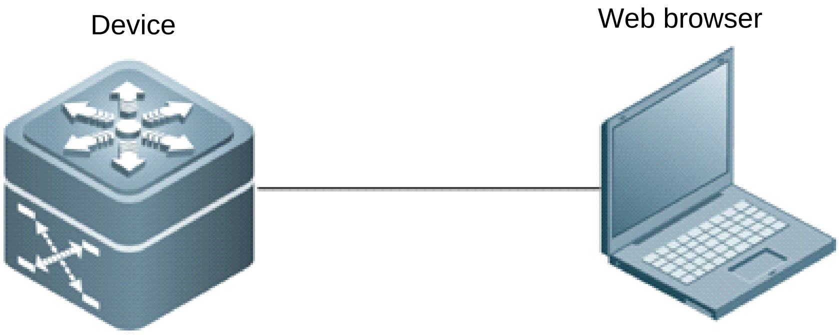
Configuration Example of HTTP Local Upgrade

Networking Requirements

- Users hope to run the latest web package, which is obtained from an official website, on a device.

Networking Topology

Figure 0-8 Networking Topology of HTTP Local Upgrade



Configuration Tips

To meet the customer's requirements, focus on the following points:

- Connect the device to a local PC whose IP address is 10.10.10.13, and configure the device with an IP address 10.10.10.131 in the same network segment.
- Download the latest web package to the device.
- Update the web package on the device.

Configuration Steps

25) Create VLAN1 and configure an IP address for the device

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#vlan 1
Ruijie(config-vlan)#exit
Ruijie(config)#interface vlan 1
Ruijie(config-VLAN 1)#ip address 10.10.10.131 255.255.255.0
```

26) Enable the TFTP server function on the PC and run the copy tftp command on the device to download the web package.

```
Ruijie#copy tftp://10.10.10.13/web_management_pack.upd flash:web_management_pack.upd
```

27) Update the web package on the device.

```
Ruijie#http web-file update
```

Verification

On the PC, log in with web authentication once again to check whether the latest web interface is displayed.

Configuring RADIUS Dynamic Authorization Extension

Understanding RADIUS Dynamic Authorization Extension

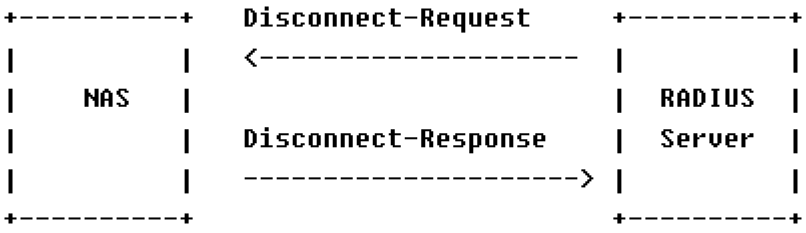
Overview

The Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS) protocol is defined in RFC 3576 by IETF. This protocol defines a user offline management method, that is, the device communicates with a RADIUS server through Disconnect-Messages (DMs) to log out authenticated users. This protocol enables devices from different vendors to communicate with a RADIUS server and log out users of these devices.

The DM mechanism is as follows: A RADIUS sends user logout requests to the device. The device logs out the users that match the session IDs in the request packets, and sends response packets that contain processing results to the server. This mechanism allows the RADIUS server to manage user logout.

Working Principle

Figure 1-1 DM exchange for RADIUS dynamic authorization extension



```
+----------+   Disconnect-Request     +----------+
|          |   <--------------------  |          |
|    NAS   |                          |  RADIUS  |
|          |   Disconnect-Response    |  Server  |
|          |   ---------------------> |          |
+----------+                          +----------+
```

The above figure shows the DM exchange between the RADIUS server and device. When the RADIUS server sends a Disconnect-Request packet to the UDP port numbered 3799, the device processes the packet and sends a Disconnect-Response packet containing the processing results to the server.

Protocol Specification

RADIUS is defined in RFC 3576.

Default Configuration

The default configuration about RADIUS dynamic authorization extension is shown in the table below.

Feature	Default Setting
RADIUS dynamic authorization extension	Disabled
The number of a UDP port for intercepting DMs	3799

Configuring RADIUS Dynamic Authorization Extension

Enabling RADIUS Dynamic Authorization Extension

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)#**radius dynamic-authorization-extension enable**	Enables RADIUS dynamic authorization extension.
Ruijie(config)# **show running-config**	Shows configuration.

Use the **no radius dynamic-authorization-extension enable** command to disable RADIUS dynamic authorization extension in global configuration mode.

The example below shows how to configure RADIUS dynamic authorization extension:

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# radius dynamic-authorization-extension enable
Ruijie(config)# show run
```

Note

By default, RADIUS dynamic authorization extension is disabled.

Viewing the Configuration

Command	Function
Ruijie# **show radius dynamic-authorization-extension statistics**	Shows statistics about RADIUS dynamic authorization extension.
Ruijie# **clear radius dynamic-authorization-extension statistics**	Clears statistics about RADIUS dynamic authorization extension.

The example below shows how to show statistics about RADIUS dynamic authorization extension.

```
Ruijie# show radius dynamic-authorization-extension statistics
Disconnect-Request Received:                        50
Incorrect Disconnect-Request Received:               1

Configuring Optional Features of RADIUS Dynamic Authorization Extension

Configuring a UDP Port

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)#**radius dynamic-authorization-extension port** *num*	Sets a UDP port for intercepting the packets about RADIUS dynamic authorization extension. The value ranges from 1024 to 65535. The default value is 3799.
Ruijie(config)# **show running-config**	Shows configuration.

Use the **no radius dynamic-authorization-extension port** command to restore the default interception port in global configuration mode.

The example below shows how to configure a UDP port intercepting the packets about RADIUS dynamic authorization extension.

# Set the port numbered 8080 to intercept RADIUS requests:

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# radius dynamic-authorization-extension port 8080
Ruijie(config)# show running-config
```

# Reset the configuration:

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# no  radius dynamic-authorization-extension port
Ruijie(config)# show running-config
```

Examples for Configuring RADIUS Dynamic Authorization Extension

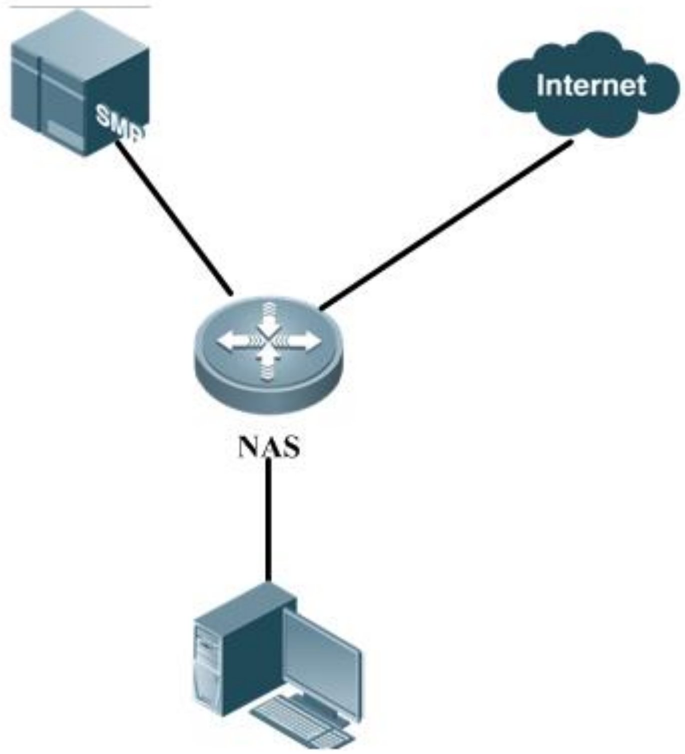
Networking Requirements

RADIUS dynamic authorization extension must work with the authentication mechanism. The network comprises SAM servers, Ruijie access devices, and PCs of users.

Ruijie access devices must support RADIUS dynamic authorization extension.

Networking Topology

Figure 4-1 Network topology of RADIUS dynamic authorization extension



Configuration Procedure

1. Configure AAA on the access authentication device.

```
aaa new-model
aaa accounting update periodic 1
aaa accounting update
aaa accounting network default start-stop group radius
aaa authentication ppp default local group radius

```

2. Configure the PPP authentication on the access device.

```
vpdn enable
vpdn-group 1
accept-dialin
protocol l2tp
  virtual-template 1

interface Virtual-Template 1
ppp authentication chap
 ip unnumbered Loopback 1
interface Loopback 1
 ip address 110.1.1.254 255.255.255.0
interface GigabitEthernet 8/1/1
```

```
ip address 100.1.1.2 255.255.255.0
duplex auto
     speed auto
```

3. Enable RADIUS dynamic authorization extension.

```
radius dynamic-authorization-extension enable
```

4. After the user logs in, the administrator uses RADIUS dynamic authorization extension on the SAM to log out the user.
5. The user is logged out and needs to be authenticated again to access the network.

Configuring Smart Status Monitoring

Overview

Introduction

A network egress generally provides two or more operator links. For example, in a campus network of a university, a network egress provides an education network link and an operator link (China Telecom, China Unicom, and China Mobile); in a government network, a network egress provides links of China Telecom, China Unicom, and China Mobile. When links in a wide area network (WAN) have different bandwidths and the number of links is no less than three, there can be 2^n adjustment policies, and, it is impossible to manually perform adjustment at any time. In view of this, the smart status monitoring module can sense network changes, and can perform complex logical operation, to obtain the final policy and implement the corresponding control script.

For example, in an aggregate port (AP) scenario where all AP members operate properly, the HQoS (Hierarchical Quality of Service) traffic policy needs to limit the traffic rate based on the sum of bandwidth of all AP members and guarantee user services based on priorities. When the link of a certain AP member is down, the HQoS traffic policy changes accordingly. In this case, the total bandwidth to be guaranteed is the sum of bandwidth of all AP members subtracted by the bandwidth of the failed member link.

Working Principle

The smart status monitoring module loads and runs different scripts to control the device according to different preset status detection situations of scheduling instances.

Detection events mainly involve the BDF session status, interface link status, the selected, unselected, and track the status of Link Aggregation Control Protocol (LACP) on the AP members. According to the configured smart status monitoring instances, unary operation or binary operation between multiple detection events are performed starting from the predetermined operation sequence. If the operation result meets the detection quantity, the smart status monitoring module loads and runs the script copied by TFTP to control the device.

Different scripts are executed according to different detection results. In this way, the device can be flexibly controlled, thereby reducing the maintenance workload.

Defaults

Feature	Default Value
Smart Status Monitoring Scheduling Instance	N/A
Smart Status Monitoring Operation Sequence	N/A
Smart Status Monitoring Detection Events	N/A
Smart Status Monitoring Heartbeat Period	5 seconds

Smart Status Monitoring Heartbeat Period

Configuring Heartbeat Period

Command	Function
config	Enters the global configuration mode.
smart-monitor tick *seconds*	Sets the scheduling heartbeat period for smart status monitoring in seconds. The value range is from **1** to **60**.
exit	Exits the global configuration mode and enters the privileged EXEC mode.

Run the **no smart-monitor tick** command to restore the default scheduling heartbeat period.

Configuration Example

#Configure the smart status monitoring heartbeat period to 2 seconds.

```
Ruijie#configure
Ruijie(config)# smart-monitor status tick 2
Ruijie(config)#exit
Ruijie#
```

Smart Status Monitoring Detection Events

Configuring Detection Event

Command	Function
config	Enters the global configuration mode.
smart-monitor status *status-id* { bfd ***peer-address*** {down **|** up**}** } [member-interface ***interface-name***]} | { **interface** *interface-name* **{ line {down | up}** | **lacp {selected | unselected}**| **link-quality { enable | disable}** *link-quality -value* } } | { **track** *track-id* {**up | down**} | { **time-range** *time-range-name* {**active | inactive** } }	Configures smart status monitoring detection events. The event ID range is from **1** to **64**. bfd *peer-address*: Indicates the peer address of the detected BFD session. down: Indicates that the detected BFD session is in the down state. up: Indicates that the detected BFD session is in the up state. *interface-name*: Indicates the name of an AP member that supports BFD session detection. *interface-name*: Indicates the name of the detected interface. down: Indicates that the line of the detected interface is down.

	up: Indicates that the line of the detected interface is up. selected: LACP of the detected interface is selected. unselected: LACP of the detected interface is not selected. *link-quality–value*: Indicates the link quality value of the detected interface. The value range is from **0** to **100**. *track-id*: Indicates detected track ID. The value range is from **1** to **700**. *time-range-name*: Indicates the name of the detected time range. active: Indicates that the detected time range is in the active state. inactive: Indicates that the detected time range is in the inactive state.
exit	Exits the global configuration mode and enters the privileged EXEC mode.

Run the **no smart-monitor status** *status-id* command to delete a smart status monitoring detection event.

Configuration Example

#Create Smart Status Detection Event 1 to detect the event that the BFD session with the peer IP address being 19.19.19.1 is up.

```
Ruijie#configure
Ruijie(config)# smart-monitor status 1 bfd 19.19.19.1 up
Ruijie(config)#exit
Ruijie#
```

#Create Smart Status Detection Event 3 to detect the event that the link of GigabitEthernet 0/0 is up.

```
Ruijie#configure
Ruijie(config)# smart-monitor status 3 interface gigabitEthernet0/0 line up
Ruijie(config)#exit
Ruijie#
```

#Create Smart Status Detection Event 4 to detect the event with the track ID being 1 and the state being up.

```
Ruijie#configure
Ruijie(config)# smart-monitor status 4 track 1 up
Ruijie(config)#exit
Ruijie#
```

#Create Smart Status Detection Event 5 to detect the event that the BFD session of the AP member Gi0/0 with the peer address being 19.19.19.1 is up.

```
Ruijie#configure
```

```
Ruijie(config)#interface Route-aggregateport 1
Ruijie(config-if-Route-aggregateport 1)# ip address 19.19.19.1 255.255.255.252
Ruijie(config-if-Route-aggregateport 1)# bfd interval 50 min_rx 50 multiplier 3
Ruijie(config-if-Route-aggregateport 1)# member interface GigabitEthernet 0/0 bind bfd
peer-ip 192.168.1.10
Ruijie(config-if-Route-aggregateport 1)# member interface GigabitEthernet 0/1 bind bfd
peer-ip 192.168.1.10
Ruijie(config-if-Route-aggregateport 1)#end
Ruijie#configure
Ruijie(config)# smart-monitor status 5 bfd 19.19.19.1 up member-interface
GigabitEthernet 0/0
Ruijie(config)#
```

#Create Smart Status Detection Event 6 to detect the event that the weekdays time range is active.

```
Ruijie(config)# smart-monitor status 6 time-range check active
```

#Create Smart Status Detection Event 7 to detect the event that the weekdays time range is inactive.

```
Ruijie(config)# smart-monitor status 7 time-range check inactive
```

#Create a time range named weekdays.

```
Ruijie(config)# time-range check
Ruijie(config-time-range)# periodic weekdays 8:30 to 17:30
```

To configure a time range, perform the following commands in privileged EXEC mode:

Command	Function
configure terminal	Enters the global configuration mode.
time-range *time-range-name*	Names a time range using a significant string.
Ruijie(config-time-range)# **absolute** [start time date] end time date	(Optional) Configures an absolute time range. For more information, see time range configuration manual.
Ruijie(config-time-range)# **periodic day-of-the-week** time to [day-of-the-week] time	(Optional) Configures a periodical time range. For details, see the time range configuration guide.
exit	Exits the global configuration mode and enters the privileged EXEC mode.

Displaying

Run the following command to display information about smart status monitoring detection events.

Command	**Function**
show smart-monitor status [status-id]	Displays information about smart status monitoring detection events. The result of a smart status monitoring detection event may be **True**, **False**, or **Fail**. **True** indicates a match, **False** indicates a mismatch, and **Fail** indicates that the configuration is incorrect and does not meet the detection target.

The displayed information is as follow:

```
Ruijie(config)# show smart-monitor status 3
Smart-monitor status 3 : final-status True
smart-monitor status 3 interface GigabitEthernet 0/0 line up
Ruijie(config)# show smart-monitor status 5
Smart-monitor status 5 : final-status False
smart-monitor status 5 bfd 19.19.19.1 up member-interface GigabitEthernet 0/0
```

Smart Status Monitoring Operation Sequence

Configuring Detection Event

Command	**Function**
config	Enters the global configuration mode.
smart-monitor status *status-id* { bfd ***peer-address*** {down **|** up} } | { **interface** *interface-name* { **line {down | up}** | **lacp {selected** | **unselected} | link-quality { enable** | **disable}** *link-quality -value* } } | { **track** *track-id* {**up | down**} **|** { **time-range** *time-range-name* {**active** | in**active** } }	Configures smart status monitoring detection events.
exit	Exits the global configuration mode and enters the privileged EXEC mode.

Run the **no smart-monitor** status ***status-id*** command to delete smart status monitoring detection events.

Configuring Operation Sequence

Command	**Function**
config	Enters the global configuration mode.

smart-monitor seq *seq-id* {**seq [not]** *seq-id*} **|** {**status [not]** *status-id*} **[** {**and | or**} {**seq [not]** *seq-id*} **|** {**status [not]** *status-id*} **]**	Configures the operation sequence for smart status detection. The operation sequence ID range is from **1** to **100**. (Optional) not: Performs the NOT operation via operators. *status-id*: Indicates the ID of a smart status monitoring detection event. The value range is from **1** to **64**. and: Indicates binary operation. The AND operation is performed via the left and right operators. or: Indicates binary operation. The OR operation is performed via the left and right operators.
exit	Exits the global configuration mode and enters the privileged EXEC mode.
show smart-monitor seq [*seq-id*]	Displays the smart status monitoring operation sequence.

Run the **no smart-monitor seq** *seq-id* command to delete a smart status monitoring operation sequence.

Configuration Example

#Configure the operation rule of Operation Sequence 1: perform negation operation on the result of Event 1 that the link of the detected interface GigabitEthernet1/1/0 is up.

```
Ruijie(config)# smart-monitor status 1 interface GigabitEthernet 0/0 line up
Ruijie(config)# smart-monitor seq 1 status not 1
```

#Configure the operation rule of Operation Sequence 2: perform binary operation, that is, perform AND operation on the statuses of Instance 2 and Instance 1 of smart status monitoring detection events.

```
Ruijie#configure
Ruijie(config)# smart-monitor status 2 interface GigabitEthernet 0/1 line up
Ruijie(config)# smart-monitor seq 2 status  2 and seq  1
```

Displaying

Run the following command to display the smart status monitoring operation sequence.

Command	Function
show smart-monitor seq *[seq-id]]*	Displays the smart status monitoring operation sequence.

The displayed information is as follow:

Run the **show smart-monitor seq** command to display all operation sequence information.

```
Ruijie#show smart-monitor schedule
```

```
smart-monitor seq 1 status not 1
smart-monitor seq 2 status  1 and seq  1
```

Smart Status Monitoring Scheduling Instance

Configuring Detection Event

Command	**Function**
config	Enters the global configuration mode.
smart-monitor status *status-id* { bfd ***peer-address*** {down **|** up**}** } } | { **interface** *interface-name* { **line** {**down | up**} | **lacp {selected** | **unselected}** | **link-quality { enable | disable}** *link-quality -value* } } | { **track** *track-id* {**up | down**} | { **time-range** *time-range-name* {**active** | **inactive** } }	Configures smart status monitoring detection events. The event ID range is from **1** to **64**. bfd *peer-address*: Indicates the peer address of the detected BFD session. down: Indicates that the detected BFD session is in the down state. up: Indicates that the detected BFD session is in the up state. *interface-name*: Indicates the name of the detected interface. down: Indicates that the line of the detected interface is down. up: Indicates that the line of the detected interface is up. selected: LACP of the detected interface is selected. unselected: LACP of the detected interface is not selected. *link-quality–value*: Indicates the link quality value of the detected interface. The value range is from **0** to **100**. *track-id*: Indicates detected track ID. The value range is from **1** to **700**. *time-range-name*: Indicates the name of the detected time range. active: Indicates that the detected time range is in the active state. inactive: indicates that the detected time range is in the inactive state.
exit	Exits the global configuration mode and enters the privileged EXEC mode.

Run the **no smart-monitor status** *status-id* command to delete a smart status monitoring detection event.

Configuring Operation Sequence

Command	Function
config	Enters the global configuration mode.
smart-monitor seq *seq-id* {**seq [not]** *seq-id*} **|** {**status [not]** *status-id*} **[** {**and | or**} {**seq [not]** *seq-id*} **|** {**status [not]** *status-id*} **]**	Configures the operation sequence for smart status detection. The operation sequence ID range is from **1** to **100**. (Optional) not: Performs the NOT operation via operators. *status-id*: Indicates the ID of a smart status monitoring detection event. The value range is from **1** to **64**. and: Indicates binary operation. The AND operation is performed via the left and right operators. or: Indicates binary operation. The OR operation is performed via the left and right operators.
exit	Exits the global configuration mode and enters the privileged EXEC mode.
show smart-monitor seq [*seq-id*]	Displays the smart status monitoring operation sequence.

Run the **no smart-monitor seq** *seq-id* command to delete a smart status monitoring operation sequence.

Configuring Scheduling Instance

Command	Function
config	Enters the global configuration mode.

smart-monitor schedule *schedule-id* **final-seq** *seq-id* **action load** *file-name tag_infor* [**times** *times-number*]	Configures a smart status monitoring scheduling instance. *schedule-id*: Indicates the serial number of a smart status monitoring scheduling instance. The value range is from **1** to **8**. *seq-id*: Indicates the serial number of an operator. The value range is from **1** to **100**.*file-name*: Indicates the name of a to-be-loaded script file. The file name contains 1 to 63 characters. *tag_infor*: Executes tagged information in the script. (Optional) times-number: Loads and runs the script labeled by **file-name** when the number of detection times reaches the value of **times-number**. The value range is from **1** to **20**. The default value is **1**.
exit	Exits the global configuration mode and enters the privileged EXEC mode.
show smart-monitor schedule [*schedule-id* [**do**]]	Displays information about smart status monitoring scheduling instances.

Run the **no smart-monitor schedule** *schedule-id* command to delete a smart status monitoring scheduling instance.

Configuration Example

#Create a smart status monitoring scheduling instance with the ID 1, perform operation starting from Operation Sequence 2, and load content of the switch_to_pos section in the configuration script ah-wh-pos-mstp-chg.text if the number of detection times reaches 3.

```
Ruijie#configure
Ruijie (config)# smart-monitor schedule 1 final-seq 2 action load
ah-wh-pos-mstp-chg.text switch_to_pos times 3
```

Syntax of the configuration file ah-wh-pos-mstp-chg.text:

```
@@@@@start
switch_to_pos:
enable
config
interface GigabitEthernet 1/4/2/7
shutdown
end
@@@@@end
```

1. Each execution section starts with @@@@@start and ends with @@@@@end.Content to be loaded is identified the section identifier in the **smart-monitor schedule 1** command.

It should be noted that the colon behind the section identifier is an English character.

Displaying

Run the following command to display information about smart status monitoring scheduling instances.

Command	Function
show smart-monitor schedule [schedule-id [do]]	Displays the smart status monitoring configuration information, automatic loading and execution information, and operation result.

The displayed information is as follow:

Example 1: Run the **show smart-monitor schedule** command to display information about all operation scheduling instances.

```
Ruijie#show smart-monitor schedule
smart-monitor schedule 1 final-seq 2 action load ah-wh-pos-mstp-chg.text switch_to_pos
times 3
smart-monitor schedule 2 final-seq 1 action load ah-wh-pos-mstp-chg.text pos_to_switch
times 1
smart-monitor schedule 3 final-seq 1 action load 3.text times 2
```

Example 2: Run the **show smart-monitor schedule** 2 command to display information about a specified operation scheduling instance.

```
Ruijie#show smart-monitor schedule 2
smart-monitor schedule 2 final-seq 1 action load ah-wh-pos-mstp-chg.text pos_to_switch
times 1
```

Example 3: Run the **show smart-monitor schedule** 2 **do** command to display information about a specified operation scheduling instance.

```
Ruijie#show smart-monitor schedule 2 do
smart-monitor schedule 2 final-seq 1 action load ah-wh-pos-mstp-chg.text pos_to_switch
times 1
```

Smart Status Monitoring Configuration Example

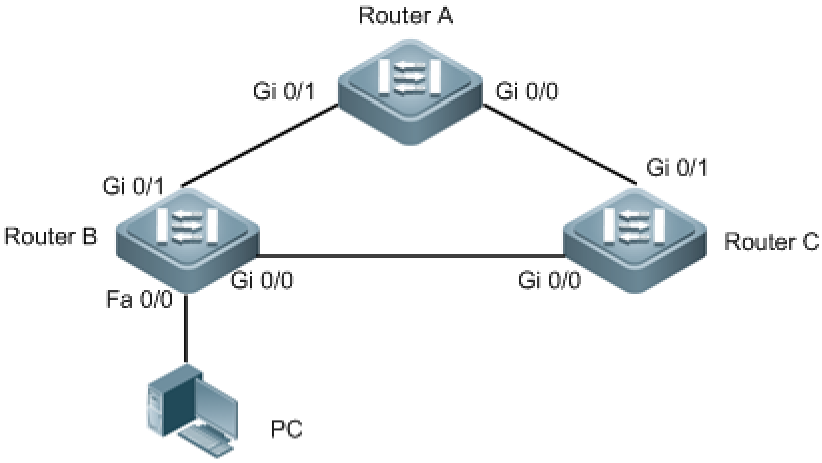
Configuration Example 1

Networking Requirements

Three routers are deployed.

Network Topology

Figure 0-1 Smart Status Monitoring



Configuration Key Points

1. Configure the flow queue, user queue, and user group queue.

2. Configure the traffic classifier, traffic behavior, and traffic policy.

3. Apply the HQoS policy.

4. Configure an AP and use LACP for detection on the AP.

5. Configure the smart status monitoring detection and dynamically adjust the HQoS policy.

Configuration Steps

#Configure the flow queue of the production service.

```
flow-queue sc_0/0
 queue be wfq weight 10
 queue af1 wfq weight 20
 queue af2 pq shaping 2666
 queue af3 wfq weight 15
 queue af4 wfq weight 15
 queue ef pq
 queue cs6 pq
 queue cs7 pq

flow-queue sc_0/1
 queue be wfq weight 10
 queue af1 wfq weight 20
 queue af2 pq shaping 5333
 queue af3 wfq weight 15
 queue af4 wfq weight 15
 queue ef pq
 queue cs6 pq
 queue cs7 pq
```

#Configure the flow queue of the office service.

```
flow-queue bg_0/1
 queue be wfq weight 10
 queue af1 wfq weight 20
 queue af2 pq shaping 2666
 queue af3 wfq weight 15
 queue af4 wfq weight 15
 queue ef pq
 queue cs6 pq
 queue cs7 pq

flow-queue bg_0/0
 queue be wfq weight 10
 queue af1 wfq weight 20
 queue af2 pq shaping 1333
 queue af3 wfq weight 15
 queue af4 wfq weight 15
 queue ef pq
 queue cs6 pq
 queue cs7 pq
```

#Configure the user queue of the production service.

```
user-queue sc_0/0 outbound
 cir 6666 pir 10000
 flow-queue sc_0/0
 user-group-queue sc_bg_0/0

user-queue sc_0/1 outbound
 cir 13333 pir 20000
 flow-queue sc_0/1
 user-group-queue sc_bg_0/1
```

#Configure the user queue of the office service.

```
user-queue bg_0/0 outbound
 cir 3333 pir 10000
 flow-queue bg_0/0
 user-group-queue sc_bg_0/0

user-queue bg_0/1 outbound
 cir 6666 pir 20000
 flow-queue bg_0/1
 user-group-queue sc_bg_0/1
```

#Configure the user group queue.

```
user-group-queue sc_bg_0/0 outbound
 shaping 10000
user-group-queue sc_bg_0/1 outbound
 shaping 20000
```

#Configure the traffic classifier of the production service.

```
traffic classifier sc_youwu_cos or
 if-match acl sc_youwu
traffic classifier sc_jinrong_cos or
 if-match acl sc_jinrong
traffic classifier sc_sudi_cos or
 if-match acl sc_sudi

traffic classifier sc_0/0 and
 if-match dst-if GigabitEthernet 0/0
 if-match src-if VLAN 2
traffic classifier sc_0/1 and
 if-match dst-if GigabitEthernet 0/1
 if-match src-if VLAN 2
```

#Configure the traffic classifier of the office service.

```
traffic classifier bg_bg_cos or
 if-match acl bg_bg
traffic classifier bg_voip_cos or
 if-match acl bg_voip
traffic classifier bg_qita_cos or
 if-match acl bg_qita

traffic classifier bg_0/0 and
 if-match dst-if GigabitEthernet 0/0
 if-match src-if VLAN 3
traffic classifier bg_0/1 and
 if-match dst-if GigabitEthernet 0/1
 if-match src-if VLAN 3
```

#Configure traffic behaviors of three sub services of the production service.

```
traffic behavior sc_jinrong_cos
 service-class be color green
traffic behavior sc_sudi_cos
 service-class af1 color green
traffic behavior sc_youwu_cos
 service-class af2 color green
```

#Configure traffic behaviors of three sub services of the office services.

```
traffic behavior bg_qita_cos
 service-class be color green
traffic behavior bg_voip_cos
 service-class af1 color green
traffic behavior bg_bg_cos
 service-class af2 color green
```

#Configure traffic behaviors of the production service.

```
traffic behavior sc_0/0
 user-queue sc_0/0 outbound
traffic behavior sc_0/1
 user-queue sc_0/1 outbound
```

#Configure traffic behaviors of the office service.

```
traffic behavior bg_0/0
 user-queue bg_0/0 outbound
traffic behavior bg_0/1
 user-queue bg_0/1 outbound
```

#Configure traffic policies of all services.

```
traffic policy sc_bg_out
 classifier sc_0/0 behavior sc_0/0 precedence 1
 classifier sc_0/1 behavior sc_0/1 precedence 2
 classifier bg_0/0 behavior bg_0/0 precedence 3
 classifier bg_0/1 behavior bg_0/1 precedence 4
```

#Configure traffic policies of three sub services of the production service.

```
traffic policy sheng_chan_in
 classifier sc_youwu_cos behavior sc_youwu_cos precedence 1
 classifier sc_jinrong_cos behavior sc_jinrong_cos precedence 2
 classifier sc_sudi_cos behavior sc_sudi_cos precedence 3
```

#Configure traffic policies of three sub services of the office service.

```
traffic policy ban_gong_in
 classifier bg_bg_cos behavior bg_bg_cos precedence 1
 classifier bg_voip_cos behavior bg_voip_cos precedence 2
 classifier bg_qita_cos behavior bg_qita_cos precedence 3
```

#Apply the HQoS policy to the AP.

```
interface AggregatePort 1
 port-user-key dst-ip
 traffic-policy sc_bg_out outbound
```

#Apply the HQoS policy to AP members and configure LACP detection.

```
interface GigabitEthernet 0/0
 port-bandwidth 10000
 port-group 1 mode active

interface GigabitEthernet 0/1
 port-bandwidth 20000
 port-group 1 mode active
```

#Configure the smart status monitoring function to detect the event that LACP of the AP member Gi0/0 is selected or not selected.

```
smart-monitor status 1 interface GigabitEthernet 0/0 lacp unselected
smart-monitor seq 1 status  1
smart-monitor seq 2 status not 1
smart-monitor schedule 1 final-seq 1 action load hqos.txt  up2down times 10
smart-monitor schedule 2 final-seq 2 action load hqos.txt down2up times 10
smart-monitor tick 10
```

#Compile the corresponding script for configuring the smart status monitoring function to detect the event that LACP of the AP member Gi0/0 is selected or not selected.

//Smart status monitoring script

```
@@@@@start
up2down:
enable
config
interface GigabitEthernet 0/0
shutdown
end
@@@@@end
@@@@@start
Down2up:
enable
```

```
config
interface GigabitEthernet 0/0
no shutdown
end
```

Verification

1. Display the smart status monitoring information on the device.

```
Ruijie# show smart-monitor status 1
Smart-monitor status 1 : final-status True
smart-monitor status 1 interface GigabitEthernet 0/0 line up

Ruijie#show smart-monitor schedule 1
smart-monitor schedule 1 final-seq 1 action load hqos.txt up2down times 3
```

Configuring Domain Name Policy

Overview

Introduction

On current routers, policy functions such as routing and flow control are implemented based on IP addresses. Although such processing is quick and accurate, an IP address involved in the processing is abstract to users and it is inconvenient to record IP addresses.

Policy routing provides a new bridge between service modules and users. Original configurations and logics of the service modules are retained and users only need to record domain names (URLs) that are easy to memorize.

Basic Concepts

URL Library

The URL library is generated in the device memory based on the URL library file and the URLs configured by the user in URL classes. The URL library includes specific domain names and domain name classification information.

URL Class

A URL class is a group of URLs with the same attribute.

URL Group

A URL group is a policy that combines a URL class and a user group.

DNS Parser

The DNS parser parses DNS response packets in depth, to obtain the domain names and corresponding IP addresses from the packets.

Working Principle

A URL group is configured on the router to specify the association between a URL class and a user group. After receiving a DNS response packet, the router searches the URL library to obtain the URL class and URL group that are corresponding to the URL in the DNS response packet, so as to further obtain the corresponding user group. The router can fill the answer IP address in the DNS response packet into the user group, and apply the user group to policy-based routing (PBR), thereby implementing routing based on the domain name.

The ultimate effect of the domain name policy function is to fill IP addresses corresponding to a type of domain names into a user group. For details about how to user this user group, refer to related configurations of other functional modules.

Application

The domain name policy module is a public module that must operate in combination with other modules to meet requirements of corresponding scenarios. For example, the domain name policy module can cooperate with HQoS to provide domain name-based service guarantee, or can associate with PBR to provide domain name-based policy routing.

Domain Name Policy Configuration

Defaults

No domain name policy is configured by default.

Configuration Prerequisites

Configuration Steps

Step	Task	Description
1	Enable the URL library.	Mandatory.
2	Configure the URL class.	Optional.
3	Configure the user group.	Mandatory.
4	Configure the URL group.	Mandatory.
5	Enable the DNS parser.	Mandatory.

Enabling URL Library

Enable the URL library by running the **lib.dat** file in the **flash:/urlib/lib.dat** path on the device. If the URL library file does not exist on the device, obtain this file and save it to the corresponding path.

Similar to other files, the library file can be downloaded to the device in TFTP or FTP mode, for example, copy the file from the **tftp://101.101.101.155/lib.dat** path or the **flash:/urlib/lib.dat** path.

Command	Function
Ruijie(config)#url-lib enable	Enables the URL library.

Configuring URL Class (Optional)

Run the following commands to configure a URL class. Because the system presets several URL classes in the URL library, this function is optional.

Command	Function
Ruijie(config)#url-class *class_name*	Enters the URL class configuration mode.
Ruijie(config-url-class)#url *url*	Adds a URL class.

Example: Configure URL redirection rules on physical interfaces.

```
Ruijie#configure terminal
Ruijie(config)# url-class test_class
Ruijie(config-url-class)#url www.ruijie.com.cn
Ruijie(config-url-class)#url *.edu.cn
```

Configuring User Group

Run the following command to configure a user group.

Command	Function
Ruijie(config)#user-group *groupname*	Configures a user group.

Example: Configure URL redirection rules on physical interfaces.

Configuring URL Group

Run the following command to configure a URL group:

Command	Function
Ruijie(config)#url-group *num*	Enters the URL group configuration mode.
Ruijie(config-url-group)#class *class_name*	Configures forward proxy mapping.
Ruijie(config-url-group)#relate user-group *group_name*	Configures a user group associated with the URL group.

Example: Configure URL redirection rules on physical interfaces.

```
Ruijie#configure terminal
Ruijie(config)# url-group 3
Ruijie(config-url-group)#class test_class
Ruijie(config-url-group)#relate user-group test_group
Ruijie(config-url-group)#exit
Ruijie(config)#
```

Enabling DNS Parser

Run the following command to enable the DNS parser on an interface:

Command	Function
Ruijie(config-if)# dns-parser enable	Enables DNS forward proxy on an interface.

Example: Configure URL redirection rules on physical interfaces.

```
Ruijie#configure terminal
Ruijie(config)#interface gigabitEthernet 1/1/1
Ruijie(config-if-GigabitEthernet 1/1/1)#dns-parser enable
Ruijie(config-if-GigabitEthernet 1/1/1)#exit
Ruijie(config)#
```

Monitoring

Run the following command to display the current URL group list.

Command	Function
Ruijie# show url-group	Displays the current URL group list.

Configuration Example

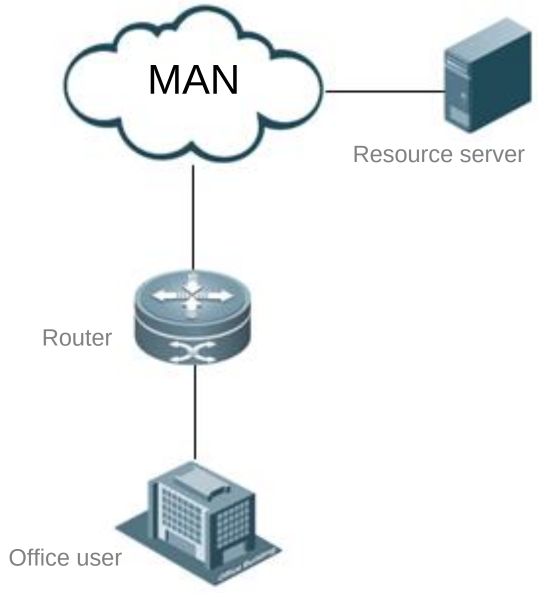
Domain Name-based Service Guarantee

Networking Requirements

A resource server is deployed in a MAN and can be accessed at www.XXX.net. The network quality of office users must be guaranteed when they access (for example, video resources in) the resource server in the MAN.

Network Topology

Figure 2-1



The office network is connected to the MAN via a router. The router is connected to the office network via GigabitEthernet0/0.

Configuration Steps

1) Configure the basic network connection.

Configure basic egresses and routes on the router based on different routing requirements and scenarios.

2) Configure the domain name policy.

```
Ruijie(config)#user-group ziyuan
Ruijie(config-user-group)#exit
Ruijie(config)#
Ruijie(config)#url-lib enable
Ruijie(config)#url-class ziyuan
Ruijie(config-url-class)#url *.XXX.net
Ruijie(config-url-class)#exit
Ruijie(config)#
Ruijie(config)# url-group 5
Ruijie(config-url-group)#class ziyuan
Ruijie(config-url-group)#relate user-group ziyuan
Ruijie(config-url-group)#exit
Ruijie(config)#
Ruijie(config)#url-group ttl 60
```

3) Configure the HQoS

The HQoS configuration is flexible. For details, see the configuration guides of router-related products and the HQoS chapter in the command reference document. In this document, HQoS is applied to the outbound direction of the inside interface of the port queue is used as an examples.

```
Ruijie(config)# ip access-list extended 100
Ruijie(config-ext-nacl)# permit ip user-group ziyuan any
Ruijie(config-ext-nacl)#exit
Ruijie(config)#
Ruijie(config)#traffic classifier aaa
Ruijie(config-traffic-classifier)#if-match acl 100
Ruijie(config-traffic-classifier)#exit
Ruijie(config)#
Ruijie(config)#traffic behavior aaa
Ruijie(config-traffic-behavior)#service-class cs6 color green
Ruijie(config-traffic-behavior)#exit
Ruijie(config)#
Ruijie(config)#traffic policy aaa
Ruijie(config-traffic-policy)#classifier aaa behavior aaa
Ruijie(config-traffic-policy)#exit
Ruijie(config)#
Ruijie(config)#port-queue test
Ruijie(config-port-queue)#exit
Ruijie(config)#
Ruijie(config)#interface gigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#traffic-policy aaa outbound
Ruijie(config-if-GigabitEthernet 0/0)#port-queue test shaping 2000
Ruijie(config-if-GigabitEthernet 0/0)#exit
Ruijie(config)#
```

4) Enable the DNS parser and DNS proxy on the interface.

```
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#dns-parser enable
Ruijie(config-if-GigabitEthernet 0/0)#exit
Ruijie(config)#
```

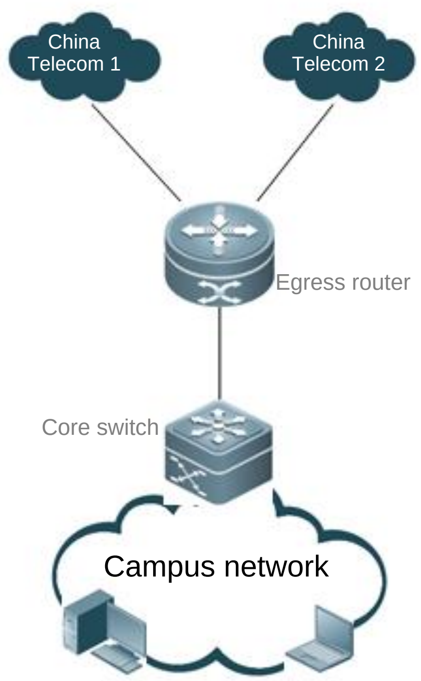
URL Routing

Networking Requirements

A campus network provides two China Telecom egresses: China Telecom 1 and China Telecom 2. All services are connected to the public network via China Telecom 2. In this example, it is required to connect the CNKI service to the public network via China Telecom 1.

Network Topology

Figure 2-2



Connection Between Interface TenGi1/1/1 and Core Switch of Campus Network

Configuration Steps

(1). Configure outbound routes for operators.

According to different routing requirements, intranet user packets are forwarded on different operator links based on operator routes, PBR routes, user routes, and the like. DNS packets as user packets are also routed based on the same policy.

(2). Configure the domain name policy.

```
Ruijie(config)#url-lib enable
Ruijie(config)#user-group cnki
Ruijie(config-user-group)#exit
Ruijie(config)#
Ruijie(config-url-class)#url *.cnki.net
Ruijie(config-url-class)#url cnki.*
Ruijie(config-url-class)#uexit
Ruijie(config)#
Ruijie(config)# url-group 3
Ruijie(config-url-group)#class cnki
Ruijie(config-url-group)#relate user-group cnki
Ruijie(config-url-group)#exit
Ruijie(config)#
```

(3). Enable the DNS parser on the interface.

```
Ruijie(config)#interface tenGigabitEthernet 1/1/1
Ruijie(config-if-TenGigabitEthernet 1/1/1)#dns-parser enable
Ruijie(config-if-TenGigabitEthernet 1/1/1)#exit
Ruijie(config)#
```

(4). Configure PBR.

The gateway address of China Telecom 1 is 177.136.69.1.

```
Ruijie(config)# ip access-list extended 100
Ruijie(config-ext-nacl)# permit ip any user-group cnki
Ruijie(config-ext-nacl)#exit
Ruijie(config)#
Ruijie(config)# route-map cnki_policy
Ruijie(config-route-map)# match ip address 100
Ruijie(config-route-map)# set ip next-hop 177.136.69.1
Ruijie(config-route-map)#exit
Ruijie(config)#
```

Configuring DDNS

Overview

Dynamic Domain Name Server (DDNS) is a method of automatically updating a name server in the Domain Name System (DNS), often in real time, with the active DDNS configuration of its configured hostnames, addresses or other information.

Configuring DDNS

Default Configuration

Feature	Default Settings
Oray client	Disabled by default.

Configuring Oray Client

Command	Description
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **peanut username** *test* **password** *test*	Configures the username and password for the oray client.
Ruijie(config)#**end**	Returns the privileged EXEC mode.
Ruijie#**show running**	Verifies the configuration.

To remove the oray client configuration, run the **no** form of this command.

The following example configures an oray client.

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# peanut username test password test
Ruijie(config)#
```

Configuring Routing Protocol

Configuring Protocol-Independent

Configuring the IP Routing

Configuring Static Routes

Static routes are manually configured to send the packets to the specified target network. It is essential to configure the static routes when the routes of some target network cannot be learned by the dynamic routing protocols. Usually, a default static route is configured for the packets without the routes.

To configure static routes, execute the following commands in global configuration mode:

Command	Function
Ruijie(config)# **ip route** [**vrf** *vrf_name1*] *network mask* {*ip-address* | *interface-type interface-number* [*ip-address*]} [*distance*] [**tag** *tag*] [**permanent** | **track** *object-number*] [**weight** *weight*]	Configures the static routes. The vrf vrf-name1 parameter can be used to specify the VRF for the routes.
Ruijie(config)# **no ip route** [**vrf** *vrf_name1*] *network mask*	Deletes the static routes.
Ruijie(config)# **ip static route-limit** *number*	Specifies the upper limit of the static routes.
Ruijie(config)# **no ip static route-limit**	Restores the static routes to the default maximum values.

For examples of configuring the static routes, see the "Example of Replacing the Static Routes with the Dynamic Routes" section.

If the static routes are not deleted, they will be retained on Ruijie products permanently. However, you can replace the static routes with the better routes learned by the dynamic routing protocols. Better routes mean that they have smaller management distances. All routes, including the static ones, carry the parameters of the management distance. The following table shows the management distances for various route sources retained on Ruijie products:

Route source	Default management distance
Directly connected network	0
Static route	1
OSPF route	110
ISIS route	115
RIP route	120
Unreachable route	255

Note

The static route redistribution shall be configured if the static routes require to be advertised by the dynamic routing protocols such as RIP and OSPF.

When an interface is "down", all routes to the interface disappear from the routing table. In addition, when Ruijie products fail to find the forwarding route to the next-hop address for a static route, the static route will also disappear from the routing table.

When the specified VRF static routes are added to the corresponding VRF, if the egress is specified at the same time, the addition fails when the VRF of the egress does not match the specified VRF. If no VRF is specified, it is added to the global routing table by default.

If the specified VRF is a multi-protocol VRF, the static route can be configured only for the multi-protocol VRF that is configured for the IPv4 address family. When the IPv4 address family of the VRF is deleted, the IPv4 static route of the VRF will also be deleted.

If the association of the static route with the track object is specified, and if the track object is advertised to be inactive, the static route also takes no effect.

By default, the weight of the static route is 1. To view the static route of non-default weights, execute the command **show ip route weight**. The weight parameter is used to enable the WCMP function. When there are load-balanced routes to a destination address, the switch assigns data flows by their weights. The higher the weight of a route is, the more data packets the route carries. The WCMP limit is generally 32 for routers. However, the WCMP limit varies depending on switch models because their chipsets support different weights. For the detailed information about the route weight value of specific models, see the product specifications. When the sum of the load-balanced route weights exceeds the WCMP limit, the excessive routes will not take effect. For example, if the WCMP limit on a device is 8, only one of the following static route configurations takes effect:

```
Ruijie(config)#ip route 10.0.0.0 255.0.0.0 172.0.1.2 weight 6
Ruijie(config)#ip route 10.0.0.0 255.0.0.0 172.0.1.4 weight 6
Ruijie(config)#show ip route 10.0.0.0

Routing entry for 10.0.0.0/8
  Distance 1, metric 0
  Routing Descriptor Blocks:
  *172.0.1.2, generated by "static"
Ruijie(config)#show ip route weight

------------[distance/metric/weight]-----------
S    10.0.0.0/8 [1/0/6] via 172.0.1.2
```

The maximum number of the static routes is 1024 by default. If the number of the configured static routes exceeds the specified upper limit, they are not be automatically deleted, but the addition fails.

To view the configurations of the IP routing, execute the **show ip route** command to view the IP routing table. For details, see Protocol-independent Command Configuration.

Configuring the Default Route

Not all devices have a complete network-wide routing table. To allow every device to route and forward all packets, it is a common practice that the powerful core device on the network is provided with a complete routing table, while the other devices have a default route to this core device. Default routes can be transmitted by the dynamic routing protocols, and can also be manually configured on every router.

Default routes can be generated in two ways: 1) manually configuring a default static route. For details, see the "Configuring Static Routes" section; 2) manually configuring a default network.

Most internal gateway routing protocols have a mechanism that transmits the default route to the entire routing domain. The device that transmits the default route must have a default route. The transmission of the default route described in this section applies only to the RIP routing protocol. The RIP always notifies the 0.0.0.0/0 network as the default route to the RIP routing domain. For details about how the OSPF routing protocols generate and transmit the default route, see related sections in Guide on Configuring the OSPF Routing Protocols.

For generating the default static route, execute the following commands in global configuration mode:

Command	Function
Ruijie(config)# **ip default-network** network	Configures the default network.
Ruijie(config)# **no ip default-network** network	Deletes the default network.

Note

Generating the default route by using the **default-network** command must meet the following requirement: The default network is not a directly-connected interface network, but is reachable in the routing table.

Note

Under the same condition, the RIP can also transmit the default route. Alternatively, the RIP can use another way to transmit the default route, that is, by configuring the default static route or learning the 0.0.0.0/0 route by other routing protocols.

If the router has a default route, whether it is learned by the dynamic routing protocol or manually configured, when you execute the show ip route command, the "gateway of last resort" area in the routing table will show information about the last gateway. A routing table may have multiple routes as alternative default routes, but only the best default route is presented in the "gateway of last resort" area.

Configuring the Number of Equivalent Routes

To enable the load-balancing function, configure the number of the equivalent routes for control. An equivalent route is an alternative path to the same destination address. When there is only one equivalent route, one destination address can be configured with only one route, then the load-balancing function is disabled.

To configure the number of the equivalent routes, execute the following command in global configuration mode. Use the no form of this command to restore the default number of the equivalent routes.

This command is valid for both the IPv4 and the IPv6. That is to say, after configuring this command, the maximum numbers of the equivalent paths to the IPv4 and IPv6 destinations are the same as the configured value.

Command	Function

Ruijie(config)# **maximum-paths** *number*	Configures the number of the equivalent routes. The maximum number of the equivalent routes configured on different products varies. The maximum number of the equivalent routes configured on routers is 32. However, this number varies depending on the chipsets for switches. Therefore, see the prompts during the configuration.

Configuring the Route-Map

The route-map is a collection of filter policies that are independent from the detailed routing protocols and used in the routing protocols and the policy-based routing. The route-map is used to filter and modify the routing information in the routing protocols, and control the packet forwarding in the policy-based routing.

To define the route-map, execute the following commands in global configuration mode:

Command	Function
Ruijie(config)# **route-map** *route-map-name* [[**permit** | **deny**] *sequence*]	Defines the route-map.
Ruijie(config)# **no route-map** *route-map-name* [{**permit** | **deny**} *sequence*]	Deletes the route-map.

When configuring the rules for a route-map, you can execute one or more **match** or **set** commands. If there is no **match** command, all routes are matched. If there is no **set** command, no operation is performed.

To define the matching conditions for the rules, execute the following commands in route-map configuration mode:

Command	Function
Ruijie(config-route-map)# **match community** {*standard-list-number* | *expanded-list-number* | *community-list-name*} [**exac-match**]…	Matches the community attribute of the BGP route.
Ruijie(config-route-map)# **match interface** [*interface-type interface-number*…]	Matches the next-hop interface of the route.
Ruijie(config-route-map)# **match ip address** *access-list-number* [*access-list-number*…]	Matches the IP address in the ACL.
Ruijie(config-route-map)# **match ip next-hop** *access-list-number* [*access-list-number*…]	Matches the next-hop IP address in the ACL.
Ruijie(config-route-map)# **match ip route-source** *access-list-number* [*access-list-number*…]	Matches the route source IP address in the ACL.
Ruijie(config-route-map)# **match ipv6 address** { *access-list-name* | **prefix-list** *prefix-list-name* }	Matches the IPv6 ACL or prefix list.
Ruijie(config-route-map)# **match ipv6 next-hop** { *access-list-name* | **prefix-list** *prefix-list-name* }	Matches the next-hop IP address in the ACL or prefix list.
Ruijie(config-route-map)# **match ipv6 route-source** { *access-list-name* | **prefix-list** *prefix-list-name* }	Matches the route source IP address in the ACL or prefix list.
Ruijie(config-route-map)# **match metric** *Metric*	Matches the route metric value. The metric value is in the range from 0 to 4294967295.

Ruijie(config-route-map)# **match origin** {**egp** | **igp** | **incomplete**}	Matches the route origin type.
Ruijie(config-route-map)# **match route-type** {**local** | **internal** | {{**external** | **nssa-external**} [**type-1**][**type-2**]} | [**level-1** | **level-2**]}	Matches the route type.
Ruijie(config-route-map)# **match tag tag**	Matches the route tag value. The tag value is in the range from 0 to 4294967295.

To define operations after matching, execute the following commands in route-map configuration mode:

Command	Function
Ruijie(config-route-map)# **set aggregator as** *as-num ip_addr*	Sets the AS attribute value for the route aggregator.
Ruijie(config-route-map)# **set as-path prepend** *as-number*	Sets the AS_PATH attribute value.
Ruijie(config-route-map)# **set comm-list** *community-list-number* | *community-list-name delete*	Deletes all COMMUNITY attribute values in the COMMUNITY_LIST.
Ruijie(config-route-map)# **set community** {*community-number*[*community-number*…] **additive** | **none**}	Sets the COMMUNITY attribute value.
Ruijie(config-route-map)# **set dampening** *half-life reuse suppress max-suppress-time*	Sets the route dampening parameters.
Ruijie(config-route-map)#**set extcommunity** {**rt** *extend-community-value* | **soo** *extend-community-value*}	Sets the extended community attribute value.
Ruijie(config-route-map)# **set interface** *interface-type interface-number*	Sets the interface for forwarding packets.
Ruijie(config-route-map)# **set ip default next-hop** *ip-address* [*weight*] [*ip-address* [*weight*] …]	Sets the default next-hop IP address.
Ruijie(config-route-map)# **set ipv6 default next-hop** *global-ipv6-address* [*weight*] [*global-ipv6-address* [*weight*]...]	Sets the default next-hop IPv6 address.
Ruijie(config-route-map)# **set ip next-hop** *ip-address* [*weight*] [*ip-address* [*weight*]…]	Sets the next-hop IP address.
Ruijie(config-route-map)# **set ipv6** [**vrf** *vrf-name* | **global**] **next-hop** *global-ipv6-address* [*weight*] [*global-ipv6-address* [*weight*]]	Sets the next-hop IPv6 address. If the **vrf** *vrf-name* parameter is specified, the VRF is crossed when packets are forwarded. If the **global** parameter is specified, packets are forwarded globally from the VRF. If the [**vrf** *vrf-name* | **global**] parameter is not specified, the IPv6 packets will inherit the VRF during transmission. That is, the next hop belongs to the VRF that receives the IPv6 packets.
Ruijie(config-route-map)# **set level** {**stub-area** | **backbone** | **level-1** | **level-1-2** | **level-2**}	Sets the routing area.
Ruijie(config-route-map)# **set local-preference** *number*	Sets the LOCAL_PREFERENCE value.
Ruijie(config-route-map)# **set metric** *metric*	Sets the metric value for the redistributed route.

Ruijie(config-route-map)# **set metric** [+ *metric-value* |- *metric-value* | *metric-value*]	Sets the metric type for the redistributed route.
Ruijie(config-route-map)# **set metric-type** {**type-1** | **type-2** | **external** | **internal**}	Sets the metric type for the redistributed route.
Ruijie(config-route-map)# **set next-hop** *next-hop*	Sets the next-hop IP address for the redistributed route. next-hop: indicates the next-hop IP address.
Ruijie(config-route-map)# **set origin** {**egp** | **igp** | **incomplete**}	Sets the route origin attribute.
Ruijie(config-route-map)#**set originator-id** *ip-addr*	Sets the route originator ID.
Ruijie(config-route-map)# **set tag** *tag*	Sets the tag value for the redistributed route.
Ruijie(config-route-map)# **set weight** *number*	Sets the BGP route weight.

Whether a route-map supports the **match** command and the **set** command depends on applications associated with the route-map. The general instructions are as follows:

- When you configure commands associated with a route-map, the system displays a prompt when the configured match command or the set command is inapplicable to the current applications associated with the route-map.
- When you configure a route-map, the match command, or the set command, the system displays a prompt when any match command or set command is inapplicable to any application associated with the route-map.

For examples of displaying the prompt when the command is not applicable, see the "*Example of Route-Map Configuration*" section.

Caution The two instructions are inapplicable to the association of the policy-based routing with the route-map.

Redistributing Routes

Configuring Route Redistribution

To enable the device to run multiple routing protocol processes, Ruijie products provide the function for redistributing the route information from one routing process to another routing process. For example, you can redistribute the routes in the OSPF routing area to the RIP routing area, and vice versa. All IP routing protocols support the mutual route redistribution.

For route redistribution, route-maps are usually used to control the mutual route redistribution between two routing areas

To redistribute routes from one routing area to another and control the route redistribution, execute the following commands in routing process configuration mode:

Command	Function
Ruijie(config-router)# **redistribute** *protocol* [*process-id*] [metric *metric*] [**metric-type** *metric-type*] [**match internal** | **external** *type*| **nssa-external** *type*] [[**tag** *tag*] [**route-map** *route-map-name*] [**subnets**]	Redistributes the routes. Protocol (protocol type): bgp, connected, isis, rip, static

Ruijie(config-router)# **default-metric** *metric*	Sets default metric values for all redistributed routes.

The route redistribution may easily cause loops, so be careful when performing the operation.

Note

When the route redistribution is configured in the OSPF routing process, the metric value of 20 is allocated to the redistributed routes with the type of Type-2 by default. This type of the routes is the least credible routes to the OSPF.

Configuring Default Route Distribution

To advertise the default route, it is necessary for the routing protocol to introduce the default route to the process, or enforce to generate a default route.

To configure the default route distribution, execute the following commands in routing process configuration mode:

Command	Function
Ruijie(config-router)# **default-information originate** [**always**] [**metric** *metric*] [**metric-type** *type*] [**route-map** *map-name*]	Introduces the default route to the routing protocol process and advertises the default route. **always** (optional): always introduces a default route to the process no matter whether the default route exists in the local routing table. **metric** (optional): sets the metric value for the introduced default route. **metric-type** (optional): sets the metric type for the introduced default route. **route-map** (optional): filters and sets the introduced default route.
Ruijie(config-router)# no default-information originate [always] [metric metric] [metric-type type] [route-map map-name]	Cancels the operation for introducing the default route to the routing protocol process and advertising the default route.

Configuring Route Filtering

The route filtering is the process to control the inbound/outbound routes so that the device only learns the necessary and predictable routes, and only advertises the necessary and predictable routes to external trusted devices. The divulgence and chaos of the routes may affect the running of the network. Therefore, it is essential to configure the route filtering, especially for telecom operators and on financial service networks**.**

Controlling Route Updating Advertising

To prevent other routers on a local network from learning unnecessary information, you can control the route updating advertisement to prevent the specified route from updating.

To prevent the route updating advertisement, execute the following commands in routing process configuration mode:

Command	Function
Ruijie(config-router)# **distribute-list** {[*access-list-number* | *access-list-name*] **prefix** *prefix-list-name*} **out** [*interface-type interface-number*| *protocol*]	According to the ACL rules, permits or denies some routes. **prefix**: This keyword specifies the prefix list for filtering the routes. The prefix list should be separately configured by using the ip prefix-list command.
Ruijie(config-router)# **no distribute-list** {[*access-list-number* | *access-list-name*] **prefix** *prefix-list-name*} **out** [*interface-type interface-number*| *protocol*]	Cancels the operation for preventing the route updating advertising.

When you configure the OSPF, you cannot specify the interface. This feature is only applicable to the external routes in the OSPF routing area.

Controlling the Process of Route Updating

To avoid processing some specified routes of the inbound route updating packets, you can configure this feature, which does not apply to the OSPF routing protocols.

To control the route updating processing, execute the following commands in routing process configuration mode:

Command	Function
Ruijie(config-router)# **distribute-list** {[*access-list-number* | *access-list-name*] | **prefix** *prefix-list-name* [**gateway** *prefix-list-name*]| **gateway** *prefix-list-name*} **in** [*interface-type interface-number*]	According to the ACL rules, permits or denies receiving the specified inbound routes. **prefix**: This keyword specifies the prefix list for filtering the routes. The prefix list should be separately configured by using the ip prefix-list command. **gateway**: Uses the prefix list to filter the inbound routes according to the route sources.
Ruijie(config-router)# **no distribute-list** {[*access-list-number* | *access-list-name*] | **prefix** *prefix-list-name* [**gateway** *prefix-list-name*]| **gateway** *prefix-list-name*} **in** [*interface-type interface-number*]	Cancels the operation for controlling the process of the route updating.

Configuring Fast Reroute

When a link or router fails, the packets that need to forwarded through this link or router will be lost or a loop will be generated to cause service suspension. This problem can be avoided by configuring the router with the static fast reroute function.

Please refer to *Configuring OSPF* for OSPF fast rerouting configuration details.

Run the following commands to enable a static fast reroute in global configuration mode.

Command	Function
Ruijie(config)# route-map fast-reroute	Enters the route map configuration mode.
Ruijie(config-route-map)# set fast-reroute backup-nexthop GigabitEthernet 0/1 192.168.1.2	Configures a backup interface and backup next hop of the fast reroute.
Ruijie(config-route-map)# exit	Returns to the global configuration mode.
Ruijie(config)# ip fast-reroute route-map fast-reroute	Configures a static fast reroute.

Configuring the Key Chain

The key chain is used to manage authentication keys, assign key IDs, and specify the authentication string and the lifetime in the sending and receiving directions. Each key is identified and stored using a unique ID.

To manage the authentication keys, run the following commands in global configuration mode.

Command	Function
Ruijie(config)# **key chain** *key-chain-name*	Configures the key chain.
Ruijie(config-keychain)# **key** *key-id*	Configures the key ID.
Ruijie(config-keychain-key)# **key-string** [**0**|**7**] *text*	Configures the authentication string.
Ruijie(config-keychain-key)# **accept-lifetime** *start-time* {**infinite** | *end-time* | **duration** *seconds*}	Configures the lifetime in the receiving direction.
Ruijie(config-keychain-key)# **send-lifetime** *start-time* {**infinite** | *end-time* | **duration** *seconds*}	Configures the lifetime in the sending direction.
Ruijie(config-keychain-key)# **end**	Exits key chain configuration mode.
Ruijie# **show key chain**	Shows configuration information about key chains.

Configuration Examples

Example of Route-Map Configuration

The route-map can be configured very flexibly and applies to the route redistribution and the policy-based routing configuration. No matter how the route-map is used, the configuration principle is the same, except that different command sets are used. Even if the route-map is used for the route redistribution, different routing protocols can use different commands.

The following examples show that the RIP routes are redistributed based on the OSPF routing protocols. It is required that only the RIP routes whose hops are 4 be redistributed. The type of these routes is the external route type-1, the default metric value is 40, and the route tag is set to 40 in the OSPF routing area.

# Configure the OSPF.

```
Ruijie(config)# router ospf 1
Ruijie(config-router)# redistribute rip subnets route-map redrip
Ruijie(config-router)# network 192.168.12.0 0.0.0.255 area 0
```

# Configure the access control list.

```
Ruijie(config)# access-list 10 permit 200.168.23.0 0.0.0.255
```

# Configure the route-map.

```
Ruijie(config)# route-map redrip permit 10
Ruijie(config-route-map)# match metric 4
Ruijie(config-route-map)# set metric 40
Ruijie(config-route-map)# set metric-type type-1
Ruijie(config-route-map)# set tag 40
```

The following examples show that the OSPF routes are redistributed based on the RIP routing protocols. It is required that only the OSPF routes whose tag is 10 be redistributed. The default metric value of these routes is set to 10.

# Configure the RIP.

```
Ruijie(config)# router rip
Ruijie(config-router)# version 2
Ruijie(config-router)# redistribute ospf 1 route-map redospf
Ruijie(config-router)# network 200.168.23.0
```

# Configure the route-map.

```
Ruijie(config)# route-map redospf permit 10
Ruijie(config-route-map)# match tag 10
Ruijie(config-route-map)# set metric 10
```

The following examples show that the OSPF routes are redistributed based on the RIP routing protocols. Since rules that are not supported in the route-map application have been configured, when the route redistribution is associated with the route-map, a prompt displays indicating that the application does not support the rules.

# Configure the route-map.

```
Ruijie(config)# route-map redrip permit 10
Ruijie(config-route-map)# match length 1 3
Ruijie(config-route-map)# match route-type external
Ruijie(config-route-map)# set level backbone
```

# Configure the OSPF.

```
Ruijie(config)# router ospf 1
Ruijie(config-router)# redistribute rip subnets route-map redrip
% ospf redistribute rip not support match length
% ospf redistribute rip not support match route-type
% ospf redistribute rip not support set level backbone
```

Example of the Static Route Redistribution

- Configuration Requirements

A device exchanges route information with other devices through the RIP. In addition, there are three static routes that require the route redistribution based on the RIP. The RIP only allows to advertise two routes 172.16.1.0/24 and 192.168.1.0/24.

- Specific Configurations of the Routers

This is a common configuration example in practice for route filtering according to the distribution list. Note that the metric value is not specified for the routes to be redistributed. Since a static route is redistributed, the RIP automatically assigns the metric value. During the RIP configuration, the version must be specified and the route aggregation must be disabled because the access list allows the 172.16.1.0/24 route. To advertise the route externally, the RIP protocol must first support the classless route, and the route cannot be aggregated to the 172.16.0.0/16 network.

# Configure the static route.

```
Ruijie(config)# ip route 172.16.1.0 255.255.255.0 172.200.1.2
Ruijie(config)# ip route 192.168.1.0 255.255.255.0 172.200.1.2
Ruijie(config)# ip route 192.168.2.0 255.255.255.0 172.200.1.4
```

# Configure the RIP.

```
Ruijie(config)# router rip
Ruijie(config-router)# version 2
Ruijie(config-router)# redistribute static
Ruijie(config-router)# network 192.168.34.0
Ruijie(config-router)# distribute-list 10 out static
Ruijie(config-router)# no auto-summary
```

# Configure the extended ACL.

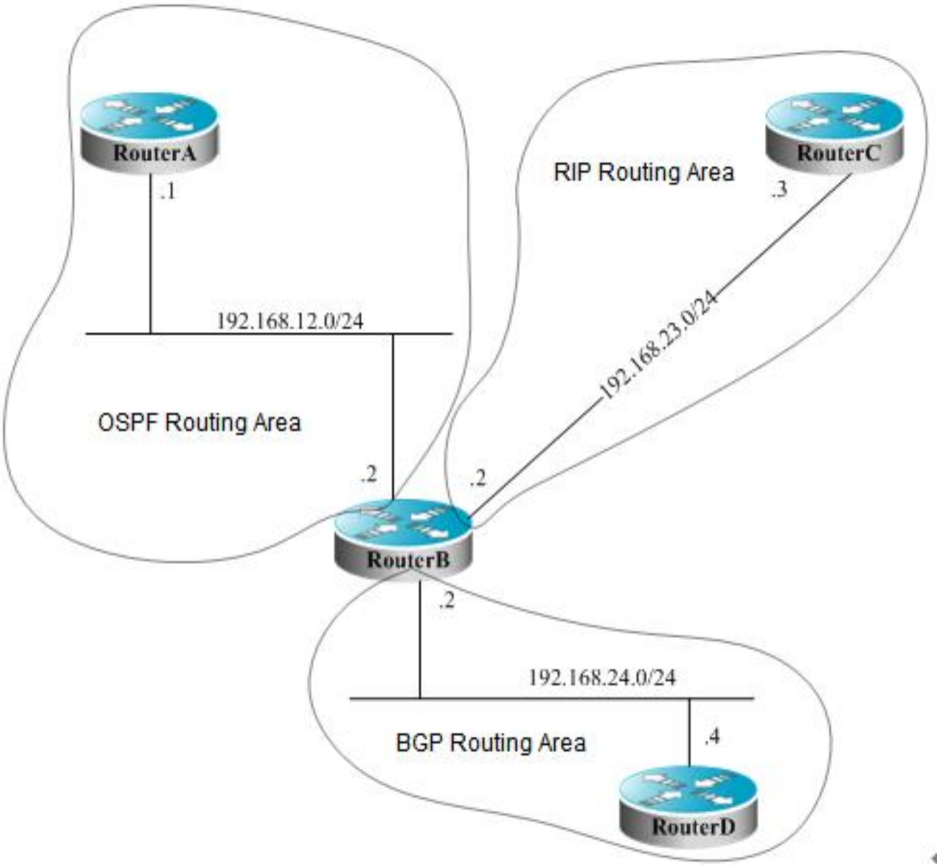
```
Ruijie(config)# ip access-list extended EXT_ACL
Ruijie(config-ext-nacl)#10 permit ip 192.168.1.0 0.0.0.255
any
Ruijie(config-ext-nacl)#10 permit ip 172.16.1.0 0.0.0.255 any
```

Example of Dynamic Routing Protocol Redistribution

- Configuration Requirements

The connection among four routers is shown in Figure 1. Router A belongs to the OSPF routing area. Router C belongs to the RIP routing area. Router D belongs to the BGP routing area. Router B is connected to the three routing areas. Router A advertises the two routes 192.168.10.0/24 and 192.168.100.1/32. Router C advertises the two routes 200.168.3.0/24 and 200.168.30.0/24. Router D advertises the two routes 192.168.4.0/24 and 192.168.40.0/24.

Figure 1 Dynamic routing protocol redistribution



On Router B, the OSPF redistributes the RIP routes with the route type of Type-1, redistributes the BGP routes whose community attribute is 11:11 in the BGP routing area. The RIP redistributes the 192.168.10.0/24 route whose metric value is set to 3 in the OSPF routing area, and advertises a default route to the RIP routing area.

- Specific Configurations of the Routers

When the routing protocols redistribute the routes among each other, the simple route filtering can be controlled by using the distribution list. However, different attributes must be set for different routes, which cannot be implemented by using the distribution list. In this case, a route-map must be used for control. The route-map provides more control functions than the distribution list, but the router configuration is more complex. Therefore, do not use the route-map if possible. The following examples use the route-map to match the community attribute of the BGP routes.

Configurations of Router A:

# Configure the network interface.

```
Ruijie(config)# interface gigabitEthernet 0/0
Ruijie(config-if)# ip address 192.168.10.1 255.255.255.0
Ruijie(config)# interface loopback 1
Ruijie(config-if)# ip address 192.168.100.1 255.255.255.255
Ruijie(config-if)# no ip directed-broadcast
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# ip address 192.168.12.1 255.255.255.0
```

# Configure the OSPF.

```
Ruijie(config)# router ospf 12
Ruijie(config-router)# network 192.168.10.0 0.0.0.255 area 0
Ruijie(config-router)# network 192.168.12.0 0.0.0.255 area 0
Ruijie(config-router)# network 192.168.100.0 0.0.0.255 area 0
```

Configurations of Router B:

# Configure the network interface.

```
Ruijie(config)# interface gigabitEthernet 0/0
Ruijie(config-if)# ip address 192.168.12.2 255.255.255.0
Ruijie(config)# interface Serial 1/0
Ruijie(config-if)# ip address 192.168.23.2 255.255.255.0
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# ip address 192.168.24.2 255.255.255.0
```

#Configure the OSPF and specify the redistribution route type.

```
Ruijie(config)# router ospf 12
Ruijie(config-router)# redistribute rip metric 100 metric-type 1 subnets
Ruijie(config-router)# redistribute bgp route-map ospfrm subnets
Ruijie(config-router)# network 192.168.12.0 0.0.0.255 area 0
```

#Configure the RIP and use the distribution list to filter the redistributed routes.

```
Ruijie(config)# router rip
Ruijie(config-router)# redistribute ospf 12 metric 3
Ruijie(config-router)# network 192.168.23.0
Ruijie(config-router)# distribute-list 10 out ospf
Ruijie(config-router)# default-information originate always
Ruijie(config-router)# no auto-summary
```

# Configure the BGP.

```
Ruijie(config)# router bgp 2
Ruijie(config-router)# neighbor 192.168.24.4 remote-as 4
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 192.168.24.4 activate
Ruijie(config-router-af)# neighbor 192.168.24.4 send-community
```

# Configure the route-map.

```
Ruijie(config)# route-map ospfrm
Ruijie(config-route-map)# match community cl_110
```

# Define the access list.

```
Ruijie(config)# access-list 10 permit 192.168.10.0
```

# Define the community list.

```
Ruijie(config)# ip community-list standard cl_110 permit 11:11
```

Configurations of Router C:

# Configure the network interface.

```
Ruijie(config)# interface gigabitEthernet 0/0
Ruijie(config-if)# ip address 192.168.30.1 255.255.255.0
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# ip address 192.168.3.1 255.255.255.0
Ruijie(config)# interface serial 1/0
Ruijie(config-if)# ip address 192.168.23.3 255.255.255.0
```

# Configure the RIP.

```
Ruijie(config)# router rip
Ruijie(config-router)# network 192.168.23.0
Ruijie(config-router)# network 192.168.3.0
Ruijie(config-router)# network 192.168.30.0
```

Configurations of Router D:

# Configure the network interface.

```
Ruijie(config)# interface gigabitEthernet 0/0
Ruijie(config-if)# ip address 192.168.40.1 255.255.255.0
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# ip address 192.168.4.1 255.255.255.0
Ruijie(config)# interface serial 1/0
Ruijie(config-if)# ip address 192.168.24.4 255.255.255.0
```

# Configure the BGP.

```
Ruijie(config)# router bgp 4
Ruijie(config-router)# neighbor 192.168.24.2 remote-as 2
Ruijie(config-router)# redistribute connected route-map bgprm
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 192.168.24.2 activate
Ruijie(config-router-af)# neighbor 192.168.24.2 send-community
```

# Configure the route-map.

```
Ruijie(config)# route-map bgprm
Ruijie(config-route-map)# match community 22:22
```

The OSPF routes found on Router A:

```
O E1 192.168.30.0/24 [110/101] via 192.168.12.2, 00:04:07, FastEthernet0/1
O E1 192.168.3.0/24 [110/101] via 192.168.12.2, 00:04:07, FastEthernet0/1
```

The RIP routes found on Router C:

```
R    0.0.0.0/0 [120/1] via 192.168.23.2, 00:00:00, Serial1/0
R    192.168.10.0/24 [120/2] via 192.168.23.2, 00:00:00, Serial1/0
```

Example of Fast Reroute Configuration

- Configuration Requirements

Three routers A, B and C are connected with each other via static routes. It is required that when the link between B and C fails, the service will be fast removed to the link between A and C and reach B after passing through C and A.

- Specific Configurations

Router A:

# Configure an Ethernet interface

```
Ruijie(config)interface GigabitEthernet 0/1
Ruijie(config-if)ip address 192.168.1.1 255.255.255.0
Ruijie(config-if)bfd interval 200 min_rx 200 multiplier 5
Ruijie(config)interface GigabitEthernet 0/2
Ruijie(config-if)ip address 192.168.2.1 255.255.255.0
Ruijie(config-if)bfd interval 200 min_rx 200 multiplier 5
```

# Configure a static route

```
Ruijie(config)ip route 1.1.1.1 255.255.255.255 192.168.2.2
```

Router B:

# Configure an Ethernet interface

```
Ruijie(config)interface GigabitEthernet 0/1
Ruijie(config-if)ip address 192.168.2.2 255.255.255.0
Ruijie(config-if)bfd interval 200 min_rx 200 multiplier 5
Ruijie(config)interface GigabitEthernet 0/2
Ruijie(config-if)ip address 192.168.3.1 255.255.255.0
Ruijie(config-if)bfd interval 200 min_rx 200 multiplier 5
Ruijie(config)interface loopback 1
Ruijie(config-if)ip address 1.1.1.1 255.255.255.255
```

Router C:

# Configure an Ethernet interface

```
Ruijie(config)interface GigabitEthernet 0/1
Ruijie(config-if)ip address 192.168.1.2 255.255.255.0
Ruijie(config-if)bfd interval 200 min_rx 200 multiplier 5
Ruijie(config-if)carrier-delay 0
Ruijie(config)interface GigabitEthernet 0/2
Ruijie(config-if)ip address 192.168.3.2 255.255.255.0
Ruijie(config-if)bfd interval 200 min_rx 200 multiplier 5
Ruijie(config-if)carrier-delay 0
```

# Configure a route map

```
Ruijie(config)access-list 1 permit host 1.1.1.1
Ruijie(config)route-map frr
Ruijie(config-route-map)match ip address 1
Ruijie(config-route-map)set fast-reroute backup-nexthop GigabitEthernet 0/1 192.168.1.1
```

# Configure a static route and a fast reroute

```
Ruijie(config)ip fast-reroute route-map frr
Ruijie(config)ip route 1.1.1.1 255.255.255.255 192.168.3.1
```

Configuring Policy-based Routing

Understanding Policy-based Routing

Overview

Policy-based Routing offers a more flexible packet routing forwarding mechanism than destination address-based routing forwarding, which enables you to route IPv4/IPv6 packets by elements like source address, destination address, port number and packet length.

In general, user networks apply different bandwidths from different ISPs. Meanwhile, to ensure resources for important users in the same user environment, the system needs to selectively forward packets rather than forwarding packets by the general routing table. In this case, policy-based routing takes full advantages of ISP resources and satisfy these flexible and diversified applications.

IP/IPv6 policy-based routing takes effect only on the packets received on interfaces, without any control on the packets sent from interfaces. Applying policy-based routing on an interface will check all the packets received on the interface. The packets not matching any policy of the routing map are forwarded by the general routing table, but the ones matching some policy of the routing map are forwarded by the policy.

Generally, policy-based routing takes preference over general routing and forwards IP/IPv6 packets in accord with defined policies. In other words, packets are forwarded by IP/IPv6 policy-based routing. If no rule of the PBR is matched, the packets are forwarded by general routings. Certainly, users can configure policy-based routing with the priority lower than general routing. Namely, the packets received on an interface are forwarded by general routing or policy-based routing in cast of no matching.

Users can configure forwarding mode like load balance or redundant backup according to real circumstances. Load balance or redundant backup is enabled on more than one next hop. The proportion of load balance can be also set. In redundant backup mode, multiple next hops are applied, that is the previous next hop has priority to take effect and the latter one takes effect only when the previous one fails. You can configure multiple next hops at the same time.

Policy-based routing falls into two types:

Policy-based routing enabled for the IP packets received on an interface. It performs PBR only on packets received on the interface instead of controlling the packets sending from the interface.

Policy-based routing enabled for the IP packets that the local device sends out. It controls IP packets sent from the local device to other devices, not the packets sent from external devices to the local device.

Basic Concepts and Features

Application Process

To use the policy-based routing, you must create a routing map for it and then apply the routing map on the interface. A routing map consists of many policies with corresponding sequence. Smaller sequence means higher priority.

Each policy consists of one or more match statements and corresponding one or more set statements. The match statement defines the matching rule of IP/IPv6 packets, and the set statement defines the processing rules of matched

IP/IPv6 packets. In the course of policy-based routing, packets are matched by priorities in descending order. Once a policy is matched, the system performs corresponding actions and quits policy-based routing.

Policy-based routing for IPv4 packets uses standard or extended ACL as matching rule. Policy-based routing for IPv6 packets, however, uses extended ACL as matching rule. For IPv6 packets, only one match ipv6 address can be configured for a policy at most.

Routing Map Policy Matching Mode

When you configure the routing map, you can specify the match mode of a policy as permit or deny, which is described as below:

- Permit: Specify the matching mode as permit, that is to apply the corresponding set rule to the IPv4/v6 packets meeting the match rules of the policy. If no match rule is met, the system applies the next policy to packets.
- Deny: Specify the matching mode as deny, that is if IPv4/v6 packets meet all match statements; the system performs common routing rather than policy-based routing.

IP/IPv6 packets are matched by the priority of every policy of the routing map in descending order. Once a policy is matched, the system performs corresponding actions and quits policy-based routing. If the packets do not match any policy of the routing map, the system performs common routing.

Next Hop Rules

Policy-based routing offers two forwarding rules-set {ip | ipv6} next-hop and set {ip | ipv6} default next-hop, which set the next hop and the egress, respectively. These two rules are described as follows:

- set {ip | ipv6} next-hop: Configure the policy-based routing’s next hop IPv4/IPv6 address, which takes precedence over common routes. The IPv4/v6 packets meeting the match rule received on the interface are first forwarded to the next hop specified by the set {ip | ipv6} next-hop command, no matter whether the real routing of the packets in the routing table and the next hop specified by the policy-based route is valid or not.
- set {ip | ipv6} default next-hop: The policy-based routing specified by this command is of the priority lower than common routes but higher than default route. For the packets meeting the match rule received on the interface, if routing in the routing table is failed or the default route is used, these packets will be forwarded to the next hop specified by this command.

The next hops specified by these two rules must be direct or otherwise the configuration does not take effect.

The priority is subject to the order of set {ip | ipv6} next-hop > network route/host route > set {ip | ipv6} default next-hop > default route. These two commands can be configured simultaneously, but only the one of higher priority takes effect.

Load Balancing Mode for Policy-based Routing Next Hop

More than one next hop can be configured in the sequence of a route map, and one of the following load balancing modes can be configured among them.

- Redundant backup: Only one next hop takes effect at a time if there are many next hops. Once the active next hop failed, another next hop will take over its works immediately.
  - When R1 of the active next hop fails, the system automatically hands over to R2 of the next next hop. When R1 recovers, the system will automatically hand over back to R1.
  - When there are many next hops in the order, for example, R1/R2/R3, R2 takes effect after you deleting and then adding R1 in the order of R2/R3/R1.

- Load balancing: Load balancing is enabled among next hops by traffic. This function is not available for the next hop in egress type.

Caution

1 Only one route map can be configured on a port. Configuring route maps repeatedly on a port will overlap the previous configurations, namely that the latest configuration takes effect.

Caution

2 Only one IPv6 ACL can be configured in the sequence of a route map in sub route map.

Caution

3 If the sub route map is configured with next hop but not ACL, all packets are matched; if the sub route map is configured with ACL but not next hop, the matched packets are forwarding by common routes; if the sub route map is not configured with ACL and next hop, all packets are forwarded by common routes.

Caution

4 The deny rule of ACE forwards packets by common routes. To meet the matching rule of policy-based routing, the deny any any command matches packets starting from the next IPv6 ACL

Caution

5 Enabling PBR will apply to incoming packets at the same time. If you do not need to apply PBR to a specific incoming IPv4/v6 packet, add “deny the specific IPv4/v6 address” in the ACL manually

Caution

6.In redundant backup mode, the IP packets matching the policy of the sub route map are forwarded to the next hop firstly resolved in the sequence. If all next hops are not resolved, the IP packets matching the policy are discarded. If the first next hop is resolved later, the IP packets matching the policy are forwarded to the first next hop.

Note

For details on the next hop of PBR set actions, refer to Rns&track Configuration Guide and Rns&track Command Reference or Link Detection Configuration Guide and DLDP Command Reference (for routers). IPv6 PBR is not supported at present

Note

For linkup of PBR and BFD, refer to BFD Configuration Guide and BFD Command Reference

Enabling Track Function

Track function can increase the insight of policy-based routing in the change of networks. When the device perceives that the next hop for forwarding failed, policy-based routing will rapidly hand the traffic over to the next valid next hop (in redundant backup mode) or all other valid next hops (in load balancing mode).

For track configuration, refer to Rns&track Configuration Guide. IPv6 PBR does not support linkup with track.

Enabling BFD Function

Linkup between policy-based routing and BFD avoids setting the policy-based routing as forwarding path when it is not reachable. If the backup forwarding path is available, the system rapidly hands over to this path.

VRF Selection Using Policy-based Routing

The PBR implementation of the VRF selection feature allows the ports that apply PBR to filter the packets based on the matching rule. If the packet matches this rule, route selection is performed in the specified VRF. Matching rule is defined in an IP access list or based on packet length. Users can balance traffic on different VRF instances as required.

In general, the packets received on an interface of a VRF are routed and forwarded through this VRF. The packets received on an interface of the global routing table are routed and forward through the global routing table. VRF selection using policy based routing can remove this limit. This feature supports VRF successor route, the route across VRFs and the route from VRF to the global routing table. In VRF successor route mode, the packets received on an interface of a VRF are routed and forwarded by the routing table of this VRF. In route across VRFs mode, the packets received on an interface of a VRF are routed and forwarded by the routing table of another specified VRF. In route from VRF to the global routing table mode, the packets received on an interface of a VRF are routed and forwarded by the global routing table.

Version 10.4(3) introduces multi-protocol VRF, which supports VRF selection using IPv6 PBR. If a single-protocol IPv4 VRF is specified, it does not take effect on IPv6 PBR. When a multi-protocol VRF is specified, if it does not configure the IPv4 address family, the multi-protocol VRF does not take effect on IPv4 PBR. Similarly, if the multi-protocol VRF does not configure the IPv6 address family, it does not take effect on IPv6 PBR. If the multi-protocol VRF configures IPv4 and IPv6 address families concurrently, the rules of the set vrf command take effect on both IPv4 and IPv6 PBRs.

Working Principles

For policy-based routing, first of all, you need to define a route map used to specify the policy of packet forwarding. The route map consists of a set of statements with permit or deny action.

Secondly, define a set of set statements in the route map to forward and control packets in order. Each statement does not refer to the previous or latter statements.

Finally, apply the policy-based routing at the inbound direction. If the policy-based routing is applied at the outbound direction, packets are forwarded by common routes.

For routers, outgoing packets can be processed by the specific policy-based routing, not the common routing table.

Protocol Specifications

None

Default Configurations

The default configurations of policy-based routing are described as follows:

Function	Default value
Load balance of many next hops	Redundance (redundant backup mode)
Next hop WCMP weight	1

Configuring Policy-based Routing

The following sections configure the basic functions of IP/IPV6 PBR.

Configuring IPv4 Policy-based Routing

You must specify a route map for the policy-based routing and create the route map before applying the policy-based routing. A route map consists of many policies with corresponding sequences. The smaller the sequence, the higher the priority is. Each policy consists of one or more match statements and corresponding one or more set statements. The match statement defines the matching rule of IPv4/IPv6 packets, and the set statement defines the processing rules of matched IPv4/IPv6 packets. In the course of policy-based routing, packets are matched by priorities in descending order. Once a policy is matched, the system performs corresponding actions and quits policy-based routing.

There are two kinds of match statements; match length and match ip address. The former statement matches packets by packet length and the latter matches packets by ACL. For a policy, you can configure only one match length statement but many match ip address statements. If both statements are configured at the same time, the action specified by the set rule of the policy is executed only when the packets match both.

Similarly, there are two types of set statements. Type 1 modifies the QoS field of IP packet, including set ip tos, set ip precedence and set ip dscp. Type 2 controls IP packet, for example, set vrf, set ip nexthop, set ip default nexthop, set interface and set default interface. Once all match rules are met, Type 1 set statements must be executed and Type 2 set statements are executed by priority in the following order:

- set vrf: Set policy-based routing as the VRF instance for IP packet routing with the priority higher than common route. The command is mutually exclusive with the set ip [default] nexthop and set [default]interface command. The IPv4 packets received on the interface that meet match rules will be routed by the routing table of the VRF instance specified by this command, no matter whether the VRF is the same as the one the interface belongs to.
- set ip nexthop: Set next hop of policy-based routing with the priority higher than common route and the one set by the set interface command. This command takes precedence over one of the following three commands. The IPv4 packets received on the interface that meet match rules will be firstly forwarded to the next hop specified by the set ip nexthop command, no matter whether the real routing of IPv4 packets in the routing table is the same as the one specified by the policy-based routing.
- set interface: Set the egress of policy-based routing with the priority higher than common route. This command takes precedence over set default interface and set ip default nexthop. The IPv4 packets received on the interface that meet match rules will be firstly forwarded through the egress specified by the set interface command, no matter whether the real routing of IPv4 packets in the routing table is the same as the egress specified by the policy-based routing.
- set default interface: Set the default interface with the priority higher than default route and the one specified by the set ip default nexthop command but lower than common route. The IPv4 packets received on the interface that meet match rules will be forwarded through the interface specified by this command in case of routing failure or the default route is used.
- set ip default nexthop: Set the policy-based routing with the priority higher than the default route but lower than common route. The IPv4 packets received on the interface that meet match rules will be forwarded to the next hop specified by this command in case of routing failure or the default route is used.

When you configure the routing map, you can specify the match mode of a policy as permit or deny, which is described as below:

- Permit: Specify the matching mode as permit, that is to apply the corresponding set rule to the IPv4/v6 packets meeting all match rules of the policy. If not all match rules are met, the system applies the next policy of the routing map to match packets.
- Deny: Specify the matching mode as permit, that is if IPv4/v6 packets meet all match statements of this packet's node, the system performs common routing rather than policy-based routing.

IPv4/IPv6 packets are matched by the priority of every policy of the routing map in descending order. Once a policy is matched, the system performs corresponding actions and quits policy-based routing. If the packets do not match any policy of the routing map, the system performs common routing.

The next hop specified by the set ip nexthop command is used for forwarding only when its tracking object is active. Track function greatly increases the insight of policy-based routing in the change of network environments, enabling PBR to adapt to dynamic changed networking topologies.

To configure a policy-based routing, perform the following steps:

1 Define an ACL as the matching rule of IP packets.

Command	**Function**
Ruijie(config)# ip access-list {extended | standard} {id | name}	Defines an ACL as the matching rule of IP packets.

2 Define a route map, which consists of many policies in sequence order. When a policy is matched, the system quits the execution of the route map.

Use the following command in global configuration mode to define a route map.

Command	**Function**
Ruijie(config)# route-map route-map-name [permit | deny] sequence	Defines a route map.
Ruijie(config)# no route-map route-map-name {[permit | deny] sequence}	Deletes a route map.

3 Define the match rule of every policy of the route map.

Use the following command in route map configuration mode to define the match rule of a policy.

Command	**Function**
Ruijie(config-route-map)# match ip address {access-list-number | access-list-name}	Matches the address in the ACL.
Or : Ruijie(config-route-map)# match length min max	Matches packet length.

4 Define the action after meeting match rule.

Use the following command in route map configuration mode to define actions after rules are matched.

Command	**Function**

Ruijie(config-route-map)# set vrf name	Routes the packets matching PBR by the routing table of the specific VRF instance.
Ruijie(config-route-map)# set ip next-hop ip-address [weight][ip-address[weight]]	Sets the next hop IP address of packets.
Ruijie(config-route-map)# set interface intf_name	Sets the egress of packets.
Ruijie(config-route-map)# set ip default next-hop ip-address[weight] [ip-address[weight]]	Sets the next hop IP address for the packets without route.
Ruijie(config-route-map)# set default interface intf_name	Sets the default egress of IP packets.
Ruijie(config-route-map)# set ip precedence	Modifies the priority of IP packet.
Ruijie(config-route-map)# set ip tos	Modifies the ToS value of IP packet.
Ruijie(config-route-map)# set ip dscp	Modifies the DSCP value of IP packet.

Caution

The set vrf, set ip [default] nexthop and set [default] interface commands cannot be configured concurrently for a policy. But the set vrf command can be configured with other set statements. The VRF must exist when you configure the VRF of policy-based routing otherwise the system prompts configuration failure.

Caution

The set ip dscp, set ip tos and set ip precedence commands cannot be configured concurrently for a policy or otherwise the corresponding domains of IP packet may be different from the expectation

Caution

The priorities of the set vrf, set ip nexthop, and set interface commands take precedence over that of common routes. IP packets matching policy-based routing are forwarded by policy-based routing, but the IP packets not matching the policy-based routing are forwarded by common routes.

Caution

The set default ip nexthop and set default interface commands are lower than common route in terms of priority. IP packets are routed and forwarded by policy-based routing only after common route failed

For details on route map configuration, refer to Protocol-independent Configuration Commands.

1 Apply the route map on the specified interface.

Use the following command in interface configuration mode to apply the policy-based routing on the specified interface.

Command	Function
Ruijie(config-if)# ip policy route-map name	Applies policy-based routing on the interface.
Ruijie(config-if)# no ip policy route-map	Removes the configuration.

2. Apply the policy-based routing to the packets sent locally.

Command	Function
Ruijie(config)# ip local policy route-map [name]	Applies the policy-based routing to the packets sent locally.
Ruijie(config)# no ip local policy route-map	Removes the configuration.

For example:

Configure policy-based routing on Fastethernet 0/0 so that all incoming packets are forwarded to the device whose next hop is 192.168.5.5.

```
Ruijie(config)# access-list 1 permit any
Ruijie(config)# route-map name
Ruijie(config-route-map)# match ip address 1
Ruijie(config-route-map)# set ip next-hop 192.168.5.5
Ruijie(config-route-map)# int fastethernet 0/0
Ruijie(config-if)# ip policy route-map name
```

3 Configure load balancing mode for policy-based routing

In redundant backup mode, the policy-based routing will automatically hand over the next valid next hop when the active next hop fails. In load balancing mode, on contrary, the traffic will be balanced on other valid next hop when the active next hop fails.

Use the following command in global configuration mode to configure load balance or redundant backup:

Command	**Function**
Ruijie(config)# ip policy {load-balance | redundance}	Configures load balance or redundant backup for policy-based routing forwarding.
Ruijie(config)# no ip policy	Removes the configuration.

Caution

In load balancing mode, Weighted Cost Multiple Path (WCMP) supports up to 4 next hops and Equal Cost Multiple Path (ECMP) supports up to 32 next hops.

Caution

In load balancing mode, Weighted Cost Multiple Path (WCMP) supports up to 4 next hops and Equal Cost Multiple Path (ECMP) supports up to 32 next hops.

Caution

For default policy-based routing, Weighted Cost Multiple Path (WCMP) supports up to 4 next hops and Equal Cost Multiple Path (ECMP) supports up to 32 next hops.

Caution

In redundant backup mode, the first resolved next hop takes effect. If all next hops are not resolved, the packets matching policy-based routing are dropped. If the originally unresolved next hop of higher priority than active next hop is resolved, the system hands over to this next hop.

Configuring IPv6 Policy-based Routing

Command	Function
Ruijie#configure terminal	Enters global configuration mode.
Ruijie(config)#ipv6 access-list access-list-name	Creates an IPv6 ACL.
Ruijie (config)#route-map route-map-name [permit | deny] sequence	Creates a route map.
Ruijie (config-route-map)#match ipv6 address access-list-name	Matches the IPv6 address in ACL.
Ruijie (config-route-map)#set ipv6 [vrf vrf-name | global] next-hop global-ipv6-address [weight][global-ipv6-address [weight]] [global-ipv6-address...]	Sets the next hop IPv6 address of packets. The [vrf vrf-name | global] parameter is supported since version 10.4(3), that is, cross VRFs and from VRF to global modes are supported. If the vrf vrf-name parameter is specified, the next hop belongs to the VRF, while if the global parameter is specified, the next hop belongs to the global. Note that the specified VRF must be a multi-protocol VRF whose IPv6 address family has been configured. VRF will be inherited when forwarding IPv6 packets if the set ipv6 next-hop command is configured. The next hop belongs to the VRF that receive the IPv6 packets and forward them internally.
Or: Ruijie (config-route-map)#set ipv6 default next-hop global-ipv6-address [weight][global-ipv6-address [weight]] [global-ipv6-address...]	Specifies the next hop IPv6 address for the packets without obvious routes in the routing table.
Ruijie (config)#interface interface-type interface-number	Enters the interface require applying PBR.
Ruijie (config-if- interface-type interface-number)#ipv6 policy route-map route-map-name	Applies policy-based routing on the interface.
Or: Ruijie (config-if- interface-type interface-number)#no pv6 policy route-map	Removes the policy-based routing applied on the interface.
Ruijie#show ipv6 policy	Shows the configuration of policy-based routing.

Or: Ruijie#show route-map	Shows the configuration of route map.

For route map configuration, refer to *Configuring Protocol-independent*.

Configuring Load Balancing Mode

Command	Function
Ruijie#configure terminal	Enters global configuration mode.
Ruijie(config)#Ipv6 policy [load-balance | redundance]	Configures load balance mode.
Ruijie(config)#no Ipv6 policy	Restores the setting to the default value.

Displaying Configuration and States

Command	Function
Ruijie#**show** { **ip** | **ipv6** } **policy**	Shows the configuration of policy-based routing.
Ruijie#**show route-map**	Shows the configuration of route map.
Ruijie#**show access-lists**	Shows the configuration of ACL.

Typical Configuration Examples

Example 1: Source address based PBR

Networking Requirements

There are two egresses of a LAN connecting to the Internet. In general, load balance and backup should be enabled for these two egresses. All streams from subnet 1 to the Internet are transmitted through GigabitEthernet 0/1 and all streams from subnet 2 to the Internet are transmitted through GigabitEthernet 0/2. If GigabitEthernet 0/1 is disconnected, the data streams on this interface should be transferred to GigabitEthernet 0/2, and vice versa.

Networking Topology

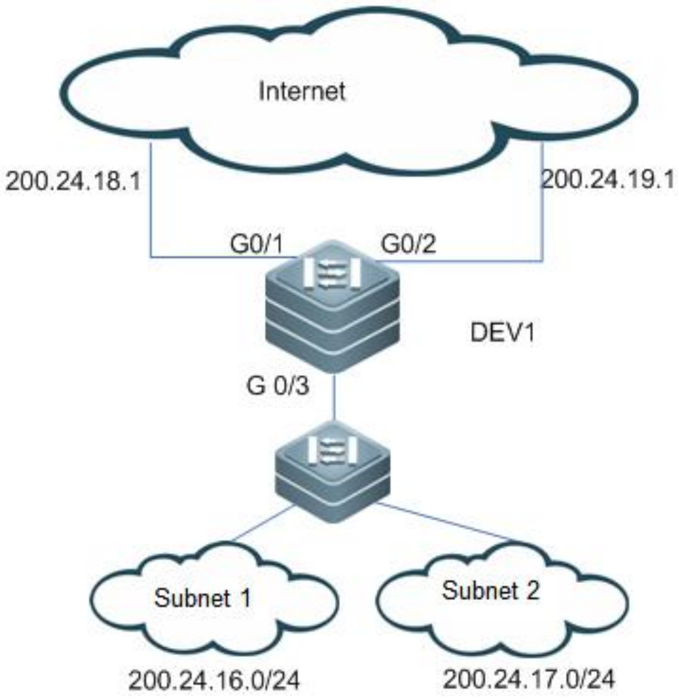


Figure 1 Network topology

As shown in the Figure-1, Layer-3 device DEV1 connects to subnets 1 and 2 through G0/3, and connects to the Internet through G0/1 and G0/2 with the next hop of 200.24.18.1 and 200.24.19.1, respectively. Subnet 1's segment is 200.24.16.0/24 and subnet 2's segment is 200.24.17.0/24.

Configuration Steps

# Create ACLs for subnet 1 and subnet 2, respectively.

```
Ruijie(config)#access-list 1 permit 200.24.16.0 0.0.0.255
Ruijie(config)#access-list 2 permit 200.24.17.0 0.0.0.255
```

# Configure a route map used to control data streams of subnet 1. Set the next hop of G0/1 prefer.

```
Ruijie(config)#route-map RM_FOR_PBR 10
Ruijie(config-route-map)#match ip address 1
Ruijie(config-route-map)#set ip nexthop 200.24.18.1
Ruijie(config-route-map)#set ip nexthop 200.24.19.1
```

# Configure a route map used to control data streams of subnet 2. Set the next hop of G0/2 prefer.

```
Ruijie(config)#route-map RM_FOR_PBR 20
Ruijie(config-route-map)#match ip address 2
Ruijie(config-route-map)#set ip nexthop 200.24.19.1
Ruijie(config-route-map)#set ip nexthop 200.24.18.1
```

# Configure redundant backup.

```
Ruijie(config)#ip policy redundance
```

# Apply policy-based routing on GigabitEthernet 0/3.

```
Ruijie(config)#interface GigabitEthernet 0/3
Ruijie(config-if)#ip policy route-map RM_FOR_PBR
```

Example 2: Enabling Track function.

Networking Requirements

There are two egresses on a LAN connecting to the Internet. In general, load balance and backup should be enabled for these two egresses. All streams from subnet 1 to the Internet are transmitted through GigabitEthernet 0/1 and all streams from subnet 2 to the Internet are transmitted through GigabitEthernet 0/2. If the next hop 200.24.18.1 fails, the data streams on this interface should be transferred to GigabitEthernet 0/2, and vice versa.

Networking Topology

As shown in Figure 1.

Configuration steps

# Track the egress GigabitEthernet 0/1’s next hop 200.24.18.1.

```
Ruijie(config)#ip rns 1
Ruijie(config-ip-rns)#icmp-echo 200.24.18.1
Ruijie(config)#track 1 rns 1
```

# Track the egress GigabitEthernet 0/2’s next hop 200.24.19.1.

```
Ruijie(config)#ip rns 2
Ruijie(config-ip-rns)#icmp-echo 200.24.19.1
Ruijie(config)#track 2 rns 2
```

# Enable the routing map to use this track object..

```
Ruijie(config)#route-map RM_FOR_PBR 10
Ruijie(config-route-map)#match ip address 1
Ruijie(config-route-map)#set ip nexthop verify-availability 200.24.18.1 track 1
Ruijie(config-route-map)#set ip nexthop verify-availability 200.24.19.1 track 2
```

# Configure a route map used to control data streams of subnet 2. Set the next hop of G0/2 prefer.

```
Ruijie(config)#route-map RM_FOR_PBR 20
Ruijie(config-route-map)#match ip address 1
Ruijie(config-route-map)#set ip nexthop verify-availability 200.24.19.1 track 2
Ruijie(config-route-map)#set ip nexthop verify-availability 200.24.18.1 track 1
```

# Configure redundant backup.

```
Ruijie(config)#ip policy redundance
```

# Apply policy-based routing on GigabitEthernet 0/3.

```
Ruijie(config)#interface GigabitEthernet 0/3
Ruijie(config-if)#ip policy route-map RM_FOR_PBR
```

Example 3: Configuring VRF Selection Using PBR

Networking Requirements

A provider edge (PE) requires applying policy-based routing to the packets received from FastEthernet 0/1. It routes the IP packets from subnet 1 by VRF1, the IP packets from subnet 2 by VRF2, and the IP packets from subnet 3 by VRF3. Other packets are routed in the public network.

Configuration Steps

# Create VRF instances.

```
Ruijie(config)#ip vrf VRF1
Ruijie(config)#ip vrf VRF2
Ruijie(config)#ip vrf VRF3
```

# Create ACLs as matching rules of the routing map.

```
Ruijie(config)#access-list 1 permit 192.168.195.0 0.0.0.255
Ruijie(config)#access-list 2 permit 192.168.196.0 0.0.0.255
Ruijie(config)#access-list 3 permit 192.168.197.0 0.0.0.255
```

# Create route maps.

```
Ruijie(config)#route-map PBR-VRF-Selection permit 10
Ruijie(config-route-map)#match ip address 1
Ruijie(config-route-map)#set vrf VRF1

Ruijie(config)#route-map PBR-VRF-Selection permit 20
Ruijie(config-route-map)#match ip address 2
Ruijie(config-route-map)#set vrf VRF2

Ruijie(config)#route-map PBR-VRF-Selection permit 30
Ruijie(config-route-map)#match ip address 3
Ruijie(config-route-map)#set vrf VRF3
```

# Import IP address of the interface to VRFs 1 to 3.

```
Ruijie(config)#interface FastEthernet 0/1
Ruijie(config-if)#ip address 192.168.195.1 255.255.255.0
Ruijie(config-if)#ip vrf receive VRF1
Ruijie(config-if)#ip vrf receive VRF2
Ruijie(config-if)#ip vrf receive VRF3
```

# Apply the policy-based routing on the interface.

```
Ruijie(config)#interface FastEthernet 0/1
Ruijie(config-if)#ip policy route-map PBR-VRF-Selection
```

The configurations are as follows if the single protocol IPv4 VRF is replaced with a multi-protocol VRF:

# Create a VRF instance.

```
Ruijie(config)#vrf definition VRF1
Ruijie(config-vrf)#address-family ipv4
Ruijie(config-vrf-af)#exit-address-family
Ruijie(config-vrf)#vrf definition VRF2
Ruijie(config-vrf)#address-family ipv4
Ruijie(config-vrf-af)#exit-address-family
Ruijie(config-vrf)#vrf definition VRF3
Ruijie(config-vrf)#address-family ipv4
Ruijie(config-vrf-af)#exit-address-family
Ruijie(config-vrf)#exit
```

# Configure an ACL as the matching rule of the routing map.

```
Ruijie(config)#access-list 1 permit 192.168.195.0 0.0.0.255
Ruijie(config)#access-list 2 permit 192.168.196.0 0.0.0.255
Ruijie(config)#access-list 3 permit 192.168.197.0 0.0.0.255
```

# Configure the routing map.

```
Ruijie(config)#route-map PBR-VRF-Selection permit 10
Ruijie(config-route-map)#match ip address 1
Ruijie(config-route-map)#set vrf VRF1

Ruijie(config)#route-map PBR-VRF-Selection permit 20
Ruijie(config-route-map)#match ip address 2
Ruijie(config-route-map)#set vrf VRF2

Ruijie(config)#route-map PBR-VRF-Selection permit 30
Ruijie(config-route-map)#match ip address 3
Ruijie(config-route-map)#set vrf VRF3
```

# Import IP address of the interface to VRFs 1 to 3.

```
Ruijie(config)#interface FastEthernet 0/1
Ruijie(config-if)#ip address 192.168.195.1 255.255.255.0
Ruijie(config-if)#vrf receive VRF1
Ruijie(config-if)#vrf receive VRF2
Ruijie(config-if)#vrf receive VRF3
```

# Apply the policy-based routing to the interface.

```
Ruijie(config)#interface FastEthernet 0/1
Ruijie(config-if)#ip policy route-map PBR-VRF-Selection
```

Example 4: Appling IPv6 Policy-based Routing on the Interface

Networking Requirements

There are two egresses on a LAN connecting to the Internet. In general, load balance and backup should be enabled for these two egresses.

Specific requirements are as follows:

- All streams from subnet 1 to the Internet are transmitted through GigabitEthernet 0/1.
- All streams from subnet 2 to the Internet are transmitted through GigabitEthernet 0/2.
- If GigabitEthernet 0/1 is disconnected, the data streams on this interface should be transferred to GigabitEthernet 0/2, and vice versa.

Networking Topology

As shown in Figure 2, Lay-3 device Device1 connects to subnets 1 and 2 through G0/3 (routed port), and connects to the Internet through G0/1 and G0/2 with the next hop of 2001::1/64 and 2002::1/64 respectively. Subnet 1's segment is 2003::/64 and subnet 2's segment is 2004::/64.

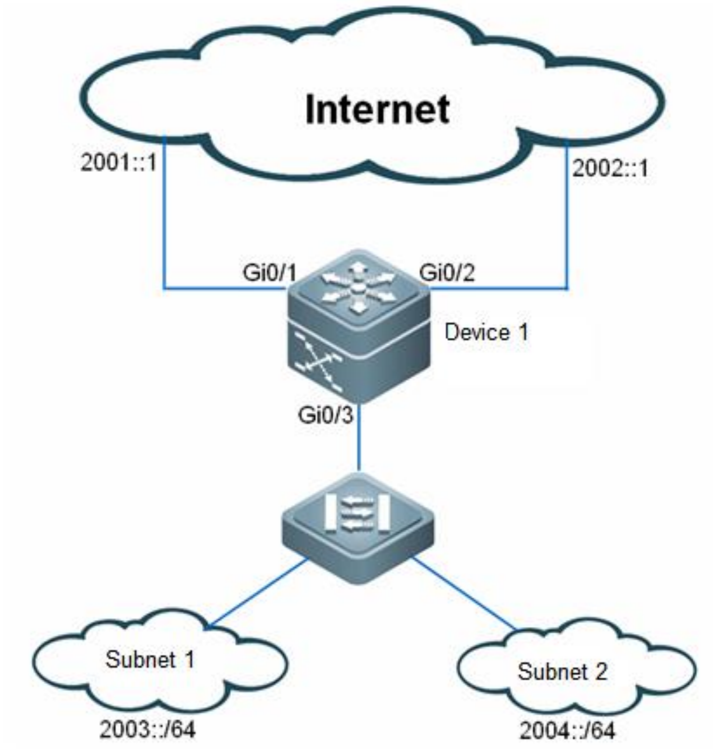

Figure 2 IPV6 PBR topology

Configuration Tips

Configuration Steps

# Create ACLs for subnet 1 and subnet 2 respectively.

```
Ruijie(config)#ipv6 access-list net1
Ruijie(config-ipv6-acl)#permit ipv6 2003::/64 any
Ruijie(config)#ipv6 access-list net2
Ruijie(config-ipv6-acl)#permit ipv6 2004::/64 any
```

# Configure a route map used to control data streams of subnet 1. Set the next hop of G0/1 prefer.

```
Ruijie(config)#route-map RM_FOR_PBR 10
Ruijie(config-route-map)#match ipv6 address net1
Ruijie(config-route-map)#set ipv6 next-hop 2001::1
Ruijie(config-route-map)#set ipv6 next-hop 2002::1
```

# Configure a route map used to control data streams of subnet 2. Set the next hop of G0/2 prefer.

```
Ruijie(config)#route-map RM_FOR_PBR 20
Ruijie(config-route-map)#match ipv6 address net2
Ruijie(config-route-map)#set ipv6 next-hop 2002::1
Ruijie(config-route-map)#set ipv6 next-hop 2001::1
```

# Configure redundant backup.

```
Ruijie(config)#ipv6 policy redundance
```

# Apply the policy-based routing on the interface GigabitEthernet 0/3.

```
Ruijie(config)#interface GigabitEthernet 0/3
Ruijie(config-if-GigabitEthernet 0/3)#ipv6 policy route-map RM_FOR_PBR
```

Verification

# Show the configuration of route map.

```
Ruijie#show route-map
route-map RM_FOR_PBR, permit, sequence 10
  Match clauses:
   ipv6 address net1
  Set clauses:
   ipv6 next-hop 2001::1 2002::1
route-map RM_FOR_PBR, permit, sequence 20
  Match clauses:
   ipv6 address net2
  Set clauses:
ipv6 next-hop 2002::1 2001::1
```

# Show the configuration of IPv6 policy-based routing.

```
Ruijie#show ipv6 policy
Interface                          Route map
GigabitEthernet 0/3                 RM_FOR_PBR
```

# Show the configuration of ACL.

```
Ruijie#show access-lists
ipv6 access-list net1
 10 permit ipv6 2003::/64 any
 (0 packets matched)
ipv6 access-list net2
 10 permit ipv6 2004::/64 any
 (0 packets matched)
```

Example 5: Configuring IPv4/IPv6 PBRs Concurrently

Networking Requirements

There are two egresses on a LAN connecting to the Internet, one of which is the egress of education network. In general, load balance and backup should be enabled for these two egresses.

Specific requirements are as follows:

- IPv4/IPv6 dual stacks are used in the networks. IPv4 and IPv6 PBRs should be enabled on an interface at the same time.
- All streams from the IPv4 education network of subnet 1 to the Internet are transmitted through the egress of education network.
- All streams from the IPv4 education network of subnet 2 to the Internet are transmitted through the egress of the Internet.
- All streams from the IPv6 education network of subnet 1 to the Internet are transmitted through GigabitEthernet 0/1.
- All streams from the IPv6 education network of subnet 2 to the Internet are transmitted through GigabitEthernet 0/2.
- Internal interactive data, for example, the data from subnet 1 to subnet 2, is transmitted using the internal dynamic route rather than policy-based routing.
- By default, data streams are transmitted through the egress of the Internet by the default route.
- If GigabitEthernet 0/1 fails, the data streams on the interface are switched over to GigabitEthernet 0/2, and vice versa.

Networking Topology

As shown in Figure 3, Device 1 connects to subnets 1 and 2 through G0/3 (routed port), and connects to the Internet through G0/1 and G0/2 with the next hop of 2001::1/64 (210.82.12.1) and 2002::1/64 (59.78.184.1) respectively. Subnet 1’s segment is 2003::/64 (202.112.144.0/25) and subnet 2’s segment is 2004::/64(218.62.95.0/24).

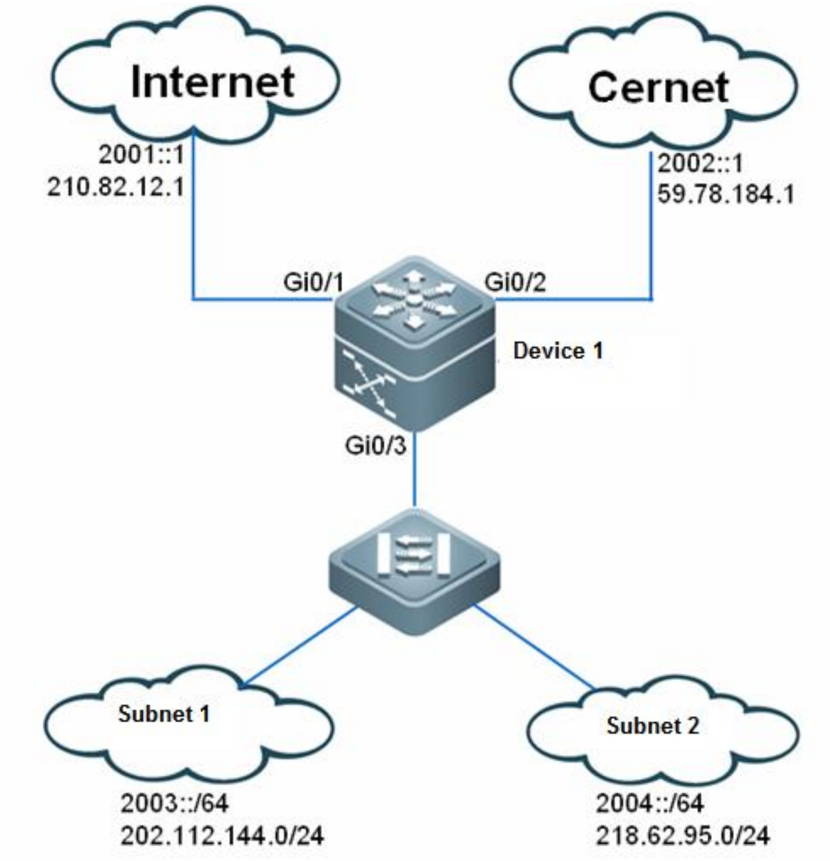

Figure 3 IPv4/IPv6 PBR topology

Configuration Tips

Configuration Steps

# Create IPv4 ACLs for subnet 1 and subnet 2, respectively.

```
Ruijie(config)#ip access-list extended 101
Ruijie(config-ip-acl)#permit ip 202.112.144.0 0.0.0.255 any
Ruijie(config)#ip access-list extended 102
Ruijie(config-ip-acl)#permit ip 218.62.95.0 0.0.0.255 any
```

# Create IPv6 ACLs for subnet 1 and subnet 2, respectively.

```
Ruijie(config)#ipv6 access-list net1
Ruijie(config-ipv6-acl)#permit ipv6 2003::/64 any
Ruijie(config)#ipv6 access-list net2
Ruijie(config-ipv6-acl)#permit ipv6 2004::/64 any
```

# Configure a route map used to control data streams of subnet 1. Set the next hop of G0/1 prefer. The default parameter is included in attributes of the IPv4 next hop.

```
Ruijie(config)#route-map RM_FOR_PBR 10
Ruijie(config-route-map)#match ip address 101
Ruijie(config-route-map)#set ip default next-hop 59.78.184.1
Ruijie(config-route-map)#set ip default next-hop 210.82.12.1

Ruijie(config-route-map)#match ipv6 address net1
Ruijie(config-route-map)#set ipv6 next-hop 2001::1
Ruijie(config-route-map)#set ipv6 next-hop 2002::1
```

# Configure a route map used to control data streams of subnet 2. Set the next hop of G0/2 prefer. The default parameter is included in attributes of the IPv4 next hop.

```
Ruijie(config)#route-map RM_FOR_PBR 20
Ruijie(config-route-map)#match ip address 102
Ruijie(config-route-map)#set ip default next-hop 210.82.12.1
Ruijie(config-route-map)#set ip default next-hop 59.78.184.1

Ruijie(config)#route-map RM_FOR_PBR 20
Ruijie(config-route-map)#match ipv6 address net2
Ruijie(config-route-map)#set ipv6 next-hop 2002::1
Ruijie(config-route-map)#set ipv6 next-hop 2001::1
```

# Configure redundant backup.

```
Ruijie(config)#ipv6 policy redundance
```

# Apply the IPv4/IPv6 policy-based routing on the interface GigabitEthernet 0/3.

```
Ruijie(config)#interface GigabitEthernet 0/3
Ruijie(config-if-GigabitEthernet 0/3)#ip policy route-map RM_FOR_PBR
Ruijie(config-if-GigabitEthernet 0/3)#ipv6 policy route-map RM_FOR_PBR
```

Verification

# Show the configuration of the route map.

```
Ruijie#show route-map
route-map RM_FOR_PBR, permit, sequence 10
  Match clauses:
    ip address 101
    ipv6 address net1
  Set clauses:
    ipv6 next-hop 2001::1 2002::1
    ip default next-hop 59.78.184.1 210.82.12.1
route-map RM_FOR_PBR, permit, sequence 20
  Match clauses:
    ip address  102
    ipv6 address net2
  Set clauses:
    ipv6 next-hop 2002::1 2001::1
    ip default next-hop 210.82.12.1 59.78.184.1

Example 6: VRF Election Using IPv6 PBR

Networking Requirements

A provider edge (PE) requires applying policy-based routing to the packets received from FastEthernet 0/1. It routes the IP packets from subnet 1 by VRF1, the IP packets from subnet 2 by VRF2, and the IP packets from subnet 3 by VRF3. Other packets are routed in the public network.

Configuration Steps

# Create a VRF instance.

```
Ruijie(config)#vrf definition VRF1
Ruijie(config-vrf)#address-family ipv6
Ruijie(config-vrf-af)#exit-address-family
Ruijie(config-vrf)#vrf definition VRF2
Ruijie(config-vrf)#address-family ipv6
Ruijie(config-vrf-af)#exit-address-family
Ruijie(config-vrf)#vrf definition VRF3
Ruijie(config-vrf)#address-family ipv6
Ruijie(config-vrf-af)#exit-address-family
Ruijie(config-vrf)#exit
```

# Configure an ACL as the matching rule of the routing map.

```
Ruijie(config)#ipv6 access-list acl1
Ruijie(config-ipv6-acl)#permit ipv6 1000::/64 any
Ruijie(config-ipv6-acl)#ipv6 access-list acl2
Ruijie(config-ipv6-acl)#permit ipv6 2000::/64 any
Ruijie(config-ipv6-acl)#ipv6 access-list acl3
Ruijie(config-ipv6-acl)#permit ipv6 3000::/64 any
```

# Configure the routing map.

```
Ruijie(config-ipv6-acl)#route-map PBR-VRF-Selection permit 10
Ruijie(config-route-map)#match ipv6 address acl1
Ruijie(config-route-map)#set vrf VRF1

Ruijie(config)#route-map PBR-VRF-Selection permit 20
Ruijie(config-route-map)#match ipv6 address acl2
Ruijie(config-route-map)#set vrf VRF2
Ruijie(config)#route-map PBR-VRF-Selection permit 30
Ruijie(config-route-map)#match ipv6 address acl3
Ruijie(config-route-map)#set vrf VRF3
```

# Import IPv6 address of the interface to VRFs 1 to 3.

```
Ruijie(config)#interface FastEthernet 0/1
Ruijie(config-if)#ipv6 address 1000::1/64
Ruijie(config-if)#vrf receive VRF1
Ruijie(config-if)#vrf receive VRF2
Ruijie(config-if)#vrf receive VRF3
```

# Apply the IPv6 PBR to the interface.

```
Ruijie(config)#interface FastEthernet 0/1
Ruijie(config-if)#ipv6 policy route-map PBR-VRF-Selection
```

Configuring RIP

Overview

The Routing Information Protocol (RIP) is a relatively old routing protocol, which is widely used in small or homogeneous networks. The RIP uses the distance-vector algorithm, and so is a distance-vector protocol. The RIPv1 is defined in RFC 1058 and the RIPv2 is defined in RFC 2453. Ruijie RGOS supports both two versions.

The RIP exchanges the routing information by using UDP packets with UDP port number 520. Usually, RIPv1 packets are broadcast packets, while RIPv2 packets are multicast packets with the multicast address of 224.0.0.9. The RIP sends an update packet at the interval of 30 seconds. If a device fails to receive the route update packets from the peer within 180 seconds, it will mark all the routes from the device unreachable. After that, the device will delete these routes from its routing table if it still fails to receive any update packets within 120s.

The RIP measures the distance to the destination in hop, known as route metric. In the RIP, zero hop exists when the device directly connects to the network. One hop exists when the destination is reachable through one device and so on. If the destination is unreachable, the hop count is 16.

The RIP-enabled device can learn the default routes from the neighbors or generate its own default route. When any of the following conditions is met, Ruijie products will introduce the default route and advertise it to its neighbor devices by using the **default-information originate** command:

- IP Default-network is configured.
- Other RIPs learn the default routes or are configured with static default routes.

The RIP will send update packets to a specified network interface. If the network is not associated with the RIP routing progress, the interface will not advertise any update packets. The RIP is available in two versions: RIPv1 and RIPv2. The RIPv2 supports plain-text authentication, MD5 cryptographic text authentication, and variable length subnet masks.

Ruijie RIP offers Split Horizon to avoid a loop.

Configuring RIP

The RIP configuration task list contains:

- Create the RIP routing process (mandatory).
- Configure RIP packets in unicast mode (optional).
- Configure Split Horizon (optional).
- Define the RIP Version (optional).
- Configure the Route Aggregation function(optional).
- Configure RIP Authentication.
- Adjust the RIP clock (optional).
- Configure the RIP Route Source Address Validation (optional).
- Control RIP interface status (optional).
- Advertise the default route through the RIP interface (optional).
- Advertise the supernet route through the RIP interface (optional).

- Configure RIP VRF (optional).
- Configure RIP BFD (optional).
- Configure RIP triggered expansion (optional).
- Configure RIP graceful restart (GR) (optional).

For the following topics, see the "IP Routing Protocol Independent Feature Configuration" chapter.

- Filter RIP route information
- Redistribute routes
- Configure default route distribution

The following table describes the default configuration of RIP.

Feature	Default Setting
Network interface	After an interface joins the RIP, it receives RIPv1 and RIPv2 packets and advertises RIPv1 packets by default. By default, when advertising RIPv1 packets: ■ The interface sends the packets in broadcast mode. ■ The interface does not advertise supernet routes. By default, when advertising RIPv2 packets: ■ The interface sends the packets in multicast mode. ■ The interface automatically converges routes into classified routes. ■ The interface advertises supernet routes. The interface enables split horizon.
RIP neighbor	Undefined
Verification of the source IP address of a packet	Enabled
Timer	By default: ■ The update time is 30 seconds. ■ The expiry time is 180 seconds. ■ The clearing time is 120 seconds.
Offset list	Undefined
Automatic convergence	Enabled
Redistribution	By default, routing redistribution is disabled. If it is enabled: ■ Redistribute OSPF, that is, redistribute all sub-type routes of this instance. ■ Redistribute ISIS, that is, redistribute level-2 sub-type routes of this instance. ■ In other cases, redistribute all routes of this type. ■ The metric value for route distribution is the default one.
Default route distribution	By default, default route distribution is disabled. If it is enabled: the metric value for route distribution is the default one.
Default metric	Redistribute metric values used by routes of other protocols. The default value is 1.
Administrative distance	120

Feature	Default Setting
RIP triggered expansion	By default, RIP triggered expansion is disabled. If it is enabled: The default interval is 5 seconds for retransmitting update request and update response packets. By default, a maximum of 36 times are allowed for retransmitting update request and update response packets.
RIP GR	By default, RIP GR is disabled. The default RIP GR period is the smaller value between twice the update time and 60 seconds.

Creating the RIP Routing Process

To run RIP for a device, create the RIP routing process and define networks associated with the RIP routing process.

Use the following commands to create the RIP routing process in global configuration mode.

Command	Function
Ruijie(config)# **router rip**	Creates the RIP routing process.
Ruijie(config-router)# **network** *network-number wildcard*	Defines associated networks.

You can configure the *network-number* and *wildcard* parameters at the same time to enable the network segments of the interface IP address within the IP address range to run RIP.

If the *wildcard* parameter is not configured, by default, RGOS will enable the network segments of the interface IP address within the classified IP address range to run RIP.

Note There are two meanings for associated networks defined by the network command:

Note The RIP only advertises the route information of associated networks.

Note The RIP only advertises and receives route update messages through the interfaces of associated networks.

Configuring RIP Packets in Unicast Mode

The RIP is usually a broadcast or multicast protocol. If the RIP route information needs to be transmitted through non-broadcast networks, a device needs to be configured to support that the RIP advertises route information update packets in unicast mode.

Use the following commands to advertise RIP information update messages in unicast mode in RIP routing process configuration mode.

Command	Function
Ruijie(conf-router)# neighbor ip-address	Configures RIP packet advertising in unicast mode.

This command enables you to control an interface about whether to advertise RIP route update packets and forbid advertising route update packets in broadcast mode through an interface. You need to configure the **passive-interface** command in routing progress configuration mode. For related descriptions on the restriction of route message advertisements, see the "Route Filtering Configuration" of *Configuring Protocol Independent*.

Note

During the configuration of FR and X.25, if the broadcast keyword is specified for IP address mapping, the neighbor command is not required because the command is mainly used for reducing broadcast packets and filtering routes.

Configuring Split Horizon

Split horizon can be used to avoid loop when multiple devices running distance-vectortype routing protocols connect to a network in which IP packets are broadcasted. Split horizon can prevent devices from advertising certain route information through an interface from which the devices learn such information. This optimizes route information exchange among multiple devices.

However, split horizon may cause the failure of some device to learn all the route information in a non-broadcast multi-access network (frame relay or X.25). In this case, you may need to disable split horizon. If an interface is configured with the secondary IP address, you need to pay attention to split horizon.

If the **poisoned-reverse** parameter is configured, split horizon with poisoned reverse is enabled. The device will advertise the route information from the interface where it learns the information, and configure the metric value of the route information as unreachable.

Use the following commands to enable or disable split horizon in interface configuration mode.

Command	Function
Ruijie(config-if)# **no ip split-horizon**	Disables split horizon.
Ruijie(config-if)# **ip split-horizon**	Enables split horizon.

Use the following commands to enable or disable split horizon with poisoned reverse in interface configuration mode.

Command	Function
Ruijie(config-if)# **no ip rip split-horizon poisoned-reverse**	Disable split horizon with poisoned reverse.
Ruijie(config-if)# **ip rip split-horizon poisoned-reverse**	Enable split horizon with poisoned reverse.

By default, all interfaces are configured as enabling split horizon without poisoned reverse.

Defining the RIP Version

Ruijie products support RIP version 1 and version 2, where RIPv2 supports authentication, key management, route convergence, CIDR, and VLSMs. For the information about key management and VLSMs, see the "*IP Routing Protocol Independent Feature Configuration*" chapter.

By default, Ruijie products can receive RIPv1 and RIPv2 packets, but they can send only RIPv1 packets. You can configure them to receive and send only RIPv1 or RIPv2 packets.

Use the following command to enable software to receive and send only the packets of a specific version in routing process configuration mode.

Command	Function
Ruijie(config-router)# **version** {**1** | **2**}	Defines the RIP version.

The above command allows the software to receive or send only the packets of a specific version by default. If necessary, you can modify the default setting of each interface.

Use the following commands to enable an interface to send only the packets of a specific version in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip rip send version 1**	Specifies to send only RIPv1 packets.
Ruijie(config-if)# **ip rip send version 2**	Specifies to send only RIPv2 packets.
Ruijie(config-if)# **ip rip send version 1 2**	Specifies to send only RIPv1 and RIPv2 packets.

Use the following commands to configure an interface to receive only the packets of a specific version in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip rip receive version 1**	Specifies to receive only RIPv1 packets.
Ruijie(config-if)# **ip rip receive version 2**	Specifies to receive only RIPv2 packets.
Ruijie(config-if)# **ip rip receive version 1 2**	Specifies to receive only RIPv1 and RIPv2 packets.

Configuring Route Convergence

Automatic RIP route convergence means that the routes of subnets are automatically converged into the routes of a classful network when they pass through the border of the classful network. By default, RIPv2 will automatically perform route convergence, while the RIPv1 does not support this function.

The automatic route convergence function of the RIPv2 improves the scalability and effectiveness of the network. If there are any converged routes, the sub-routes contained in them cannot be seen in the routing table. This greatly reduces the size of the routing table.

It is more efficient to advertise converged routes than the separated routes. Factors are as follows:

- Converged routes will be handled first when you search the RIP database.
- Any sub-routes will be ignored when you search the RIP database, and thus reducing the handling time.

Sometimes, you want to learn the specific sub-net routes rather than the converged network routes. In this case, you need to disable the automatic route convergence function.

Use the following commands to configure automatic route convergence in RIP routing progress mode.

Command	Function
Ruijie(config-router)# **no auto-summary**	Disables automatic route convergence.
Ruijie(config-router)# **auto-summary**	Enables automatic route convergence.

Use the following commands to configure interface-level convergence in interface mode. Then, configure route convergence within the specified classified subnet range on an interface.

Command	Function

Command	Function
Ruijie(config-if)# **ip summary-address** *rip ip-address ip-network-mask*	Enables route convergence on the interface.
Ruijie(config-if)# **no ip summary-address** *rip ip-address ip-network-mask*	Disables route convergence on the interface.

Configuring RIP Authentication

RIPv1 does not support authentication. If a device is configured with the RIPv2, you can configure authentication on an appropriate interface.

RIPv2 for Ruijie products supports two RIP authentication modes: plain-text authentication and MD5 authentication. The default authentication mode is plain-text authentication.

In plain-text authentication mode, you can run the **ip rip authentication text-password** command to configure the plain-text authentication password or obtain the plain-text authentication password through an associated key chain. The latter takes precedence over the former.

In MD5 authenticaiton mode, you must implement MD5 authentication through an associated key chain.

For plain-text authentication, no authentication occurs if no plain-text authentication password or associated key chain is configured. Similarly, for MD5 authentication, no authentication occurs if no associated key chain is configured.

If a key chain is specified in interface configuration mode, you need to use the **key chain** command in global configuration mode to define the key chain. Otherwise, authentication of RIP data packets may fail.

Use the following commands to configure RIP authentication in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip rip authentication mode** {**text** | **md5**}	Uses the key chain, enables RIP authentication, and configures RIP authentication through the interface. text: indicates plain-text authentication. md5: indicates MD5 authentication.
Ruijie(config-if)# **ip rip authentication text-password** [**0**|**7**] *password-string*	Configures the plain-text authentication password in the length of 1 – 16 bytes. 0 Displays a key in plain text manner. 7 Displays a key in encrypted manner.
Ruijie(config-if)# **ip rip authentication key-chain** *key-chain-name*	Configures authentication using a key chain.

Configuring RIP Clock Adjustment

The RIP provides the clock adjustment function, which allows you to adjust a clock based on network conditions so that the RIP can run in a better way. You can adjust the following clocks:

Route update time: It defines the period in seconds for a device to send route update packets;

Route expiry time: It defines the time in seconds after which the routes in the routing table will become invalid if not updated;

Route clearing timer: It defines the time in seconds after which the routes in the routing table will be cleared;

By adjusting above clocks, the convergence and fault recovery of the routing protocol may be accelerated. Use the following command to adjust an RIP clock in RIP routing process configuration mode.

Command	Function
Ruijie(config-router)# **timers basic** *update invalid flush*	Adjusts the RIP clock.

By default, the update time is 30 seconds, the expiry time is 180 seconds, and the clearing time is 120 seconds.

Note For devices connected on the same network, the values of the RIP clocks must be the same.

Configuring Verification of the Source IP Address of an RIP Route

By default, the RIP will verify the source IP address of a received route update packet. The RIP will discard the packet if the source IP address is invalid. Judging whether the source IP address is valid, that is, judging whether the source IP address is in the same network as the IP address of the interface. No validation authentication will be performed on the interface of no numbered IP address.

Use the following commands to configure verification of route source IP address in RIP routing process configuration mode.

Command	Function
Ruijie(config-router)# **no validate-update-source**	Disables the source IP address validation.
Ruijie(config-router)# **validate-update-source**	Enables the source IP address validation.

Configuring Control of the RIP Interface Status

In some case, it is necessary to configure the RIP flexibly. If you only need to enable a device to learn RIP routes rather than advertising RIP routes, you can configure a passive interface. Or, if you need to configure the status of a certain interface individually, you can use a command to control the sending or receiving of the RIP packets on a specific interface.

Use the following commands to configure an interface as the passive interface in RIP routing process configuration mode.

Command	Function
Ruijie(config-router)# **passive-interface** {**default** | *interface-type interface-num*}	Configures a passive interface.
Ruijie(config-router)#**no passive-interface** {**default** | *interface-type interface-num*}	Cancels the configuration.

Caution A passive interface responds the non-RIP requests (such as the route diagnosis program) rather than the RIP requests because these request programs hope to learn about the routes of all devices.

Use the following commands to disable or allow an interface to receive RIP packets in interface configuration mode.

Command	Function

Command	Function
Ruijie(config-if)# **no ip rip receive enable**	Forbids the interface to receive the RIP packets.
Ruijie(config-if)# **ip rip receive enable**	Allows the interface to receive the RIP packets.

Use the following commands to disable or allow an interface to send RIP packets in interface configuration mode.

Command	Function
Ruijie(config-if)# **no ip rip send enable**	Forbids the interface to send the RIP packets.
Ruijie(config-if)# **ip rip send enable**	Allows the interface to send the RIP packets.

Configuring Default Route Advertisement through an Interface

Use the following command to generate a default route (0.0.0.0/0) in the update packet through a specified interface in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip rip default-information originate** [**metric** *metric-value*]	Advertises the default route and other routes.
Ruijie(config-if)# **no ip rip default-information**	Cancels default route advertising through the interface.

In interface configuration mode, use the following commands to generate a default route (0.0.0.0/0) in the update route through a specified interface, and advertise only this default route instead of other RIP routes through this interface.

Command	Function
Ruijie(config-if)# **ip rip default-information only** [**metric** *metric-value*]	Advertises the default route only.
Ruijie(config-if)# **no ip rip default-information**	Cancels default route advertising through the interface.

If both the **ip rip default-information** command on the interface and the **default-information originate** command in the RIP progress are configured, only the default route configured on the interface is advertised.

Configuring Supernet Route Advertisement through the RIP Interface

A supernet route (for example, 80.0.0.0/6) is defined when the mask length is less than its natural mask length. According to IP address classification, 80.0.0.0 belongs to class-A network and its natural mask legnth is 8. Therefore, 80.0.0.0/6 is a supernet route.

When an RIPv1-enabled device monitors RIPv2 route response packets, it will learn incorrect routes because RIPv1 ignores the subnet masks of the routes in the packets if information about the supernet routes is received. In this case, an RIPv2-enabled device needs to disable advertising super network route on its interface.

Use the following command to configure whether to advertise the supernet route through an interfacein interface configuration mode.

Command	Function
Ruijie(config-if)#**no ip rip send supernet-routes**	Disables advertising the supernet route through the interface.
Ruijie(config-if)# **ip rip send supernet-routes**	Enables advertising the supernetwork route through the interface.

Note

1. When only RIPv1 packets rather than RIPv2 packets are received through the interface, no supernet route is received.
2. Supernet routes can be received when RIPv2 packets are allowed to be received through the interface.
3. No supernet route is sent when RIPv1 packets are sent through the interface.
4. Supernet routes are permitted to be sent by default when RIPv2 packets are sent through the interface.
5. The **no rip rip send supernet-routes** command prohibits sending supernet routes.

The **auto-summary** command takes no effect for supernet routes, that is, supernet routes are not converged.

The **ip rip summary** command does not support configuration of supernet routes.

Configuring RIP VRF

The RIP supports VRFs. Multiple RIP instances can be created to manage the corresponding VRFs in the RIP process. By default, there is only one RIP instance in the RIP process, which is used to manage the global routing table. After a VRF is created, you can manage the routing table of the VRF by creating a new RIP instance.

Run the **address-family** command to enable a router device to enter the address family configuration mode (with the prompt (config-router-af)#). When you specify the VRF associated with the sub mode at the first time, the RIP will create a RIP instance corresponding to the VRF. Under this mode, you can configure the RIP instance of the VRF in the same way as that in global route configuration mode.

To exit the address family configuration sub mode and return to the route configuration mode, run the **exit-address-family** command.

Use the following commands to configure a RIP instance managng the VRF in RIP routing process configuration mode.

Command	Function
Ruijie(config-router)# **address-family ipv4 vrf** *vrf-name*	Creates the RIP instance managing the VRF.
Ruijie(config-router)#**no address-family ipv4 vrf** *vrf-name*	Removes the RIP instance managing the VRF.

Configuring RIP BFD

For details on RIP BFD configuration, see *BFD Configuration Guide*.

Configuring TRIP

Triggered RIP (TRIP) is a RIP extension on a wide area network(WAN), and is mainly used on the on-demand link.

When TRIP is enabled, RIP protocol will no longer periodically send route updates but only send route updates to WAN interfaces in the following cases:

- When route update request packets are received.
- When RIP routing information has changed.
- When interface state changes.
- When routers start.

Since the periodic RIP update is canceled, an acknowledgement and retransmission mechanism is required to guarantee successful update packet transmission and receiving on the WAN. RIP uses three new types of packets which are identified by the value of the command field in the RIP header:

- Update request (Type-9): requests the peer to send the routing information needed.
- Update response (Type-10): contains the route updates requested by the peer.
- Update Acknowledge (Type-11): acknowledges the received update responses, indicating that the route updates sent by peer have been received.

Caution

1. This function can be used in the following cases: (1) The interface is connected to only one neighbor; (2) The interface is connected to multiple neighbors using unicast communication mode. You are advised to enable this feature on PPP, frame relay, X.25, and similar link layer protocols.
2. You are advised to enable split horizon with poisoned reverse on TRIP-enabled interface. Otherwise, there may be residual invalid routing information.
3. It shall be guaranteed that the feature is enabled on all routers on the same link. Otherwise, the function may fail and routing information cannot be exchanged properly.
4. This function cannot be used together with BFD for RIP;
5. When this function is enabled, make sure that the RIP configurations on both ends of the link are identical, such as RIP authentication and version of RIP protocol supported by the interface and etc.
6. With this function enabled on the interface, the valid-update-source will be performed for the packets of this interface no matter whether the valid-update-source function is enabled.

Use the following commands to enable or disable this function in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip rip triggered**	Enables Triggered RIP.
Ruijie(config-if)# **no ip rip triggered**	Disables Triggered RIP.

Configuring RIP GR

RIP graceful restart (GR) guarantees non-stop data forwarding during the process of protocol restart. When RIP GR is enabled on the router, the forwarding table will be maintained during the process of RIP restart, and request packets will be sent to neighbors to re-learn routes in order to complete route re-convergence within the period of graceful restart. Upon expiration of the GR period, GR will exit and forwarding table entries will be updated and advertised to neighbors.

The GR period is the maximum duration from RIP GR execution to RIP GR completion. During this period, the forwarding table will be maintained and RIP route recovery will be implemented in order to restore RIP to the state before GR. Upon expiration of grace period, RIP will exit from the GR state and perform common RIP operations.

graceful-restart grace-period allows users to explicitly change the restart period. Please note that GR must be completed within the RIP expiration time and one RIP route update cycle is completed. If this value is not properly configured, non-stop data forwarding cannot be guaranteed during the GR process. For example, if the GR period is longer than the expiration time of neighbor routers and GR is not completed within such expiration time, the neighbor's routes will not be sent upon expiration of the expiration time, thus causing interruption of data forwarding. Therefore, unless otherwise specified, it is not allowed to adjust the GR period. If the GR period is adjusted, please refer to the configuration of the **timers basic** command and make sure the GR period is longer than the update time and smaller than the expiration time.

Use the following commands to enable or disable this function in RIP routing process configuration mode.

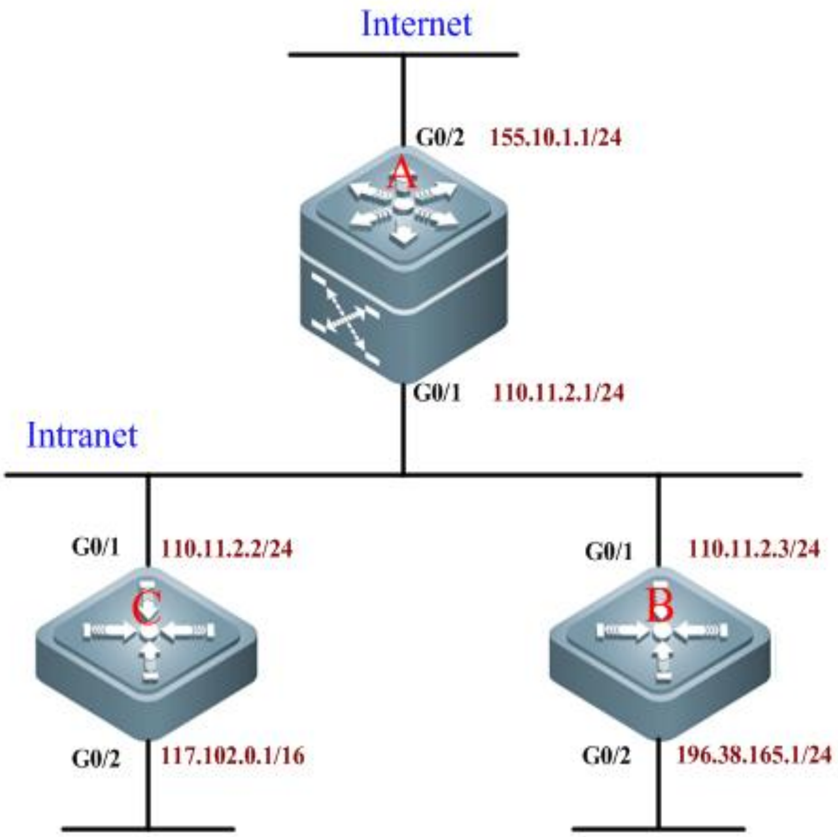
Command	Function
Ruijie(config-router)# **graceful-restart** [**grace-period** *grace-period*]	Enables RIP GR.
Ruijie(config-router)# **no graceful-restart** [**grace-period**]	Disables RIP GR.

RIP Configuration Examples

Configuring RIP Routes and Defining RIP Versions

Networking Topology

Figure 1 Configuring RIP routes and defining RIP versions



Networking Requirements

A small-sized company runs on a small office network, and requires network layer intercommunication between any two nodes. Networking requirements are as follows:

- Devices shall be able to adapt to the changes in the network topology, in order to reduce the workload of manual maintenance;
- Route updates can carry subnet masks;
- Device A only receives the routing information from external networks, but will not advertise routing information of internal network.
- RIP information can be exchanged between devices A, B, and C, so that internal hosts can access Internet.

Configuration Tips

- According to user's requirements and network environment, the RIPv2 routing protocol is selected to achieve user network intercommunication;
- To allow device A to receive routing information sent from external network without advertising the routing information of internal network, the G0/2 port of device A shall be configured as a passive interface.

Configuration Steps

# Configure device A

! Configure the IP address of the corresponding port on device A.

```
Ruijie>enable
Ruijie#configure terminal
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if)#ip address 110.11.2.1 255.255.255.0
Ruijie(config-if)#exit
Ruijie(config)#interface gigabitEthernet 0/2
Ruijie(config-if)#ip address 155.10.1.1 255.255.255.0
```

! Create the RIP routing progress.

```
Ruijie(config)#router rip
```

! Configure RIP version as version 2.

```
Ruijie(config-router)#version 2
```

! Configure G0/2 as a passive interface.

```
Ruijie(config-router)#passive-interface gigabitEthernet 0/2
```

! Disable automatic route convergence.

```
Ruijie(config-router)#no auto-summary
```

! Specify the associated network.

```
Ruijie(config-router)#network 110.11.2.0 255.255.255.0
Ruijie(config-router)#network 155.10.1.0
```

# Configure device B

! Configure the IP address of the corresponding port on device B.

```
Ruijie>enable
Ruijie#configure terminal
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if)#ip address 110.11.2.2 255.255.255.0
Ruijie(config-if)#exit
Ruijie(config)#interface gigabitEthernet 0/2
Ruijie(config-if)#ip address 196.38.165.1 255.255.255.0
Ruijie(config-if)#exit
```

! Create RIP routing progress.

```
Ruijie(config)#router rip
```

! Configure the RIP version as version 2.

```
Ruijie(config-router)#version 2
```

! Disable automatic route convergence.

```
Ruijie(config-router)#no auto-summary
```

! Specify the associated network.

```
Ruijie(config-router)#network 110.11.2.0
Ruijie(config-router)#network 196.38.165.0
```

# Configure device C

! Configure the IP address of the corresponding port on device C.

```
Ruijie>enable
Ruijie#configure terminal
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if)#ip address 110.11.2.3 255.255.255.0
Ruijie(config-if)#exit
Ruijie(config)#interface gigabitEthernet 0/2
Ruijie(config-if)#ip address 117.102.0.1 255.255.0.0
Ruijie(config-if)#exit
```

! Create RIP routing progress.

```
Ruijie(config)#router rip
```

! Configure RIP version as version 2.

```
Ruijie(config-router)#version 2
```

! Disable automatic route convergence.

```
Ruijie(config-router)#no auto-summary
```

! Specify the associated network.

```
Ruijie(config-router)#network 110.11.2.0
Ruijie(config-router)#network 117.102.0.0
```

Verification

View the routing table of each device;

View the routing table on A, as shown below (the bold figures are the routing information learned through RIP):

```
Ruijie#show ip route
Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default

```

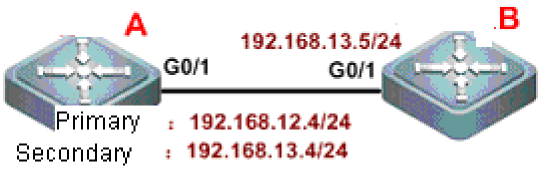
RIP Split Horizon

Networking Topology

Figure 2 Topology for RIP split horizon



Networking Requirements

There are two devices on the network. Device A is configured with a secondary IP address.

The following requirements shall be met:

- The RIP routing protocol runs on both devices;
- Device B can learn the routes of network segment 192.168.12.0/24.

Configuration Tips

To meet the above requirements, the following configurations are required:

- RIPv2 routing protocol is run on both devices;
- Split horizon shall be disabled on device A (by default, split horizon is enabled on all interfaces), or else device A won't advertise network segment 192.168.12.0 to device B.

Configuration Steps

# Configure device A

! Configure Ethernet ports.

```
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)#ip address 192.168.12.4 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/1)#ip address 192.168.13.4 255.255.255.0 secondary
```

! Disable split horizon.

```
Ruijie(config-if-GigabitEthernet 0/1)#no ip rip split-horizon
```

! Configure the RIP routing protocol.

```
Ruijie(config)#route rip
Ruijie(config-router)#version 2
Ruijie(config-router)#network 192.168.12.0
Ruijie(config-router)#network 192.168.13.0
```

! Disable automatic route convergence.

```
Ruijie(config-router)#no auto-summary
```

# Configure device B

! Configure Ethernet ports.

```
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)#ip address 192.168.13.5 255.255.255.0
```

! Configure the RIP routing protocol.

```
Ruijie(config)#route rip
Ruijie(config-router)#version 2
Ruijie(config-router)#network 192.168.13.0
```

Verification

View the routing table on device B before and after disabling split horizon.

Before split horizon is disabled, view the routing table on device B, as shown below:

```
Ruijie#show ip route

Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default
Gateway of last resort is no set
C    192.168.13.0/24 is directly connected, GigabitEthernet 0/1
C    192.168.13.5/32 is local host.
```

After split horizon is disabled, view the routing table on device B, as shown below (the bold figures are the routing information learned through RIP):

```
Ruijie#show ip route

Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default

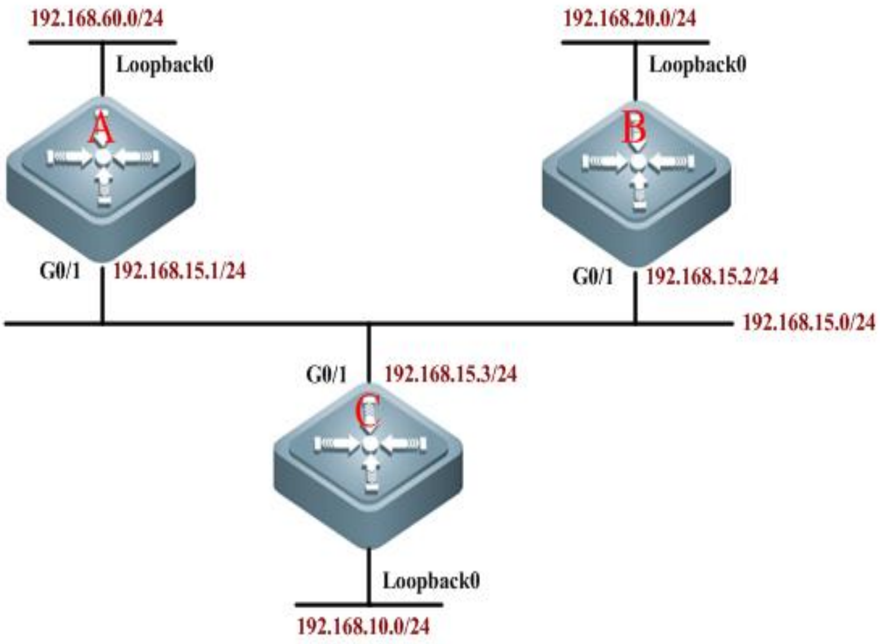
Gateway of last resort is no set
R    192.168.12.0/24 [120/1] via 192.168.13.4, 00:00:10, GigabitEthernet 0/1
```

```
C    192.168.13.0/24 is directly connected, GigabitEthernet 0/1
C    192.168.13.5/32 is local host.
```

RIP Unicast Update

Networking Topology

Figure 3 Topology for RIP unicast update



Networking Requirements

As shown below, three devices are connected to the LAN and run the RIP routing protocol.

- Device A can learn the routes advertised by devices B and C;
- Device C can learn the routes advertised by devices A and B;
- Device B cannot learn the routes advertised by device C.

Configuration Tips

To meet the above configuration requirements, RIP unicast packets must be configured on device C. Add the command of **neighbor** during the RIP configuration of device C, so that the RIP protocol can send advertisements to the interface of device A in unicast mode. Configure the **passive-interface** command on G0/1 of device C to avoid broadcast update on this link.

Configuration Steps

# Configure device A

! Configure the IP address of corresponding interface.

```
Ruijie>enable
Ruijie#configure terminal
```

```
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if)#ip address 192.168.15.1 255.255.255.0
Ruijie(config-if)#exit
Ruijie(config)#interface Loopback 0
Ruijie(config-if)#ip address 192.168.60.1 255.255.255.0
Ruijie(config-if)#exit
```

! Create RIP routing progress.

```
Ruijie(config)#router rip
```

! Specify the associated network.

```
Ruijie(config-router)#network 192.168.60.0
Ruijie(config-router)#network 192.168.15.0
```

# Configure device B

! Configure the IP address of corresponding interface.

```
Ruijie>enable
Ruijie#configure terminal
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if)#ip address 192.168.15.2 255.255.255.0
Ruijie(config-if)#exit
Ruijie(config)#interface Loopback 0
Ruijie(config-if)#ip address 192.168.20.1 255.255.255.0
Ruijie(config-if)#exit
```

! Create RIP routing progress.

```
Ruijie(config)#router rip
```

! Specify the associated network.

```
Ruijie(config-router)#network 192.168.20.0
Ruijie(config-router)#network 192.168.15.0
```

# Configure device C

! Configure the IP address of corresponding interface.

```
Ruijie>enable
Ruijie#configure terminal
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if)#ip address 192.168.15.3 255.255.255.0
Ruijie(config-if)#exit
Ruijie(config)#interface Loopback 0
Ruijie(config-if)#ip address 192.168.10.1 255.255.255.0
Ruijie(config-if)#exit
```

! Create RIP routing progress.

```
Ruijie(config)#router rip
```

! Specify the associated network.

```
Ruijie(config-router)#network 192.168.15.0
Ruijie(config-router)#network 192.168.10.0
```

! Configure G0/1 as a passive interface.

```
Ruijie(config-router)#passive-interface gigabitEthernet 0/1
```

! Enable unicast update.

```
Ruijie(config-router)#neighbor 192.168.15.1
```

Verification

View the routing table of each device (mainly the routing information on devices C and B):

View the routing table on device B, as shown in the following figure:

```
Ruijie#show ip route

Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2

C    192.168.15.2/32 is local host.
R 192.168.60.0/24 [120/1] via 192.168.15.1, 00:15:21, GigabitEthernet 0/1
```

View the routing table on device C, as shown below (the bold figures are the routing information learned through RIP):

```
Ruijie#show ip route

Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default

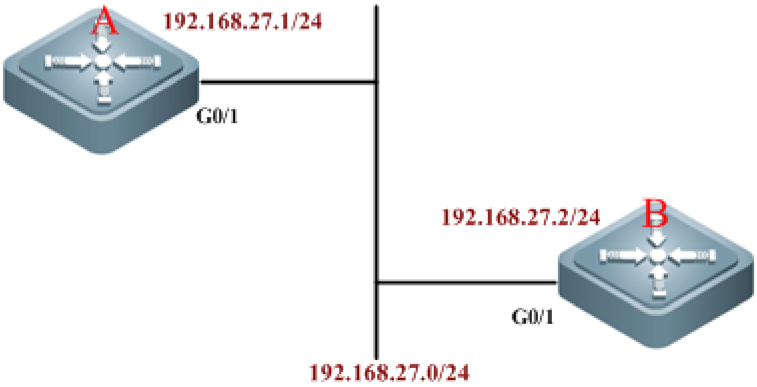
Gateway of last resort is no set
C    192.168.10.0 is directly connected, Loopback 0
C    192.168.10.1/32 is local host.
R 192.168.60.0/24 [120/1] via 192.168.15.1, 00:15:21, GigabitEthernet 0/1
C    192.168.15.0/24 is directly connected, GigabitEthernet 0/1
```

```
C    192.168.15.3/32 is local host.
R 192.168.20.0 [120/1] via 192.168.15.2, 00:00:47, GigabitEthernet 0/1
```

RIP Authentication

Networking Topology

Figure 4 Topology for RIP authentication



Networking Requirements

Interconnected through Ethernet, two devices run the RIP routing protocol and use MD5 authentication. The requirements are as follows:

- The authentication key for device A to send RIP packets is "Hello", and device A can receive RIP packets with authentication keys being "Hello" and "World";
- The authentication key for device B to send RIP packets is "World", and device B can receive RIP packets with authentication keys being "Hello" and "World";
- The first key is used from 4:30pm October 1st, 2010 for 12 hours (43200s)
- The second key becomes permanently valid from 4:00 am October 2, 2010.

Configuration Tips

Authentication is not supported in RIPv1. If the RIPv2 routing protocol is configured on the device, authentication can then be configured on the corresponding interface.

The key string specifies the key set that can be used by this interface. If the key string is not configured and even if the interface uses the key chain, no authentication occurs. Therefore, before configuring authentication, the key chain and the associated key string must be configured first.

RGOS supports two RIP authentication modes: plain text and MD5, while plain text is the default authentication mode.

- The authentication key for sending RIP packets must be configured with the first key on keychain;
- When configuring the authentication key that can be received, configure any key on the keychain.

Configuration Steps

# Configure device A:

! Configure the IP address of Ethernet interface.

```
Ruijie>enable
Ruijie#configure terminal
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if)#ip address 192.168.27.1 255.255.255.0
Ruijie(config-if)#exit
```

! Configure the key chain named "ripchain".

```
Ruijie(config)#key chain ripchain
```

! Configure the first key of "Key 1", which contains the key-string of "Hello", and configure the corresponding period needed.

```
Ruijie(config-keychain)#key 1
Ruijie(config-keychain-key)#key-string Hello
Ruijie(config-keychain-key)#accept-lifetime 16:30:00 Oct 1 2010 duration 43200
Ruijie(config-keychain-key)#send-lifetime 16:30:00 Oct 1 2010 duration 43200
Ruijie(config-keychain-key)#exit
```

! Configure the second key of "Key 2", which contains the key-string of "World", and configure the corresponding period needed.

```
Ruijie(config-keychain)#key 2
Ruijie(config-keychain-key)#key-string World
Ruijie(config-keychain-key)#accept-lifetime 04:00:00 Oct 2 2010 infinite    //Beginning time that the key is valid to be received
Ruijie(config-keychain-key)#send-lifetime 04:00:00 Oct 2 2010 infinite        //Beginning time that the key is valid to be sent
Ruijie(config-keychain-key)#end
```

! Configure G0/1 to use the MD5 authentication key to authenticate the update messages sent from device B.

```
Ruijie#configure terminal
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if)#ip rip authentication key-chain ripchain
Ruijie(config-if)#ip rip authentication mode md5
Ruijie(config-if)#exit
```

! Configure the RIP routing protocol.

```
Ruijie(config)#router rip
Ruijie(config-router)#version 2
Ruijie(config-router)#network 192.168.27.0
```

#Configure device B:

! Configure the IP address of Ethernet interface.

```
Ruijie>enable
Ruijie#configure terminal
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if)#ip address 192.168.27.2 255.255.255.0
Ruijie(config-if)#exit
```

! Configure the key chain.

```
Ruijie(config)#key chain ripchain //The name of key chain is only valid on the local device.
You can also use other names.
```

! Configure the first key of "Key 1", which contains the key-string of "Hello", and configure the corresponding period needed.

```
Ruijie(config-keychain)#key 1
Ruijie(config-keychain-key)#key-string Hello
Ruijie(config-keychain-key)#accept-lifetime 16:30:00 Oct 1 2010 duration 43200
Ruijie(config-keychain-key)#send-lifetime 16:30:00 Oct 1 2010 duration 43200
Ruijie(config-keychain-key)#exit
```

! Configure the second key of "Key 2", which contains the key-string of "World", and configure the corresponding period needed.

```
Ruijie(config-keychain)#key 2
Ruijie(config-keychain-key)#key-string World
Ruijie(config-keychain-key)#accept-lifetime 04:00:00 Oct 2 010 infinite
Ruijie(config-keychain-key)#send-lifetime 04:00:00 Oct 2 2010 infinite
Ruijie(config-keychain-key)#end
```

! Configure G0/1 to use the MD5 authentication key to authenticate the update messages sent from device A.

```
Ruijie#configure terminal
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if)#ip rip authentication key-chain ripchain
Ruijie(config-if)#ip rip authentication mode md5
Ruijie(config-if)#exit
```

! Configure the RIP routing protocol.

```
Ruijie(config)#router rip
Ruijie(config-router)#version 2
Ruijie(config-router)#network 192.168.27.0
```

Verification

Run the show run command to verify the correctness of configurations (taking device A as the example):

```
Ruijie#show run

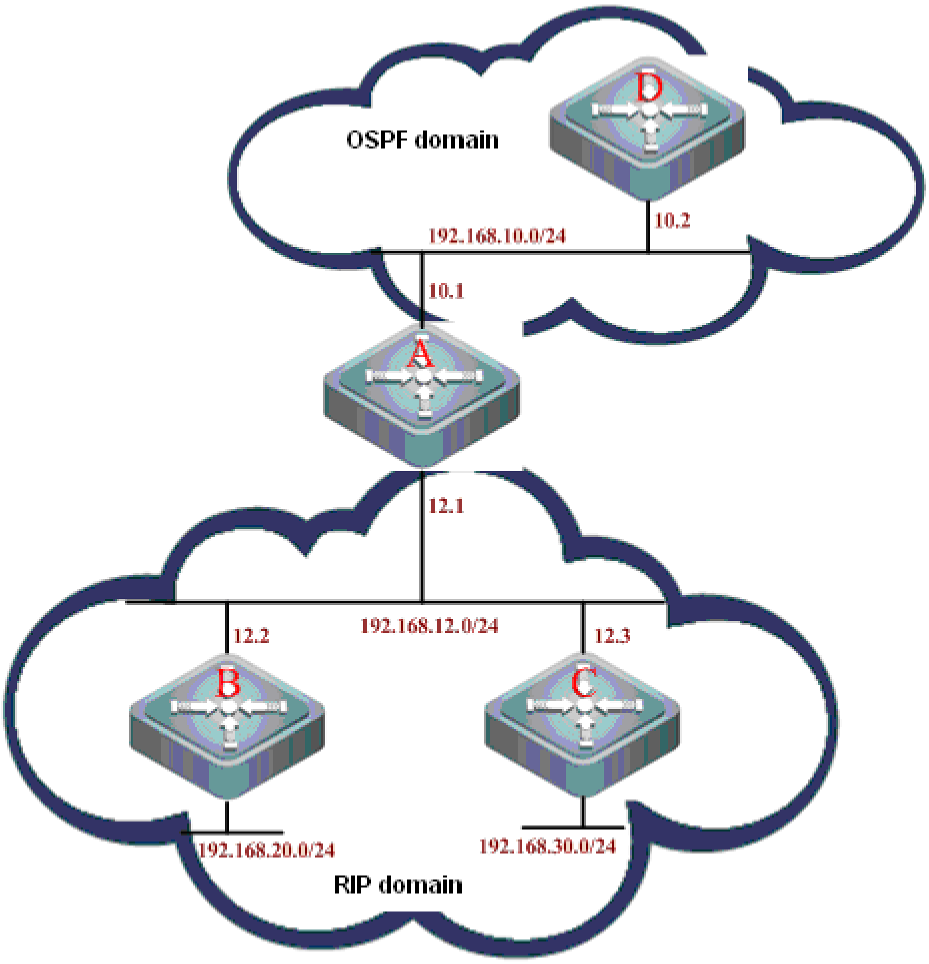
RIP Redistribution and Default Route

Networking Topology

Figure 5 Topology for RIP redistribution and default route



Networking Requirements

Devices A, B, and C are interconnected in the same network segment and run the RIP routing protocol. Devices A and D are interconnected in the same network segment and run the OSPF routing protocol. Configure these four devices to achieve the following goals:

- Device A can learn the OSPF routes advertised by device D;
- Device A can redistribute OSPF routes to RIP;
- Device A advertises the redistributed routes to devices B and C;
- Device C advertises the default routing to devices A and B.

Configuration Tips

- Configure to redistribute OSPF routes to RIP in the RIP process of device A;
- Configure to advertise the default routing on the corresponding interface of device C;

Configuration Steps

#Configure device A:

! Configure Ethernet ports.

```
Ruijie(config)#interface FastEthernet 0/1
Ruijie(config-if-FastEthernet 0/1)#ip address 192.168.12.1 255.255.255.0
Ruijie(config-if-FastEthernet 0/1)#exit
Ruijie(config)#interface FastEthernet0/2
Ruijie(config-if-FastEthernet 0/2)#ip address 192.168.10.1 255.255.255.0
```

# Configure the RIP routing protocol.

```
Ruijie(config)#router rip
Ruijie(config-router)#version 2
Ruijie(config-router)#network 192.168.12.0
Ruijie(config-router)#redistribute ospf 10 metric 3
```

//Redistribute the OSPF routing progress in the RIP progress, with metric value being 3

# Configure the OSPF routing protocol.

```
Ruijie(config)#router ospf 10
Ruijie(config-router)#network 192.168.10.0 0.0.0.255 area 0
```

#Configure device B:

! Configure Ethernet ports.

```
Ruijie(config)#interface FastEthernet 0/1
Ruijie(config-if-FastEthernet 0/1)#ip address 192.168.12.2 255.255.255.0
Ruijie(config-if-FastEthernet 0/1)#exit
```

! Configure loopback ports.

```
Ruijie(config)#interface Loopback 0
Ruijie(config-if-Loopback 0)#ip address 192.168.20.1 255.255.255.0
```

! Configure the RIP routing protocol.

```
Ruijie(config)#router rip
Ruijie(config-router)#version 2
Ruijie(config-router)#network 192.168.12.0
Ruijie(config-router)#network 192.168.20.0
```

# Configure device C:

! Configure Ethernet ports.

```
Ruijie(config)#interface FastEthernet 0/1
Ruijie(config-if-FastEthernet 0/1)#ip address 192.168.12.3 255.255.255.0
Ruijie(config-if-FastEthernet 0/1)#ip rip default-information originate metric 5
```

//Advertise default route, with metric value being 5

! Configure loopback ports.

```
Ruijie(config)#interface Loopback 0
Ruijie(config-if-Loopback 0)#ip address 192.168.30.1 255.255.255.0
```

# Configure the RIP routing protocol.

```
Ruijie(config)#router rip
Ruijie(config-router)#version 2
Ruijie(config-router)#network 192.168.12.0
Ruijie(config-router)#network 192.168.30.0
```

# Configure device D:

! Configure Ethernet ports.

```
Ruijie(config)#interface FastEthernet 0/1
Ruijie(config-if-FastEthernet 0/1)#ip address 192.168.10.2 255.255.255.0
```

! Configure the OSPF routing protocol.

```
Ruijie(config)#router ospf 10
Ruijie(config-router)#network 192.168.10.0 0.0.0.255 area 0
```

Verification

View the routing table of each device (mainly the routing information on devices A, B, and C):

View the routing table on device A, as shown below (the bold figures are the routing information learned through RIP):

```
Ruijie#show ip route

Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area

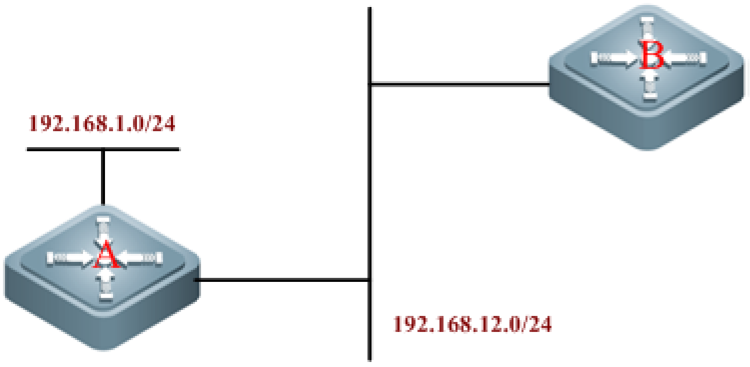
RIP Supernet Route

Networking Topology

Figure6 Topology for the RIP supernet route



Networking Requirements

Two devices are interconnected through Ethernet. Device A runs RIPv2, and device B only supports the RIPv1 protocol and is unable to learn supernet routes.

Requirements:

- Configure supernet route 80.0.0.0/6 on device A, with next hop pointing to interface loopback 1 (192.168.1.0);
- Redistribute the aforementioned static route to RIP;
- Prohibit advertising supernet routes on device A.

Configuration Tips

Device B supports only the RIPv1 protocol. According to RFC 1058, such device is able to receive update packets of higher-version RIP, but such fields as subnet mask and next hop in the packets must be neglected. Therefore, route 80.0.0.0/6 received by device B will be treated as 80.0.0.0/8. To prevent device B from learning incorrect routes, device A must be configured to prohibit supernet route advertisement.

Configuration Steps

# Configure device A:

! Configure Ethernet ports.

```
Ruijie(config)#interface FastEthernet 0/1
Ruijie(config-if-FastEthernet 0/1)#ip address 192.168.12.1 255.255.255.0
Ruijie(config-if-FastEthernet 0/1)#no ip rip send supernet-routes
```

//Prohibit supernet route advertisement

! Configure loopback ports.

```
Ruijie(config)#interface loopback 1
Ruijie(config-if-Loopback 1)#ip address 192.168.1.1 255.255.255.0
```

! Configure static routes.

```
Ruijie(config)#ip route 80.0.0.0 252.0.0.0 loopback 1
```

! Configure the RIP routing protocol.

```
Ruijie(config)#router rip
Ruijie(config-router)#version 2
Ruijie(config-router)#network 192.168.12.0
Ruijie(config-router)#network 192.168.1.0
Ruijie(config-router)#redistribute static
```

//Redistribute static route

# Configure device B (supporting RIPv1 only):

! Configure Ethernet ports.

```
Ruijie(config)#interface FastEthernet 0/1
Ruijie(config-if-FastEthernet 0/1)#ip address 192.168.12.3 255.255.255.0
```

! Configure the RIP routing protocol.

```
Ruijie(config)#router rip
Ruijie(config-router)#network 192.168.12.0
```

Verification

View the routing table of each device;

View the routing table on device A, as shown below:

```
Ruijie#show ip route

Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default

Gateway of last resort is no set
S    80.0.0.0/6 is directly connected, Loopback 1
C    192.168.1.0/24 is directly connected, Loopback 1
C    192.168.1.1/32 is local host.
C    192.168.12.0/24 is directly connected, FastEthernet 0/1
C    192.168.12.1/32 is local host.
```

View the routing table on device B, as shown below (the bold figures are the routing information learned through RIP):

```

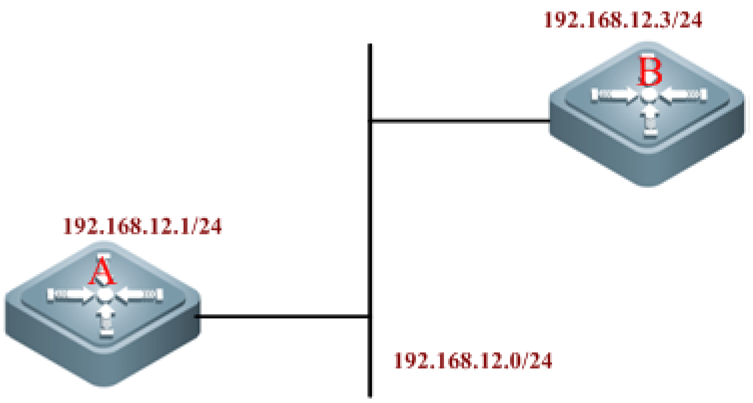
C    192.168.12.2/32 is local host.
```

RIP VRF Configuration Examples

Networking Requirements

Two routing devices are interconnected through Ethernet and run the RIP routing protocol. The connection layout and IP address distribution are shown in Figure 7.

Figure7 Example of RIP VRF configuration



Through RIP, routing information is exchanged between VRF "redvpn" of device A and VRF "bluevpn" of device B.

By enabling RIP GR on device A and setting the GR period to 90 seconds, non-stop data forwarding can be realized during hot standby switchover between main and slave management boards on device A. Meanwhile, since the GR period has been changed, timers basic shall be configured to a reasonable value.

Detailed Configurations

Configure device A:

# Create VRF.

```
ip vrf redvpn
```

# Bind the interface to VRF and configure the interface IP address.

```
interface fastEthernet 0/1
ip vrf forwarding redvpn
ip address 192.168.12.1 255.255.255.0
```

# Configure the RIP routing protocol and create a RIP instance.

```
router rip
address-family ipv4 vrf redvpn
network 192.168.12.0
graceful-restart grace-period 90
timers basic 45 270 180
exit-address-family
```

Configure device B:

# Create VRF.

```
ip vrf  bluevpn
```

# Bind the interface to VRF and configure the interface IP address.

```
interface fastEthernet 0/1
ip vrf forwarding bluevpn
ip address 192.168.12.3 255.255.255.0
```

# Configure the RIP routing protocol and create a RIP instance.

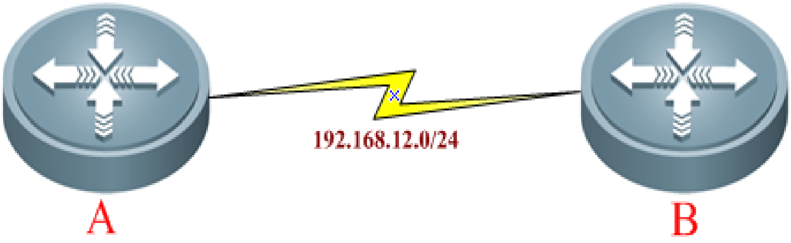
```
router rip
address-family ipv4 vrf bluevpn
network 192.168.12.0
timers basic 45 270 180
exit-address-family
```

TRIP Configuration Examples

Networking Requirements

Two routers are interconnected through the PPP link and run the RIP routing protocol. The connection layout and IP address distribution are shown in Figure 8.

Figure 8 Example of TRIP configuration



By configuring TRIP, routing information can be exchanged between devices A and B on the WAN link, and split horizon with poisoned reverse shall be enabled.

Detailed Configurations

Configure device A:

# Enable the PPP link protocol on the interface and configure the interface IP address; Enable TRIP and split horizon with poisoned reverse.

```
interface Serial 0/0
encapsulation ppp
ip address 192.168.12.1 255.255.255.0
ip rip triggered
ip rip split-horizon poisoned-reverse
```

# Configure the RIP routing protocol.

```
router rip
```

```
network 192.168.12.0
```

Configure device B:

# Enable the PPP link protocol on the interface and configure the interface address; Enable TRIP and split horizon with poisoned reverse.

```
interface Serial 0/0
encapsulation ppp
ip address 192.168.12.2 255.255.255.0
ip rip triggered
ip rip split-horizon poisoned-reverse
```

# Configure RIP routing protocol

```
router rip
network 192.168.12.0
```

Configuring RIPng

Overview

Similar to RIP, RIPng is a distance-vector routing protocol using hop count as the routing metric. RIPng is an interior gateway protocol applicable to small- and medium-sized networks. RIPng is the necessary extension of RIP to address the routing requirements of IPv6. Therefore, RIPng and RIP have basic working principles in common. The main differences rise from the format of their address and packet. Based on IPv6, RIPng supports and uses the multicast group address of FF02::9 for update messages. Security authentication used in RIP is also cancelled. Instead, RIPng enables security authentication by the security mechanism of IPv6. 521 port is used. Packet format, mask and maximum packet length are all different. Please refer to RFC2080 and RFC2081 for details. Given the difference from RIP, the corresponding CLI commands are also lesser.

RIPng Configuration List

- Creating RIPng routing process (Required)
- Enabling RIPng on the interface (Required)
- Adjusting RIPng timer (Optional)
- Configuring Split Horizon (Optional)
- Configuring default metric for redustribution
- Adjusting interface metric
- Configuring the advertisement default route on the interface
- Configuring passive interface
- Configuring RIPng route filtering
- Showing RIPng configuration

Please refer to the chapter of “Protocol independent Configuration” for the configuration of route redistribution.

The default configurations of RIPng are given below:

Function	Default setting
Network interface	The default metric-offset is 1.
Redistribution	The route redistribution is disabled by default. If enabled: ■ All sub-routes of the routing process are redistributed. ■ The metric of redistributed route is the default metric.
Split horizon	Enabled
Poisoned reverse	Disabled

Timer	By default: ■ Update time is 30 seconds ■ Invalid time is 180 second ■ Clearing time is 120 seconds
Default metric	Redistribute the metric used by the routes of other protocols，1 by default.
Administrative distance	120

Creating RIPng Routing Process

In order to run RIPng routing protocol, the routing device first needs to create the RIPng routing process and define the network or interface address associated with RIPng routing process.

To create RIPng routing process, input the following command in the global configuration mode:

Command	Function
Ruijie(config)# **ipv6 router rip**	Create RIPng routing process.

Enabling RIPng on the Interface

To enable RIPng on the interface, input the following command in the interface configuration mode:

Command	Function
Ruijie(config-if)# **ipv6 rip enable**	Enable RIPng on the interface.

In the following example, enable RIPng on ethernet 0/0. Routes in the range of 2001:db8:6::/64 are converged into 2001:db8:6::/64 for advertisement.

```
Ruijie(config)# interface ethernet 0/0
Ruijie(config-if)# ipv6 address 2001:db8:6::1/64
Ruijie(config-if)# ipv6 rip enable
```

Note

Different from RIP, this command enables RIPng on the interface directly without configuring Network command.

Adjusting RIPng Timer

RIPng provides the feature of timer adjustment. You can adjust the timer according to the physical circumstances of the network, so that the RIPng routing protocol can run better. The following timers can be adjusted:

- Route update time (second): defines the interval by which the routing device will send the route update message;

- Route invalid time (second): defines the time by which the route in the routing table becomes invalid upon no update;
- Route clearing time (second): upon expiration of this time, the route will be removed from the routing table.
- By adjusting the aforementioned times, the convergence time and failure recovery time of routing protocol can be accelerated. To adjust RIPng timer, input the following command in the RIPng routing process configuration mode:

Command	Function
Ruijie(config-router)# **times** *update invalid garbage-collection*	Adjust RIPng times.

The following example adjusts the values of three RIPng times:

```
Ruijie(config-router)# timers 10 30 90
```

Caution

Consistency of RIPng times is mandatory for routing devices in the same network.

Configuring Split Horizon

When multiple routing devices are linked to the IP broadcast network and running distance-vector routing protocol, it is necessary to adopt the mechanism of split horizon to avoid loop. Split horizon can prevent routing device from sending routing information to the port from which such routing information was learned. Such mechanism optimizes the routing information exchange between multiple routing devices.

However, for non-broadcast multiple-access network (such as frame relay, X.25 network), split horizon may cause disable certain routing devices from learning all routing information. In such a case, the split horizon will need to be disabled.

To disable or enable split horizon, input the following command in the routing process configuration mode:

Command	Function
Ruijie(config-router)# **no split-horizon**	Disable split horizon.
Ruijie(config-router)# **split-horizon**	Enable split horizon.

By default, split horizon is enabled on all RIPng ports.

Note

The current version can only support split horizon configuration in RIPng routing process, i.e., this command will be applied to all RIPng interfaces. The subsequent RGOS software will realize interfaced-based split horizon configuration.

Different from split horizon, when poison reverse is enabled, the routing device will advertise certain route information from the interface from which such route information was learned. Just set the corresponding metric to infinity (16).

To enable or disable poison reverse, input the following command in the routing process configuration mode:

Command	Function
Ruijie(config-router)#**split-horizon poisoned-reverse**	Enable split horizon with poison reverse
Ruijie(config-router)#**no split-horizon poisoned-reverse**	Disable split horizon with poison reverse

Caution Enabling poison reverse will consume considerable bandwidth.

Configuring Default Metric for Redistribution

When a protocol redistributes routes of other protocols, you need to configure the metric for such redistribution for metric varies by protocols. The default metric of RIPng is 1.

To define the default RIPng metric during the redistribution of other routing protocols, please use the routing process configuration command of "**default-metric"**. Use "**no default-metric"** command to reset the default value to 1.

Command	Function
Ruijie(config-router)# **default-metric** *metric*	The metric of RIPng is set to *metric*
Ruijie(config-router)# **no default-metric**	Reset the default value to 1

Adjusting Interface Metric

Before adding the learned routes into the routing table, you need to add the metric set for the interface to the ones of learned routes. Therefore, you can control the use of routes by configuring the interface metric.

To configure the interface metric, input the following command in the interface configuration mode:

Command	Function
Ruijie(config-if)# **ipv6 rip metric-offset** *value*	Configure interface metric within the scope of 1-16.

The following example sets the metric of ethernet 0/0 to 6:

```
Ruijie(config)# interface ethernet 0/0
Ruijie(config-if)# ipv6 rip metric-offset 6
```

Configuring the Advertisement Default Route on the Interface

To generate an IPv6 default route in the update message of this RIPng process (::/0), input the following command in the interface configuration mode:

Command	Function

Ruijie(config-if)# **ipv6 rip default-informaton originate**	Generate a default route to RIPng on the interface and advertise it with other routes.

To generate an IPv6 default route in the update message of this RIPng process (::/0), and advertise only this default route on this interface, input the following command in the interface configuration mode:

Command	Function
Ruijie(config-if)# **ipv6 rip default-informaton only**	Generate a default route to RIPng on the interface and advertise only this default route.

Configuring Passive Interface

To prevent other routing devices in the local network from learning the routing information sent by the routing device, configure passive interface to disable sending routing update message from this network interface.

To disable sending update messages from an interface, input the following command in the routing process configuration mode:

Command	Function
Ruijie(config-router)# **passive-interface** {**default** | *interface-type interface-num*}	Disable sending update messages from the interface.

Note

When applying the **default** option, all interfaces will be set to passive mode; when applying the **interface** option, the corresponding interface will set to passive mode.

Configuring RIPng Route Filtering

Controlling Route Update Advertisement (RIPng)

To prevent other routing devices in the local network from learning unnecessary routing information, disable the update of specific routes by controlling RIPng route update advertisement.

To disable route update advertisement, input the following command in the routing process configuration mode:

Command	Function
Ruijie(config-router)# **distribute-list prefix-list** *prefix-list-name* **out** [*interface-type interface-name*]	According to the rule of prefix list, enable or disable the advertisement of certain routes.
Ruijie(config-router)# **no distribute-list prefix-list** *prefix-list-name* **out** [*interface-type interface-name*]	Remove the configuration.

In the following example, filtering is only applied to update messages sent from interface eth0, and only update routes included in the prefix-list *outlist* will be sent out.

```
Ruijie(config)# ipv6 router rip
Ruijie(config-router)# distribute-list prefix-list outlist out eth0
```

Controlling Route Update Processing (RIPng)

This feature can be configured to avoid receiving certain routes in the route update message.

To control route update processing, input the following command in the routing process configuration mode:

Command	Function
Ruijie(config-router)# **distribute-list prefix-list** *prefix-list-name* **in** [*interface-type interface-name*]	According to the rule of access list, enable or disable the receipt of certain routes in the route update.
Ruijie(config-router)# **no distribute-list prefix-list** *prefix-list-name* **in** [*interface-type interface-name*]	Remove the configuration.

In the following example, filtering is only applied to update messages received by interface eth0, and only update routes included in the prefix-list *inlist* will be received.

```
Ruijie(config)# ipv6 router rip
Ruijie(config-router)# distribute-list prefix-list inlist in eth0
```

Showing RIPng Configuration

RIPng Debugging Switch

To show the debugging information of RIPng and observe the route processing behaviors of RIPng, input the following command in the privilege configuration mode:

Command	Function
Ruijie# **debug ipv6 rip** [{*interface-type interface-num* **| nsm**}]	Turn on RIPng debugging switch.
Ruijie# **no debug ipv6 rip** [{*interface-type interface-num* **| nsm**}]	Turn off RIPng debugging switch.

Showing RIPng Routing Table

To show RIPng routing table, input the following command in user mode or privileged EXEC mode:

Command	Function
Ruijie# **show ipv6 rip database**	Display RIPng routing table information.

Showing RIPng Routing Process

To display the parameters and various statistical data of RIPng routing process, input the following command in user mode or privilege mode:

Command	Function
Ruijie# **show ipv6 rip**	Display RIPng routing process information.

Showing RIPng Debugging Information

To display the debugging information of RIPng routing process, input the following command in the privileged EXEC mode or global configuration mode:

Command	Function
Ruijie# **show debugging**	Display the debugging information of RIPng routing process.

Configuration Examples

Configuring Default Route Advertisement

Configuration Requirements

There are three devices (see Fig 1 for device connection) running RIPng. The gateway device of Router A advertises the default route to Router B and Router C, with metric being 3. All RIPng interfaces of Router B and Router C are configured to passive mode, so as not to send out RIPng update messages.

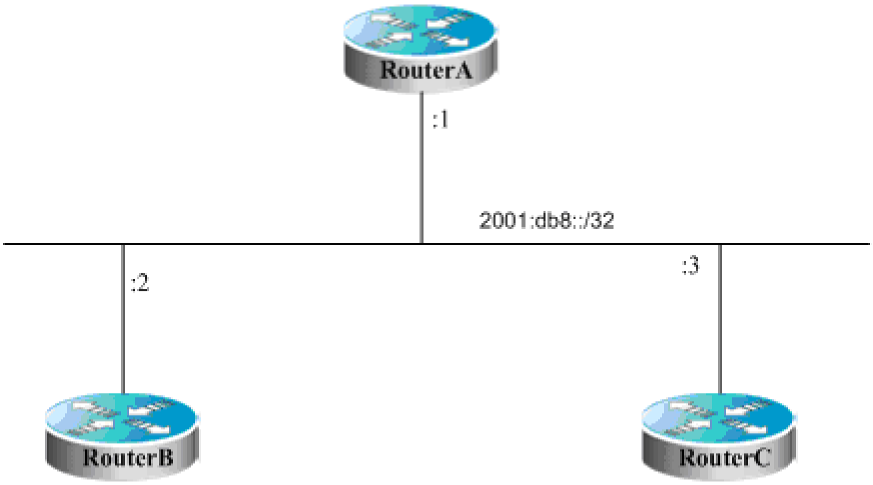


Figure 2 Configuration of default route advertisement

Detailed Configuration of Routing Devices

Router A:

# Configure network interface

```
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# ipv6 enable
Ruijie(config-if)# ipv6 address 2001:db8::1/32
Ruijie(config-if)# ipv6 rip enable
Ruijie(config-if)# ipv6 rip default-information originate
metric 3
# Configure RIPng
Ruijie(config)# ipv6 router rip
Ruijie(config-router)# exit
Router B:
# Configure network interface.
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# ipv6 enable
Ruijie(config-if)# ipv6 address 2001:db8::2/32
Ruijie(config-if)# ipv6 rip enable
# Configure RIPng.
Ruijie(config)# ipv6 router rip
Ruijie(config-router)# passive-interface default
Ruijie(config-router)# exit
Router C:
# Configure network interface.
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# ipv6 enable
Ruijie(config-if)# ipv6 address 2001:db8::3/32
Ruijie(config-if)# ipv6 rip enable
# Configure RIPng.
Ruijie(config)# ipv6 router rip
Ruijie(config-router)# passive-interface default
Ruijie(config-router)# exit
```

Redistribution Configuration

Configuration Requirements

There are three devices (see Fig 1 for device connection). Router A runs RIPng; Router C runs BGP and introduces static routes; Router B needs to redistribute the static routes redistributed by Router C to RIPng domain.

In order to meet such requirements, we can configure the specified community attribute for static routes redistributed to BGP on Router C, while Router B can redistribute BGP routes with specified community attribute to the RIPng domain.

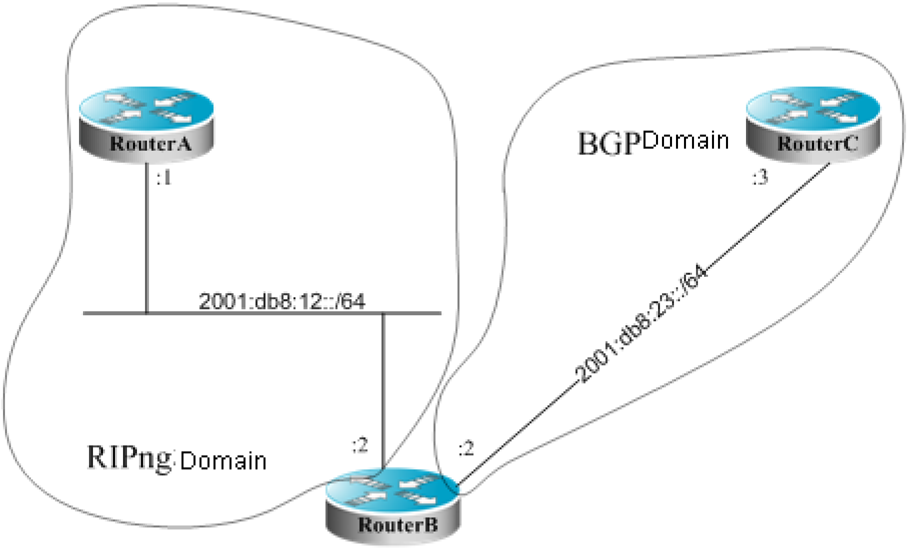

Figure 3 Redistribution configuration

Detailed Configuration of Routing Devices

Router A:

```
# Configure network interface.
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# ipv6 enable
Ruijie(config-if)# ipv6 address 2001:db8:12::1/64
Ruijie(config-if)# ipv6 rip enable
# Configure RIPng.
Ruijie(config)# ipv6 router rip
Ruijie(config-router)# exit
Router B:
# Configure network interface.
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# ipv6 enable
Ruijie(config-if)# ipv6 address 2001:db8:12::2/64
Ruijie(config-if)# ipv6 rip enable
Ruijie(config)# interface gigabitEthernet 0/2
Ruijie(config-if)# ipv6 enable
Ruijie(config-if)# ipv6 address 2001:db8:23::2/64
# Configure RIPng.
Ruijie(config)# ipv6 router rip
Ruijie(config-router)# redistribute bgp route-map riprm
Ruijie(config-router)# exit
# Configure BGP.
Ruijie(config)# router bgp 2
Ruijie(config-router)# neighbor 2001:db8:23::3 remote-as 3
Ruijie(config-router)# address-family ipv6
Ruijie(config-router-af)# neighbor 2001:db8:23::3 activate
# Configure route map.
```

```
Ruijie(config)# route-map riprm
Ruijie(config-route-map)# match community cl_110
# Define community list.
Ruijie(config)# ip community-list standard cl_110 permit 22:22
Router C:
# Configure network interface.
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# ipv6 enable
Ruijie(config-if)# ipv6 address 2001:db8:23::3/64
# Configure BGP.
Ruijie(config)# router bgp 3
Ruijie(config-router)# neighbor 2001:db8:23::2 remote-as 2
Ruijie(config-router)# address-family ipv6
Ruijie(config-router-af)# redistribute static route-map bgprm
Ruijie(config-router-af)# neighbor 2001:db8:23::2 activate
Ruijie(config-router-af)# neighbor 2001:db8:23::2 send-community
# Configure static route.
Ruijie(config)# ipv6 route 2001:db8:88::/64 null 0
Ruijie(config)# ipv6 route 2001:db8:99::/64 null 0
# Configure route map.
Ruijie(config)# route-map bgprm
Ruijie(config-route-map)# set community 22:22
```

Configuring OSPF

Overview

An open shortest path first (OSPF) routing protocol is an internal gateway routing protocol based on link status developed by the IETF OSPF work group It is designed for the IP environment and directly runs on the IP layer. With the protocol number being 89, this routing protocol exchanges OSPF packets in a manner of multicast by using the multicast address 224.0.0.5 (for all OSPF routers) and 224.0.0.6 (for specified routers).

The link status algorithm is an algorithm totally different from the Huffman vector algorithm (distance vector algorithm). The traditional RIP routing protocol uses the Huffman vector algorithm, while the OSPF routing protocol uses the link status algorithm. Compared with the RIP routing protocol, the OSPF routing protocol uses a different algorithm and introduces new concepts such as route update authentication, VLSMs, and route aggregation. Even if the RIPv2 has been improved greatly and also supports the features such as route update authentication and VLSM, the RIP routing protocol still has the following fatal weaknesses: 1) Slow convergence; 2) Limited network scale (with the maximum number of hops counting less than 16). The OSPF routing protocol overcomes these weaknesses, enabling the IGP protocol to be used in large and complicated network environments.

The OSPF routing protocol establishes and calculates the shortest path to each target network by using this complicated link status algorithm. Brief information about how the link status algorithm works is as follows:

- In the initialization stage, a router generates a link status notification that contains all link status of its own.
- All routers exchange the link status information in the multicast way. Upon receiving a link status update packet, each router copies the packet into the local database and then transmits the packet to other routers.
- After every router has a complete link status database, a router uses the Dijkstra algorithm to calculate the shortest path trees to all target networks. The results include the target network, next-hop address, and cost, which are the key parts of an IP routing table.

When there is no link cost or network change, the OSPF is inactive. When any changes occur on the network, the OSPF advertises the link status changes of only the changed links. The routers involved in the changes will run the Dijkstra algorithm again to generate new shortest path trees.

A group of routers running the OSPF routing protocol form the autonomous system of the OSPF routing area. An autonomous system consists of all the routers that are controlled and managed by one organization. Within the autonomous system, only one IGP routing protocol is run. However, between multiple autonomous systems, the BGP routing protocol is used to exchange routing information. Different autonomous area systems may use the same IGP routing protocol. Every autonomous system needs to request the related organization for the autonomous system number to connect to the Internet.

When the OSPF routing area is large, the hierarchical structure can be used. In other words, the OSPF routing area can be divided into several areas, which are connected via a backbone area. Every non-backbone area must be directly connected to the backbone area.

There are three roles for the routers in the OSPF routing area based on their deployment positions:

1) Area internal router: All interface networks of this router belong to a same area.

2) Area border router (ABR): The interface network of this router belongs at least to two areas, one of which must be the backbone area.

3) Autonomous system boundary router (ASBR): It is the router through which routes are exchanged between the OSPF route area and the external route area.

Ruijie products use the OSPF by fully complying with the OSPFv2 defined in RFC 2328. The main features are described as follows:

- Support multiple OSPF processes.
- Support the VRF. You can run the OSPF routing protocol based on different VRFs.
- Support the definition of the stubby area.
- Support route redistribution of static routes, directly-connected routes, dynamic routes, and the routing information among dynamic routing protocols such as RIP and BGP.
- Support plain-text or MD5 authentication between neighbors.
- Support virtual links.
- Support VLSMs.
- Support area division.
- Support the not so stubby area (NSSA) feature, as defined in RFC 3101.
- Support the graceful restart feature, as defined in RFC 3623.

☑ Ruijie products do not support the following functions now: OSPF line support on demand, as defined in RFC 1793; OSPF fast convergence.

Configuration Task List

The configuration of OSPF should be cooperated with various routers, including internal routers, area border routers, and autonomous system boundary routers. When no configuration is performed on routers, default parameters are used. In this case, packets are sent and received without authentication, and the interface does not belong to any area of an autonomous system. When changing the default parameters, you must ensure that the routers have the same configurations.

To configure an OSPF routing protocol, you must perform the following tasks. Among these tasks, creating the OSPF routing process is mandatory. Other tasks may be optional or mandatory in particular applications. The detailed tasks to configure the OSPF routing protocol are described as follows:

- Creating an OSPF routing process (mandatory)
- Configuring OSPF interface parameters (optional)
- Configuring the OSPF used on different physical networks (optional)
- Configuring OSPF area parameters (optional)
- Configuring an OSPF NSSA (optional)
- Configuring OSPF route aggregation (optional)
- Creating a virtual link (optional)
- Generating a default route (optional)
- Using the loopback interface address as the router ID (optional)
- Changing the default OSPF management distance (optional)
- Configuring the route calculation timer (optional)
- Configuring the link status advertisement (LSA) group pacing timer (optional)

- Configuring the cost for the OSPF interface (optional)
- Configuring an OSPF stub router (optional)
- Configuring whether to perform the MTU check on an interface (optional)
- Disabling an Interface to send the OSPF packets (optional)
- Configuring whether to perform the source address check (optional)
- Configuring the OSPF fast convergence function (optional)
- Configuring the OSPF capacity protection function (optional)
- Configuring the OSPF network management function(optional)
- Configuring the OSPF GR function (optional)
- Configuring the OSPF BFD function (optional)
- Configuring the OSPF VPN function (optional)
- Monitoring and maintaining the OSPF

For the configuration information about the following topics, see related sections in *Configuring Protocol-Independent Information*.

- Filtering the routing information
- Redistributing routes

Default OSPF configurations are described as follows:

Feature	Default Setting
Interface parameters	Interface metric: Not preset. LSA retransmission interval: 5 seconds. LSA transmission delay: 1 second. Interval for transmitting Hello packets: 10 seconds (30 seconds for non-broadcast networks) Failure time of adjacent routers: 4 times the interval for transmitting the Hello packets. Fast Hello: Disabled. Priority: 1. Authentication type: 0 (No authentication). Authentication password: None.
Area	Authentication type: 0 (No authentication). Default metric of aggregated routes to a Stub or NSSA area: 1. Inter-area aggregation scope: Undefined. Stub area: Undefined. NSSA: Undefined. Translator for translating Type-7 LSAs to Type-5 LSAs: Alternative. Interval of stabilizing the translation from Type-7 LSAs to Type-5 LSAs: 40 seconds.
Virtual links	No virtual link is defined. The default parameters of the virtual link are as follows: LSA retransmission interval: 5 seconds. LSA transmission delay: 1 second. Interval for transmitting Hello packets: 10 seconds. Failure time of adjacent routers: 4 times the interval for transmitting the

Feature	Default Setting
	Hello packets. Fast Hello: Disabled. Authentication type: No authentication. Authentication password: None.
Automatic cost calculation	Enabled. Default value automatically calculated is 100 Mbit/s.
Default route generation	Disabled. The default metric is 1 and the type is type-2 if enabled.
Default metric (Default metric)	Default metric used to redistribute other routing protocols
Management distance	Intra-area routing information: 110 Inter-area routing information: 110 External routing information: 110
Database filter	Disabled. All interfaces can receive the status update information (LSA).
Neighbor change log	Enabled.
Neighbor	N/A
Neighbor database filter	Disabled. All output LSAs are sent to all neighbors.
Network area (network area)	N/A
Router ID	Undefined. The OSPF protocol does not run on a router by default.
External route aggregation (summary-address)	Undefined.
Changing time of the status update information	240 seconds
Shortest path first (SPF) calculation timer	The time delay between the time for receiving information about topology changes and the next time for invoking the SPF calculation: 1000 milliseconds. The minimum interval between two calculating operations using the SPF algorithm: 5000 milliseconds. The maximum interval between two calculating operations using the SPF algorithm: 10000 milliseconds.
Optimal path rule used to calculate the external routes	Rules defined in RFC1583
OSPF stub router	Disabled.
OSPF two-way maintenance	Enabled.
Sending LSA packet updates	Time interval for sending data packets: 40 milliseconds. Number of LS-UPD packets in each data packet: 10.
OSPF overflow	Enter the overflow state when the memory lacks.
OSPF GR	GR restarter: Disabled. GR helper: Enabled.
OSPFv2 MIB binding	OSPFv2 process with the smallest process number
OSPFv2 TRAP sending	Disabled.

Creating an OSPF Routing Process

You can create an OSPF routing process and define the range of the IP addresses associated with the OSPF routing process and the OSPF area to which these IP addresses belong. The OSPF routing process only sends and receives the OSPF packets at the interface within the IP address range and advertises the link status of the interface to external routers.

Use the following commands to create the OSPF routing process.

Command	Function
Ruijie # **configure terminal**	Enters global configuration mode.
Ruijie (config)# **ip routing**	Enables the IP routing function (if disabled).
Ruijie (config)# **router ospf** [*process_id* [**vrf** *vrf-name*]]	Enables the OSPF and enters OSPF configuration mode.
Ruijie (config-router)# **network** *address wildcard-mask* **area** *area-id*	Defines an IP address range for an area.
Ruijie (config-router)# end	Returns to privileged EXEC mode.
Ruijie # show ip protocols	Displays the routing protocol that is running currently.
Ruijie # write	Saves the configurations.

Note

You can use the parameter *vrf vrf-name* to specify the VRF which the OSPF belongs to. If you do not specify this parameter when creating the OSPF routing process, the default VRF is used. For the **network** command, 32 bit wildcards are opposed to the mask. The value 1 indicates that the bit is not compared, and the value 0 indicates that the bit is compared. However, if you configure the command with masks, Ruijie products automatically translate the masks into bit wildcards. An interface belongs to the specific area as long as the address of the interface is within the IP address range defined in the **network** command. When the address of an interface is within more than one IP address ranges defined in the **network** command of multiple OSPF processes, the OSPF process that the interface involves in is determined based on the optimal mapping.

To disable the OSPF protocol, use the **no router ospf** *process-id* command. The following example shows how to enable the OSPF protocol:

```
Ruijie (config)# router ospf 1
Ruijie (config-router)# network 192.168.0.0 255.255.255.0 area 0
Ruijie (config-router)# end
```

Configuring OSPF Interface Parameters

You are allowed to change some particular interface parameters and configure the interface parameters on demand. It should be noted that some parameters must match those of the adjacent router of the interface. These parameters are set by using the **ip ospf hello-interval**, **ip ospf dead-interval**, **ip ospf authentication**, **ip ospf authentication-key**, and **ip ospf message-digest-key** commands. When you use these commands, make sure that the adjacent routers have the same configurations.

Use the following commands to configure the OSPF interface parameters in interface configuration mode.

Command	Function
Ruijie# **configure** terminal	Enters global configuration mode.

Command	Function
Ruijie(config)# **ip routing**	Enables the IP routing function (if disabled).
Ruijie(config)# **interface** *interface-id*	Enters interface configuration mode.
Ruijie(config-if)# **ip ospf cost** *cost-value*	(Optional) Defines the cost value for the interface.
Ruijie(config-if)# **ip ospf retransmit-interval** *seconds*	(Optional) Sets the link status retransmission interval.
Ruijie(config-if)# **ip ospf transmit-delay** *seconds*	(Optional) Sets the transmission delay for the link status update packets.
Ruijie(config-if)# **ip ospf hello-interval** *seconds*	(Optional) Sets the interval for sending the Hello packets, which must be same for all the nodes of the entire network.
Ruijie(config-if)# **ip ospf dead-interval** *seconds*	(Optional) Sets the dead interval for the adjacent routers, which must be same for all the nodes of the entire network.
Ruijie(config-if)# **ip ospf priority** *number*	(Optional) Priority, used to select the dispatched routers (DR) and backup dispatched routers (BDR).
Ruijie(config-if)# **ip ospf authentication [message-digest | null]**	(Optional) Sets the authentication type on the interface.
Ruijie(config-if)# **ip ospf authentication-key [0|7]** *key*	(Optional) Configures the text authentication key on the interface.
Ruijie(config-if)# **ip ospf message-digest-key *keyid* md5 [0|7**] *key*	(Optional) Configures the key for the MD5 authentication on the interface.
Ruijie (config-if)# **ip ospf database-filter all out**	(Optional) Prevents the interface from flooding the link status update packets. By default, the OSPF floods the LSA information over all interfaces in the same area except the interface on which the LSA information is received.
Ruijie (config-if)# **end**	Returns to privileged EXEC mode.
Ruijie # show **ip ospf interface** [*interface-id*]	Displays the OSPF interface information.
Ruijie # **write**	(Optional) Saves the configurations.

To restore the default value, use the **no** form of the above commands.

Configuring the OSPF Used on Different Physical Networks

According to the transmission features of different media, the networks are classified into three types according to the OSPF protocol:

- Broadcast network (Ethernet, token network, and FDDI)
- Non-broadcast network (frame relay, X.25)
- Point-to-point network (HDLC, PPP, and SLIP)

The non-broadcast networks include two types of networks according to the operation modes of the OSPF:

1) Non-broadcast multi-access (NBMA) network: The NBMA network requires direct communication for all interconnected routers. Only fully meshed networks can meet this requirement. If the SVC (for example, X.25) networking is used, this requirement can be met. However, it is difficult to use the PVC (for example, frame relay)

networking to meet this requirement. The operation of the OSPF on the NBMA network is similar to that on the broadcast network. That is, a designated router must be specified to advertise the link status on the NBMA network.

2) Point-to-multipoint network: If the network is not a fully meshed non-broadcast network, you need to set the network type of the interface to the point-to-multipoint network type according to the OSPF routing protocol. In a point-to-multipoint network, the connections between all routers are treated as point-to-point links according to the OSPF routing protocol, so you do not need to specify the designated router.

Whatever the default network type of the interface is, you can set it to the broadcast network type. For example, you can set the non-broadcast multi-access network (frame relay, X.25) to a broadcast network. The step to configure the neighbor routers can be omitted during the OSPF routing process configuration. By using the **X.25 map** and **Frame-relay map** commands, you can enable the broadcast function on the X.25 and frame relay networks. In this case, the X.25 and frame relay networks are treated as the broadcast networks.

The point-to-multipoint network interface can be seen as the marked point-to-point interface of one or more neighbors. When the network type of is configured to the point-to-multipoint network type according to the OSPF routing protocol, multiple host routes are generated. Compared with the NBMA network, the point-to-multipoint network has the following advantages:

- Easy configuration without configuring the neighbors or specifying the designated router.
- Low cost without requiring fully meshed topology

Use the following command to configure the network type in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip ospf network** {**broadcast** | **non-broadcast** | **point-to-point** | {**point-to-multipoint** [**non-broadcast**]}}	Configures the OSPF network type.

For different link encapsulation types, the default network types described as follows:

- Point-to-point network type:

For PPP, SLIP, frame relay point-to-point subinterface, and X.25 point-to-point subinterface encapsulation

- NBMA (non-broadcast) network type:

For frame relay, X.25 encapsulation (except the point-to-point subinterface)

- Broadcast network type:

For Ethernet encapsulation

- The point-to-multipoint network type has no default.

It should be noted that the network type should be consistent at both sides. Otherwise, exceptions occur. For instance, the neighbor is Full and the routing calculation is incorrect.

Configuring a Point-to-multipoint Broadcast Network

When routers are interconnected using the X.25 and frame relay networks, if the network is not a fully meshed network or you do not want to specify the designated router, you can set the network type of the OSPF interface to the point-to-multipoint type. Since the links are treated as point-to-point links on the point-to-multipoint network, multiple host routes are generated. In addition, all neighbors have the same cost value on the point-to-multiple network. If you want to enable different neighbors to have different cost values, you can set the cost by using the **neighbor** command.

Use the following commands to configure the point-to-multipoint network type in interface configuration mode.

Command	**Function**
Ruijie(config-if)# **ip ospf network point-to-multipoint**	Sets the broadcast network type for an interface to point-to-multipoint.
Ruijie(config-if)# **exit**	Returns to global configuration mode.
Ruijie(config)# **router ospf *1***	Enters routing process configuration mode.
Ruijie(config-router)# **neighbor ip-address cost** *cost*	(Optional). Specifies the cost of the neighbor router.

Note

Although the OSPF point-to-multipoint network is a non-broadcast network, the non-broadcast network is allowed to have the broadcast capability by manual configuration or self-learning according to the frame relay and X.25 mapping. Therefore, you do not need to specify neighbors when configuring the point-to-multipoint network.

Configuring a Non-broadcast Network

When the OSPF routing protocol works on a non-broadcast network, you can set the network type to the NBMA or point-to-multipoint non-broadcast type. Since a non-broadcast network do not have the broadcast capability and cannot dynamically discover neighbors, you must manually configure neighbors for the non-broadcast network when the OSPF routing protocol is used.

Set the network type as the NBMA type in the following conditions:

- When a non-broadcast network has the fully meshed topology;
- When a broadcast network is configured as the NBMA network type to reduce the generation of the broadcast packets, save the network bandwidth, and avoid some arbitrary reception and transmission of routers. During the configuration of the NBMA network, you must specify neighbors and the designated router. Therefore, you must configure the priorities for the routers. It is more possible for the route with a higher priority to be specifies as the designated router.

Use the following commands to set the network type to the NBMA type in interface configuration mode.

Command	**Function**
Ruijie (config-if)# **ip ospf network non-broadcast**	Specifies the network type of the interface to NBMA.
Ruijie (config-if)# **exit**	Returns to global configuration mode.
Ruijie (config)# **router ospf** *1*	Enters routing process configuration mode.
Ruijie(config-router)# **neighbor** *ip-address* [*priority number*] [*poll-interval seconds*]	Specifies the neighbor, its priority, and polling interval of Hello packets.

The best solution is to set the network where the OSPF is used to the point-to-multipoint non-broadcast network when you cannot make sure whether any two routers on a non-broadcast network are reachable directly.

All neighbors on the point-to-multipoint broadcast or non-broadcast network have the same cost value which is configured by using the **ip ospf cost** command. However, the bandwidth of each neighbor may be different, so the cost is different. You can specify the cost for each neighbor by using the **neighbor** command. However, this only applies to the interface used on the point-to-multipoint type (broadcast or non-broadcast) network.

Use the following commands to set the type of the interface as the point-to-multipoint type on a non-broadcast network in interface configuration mode.

Command	Function
Ruijie (config-if)# **ip ospf network point-to-multipoint non-broadcast**	Specifies the network type of the interface to be the point-to-multipoint non-broadcast network type.
Ruijie (config-if)# **exit**	Returns to global configuration mode.
Ruijie (config)# **router ospf** *1*	Enters routing process configuration mode.
Ruijie(config-router)# **neighbor** *ip-address* [*cost number*]	Specifies the neighbor and the cost to the neighbor.

Pay attention to step 4. If you have not specified the cost for the neighbor, the cost referenced in the **ip ospf cost** command in interface configuration mode is used.

Configuring the Broadcast Network Type

It is necessary to specify the designated router (DR) and backup designated router (BDR) for the OSPF broadcast network. The DR advertises the link status of this network to external devices. All routers keep the neighbor relationship with each another and only the adjacent relationship with the designated router and backup designated router. That is to say, each router only exchanges the link status packets with the designated router and backup designated router. Then the designated router advertises the link status information to all other routers. As a result, each router can store a consistent link status database.

You can control the specifying result of the designated router by configuring the OSPF priority. This parameter does not take effect immediately until the new round for specifying the designated router. The new round for specifying the designated router occurs only when the OSPF neighbors do not receive the Hello packets from the designated router within the specified time and judge that the DR is down.

Use the following commands to configure the broadcast network type in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip ospf network broadcast**	Specifies the type of the interface to be the broadcast network type.
Ruijie(config-if)# **ip ospf priority** *priority*	(Optional) Specifies the priority of the interface.

Configuring OSPF Area Parameters

To configure area authentication, stub area, and default route summary cost, you need to configure area commands.

The area authentication is used to prevent from learning non-authenticated and invalid routes and advertising valid routes to non-authenticated routers. In a broadcast network, the area authentication can also prevent the non-authenticated routers from becoming the designated routers, therefore improving the stability and intrusion prevention capability of the routing system.

When an area is an OSPF leaf area, that is, the area neither acts as a transit area nor injects external routes to the OSPF area, you can configure the area as a stub area. The routers in a stub area can only learn about three routes: 1) Routes in the stub area, 2) Routers in other areas, and 3) Default routes advertised by the stub area border router. There are few external routes, so the size of the routing tables of the routers in the stub area is small, and fewer router resources are used. The routers in the stub area may be low- or middle-level routers. To further reduce the number of the LSAs sent to the stub area, you can configure the area as a totally stub area (configured with the **no-summary** option). The routers in the totally stub area can learn two types of routes: 1) Routes in the totally stub area; 2) Default routes advertised by the border router in the totally stub area. After the totally stub area is configured, the router resources occupied by the OSPF are minimized, therefore improving the network transmission efficiency.

If the routers in a stub area can learn multiple default routes, you need to set the costs for these default routes by using the **area default-cost** command, so that the routers in the stub area use the specified default routes with priority.

Pay attention to the following aspects when configuring a stub area:

- A backbone area cannot be configured as a stub area, and the stub area cannot be used as the transmission area of virtual links.
- There is no ASBR in the stub area. In other words, the routes outside an autonomous system cannot be transmitted in this area.
- To set an area as the STUB area, configure all routers in this area with the same attribute.

Use the **no area *area-id*** command to remove the configurations of the specified OSPF area and delete the area, including deleting the area-based configuration commands such as **area authentication**, **area default-cost**, **area filter-list**, **area stub**, and **area nssa**. However, the user cannot remove the OSPF area configurations in the following circumstances:

3) The user needs to remove all configurations of the backbone area, however, configurations of virtual links exist. In this case, the user can delete the backbone area only when the configurations of virtual links are removed.

4) The corresponding **network area** command exists in any area. In this case, the user can delete the area only when all network segment commands added in this area are removed.

Use the following commands to configure the OSPF area parameters in routing process configuration mode.

Command	Function
Ruijie (config-router)#**area** *area-id* **authentication**	Sets plain-text authentication for the area.
Ruijie (config-router)#**area** *area-id* **authentication message-digest**	Sets MD5 authentication for the area.
Ruijie (config-router)#area *area-id* **stub** [**no-summary**]	Sets the area as a stubby area. **no-summary**: Sets the area as a stubby area to prevent the ABR in a stub area from sending summary-LSA information to the stub area.
Ruijie (config-router)#**area** *area-id* **default-cost** *cost*	Configures the cost of the default route sent to the stub area.

Note

When configuring the authentication, you need to configure the authentication parameters on an interface. For more details, see the "Configuring OSPF Interface Parameters" section. You must configure all routers in the area to have the same configuration with the stub area. To configure a totally stub area, you also have to configure the totally stub area parameters on the border routers in the stub area in addition to the basic configuration of the stub area, and you do not need to change the configurations of other routers.

Configuring an OSPF NSSA

The NSSA is an expansion of the OSPF stub area. In the NSSA, the consumption of router resources is reduced by preventing the type-5 LSAs (AS-external-LSA) from flooding to the NSSA. However, unlike the stub area, the NSSA can inject some routing information outside the autonomous system to the OSPF routing area.

Through the route redistribution, the external AS routes (type-7) are allowed to import to the NSSA. These external type-7 LSAs are converted into the type-5 LSAs on an area border router in the NSSA and flooded to the entire autonomous system. In this process, the external routes are aggregated and filtered.

Pay attention to the following aspects when configuring the NSSA:

- A backbone area cannot be configured as an NSSA, and the NSSA cannot be used as the transmission area of virtual links.
- To set an area as the NSSA, configure all routers connected to the NSSA with the NSSA attribute by using the **area nssa** command.

Use the following commands to configure an area as the NSSA area in routing process configuration mode.

Command	Function
Ruijie (config-router)# area *area-id* **nssa** [**no-redistribution**] [**no-summary**] [**default-information-originate[metric** *metric*][**metric-type** [**1** | **2**]]] [**translator** [**stability-interval** *seconds* | **always**]]	(Optional) Defines an NSSA area.
Ruijie (config-router)# **area** *area-id* **default-cost** *cost*	Configures the cost of the default route sent to the NSSA area.

Use the *default-information-originate* parameter to generate the default Type-7 LSA. This option varies slightly between the ARR and ASBR in the NSSA. On the ABR, whether the routing table contains a default route or not, the default Type-7 LSA route is generated. On the ASBR, the default Type-7 LSA route is generated only when the routing table of the ASBR contains a default route.

If the *no-redistribution* parameter is configured on the ASBR, other external routes introduced by using the **redistribute** commands are not allowed to be distributed to the NSSA. This option is usually used when the router in the NSSA is both an ASBR and an ABR. This option can also prevent the external routing information from entering the NSSA.

To further reduce the number of the LSAs sent to the NSSA, you can configure the *no-summary* parameter on the ABR to prevent the ABR from sending the aggregated LSAs (Type-3 LSAs) to the NSSA.

In addition, the *area default-cost* parameter is used on the ABR/ASBR connected to the NSSA. This option is used to configure the cost of the default route sent by the ABR/ASBR to the NSSA. By default, the cost value of this default route is 1.

If two or more than two ABRs exist in an NSSA area, the ABR with the largest ID is selected as the translator to translate the Type-7 LSAs to the Type-5 LSAs by default. You can use the *translator always* parameter to configure the current router as the permanent translator ABR.

If the translator role is acted by other ABRs, the current router keeps the capability within the **stability-interval** time. If the router is not configured as the translator again within this period, after the **stability-interval** time expires, LSAs translated from Type-7 to Type-5 will be removed from the AS.

Note

The Type-5 LSAs aggregated and translated from the Type-7 LSAs are removed immediately after the current router becomes translator-disabled without waiting for the **stability-interval** timeout to prevent routing loop.

In the same NSSA area, it is recommended to configure the *translator always* parameter for only one ABR.

Configuring OSPF Route Aggregation

Configuring the Route Aggregation between Areas

An area border router (ABR) has at least two interfaces that belong to different areas, one of which must be a backbone area. The ABR acts as the pivot in the OSPF routing area. It can advertise the routes of one area to another area. If the network addresses of the routes of this area are continual, the ABR can advertise only one aggregated route to other areas. The route aggregation function between areas greatly reduces the size of the routing table and improves the network efficiency.

Use the following command to configure the route aggregation between areas in routing process configuration mode.

Command	Function
Ruijie (config-router)# **area** *area-id* **range** *ip-address mask* [**advertise** | **not-advertise**] [**cost** *cost*]	Configures the route aggregation between areas.

Note

If the route aggregation is configured, the ABR does not advertise the detailed routes in this area to other areas.

Configuring the External Route Aggregation

When routes are redistributed in other routing processes and imported into the OSPF routing process, every route is advertised to the OSPF-enabled router as a separate link. If the injected routes have continuous IP addresses, an ASBR can advertise only one aggregated route, therefore reducing the size of the routing table significantly.

Use the following command to configure the external route aggregation in routing process configuration mode.

Command	Function
Ruijie (config-router)# **summary-address** *ip-address mask* [**not-advertise** | **tag** *tag-id*]	Configures the external route aggregation.

Controlling the Aggregated Routes to Be Added to the Routing Table

The network range after the route aggregation may exceed the original network range in the routing table. If data are sent to the network beyond the aggregation range, routing loop may incur or load on the router may increase. Therefore, add a discard route to the routing table of the ABR or ASBR to prevent that problem.

Use the following commands to allow or forbid adding the discarded routes to the routing table in routing process configuration mode.

Command	Function
Ruijie (config-router)# **discard-route** {**internal** | **external**}	Allows adding the discarded routes to the routing table.
Ruijie (config-router)# **no discard-route** {**internal** | **external**}	Forbids adding the discarded routes to the routing table.

By default, adding the discarded routes to the routing table is allowed.

Creating a Virtual Link

In an OSPF routing area, the OSPF route update between non-backbone areas is performed by using the backbone area. All non-backbone areas are connected to the backbone area. If the backbone area is disconnected with the non-backbone areas, you need to configure virtual links to connect the non-backbone areas to the backbone area. Otherwise, the network communication fails. Create virtual links for the connections when physical links cannot meet the requirements due to the limitation of the network topology.

A virtual link can be created between two ABRs. The common area that the two ABRs belong to is a transit area. A stub area and NSSA area cannot be used as the transit area. The virtual link can be seen as a logical connection channel established between the two ABRs via the transit area. On both ends of the virtual link deploy ABRs and configuration on both ends must be performed synchronously. The virtual link is identified with the router ID of the peer router. The area that provides the two ends of the virtual link with an internal non-backbone area route is called the transit area, whose number must be specified during the configuration.

The virtual link will be activated after the route in the transit area has been calculated (that is, the route to the peer router). You can see it as a point-to-point link, on which most parameters of the interface, such as the *hello-interval* and *dead-interval* parameters, can be configured like a physical interface.

A logical channel means that multiple routers running the OSPF routing protocol between the two ABRs. The logical channel is only used to forward packets. (Since the destination of the protocol packets are not these routers, the packets are transparent to them and are simply forwarded as common IP packets.) The two ABRs exchange routing information directly, and the synchronization mode in the area is not changed. The routing information means the Type-3 LSAs generated by the ABR.

Use the following command to create a virtual link in routing process configuration mode.

Command	**Function**
Ruijie (config-router)# **area** *area-id* **virtual-link** *router-id* [[**hello-interval** *seconds*]| [**retransmit-interval** *seconds*] |[transmit-delay *seconds*]|[**dead-interval** *seconds*]| [**authentication** [**message-digest** | **null**] |[[**authentication-key** [**0**|**7**] *key* | **message-digest-key** *keyid* **md5** [**0**|**7**] *key*]]]	Creates a virtual link.

Caution

If the autonomous system is divided into more than one area, one of the areas must be the backbone area to which the other areas must be connected directly or logically. Also, the backbone area must be in good connection.

Note

The *router-id* is the ID of an OSPF neighbor router. If you are not sure of the router-id, you can use the **show ip ospf** or **show ip ospf neighbor** command to check it. For information about how to manually configure the router-id, see the "Using the Loopback Interface Address as the Route ID" section.

Generating a Default Route

An ASBR can be forced to generate a default route, which is injected to the OSPF routing area. If a router is forced to generate the default route, it is configured to be the ASBR automatically. However, the ASBR does not automatically generate the default route.

Use the following command to force the ASBR to generate a default route in routing process configuration mode.

Command	**Function**
Ruijie (config-router)# **default-information originate** [**always**] [**metric** *metric-value*] [**metric-type** ***type***-*value*] [**route-map** ***map***-*name*]	Generates a default route.

Note

When the stub area is configured, the ABR generates the default route automatically and advertises the default route to all routers within this stub area.

Using the Loopback Interface Address as the Router ID

In an OSPF routing process, the largest interface IP address is always used as the router ID. If the interface is disabled or the IP address does not exist, the router ID must be calculated again and all the routing information is sent to the neighbors.

If the loopback interface address (local loop address) is configured, then in the routing process, the IP address of the loopback interface is used as the router ID. If there are multiple loopback interfaces, the largest IP address is selected as the router ID. The loopback address always exists, therefore improving the stability of the routing table.

Use the following commands to configure the loopback address in global configuration mode.

Command	Function
Ruijie (config)# **interface loopback** *1*	Creates the loopback interface.
Ruijie (config-if)# **ip address** *ip-address mask*	Configures the loopback IP address.

Note

When the IP address of a common interface is specified as the route identifier in the OSPF routing process, even if the loopback interface is configured, the identifier is not specified once again in the OSPF process.

Changing the Default OSPF Management Distance

The management distance of a route represents the credibility of the route source. The management distance ranges from 0 to 255. The greater this value is, the lower the credibility of the route source is.

The OSPF function supported on Ruijie products supports intra-area, inter-area, and external routes, whose management distances are all 110 by default. A route belongs to a same area is called the intra-area route, a route to another area is called the inter-area route, and a route to another routing area (learned through redistribution) is called the external route.

Use the following command to change the OSPF management distance in routing process configuration mode.

Command	Function
Ruijie(config-router)# **distance** {*distance* | **ospf** {**intra-area** *distance* | **inter-area** *distance* | **external** *distance*}}	Changes the OSPF management distance.

Configuring the Route Calculation Timer

When receiving a notification about route topology changes in the OSPF routing process, the system runs the SPF algorithm for route calculation after a time delay. You can configure this delay and also configure the minimum interval between two SPF calculations.

Use the following command to configure the OSPF route calculation timer in routing process configuration mode.

Command	Function
Ruijie (config-router)# **timers throttle spf** *spf-delay spf-holdtime spf-max-waittime*	Configures the route calculation timer.

Note

The *spf-delay* refers to the delay time from the time when the topology changes to the time when the SPF calculation is performed. The *spf-holdtime* refers to the minimum time interval between two SPF calculations. Later, the time interval of the consecutive SPF calculations shall be at least twice as the last time interval until the time interval reaches the *spf-max-waittime* value*.* If the time interval between two SPF calculations has exceeded the minimum value, then the time interval is recalculated from the *spf-holdtime*.

Normally, reducing the value of *spf-delay* and *spf-holdtime* can speed up the OSPF convergence if the link turbulence occurs occasionally. Increasing the value of the *spf-max-waittime* can avoid the CPU consumption by the OSPF routing process due to the consecutive link turbulence.

For example, timers throttle spf 1000 5,000 100,000

If the topology changes constantly, the time interval for SPF calculations increases in the ascend order as follows when calculated by using the binary exponential backoff algorithm, but this time interval does not exceed the *spf-max-waittime*:

1 second, 6 seconds, 16 seconds, 36 seconds, 76 seconds, 156 seconds, 256 seconds, 256+100 seconds…

Use the following command to configure only the OSPF route calculation delay and hold-time in routing process configuration mode.

Command	Function
Ruijie (config-router)# **timers spf** *spf-delay spf-holdtime*	Configures the route calculation timer in seconds.

Caution

The **timers spf** and **timers throttle spf** commands overwrite each other during the configuration. The latter configured command takes effect. If neither of the two commands are configured, the default value is the value configured in the **timers throttle spf** command.

The **timers throttle spf** command is more powerful than the **timers spf** command. Therefore, you are advised to use the **timers throttle spf** command.

Changing the LSA Group Pacing Timer

Each LSA has its own refresh and aging time. Calculating the refresh and aging time for each LSA respectively consumes lots of CPU. To make full use of the CPU, perform the refresh and aging operations for the LSAs uniformly.

The default refresh and aging time is 4 minutes. You do not need to adjust this parameter often. The optimum group pacing interval is inversely proportional to the number of LSAs that need to be calculated. For example, if approximately 10,000 LSAs exist in the database, decreasing the pacing interval would be better. If only 40 to 100 LSAs exist in the database, increasing the pacing interval to 10 to 20 minutes might be better.

Use the following commands in routing process configuration mode.

Command	Function
Ruijie # **configure terminal**	Enters global configuration mode.
Ruijie (config)# **router ospf** *1*	Enables the OSPF and enters OSPF configuration mode.
Ruijie (config-router)# **timers pacing lsa-group** *seconds*	(Optional) Changes the LSA group pacing.
Ruijie (config-router)# **end**	Returns to privileged EXEC mode.
Ruijie # **show running-config**	Verifies the configurations.

Command	Function
Ruijie # **write**	(Optional) Saves the configurations.

To restore the default value, use the **no timers pacing lsa-group** in global configuration mode.

Configuring the Cost for the OSPF Interface

The OSPF system calculates the destination route based on cost. The route with the least cost is the shortest route. The default route cost is based on network bandwidth. When you configure the OSPF-enabled router, you can set the link cost according to the factors such as link bandwidth, time delay or economic cost. The lower the link cost is, the higher the possibility is for the link to be selected as the route. If route aggregation is enabled, the maximum cost of all the aggregated links are used as the cost of the aggregated information.

Routing configuration includes two steps. First, specify a reference value for the generated cost based on the bandwidth. This value and the interface bandwidth are used to calculate the default cost. Second, set the cost for each interface by using the **ip ospf cost** command. In this case, the default cost takes no effective on the interface. For example, if the default reference value is 100 Mbit/s, and the bandwidth of an Ethernet interface is 10 Mbit/s, the default cost of this interface is 100/10 + 0.5 ≈ 10.

The interface cost is selected in the following way according to the OSPF protocol: The cost of the interface specified by the user has the highest priority. If you have specified the interface cost, the cost is used as the interface cost. If you do not specify the interface cost but the automatic cost generation function is enabled, the automatically calculated value is used. If the automatic cost generation function is disabled, the default value 10 is used.

Use the following commands to perform the configuration.

Command	Function
Ruijie # **configure terminal**	Enters global configuration mode.
Ruijie (config)# **router ospf** *1*	Enters routing protocol configuration mode.
Ruijie(config-router)# **auto-cost reference-bandwidth** *ref-bw*	(Optional) Sets the default cost based on the bandwidth on an interface. The cost value is determined based on the *ref-bw* parameter.
Ruijie (config-router)# **end**	Returns to privileged EXEC mode.
Ruijie # **show ip protocols**	Displays the routing protocol that is running currently.
Ruijie # **write**	(Optional) Saves the configurations.

To remove the setting, use the **no ip ospf cost** and **auto-cost** command.

Configuring an OSPF Stub Router

A router that only forwards packets to its directly-connected links is called a stub router. To prevent low-level routers from handling massive LSAs or to enable the routers to smoothly join/exit a network, you can configure such routers as stub routers. The stub router can advertise its maximum cost so that other routers will not preferentially use this router as a transit node during SPF calculation.

After the **max-metric router-lsa** command is enabled, the metric of non-stub links carried in the Router LSA generated by the router will be used as the maximum value (0xFFFF). After the user removes the setting or the timer expires, the default metric of the links is restored.

By default, after this command is enabled, the ordinary metric of stub links is advertised, namely the cost of the egress. If the *include-stub* parameter is configured, the maximum metric of the stub links is advertised.

If you do not want to transmit the data in an area, use the *summary-lsa* parameter to configure the summary LSA as the maximum metric for the ABR.

If you do not want to transmit the data in an external area, use the *external-lsa* parameter to configure the external LSA as the maximum metric for the ASBR.

The **max-metric router-lsa** command is generally used in the following circumstances:

- Restart the router. After the router is restarted, the IGP protocol is converged more quickly, and other routers may try to forward the data through the restarted router. If the router is still building BGP routing tables and certain BGP routes have not be learned, packets sent to such router will be discarded. In this case, use the on-startup parameter to configure a delay timer, so that the restarted router can act as the transit node after the timer runs out.
- Connect the router to the network without using the router to transmit the packets. If alternative paths exist, the current router will not be used to transmit the packets. If no alternative path exists, the current router will still be used to transmit the packets.
- Gracefully remove the router from the network. By using this command, the current router can advertise a maximum metric value, so that other routers on the network will select the alternative paths to transmit the packets before the router is shut down.

Use the following commands to configure a router to advertise a maximum metric in routing process configuration mode.

Command	Function
Ruijie # **configure terminal**	Enters global configuration mode.
Ruijie (config)# **router ospf** *1*	Enables the OSPF and enters OSPF configuration mode.
Ruijie (config-router)# **max-metric router-lsa** [**external-lsa** [*max-metric-value*]] [**include-stub**] [**on-startup** [*seconds*]] [**summary-lsa** [*max-metric-value*]]	(Optional) Configures the router to advertise a maximum metric.
Ruijie (config-router)# **end**	Returns to privileged EXEC mode.
Ruijie # **show ip protocols**	Displays the routing protocol that is running currently.
Ruijie # **write**	(Optional) Saves the configurations.

Caution

In the earlier versions of the OSPF (RFC 1247 or earlier versions), links with the maximum metric (0xFFFF) in the LSAs are not involved in the SPF calculation, that is, no packet is sent to routers generating these LSAs.

Configuring Whether to Perform the MTU Check on an Interface

When the OSPF system receives database description packets, it will check whether the MTU of a neighbor interface is the same as its own MTU. If the MTU of the interface indicated in the received database description packets is greater than that of the receiving interface, the adjacency relationship cannot be established. In this case, you can disable the MTU check function.

Use the following command to disable the MTU check on an interface in interface configuration mode.

Command	Function
Ruijie (config-if)# **ip ospf mtu-ignore**	Disables the MTU check on the interface when the interface receives the database description packets.

The MTU check on an interface is disabled by default.

Disabling an Interface to Send the OSPF Packets

To prevent other routers on the network from dynamically learning the routing information of the local router, you can use the **passive-interface** command to set the specified network interface of the local router as a passive interface to prevent the local router from sending the OSPF packets.

Use the following commands to configure an interface as a passive interface in privileged EXEC mode.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router ospf** *1*	Enters routing protocol configuration mode.
Ruijie(config-router)# **passive-interface** *interface-name*	(Optional) Sets the specified interface as a passive interface.
Ruijie(config-router)# **passive-interface default**	(Optional) Sets all network interfaces as the passive interfaces
Ruijie(config-router)# **end**	Returns to privileged EXEC mode.
Ruijie# **write**	Saves the configurations.

By default, all interfaces are allowed to receive and send the OSPF packets. To re-enable the network interface to send the routing information, use the **no passive-interface *interface-id*** command. To re-enable all network interfaces, use the keyword **default.**

Configuring Whether to Perform the Source Address Check

According to the OSPF requirements, the source address of the received packets must be in the same network segment with the address of the interface that receives the packets. However, for a point-to-point link, the addresses of the two link ends are configured independently, so the addresses are not required to be in the same network segment. In the negotiation process of a point-to-point link, the address information about the peer end is advertised. Therefore, the OSPF system will check whether the source address of the packets is the address advertised by the peer end during the negotiation. If the two addresses are not consistent, the system will treat the packets as unauthorized packets and discard the packets. The negotiated address may be shielded in some applications. In this case, disable this source address check function to establish the OSPF adjacency relationship properly. In particular, this function is disabled on the unnumbered interface all the time.

Use the following command to configure whether to perform the source address check on a point-to-point link in interface configuration mode.

Command	Function
Ruijie (config-if)# **ip ospf source-check-ignore**	Disables the source address check on the point-to-point link.

The source address check on a point-to-point link is enabled by default.

Configuring the OSPF Fast Convergence Function

Configuring the OSPF Fast Hello

The OSPF Fast Hello function facilitates fast discovery of OSPF neighbors and supports quick detection of lost OSPF neighbors. The OSPF Fast Hello function is enabled by specifying the **minimal** and **hello-multiplier** keywords and the *multiplier* parameter. The **Minimal** keyword is used to set the dead interval to 1 second, and the **hello-multiplier** keyword is used to configure the times for sending Hello packets during the dead interval, therefore the interval for sending the Hello packets is reduced to less than 1 second.

When the Fast Hello function is enabled on the interface, the **Hello interval** field for the interface sending the Hello packets is set to 0. The **Hello interval** field for the interface receiving the Hello packets is ignored.

No matter whether the Fast Hello function is enabled or not, the dead interval must be consistent on a same network segment. However, the *hello-multiplier* parameter is not required to be consistent on a same network segment as long as at least one Hello packet is received within the dead interval.

Use the following commands to configure the Fast Hello on an interface.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **ip routing**	Enables the IP routing function (if disabled).
Ruijie(config)# **interface** *interface-id*	Enters interface configuration mode.
Ruijie(config-if)# **ip ospf dead-interval minimal hello-multiplie**r *multiplier*	(Optional) Enables the OSPF Fast Hello on the interface.
Ruijie (config-if)# **end**	Returns to privileged EXEC mode.
Ruijie # **show ip ospf** [*process-id*]**interface** [*interface-id*]	Displays the OSPF interface information.
Ruijie # **write**	Saves the configurations.

Use the following commands to configure the Fast Hello on a virtual link.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie (config)# **ip routing**	Enables the IP routing function (if disabled).
Ruijie (config)# **router ospf** *process_id* [**vrf** *vrf-name*]	Enables the OSPF and enters OSPF configuration mode.
Ruijie (config-router)# **area** *area-id* **virtual-link** *router-id* [**dead-interval** | **minimal hello-multiplier** *multiplier*]	Enables the Fast Hello on the virtual link
Ruijie (config-router)# **end**	Returns to privileged EXEC mode.
Ruijie # **write**	Saves the configurations.

Caution

You cannot configure the *dead-interval minimal hello-multiplier* parameter and the *hello-interval* parameter at the same time.

Configuring the OSPF Two-Way Maintenance

On a large scale network, a large number of packets may be received and transmitted, which occupies high CPU and memory resources, therefore causing the delay or drop of certain packets. If the time for processing the Hello packets goes beyond the dead interval, the corresponding adjacent routers will be disconnected. In this case, enable the OSPF two-way maintenance function. If a large number of packets exist on the network, besides the Hello packets, the DD, LSU, LSR and LSAck packets from a certain neighbor can also be used to maintain the two-way adjacency relationship, therefore avoiding the disconnection of neighbors caused by the delay or drop of the Hello packets.

The OSPF two-way maintenance function is enabled by default. Use the following commands to disable the OSPF two-way maintenance function in routing process configuration mode.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router ospf** *1*	Enters routing protocol configuration mode.
Ruijie(config-router)# **no two-way-maintain**	(Optional) Disables the OSPF two-way maintenance function.
Ruijie(config-router)# **end**	Returns to privileged EXEC mode.
Ruijie# **write**	Saves the configurations.

Configuring the Interval of Receiving the Same LSA

On a broadcast network or in the environment featured by frequent network oscillation, the router may receive the same LSA updates from one or multiple interfaces and different neighbors. If the same LSAs are processed every time, excessive system resources are wasted. According to the OSPF protocol, the same LSAs are considered to be valid after a period of time. The same LSAs received within a short period of time will be ignored. This time interval is the constant MinLSArrival with the value set to 1 second.

Different types of networks have different requirements on the interval for processing LSA changes. The user can configure this parameter according to different network planning and performance requirements to optimize the network.

Use the following commands to configure the interval of receiving the same LSA in routing process configuration mode.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router ospf** *1*	Enters routing protocol configuration mode.
Ruijie(config-router)# **timers lsa arrival *arrival***-*time*	(Optional) Configures the interval of receiving the same LSA. The default value is 1000 milliseconds.
Ruijie(config-router)# **end**	Returns to privileged EXEC mode.
Ruijie# **write**	Saves the configurations.

Configuring to Send the LSA Packet Updates

To relieve the impacts on network devices caused by the flooding of a large number of update packets, the LSP packet update function is introduced. By specifying the delay interval for the update packets, the LSAs to be flooded during the interval can be collected, so that these LSAs can be sent with the least number of packets. Meanwhile, the CPU can process other tasks and the system performance is optimized.

When a large number of LSAs exist on the network and the router loads excessively, you need to configure the **transmit-time** and **transmit-count** commands properly to control the number of LS-UPD packets flooded on the network. When the load of CPU is low and the network bandwidth is small, you can reduce the transmit-time value and increase the transmit-count value to speed up the network convergence.

Use the following commands to configure the LSA to send the packet updates in routing process configuration mode.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router ospf** *1*	Enters routing protocol configuration mode.
Ruijie(config-router)# **timers pacing lsa-transmit** *transmit-time transmit-count*	(Optional) Configures the LSA to send the packet updates.
Ruijie(config-router)# **end**	Returns to privileged EXEC mode.
Ruijie# **write**	Saves the configurations.

Configuring the Exponential Backoff Algorithm for Generating LSAs

To prevent multiple events from triggering the same LSAs within a short time, causing frequent LSA updates, and consuming excess CPU resources, you can specify the minimum time interval "MinLSInterval" for generating the LSAs according to the OSPF routing protocol. The default minimum time interval is 5 seconds. During this time interval, the same LSA instances cannot be generated repeatedly, therefore preventing frequent LSA oscillation from causing impacts on the network. However, this configuration slows down the LSA generation speed and fails to advertise the network topology changes immediately.

To quickly respond to the network topology changes and avoid excessively frequent route calculations, use the exponential backoff algorithm to dynamically change the time interval for generating the LSAs. The **timers throttle lsa all** command has three parameters: *delay-time*, *hold-time*, and *max-wait-time*, which allow the system to automatically adjust the time interval for generating the LSAs according to the frequency of the network topology changes. Generally, *delay-time* is set to a small value or 0 to trigger LSA instances immediately when the network topology is comparatively stable. When the network topology changes frequently, the time interval for generating the LSAs increases from the *hold-time* and follows the algorithm of *hold-time* x 2^{n-1}. n refers to the times of changes. With the times for generating LSAs repeatedly increasing, the time interval for generating the LSAs becomes greater and greater until the *max-wait-time* is reached. When the time interval for generating the LSAs is greater than the *max-wait-time*, the *delay-time* for generating the LSAs restores to the initial value.

By default, the initial value is 0 milliseconds, the *hold-time* is 5000 milliseconds, and the *max-wait-time* is 5000 milliseconds. The shortest interval for consecutively generating the same LSA is the *MinLSInterval*, which complies with the rules defined in RFC 2328.

Use the following commands to configure the exponential backoff algorithm for generating the LSAs in routing process configuration mode.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router ospf** *1*	Enters routing protocol configuration mode.
Ruijie(config-router)# **timers throttle lsa all** *delay-time hold-time max-wait-time*	(Optional) Configures the exponential backoff algorithm for generating the LSAs. By default, the initial value is 0 milliseconds, the *hold-time* is 5000 milliseconds, and the *max-wait-time* is 5000 milliseconds.
Ruijie(config-router)# **end**	Returns to privileged EXEC mode.
Ruijie# **write**	Saves the configurations.

Caution During the configuration, the *hold-time* cannot be less than the *delay-time*, and the *max-wait-time* cannot be less than the *hold-time*.

Configuring the OSPF Capacity Protection Function

When the memory lacks, the OSPF system enters the overflow state. In the overflow state, the OSPF protocol triggers the following operations:

- For the learned LSAs: receive the inter-area and intra-area LSAs, and only receive the external LSAs indicating that the route to the destination address is a specific non-default route.
- For the external LSAs generated by itself: clear the external LSAs except for the LSAs indicating the default routes.
- The incompleteness of route learning and advertisement may lead to the routing loop on the network. The OSPF system generates a default route to the NULL interface to prevent the routing loop. The generated default route exists in the overflow state all the time.

Use the following commands to configure the OSPF router to enter the overflow state when the memory lacks.

Command	Function
Ruijie(config)#**router ospf** *process-id*	Enters OSPF configuration mode.
Ruijie(config-router)#**overflow memory-lack**	Configures the OSPF system to enter the overflow state when the memory lacks.

Note By default, the OSPF system enters the overflow state automatically when the memory lacks. You can use the **no overflow memory-lack** command to disable this function.

Caution You must use the **clear ip ospf process** command or restart the OSPF protocol to exit from the overflow state.

Configuring the OSPF Network Management Function

Configuring the OSPFv2 MIB Binding

The user can only operate a sole OSPFv2 process by SNMP since the OSPFv2 MIB does not have the OSPFv2 process information. By default, the OSPFv2 MIB is bound to the OSPFv2 process with the smallest scale, and this process takes effect over all user operations.

The user can bind the OSPFv2 MIB to the process manually to operate the specified OSPFv2 process by using SNMP.

Use the following commands in routing process configuration mode.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.

Ruijie(config)# **router ospf** *1*	Enters routing protocol configuration mode.
Ruijie(config-router)# **enable mib-binding**	(Optional) Binds the OSPFv2 MIB to the specified OSPFv2 process.
Ruijie(config-router)# **end**	Returns to privileged EXEC mode.
Ruijie# **write**	Saves the configurations.

Configuring the OSPFv2 TRAP Binding

The OSPFv2 protocol defines several types of OSPF TRAP information, which is used to report various events about the OSPFv2 protocol. Sending the OSPFv2 TRAP information is not restricted by the MIB binding to the OSPFv2 process. The TRAP switch is allowed to be enabled for different processes at the same time.

Use the following commands in global configuration mode.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **snmp-server enable traps ospf**	(Optional) Enables the OSPF TRAP sending switch.
Ruijie(config)# **router ospf** *1*	Enters routing protocol configuration mode.
Ruijie(config-router)# **enable traps [error [IfAuthFailure | IfConfigError | IfRxBadPacket | VirtIfAuthFailure | VirtIfConfigError | VirtIfRxBadPacket] | lsa [LsdbApproachOverflow | LsdbOverflow | MaxAgeLsa | OriginateLsa] | retransmit [IfTxRetransmit | VirtIfTxRetransmit] | state-change [IfStateChange | NbrRestartHelperStatusChange | NbrStateChange | NssaTranslatorStatusChange | RestartStatusChange | VirtIfStateChange | VirtNbrRestartHelperStatusChange | VirtNbrStateChange]]**	(Optional) Enables the specified OSPF TRAP switch.
Ruijie(config-router)# **end**	Returns to privileged EXEC mode.
Ruijie# **write**	Saves the configurations.

Configuring the OSPF GR Function

The graceful restart (GR) function is used to enable data packets to be forwarded continuously during the restart process of the OSPF protocol. Currently, the GR function is supported on the switchover between our primary and secondary high-end devices to ensure that the key service is not interrupted.

Working Principles of the OSPF GR

OSPF GR standard:

RFC3623: Graceful OSPF Restart

Working principles of RFC3623:

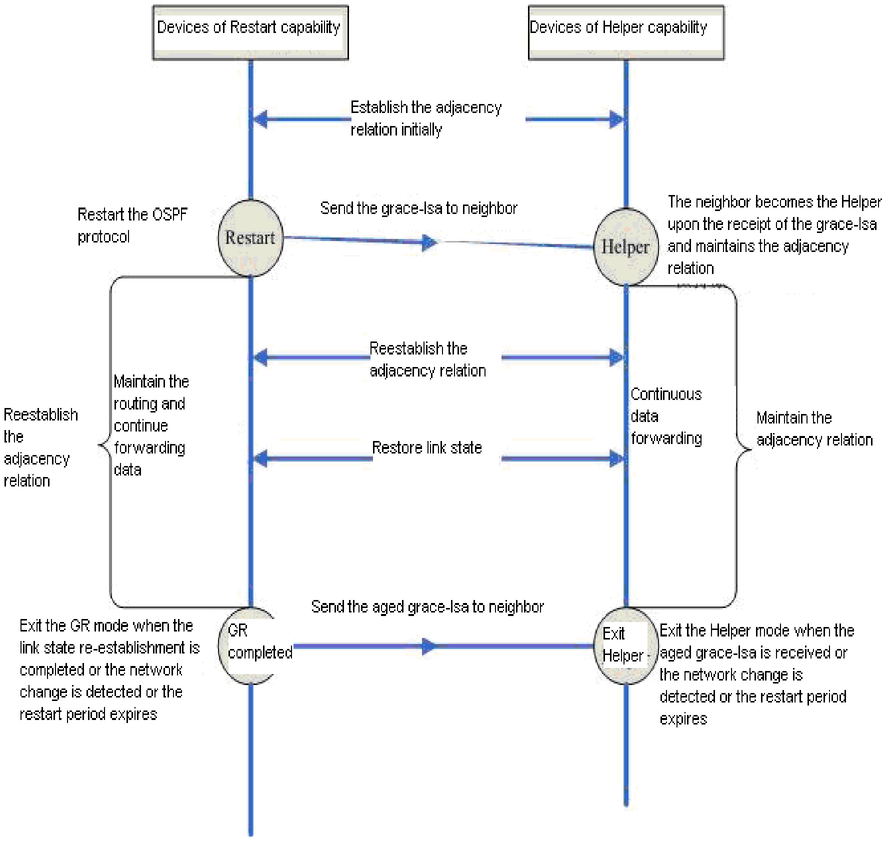
As a standard GR protocol defined by the IETF for the OSPF, RFC3623 defines the conditions, operations and precautions required for executing the Graceful Restart. As specified in RFC3623, two GR principles are important.

Namely, the network topology should be stable and the router for restarting the protocols can maintain the forwarding table during the restarting process.

The execution of OSPF GR is not an independent process. The OSPF GR has the GR Restart and GR Help functions. The device with the GR Restart capability can automatically perform the graceful restart operation, and the device with the GR Help capability can receive Grace_LSAs and help the neighbors to perform the graceful restart operation.

Generally, the device that has the GR Restart capability and is performing the GR operation is called the GR Restarter. The device that has the GR Help capability and is helping the GR Restarter to perform the GR operation is called the GR Helper. The GR process begins from the operation where the GR Restarter sends a Grace LSA. The neighbor becomes the GR Helper upon receiving the Grace LSA and assists the GR Restarter to reestablish the adjacency relationship. Meanwhile, the neighbor maintains the adjacency relationship with the GR Restarter for continuous data forwarding.

OSPF GR execution flowchart



Devices of Restart capability
Devices of Helper capability
Establish the adjacency relation initially
Restart the OSPF protocol
Restart
Send the grace-lsa to neighbor
Helper
The neighbor becomes the Helper upon the receipt of the grace-lsa and maintains the adjacency relation
Reestablish the adjacency relation
Maintain the routing and continue forwarding data
Reestablish the adjacency relation
Restore link state
Continuous data forwarding
Maintain the adjacency relation
Send the aged grace-lsa to neighbor
Exit the GR mode when the link state re-establishment is completed or the network change is detected or the restart period expires
GR completed
Exit Helper
Exit the Helper mode when the aged grace-lsa is received or the network change is detected or the restart period expires

The above figure outlines the execution process of the OSPF GR. The GR period is the longest time for reestablishing the link status. When the period for the link reestablishment or the graceful restart expires, the GR Restarter exits the GR operation.

Configuring the OSPF GR Restarter

Use the **graceful-restart** command to enable the OSPF GR restarter.

Command	Function
Ruijie # **configure terminal**	Enters global configuration mode.
Ruijie (config)# **router ospf** *1*	Enables the OSPF and enters OSPF configuration mode.

Ruijie (config-router)# **graceful-restart**	Enables the OSPF GR restarter.
Ruijie (config-router)# **end**	Returns to privileged EXEC mode.
Ruijie # **show running-config**	Verifies the configurations.
Ruijie # **write**	(Optional) Saves the configurations.

By default, the GR restarting period is 120 seconds. Use the **graceful-restart grace-period** command to modify the restarting period.

Command	Function
Ruijie # **configure terminal**	Enters global configuration mode.
Ruijie (config)# **router ospf** *1*	Enables the OSPF and enters OSPF configuration mode.
Ruijie (config-router)# **graceful-restart** grace-period *100*	Enables the OSPF GR restarter and sets the GR restarting period to 100 seconds.
Ruijie (config-router)# **end**	Returns to privileged EXEC mode.
Ruijie # **show running-config**	Verifies the configurations.
Ruijie # **write**	(Optional) Saves the configurations.

Note

The routers do not support this function.

Configuring the OSPF GR Helper

The OSPF GR Helper is enabled by default. The software provides the functions to disable the GR Helper and configure the GR Helper to detect the network changes. The following example shows how to disable and re-enable the GR Helper function and how to configure the Helper to detect the network changes.

Command	Function
Ruijie # **configure terminal**	Enters global configuration mode.
Ruijie (config)# **router ospf** *1*	Enables the OSPF and enters OSPF configuration mode.
Ruijie (config-router)# **graceful-restart helper disable**	Disables the OSPF GR Helper (for disabling the GR help to neighbors).
Ruijie (config-router)# **no graceful-restart helper disable**	Enables the OSPF GR Helper again.
Ruijie (config-router)# **graceful-restart helper** {**strict-lsa-checking** | **internal-lsa-checking**}	Enables the OSPF GR Helper to check the LSA changes to detect the network changes. If the network changes, exit the GR Helper. By default, the network changes are not detected after the GR Helper is enabled. **strict-lsa-checking:** checks the changes of types 1 to 5 and type 7 LSAs. **internal-lsa-checking:** checks the changes of types 1 to 3 LSAs.
Ruijie (config-router)# **end**	Returns to privileged EXEC mode.
Ruijie # **show running-config**	Verifies the configurations.
Ruijie # **write**	(Optional) Saves the configurations.

Changes in a part of the network may disable the GR function and cause low convergence performance on the entire network. Therefore, it is not recommended that the user enable the LSA detection function when the network is in a large scale.

Configuring the OSPF BFD Function

For details about the OSPF BFD configuration, see *BFD Configuration Guide*.

Configuring the OSPF VPN Function

For details about the OSPF VPN configuration, see *Configuring the OSPF VPN extension*.

Monitoring and Maintaining the OSPF

The following table shows the data such as the OSPF routing table, cache, and database that can be displayed.

Command	Function
show ip ospf [*process-id*]	Displays the general information about the corresponding processes of the OSPF protocol. All processes are displayed if no process number is specified.
show ip ospf [*process-id area-id*] **database** [**adv-router** *ip-address* | {**asbr-summary** | **external** | **network** | **nssa-external | opaque-area | opaque-as | opaque-link | router** | **summary**} [*link-state-id*] [{**adv-router** *ip-address* | **self-originate}**] | **database-summary** | **max-age** | **self-originate**]	Displays the OSPF database information. You can view the information about each type of LSAs in the specified process.
show ip ospf [*process-id*] **border-routers**	Shows the routing information about the specified process after reaching the ABR and ASBR.
show ip ospf interface [*interface-name*]	Shows the information about the interface involved in the OSPF routing.
show ip ospf [*process-id*] **neighbor**[*interface-name*] [*neighbor-id*] **[detail]**	Shows the information about the adjacent routers of the interface. *interface-name*: local interface connected to the neighbor *neighbor-id*: router ID of the neighbor.
show ip ospf [*process-id*] **virtual-links**	Views the virtual link information about the specified process.
show ip ospf [*process-id*] **route [count]**	Shows the routes in the OSPF routing table.
show ip ospf [*process-id*] **spf**	Shows the times for calculating inter-area routes.

For specific explanations about the commands, see *OSPF Routing Protocol Configuration Command*. The commonly used commands for monitoring and maintenance are described as follows:

5) Show the status of the OSPF neighbors.

Use the **show ip ospf** [*process-id*] **neighbor** command to show all information about neighbors in the OSPF process, including the status, role, router ID, IP address, and BFD state.

```
Ruijie# show ip ospf neighbor
```

```
OSPF process 1:
Neighbor ID     Pri State BFD State Dead Time   Address:        Interface
10.10.10.50 1 Full/DR  UP   00:00:38        10.10.10.50     eth0/0
OSPF process 100:
Neighbor ID     Pri State BFD State Dead Time   Address:    Interface
10.10.11.50 1   Full/Backup     DOWN 00:00:31   10.10.11.50     eth0/1
Ruijie# show ip ospf 1 neighbor
OSPF process 1:
Neighbor ID     Pri State BFD State Dead Time   Address:    Interface
10.10.10.50 1   Full/DR         UP 00:00:38     10.10.10.50     eth0/0
Ruijie# show ip ospf 100 neighbor
OSPF process 100:
Neighbor ID     Pri State   BFD State Dead Time     Address:    Interface
10.10.11.50 1   Full/Backup     DOWN 00:00:31   10.10.11.50     eth0/1
```

6) Show the status of the OSPF interfaces

According to the following message, the FastEthernet 0/1 interface belongs to Area 0 in the OSPF routing area, the router ID is 192.168.1.1, and the network type is BROADCAST. Pay special attention to the parameters such as *Area*, *Network Type*, *Hello*, and *Dead*. If these parameters are different from the neighbor, no adjacency relationship is established.

```
Ruijie# sh ip ospf interface fastEthernet 0/1
FastEthernet 1/0 is up, line protocol is up
Internet Address 192.168.1.1/24, Ifindex: 2 Area 0.0.0.0, MTU 1500
Matching network config: 192.168.1.0/24,
Process ID 1, Router ID 192.168.1.1, Network Type BROADCAST, Cost: 1
Transmit Delay is 1 sec, State DR, Priority 1
Designated Router (ID) 192.168.1.1, Interface Address 192.168.1.1
Backup Designated Router (ID) 192.168.1.2, Interface Address 192.168.1.2
Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
Hello due in 00:00:04
Neighbor Count is 1, Adjacent neighbor count is 1
Crypt Sequence Number is 30
Hello received 972 sent 990, DD received 3 sent 4
LS-Req received 1 sent 1, LS-Upd received 10 sent 26
LS-Ack received 25 sent 7, Discarded 0
```

7) Show the information about the OSPF routing process

Run the following command to show the information about the route ID, router type, area information, and area route aggregation.

```
Ruijie# show ip ospf
Routing Process "ospf 1" with ID 1.1.1.1
Process uptime is 4 minutes
Process bound to VRF default
Conforms to RFC2328, and RFC1583 Compatibility flag is enabled
Supports only single TOS(TOS0) routes
Supports opaque LSA
```

```
Enable two-way-maintain
This router is an ASBR (injecting external routing information)
Initial SPF schedule delay 1000 msecs
Minimum hold time between two consecutive SPFs 5000 msecs
Maximum wait time between two consecutive SPFs 10000 msecs
Initial LSA throttle delay 0 msecs
Minimum hold time for LSA throttle 5000 msecs
Maximum wait time for LSA throttle 5000 msecs
Lsa Transmit Pacing timer 40 msecs, 10 LS-Upd
Minimum LSA arrival 1000 msecs
Pacing lsa-group: 240 secs
Number of incoming current DD exchange neighbors 0/5
Number of outgoing current DD exchange neighbors 0/5
Number of external LSA 4. Checksum 0x0278E0
Number of opaque AS LSA 0. Checksum 0x000000
Number of non-default external LSA 4
External LSA database is unlimited.
Number of LSA originated 6
Number of LSA received 2
Log Neighbor Adjacency Changes: Enabled
Graceful-restart disabled
Graceful-restart helper support enabled
Number of areas attached to this router: 1
Area 0 (BACKBONE)
Number of interfaces in this area is 1(1)
Number of fully adjacent neighbors in this area is 1
Area has no authentication
SPF algorithm last executed 00:01:26.640 ago
SPF algorithm executed 4 times
Number of LSA 3. Checksum 0x0204bf
Routing Process "ospf 20" with ID 2.2.2.2
Process uptime is 4 minutes
Process bound to VRF default
Conforms to RFC2328, and RFC1583 Compatibility flag is enabled
Supports only single TOS(TOS0) routes
Supports opaque LSA
Enable two-way-maintain
Initial SPF schedule delay 1000 msecs
Minimum hold time between two consecutive SPFs 5000 msecs
Maximum wait time between two consecutive SPFs 10000 msecs
Initial LSA throttle delay 0 msecs
Minimum hold time for LSA throttle 5000 msecs
Maximum wait time for LSA throttle 5000 msecs
Lsa Transmit Pacing timer 40 msecs, 10 LS-Upd
Minimum LSA arrival 1000 msecs
```

```
Pacing lsa-group: 240 secs
Number of incoming current DD exchange neighbors 0/5
Number of outgoing current DD exchange neighbors 0/5
Number of external LSA 0. Checksum 0x000000
Number of opaque AS LSA 0. Checksum 0x000000
Number of non-default external LSA 0
External LSA database is unlimited.
Number of LSA originated 0
Number of LSA received 0
Log Neighbor Adjacency Changes: Enabled
Number of areas attached to this router: 0
```

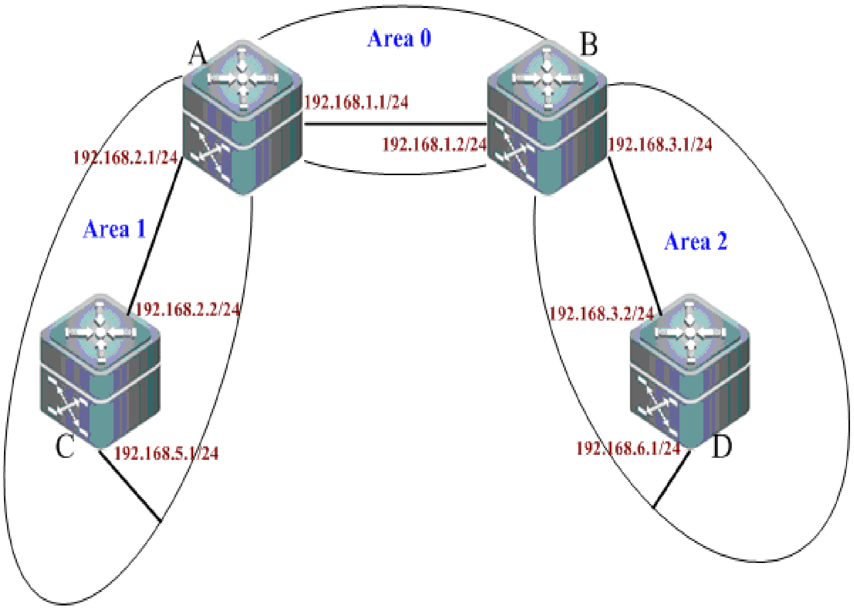
Configuration Examples

Example of Multi-Area OSPF Configuration

Networking Topology

The following figure shows the networking topology of an OSPF autonomous system. The entire autonomous system is divided into three areas: Area 0, Area 1, and Area 2. Each router runs the OSPF routing protocol.

Networking topology for the multi-area OSPF configuration



Applications

Configure Router A and Router B as area border routers (ABR) and Router C and Router D as intra-AS routers. Based on the basic OSPF configurations, every switch can successfully learn the routes in the autonomous system to all network segments.

Configuration Tips

- Configure the IP address for each interface on the routers.
- Enable the basic OSPF functions.

1. Enable the routing function (enabled by default).
2. Create an OSPF routing process.
3. Specify the IP address range associated with this routing process and the OSPF area to which the IP addresses within the range belong.

Configuration Steps

- Configuration steps of A

Step 1: Configure the IP address for the interface.

```
A(config)#interface gigabitEthernet 0/1
A(config-if-GigabitEthernet 0/1)#ip address 192.168.1.1 255.255.255.0
A(config-if-GigabitEthernet 0/1)#exit
A(config)#interface gigabitEthernet 0/2
A(config-if-GigabitEthernet 0/2)#ip address 192.168.2.1 255.255.255.0
A(config-if-GigabitEthernet 0/2)#exit
```

Step 2: Configure the basic OSPF functions.

```
A(config)#router ospf 1
A(config-router)#network 192.168.1.0 0.0.0.255 area 0
A(config-router)#network 192.168.2.0 0.0.0.255 area 1
```

- Configuration steps of B

Step 1: Configure the IP address for the interface.

```
B(config)#interface gigabitEthernet 0/1
B(config-if-GigabitEthernet 0/1)#ip address 192.168.1.2 255.255.255.0
B(config-if-GigabitEthernet 0/1)#exit
B(config)#interface gigabitEthernet 0/2
B(config-if-GigabitEthernet 0/2)#ip address 192.168.3.1 255.255.255.0
B(config-if-GigabitEthernet 0/2)#exit
```

Step 2: Configure the basic OSPF functions.

```
B(config)#router ospf 1
B(config-router)#network 192.168.1.0 0.0.0.255 area 0
B(config-router)#network 192.168.3.0 0.0.0.255 area 2
```

- Configuration steps of C

Step 1: Configure the IP address for the interface.

```
C(config)#interface gigabitEthernet 0/3
```

```
C(config-if-GigabitEthernet 0/3)#ip address 192.168.2.2 255.255.255.0
C(config-if-GigabitEthernet 0/3)#exit
C(config)#interface gigabitEthernet 0/4
C(config-if-GigabitEthernet 0/4)#ip address 192.168.5.1 255.255.255.0
C(config-if-GigabitEthernet 0/4)#exit
```

Step 2: Configure the basic OSPF functions.

```
C(config)#router ospf 1
C(config-router)#network 192.168.2.0 0.0.0.255 area 1
C(config-router)#network 192.168.5.0 0.0.0.255 area 1
```

- Configuration steps of D

Step 1: Configure the IP address for the interface.

```
D(config)#interface gigabitEthernet 0/3
D(config-if-GigabitEthernet 0/3)#ip address 192.168.3.2 255.255.255.0
D(config-if-GigabitEthernet 0/3)#exit
D(config)#interface gigabitEthernet 0/4
D(config-if-GigabitEthernet 0/4)#ip address 192.168.6.1 255.255.255.0
D(config-if-GigabitEthernet 0/4)#exit
```

Step 2: Configure the basic OSPF functions.

```
D(config)#router ospf 1
D(config-router)#network 192.168.3.0 0.0.0.255 area 2
D(config-router)#network 192.168.6.0 0.0.0.255 area 2
```

Verification

Step 1: Display information about neighbors (taking A and B as the examples).

```
A#show ip ospf neighbor
OSPF process 1, 2 Neighbors, 2 is Full:
Neighbor ID  Pri  State   Dead Time  Address        Interface
192.168.1.2 1  Full/DR  00:00:40 192.168.1.2 GigabitEthernet 0/1
192.168.2.2 1 Full/BDR  00:00:34 192.168.2.2  GigabitEthernet 0/2
B#show ip ospf neighbor
OSPF process 1, 2 Neighbors, 2 is Full:
Neighbor ID Pri  State Dead Time  Address        Interface
192.168.1.1 1 Full/BDR  00:00:32 192.168.1.1  GigabitEthernet 0/1
192.168.3.2 1 Full/BDR  00:00:30 192.168.3.2  GigabitEthernet 0/2
```

Step 2: Display OSPF routing information about A.

```
A#show ip route
Codes: C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
```

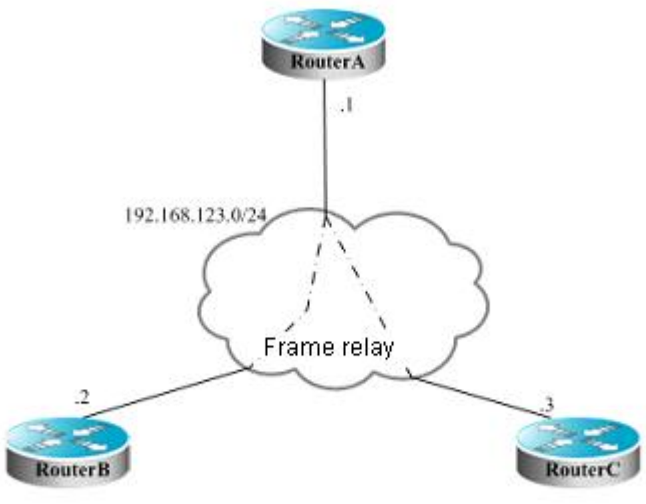
```
i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
ia - IS-IS inter area, * - candidate default
Gateway of last resort is no set
C    192.168.1.0/24 is directly connected, GigabitEthernet 0/1
C    192.168.1.1/32 is local host.
C    192.168.2.0/24 is directly connected, GigabitEthernet 0/2
C    192.168.2.1/32 is local host.
O IA 192.168.3.0/24 [110/2] via 192.168.1.2, 00:18:03, GigabitEthernet 0/1   //inter-AS route
O    192.168.5.0/24 [110/2] via 192.168.2.2, 00:00:02, GigabitEthernet 0/2
O IA 192.168.6.0/24 [110/3] via 192.168.1.2, 00:01:02, GigabitEthernet 0/1   //inter-AS route
C#show ip route
Gateway of last resort is no set
O IA 192.168.1.0/24 [110/2] via 192.168.2.1, 00:19:05, GigabitEthernet 0/3   //inter-AS route
C    192.168.2.0/24 is directly connected, GigabitEthernet 0/3
C    192.168.2.2/32 is local host.
O IA 192.168.3.0/24 [110/3] via 192.168.2.1, 00:19:05, GigabitEthernet 0/3
C    192.168.5.0/24 is directly connected, GigabitEthernet 0/4
C    192.168.5.1/32 is local host.
O IA 192.168.6.0/24 [110/4] via 192.168.2.1, 00:03:19, GigabitEthernet 0/3   //inter-AS route
```

Example of OSPF NBMA Network Configuration

Configuration Requirements

Full mesh connection of three routers can be implemented through a frame relay network. Each router has only one frame relay link and the same link bandwidth and PVC rate. The following figure shows details about the IP address assignment and connections of the three routers.

Networking topology for OSPF NBMA network configuration



Requirements:

- The network among A, B, and C must configured as an NBMA network.

- A is the designated router, and B is the backup designated router.
- All networks are in the same area.
- Topological convergence is quickened.

Specific Configurations

Since there is no special configuration about the OSPF, you can detect neighbors in the multicast manner. If the NBMA network has been configured for the interface, the interface does not send OSPF multicast packets. Therefore, you must specify the IP addresses of neighbors. You can configure shorter SPF calculation wait-time to quicken the topological convergence.

Configurations on Router A:

# Configure the WAN interface.

```
interface Serial 1/0
ip address 192.168.123.1 255.255.255.0
encapsulation frame-relay
ip ospf network non-broadcast
ip ospf priority 10
```

# Configure the OSPF routing protocol.

```
router ospf 1
network 192.168.123.0 0.0.0.255 area 0
neighbor 192.168.123.2  priority 5
neighbor 192.168.123.3
timers throttle spf 500 1000 10000
```

Configurations on Router B:

# Configure the WAN interface.

```
interface Serial 1/0
ip address 192.168.123.2 255.255.255.0
encapsulation frame-relay
ip ospf network non-broadcast
ip ospf priority 5
```

# Configure the OSPF routing protocol.

```
router ospf 1
network 192.168.123.0 0.0.0.255 area 0
neighbor 192.168.123.1 priority 10
neighbor 192.168.123.3
timers throttle spf 500 1000 10000
```

Configurations on Router C:

# Configure the WAN interface.

```
interface Serial 1/0
```

```
ip address 192.168.123.3 255.255.255.0
encapsulation frame-relay
ip ospf network non-broadcast
```

# Configure the OSPF routing protocol.

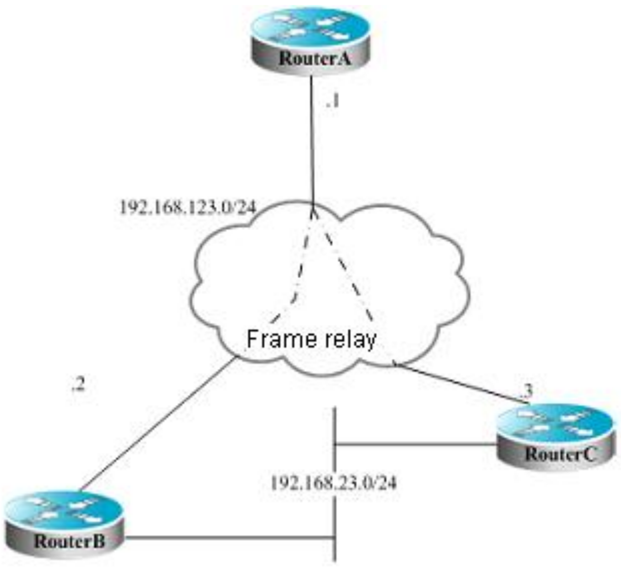
```
router ospf 1
network 192.168.123.0 0.0.0.255 area 0
neighbor 192.168.123.1 10
neighbor 192.168.123.2 5
timers throttle spf 500 1000 10000
```

Example of OSPF Point-to-multipoint Broadcasting Network Configuration

Configuration Requirements

Interconnection of three routers can be implemented through a frame relay network. Each router has only one frame relay link and the same link bandwidth and PVC rate. The following figure shows details about the IP address assignment and connections of the three routers.

Networking topology for OSPF point-to-multipoint network configuration



Requirements:

- The network among A, B, and C must configured as a point-to-multipoint network.

Specific Configurations

The point-to-multipoint network has been configured for the interface. For this network type, there is no need to specify the designated router. The OSPF operations are similar to the steps of configuring the point-to-point network.

Configurations on Router A:

# Configure the Ethernet interface.

```
interface FastEthernet 0/1
ip address 192.168.12.1 255.255.255.0
```

# Configure the WAN interface.

```
interface Serial 1/0
ip address 192.168.123.1 255.255.255.0
encapsulation frame-relay
ip ospf network point-to-multipoint
```

# Configure the OSPF routing protocol.

```
router ospf 1
network 192.168.12.0 0.0.0.255 area 0
network 192.168.123.0 0.0.0.255 area 0
```

Configurations on Router B:

# Configure the Ethernet interface.

```
interface FastEthernet 0/1
ip address 192.168.23.2 255.255.255.0
```

# Configure the WAN interface.

```
interface Serial 1/0
ip address 192.168.123.2 255.255.255.0
encapsulation frame-relay
ip ospf network point-to-multipoint
```

# Configure the OSPF routing protocol.

```
router ospf 1
network 192.168.23.0 0.0.0.255 area 0
network 192.168.123.0 0.0.0.255 area 0
```

Configurations on Router C:

# Configure the Ethernet interface.

```
interface FastEthernet 0/1
ip address 192.168.23.3 255.255.255.0
```

# Configure the WAN interface.

```
interface Serial 1/0
ip address 192.168.123.3 255.255.255.0
encapsulation frame-relay
ip ospf network point-to-multipoint
```

# Configure the OSPF routing protocol.

```
router ospf 1
network 192.168.23.0 0.0.0.255 area 0
network 192.168.123.0 0.0.0.255 area 0
```

Assuming that there is another configuration requirement for the above figure:

Router A selects Router B with priority to reach the target network 192.168.23.0/24. To meet the routing requirement, you must specify the cost for a neighbor when configuring the neighbor.

You can execute the following commands on Router A:

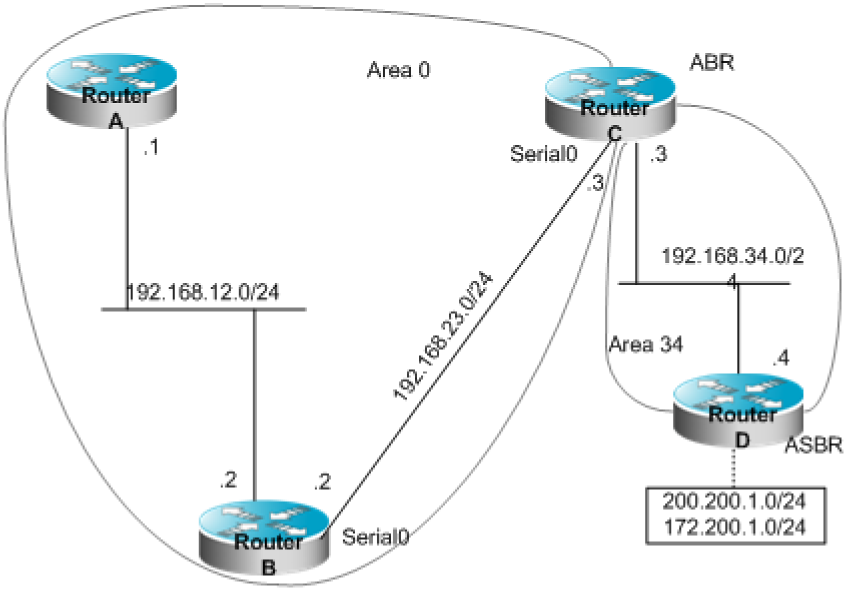
```
router ospf 1
neighbor 192.168.123.2 cost 100
neighbor 192.168.123.3 cost 200
```

Example of OSPF ABR/ASBR Configuration

Configuration Requirements

Four routers form an OSPF routing area. The networks 192.168.12.0/24 and 192.168.23.0/24 belong to Area 0, and the network 192.168.34.0/24 belongs to Area 34. The following figure shows details about the IP address assignment and router connection.

Networking topology for OSPF ABR/ASBR configuration



As shown in the figure, Router A and Router B are intra-area routers. Router C is an area border router. Router D is an AS boundary router. 200.200.1.0/24 and 172.200.1.0/24 are network segments outside the OSPF routing area. All OSPF routers shall be able to learn external routes after configuration. External routes shall be type 1 routes and carry tag 34.

Specific Configurations

While the OSPF redistributes routes of other sources, the routes to be redistributed are type-II routes and carry no tag by default.

Configurations on Router A:

# Configure the Ethernet interface.

```
interface FastEthernet 0/1
ip address 192.168.12.1 255.255.255.0
```

# Configure the OSPF routing protocol.

```
router ospf 1
network 192.168.12.0 0.0.0.255 area 0
```

Configurations on Router B:

# Configure the Ethernet interface.

```
interface FastEthernet 0/1
ip address 192.168.12.2 255.255.255.0
```

# Configure the WAN interface.

```
interface Serial 1/0
ip address 192.168.23.2 255.255.255.0
```

# Configure the OSPF routing protocol.

```
router ospf 1
network 192.168.12.0 0.0.0.255 area 0
network 192.168.23.0 0.0.0.255 area 0
```

Configurations on Router C:

# Configure the Ethernet interface.

```
interface FastEthernet 0/1
ip address 192.168.34.3 255.255.255.0
```

# Configure the WAN interface.

```
interface Serial 1/0
ip address 192.168.23.3 255.255.255.0
```

# Configure the OSPF routing protocol.

```
router ospf 1
network 192.168.23.0 0.0.0.255 area 0
network 192.168.34.0 0.0.0.255 area 34
```

Configurations on Router D:

# Configure the Ethernet interface.

```
interface FastEthernet 0/1
ip address 192.168.34.4 255.255.255.0
```

# Configure interfaces on the Ethernet adapter.

```
interface FastEthernet 0/1
ip address 200.200.1.1 255.255.255.0
interface FastEthernet 0/2
```

```
ip address 172.200.1.1 255.255.255.0
```

# Configure the OSPF routing protocol and redistribute the RIP routes.

```
router ospf 1
network 192.168.34.0 0.0.0.255 area 34
redistribute rip metric-type 1 subnets tag 34
```

# Configure the RIP routing protocol.

```
router rip
network 200.200.1.0
network 172.200.0.0
```

The OSPF routes generated on Router B are shown as follows: (Note that the type of external routes has changed to E1.)

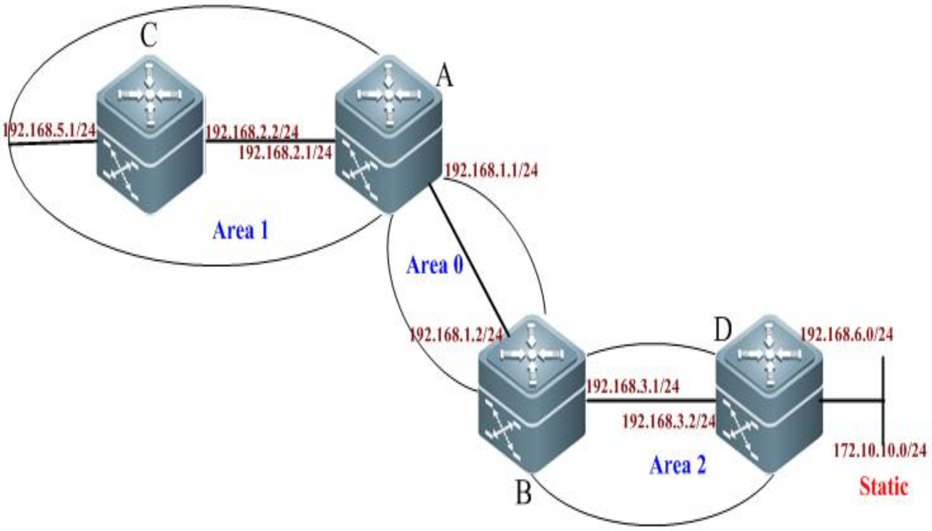
```
O E1 200.200.1.0/24 [110/85] via 192.168.23.3,00:00:33,Serial 1/0
O IA 192.168.34.0/24 [110/65] via 192.168.23.3,00:00:33,Serial 1/0
O E1 172.200.1.0 [110/85] via 192.168.23.3,00:00:33,Serial 1/0
```

Example of OSPF Static Route Redistribution Configuration

Networking Topology

The following figure shows the networking topology of an OSPF autonomous system. The entire autonomous system is divided into three areas: Area 0, Area 1, and Area 2. The network segment 172.10.10.0 is outside the routing area.

Networking topology for OSPF static route redistribution configuration



Applications

Configure Router A and Router B as area border routers (ABR) and Router C as an intra-area router. Configure Router D as an ASBR and introduce an external static route, so that all OSPF routers in non-stub area can successfully learn this external route.

Configuration Tips

- Configure the IP address for interfaces on the routers (omitted).
- Configure the basic OSPF functions (see "Example of Multi-Area OSPF Configuration")
- Introduce and configure the external static route.

Configuration Steps

Step 1: On Router D, configure a static route to the network segment 172.10.10.0.

```
D(config)#ip route 172.10.10.0 255.255.255.0 192.168.6.2
```

Step 2: Display the routing table of Router A.

```
A#show ip route ospf
O IA 192.168.3.0/24 [110/2] via 192.168.1.2, 15:33:00, GigabitEthernet 0/1
O    192.168.5.0/24 [110/2] via 192.168.2.2, 15:14:59, GigabitEthernet 0/2
O IA 192.168.6.0/24 [110/3] via 192.168.1.2, 00:17:58, GigabitEthernet 0/1
```

In this case, there is no route to the network segment 172.10.10.0.

Step 3: Redistribute the static route on Router D

```
D(config)#router ospf 1
D(config-router)# redistribute static subnets
```

Verification

Step 1: Display the routing table of Router D.

```
D#show ip route
Codes:  C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
ia - IS-IS inter area, * - candidate default

Gateway of last resort is no set
S    172.10.10.0/24 [1/0] via 192.168.6.2
O IA 192.168.1.0/24 [110/2] via 192.168.3.1, 15:25:19, GigabitEthernet 0/3
O IA 192.168.2.0/24 [110/3] via 192.168.3.1, 15:25:19, GigabitEthernet 0/3
C    192.168.3.0/24 is directly connected, GigabitEthernet 0/3
C    192.168.3.2/32 is local host.
O IA 192.168.5.0/24 [110/4] via 192.168.3.1, 15:11:56, GigabitEthernet 0/3
C    192.168.6.0/24 is directly connected, GigabitEthernet 0/4
C    192.168.6.1/32 is local host.
```

Step 2: View OSPF information about Router D. Key point: Router D is an AS boundary router (ASBR).

```
D#show ip ospf
```

```
 Routing Process "ospf 1" with ID 192.168.3.2
 Process uptime is 15 hours 27 minutes
 Process bound to VRF default
 Conforms to RFC2328, and RFC1583 Compatibility flag is enabled
 Supports only single TOS(TOS0) routes
 Supports opaque LSA
 Enable two-way-maintain
 This router is an ASBR (injecting external routing information)
 Initial SPF schedule delay 1000 msecs
Minimum hold time between two consecutive SPFs 5000 msecs
Maximum wait time between two consecutive SPFs 10000 msecs
Initial LSA throttle delay 0 msecs
Minimum hold time for LSA throttle 5000 msecs
Maximum wait time for LSA throttle 5000 msecs
Lsa Transmit Pacing timer 40 msecs, 10 LS-Upd
Minimum LSA arrival 1000 msecs
 Pacing lsa-group: 240 secs
 Number of incoming current DD exchange neighbors 0/5
 Number of outgoing current DD exchange neighbors 0/5
 Number of external LSA 1. Checksum 0x006DB0
 Number of opaque AS LSA 0. Checksum 0x000000
 Number of non-default external LSA 1
 External LSA database is unlimited.
 Number of LSA originated 2
 Number of LSA received 173
 Log Neighbor Adjacency Changes: Enabled
  Number of areas attached to this router: 1: 1 normal 0 stub 0 nssa
    Area 2
        Number of interfaces in this area is 2(2)
        Number of fully adjacent neighbors in this area is 1
        Number of fully adjacent virtual neighbors through this area is 0
        Area has no authentication
        SPF algorithm last executed 00:06:27.540 ago
        SPF algorithm executed 9 times
        Number of LSA 6. Checksum 0x0212ff
```

Step 3: Display the routing table of Router A.

```
A#show ip route ospf
O E2 172.10.10.0/24 [110/20] via 192.168.1.2, 00:07:37, GigabitEthernet 0/1
O IA 192.168.3.0/24 [110/2] via 192.168.1.2, 15:33:00, GigabitEthernet 0/1
O    192.168.5.0/24 [110/2] via 192.168.2.2, 15:14:59, GigabitEthernet 0/2
O IA 192.168.6.0/24 [110/3] via 192.168.1.2, 00:17:58, GigabitEthernet 0/1
```

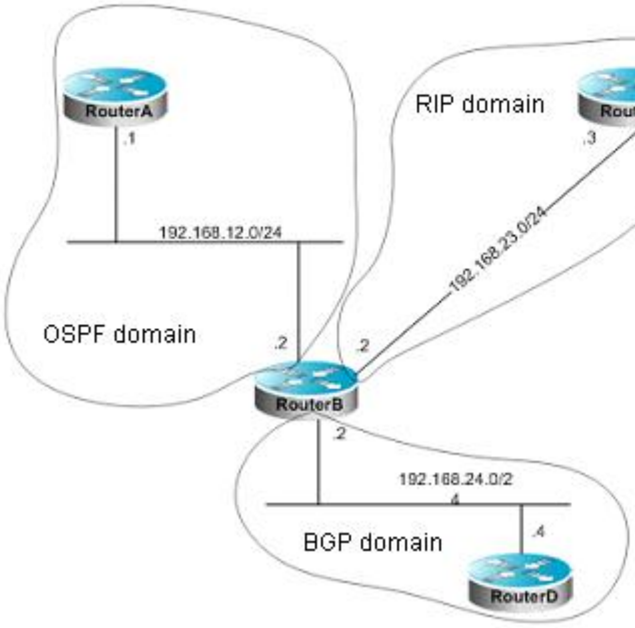
In this case, Router A has successfully learned the route to the network segment 172.10.10.0.

Example of OSPF Dynamic Route Redistribution Configuration

Configuration Requirements

The following figure shows the topology of four routers. Router A belongs to the OSPF routing area. Router C belongs to the RIP routing area. Router D belongs to the BGP routing area. Router B is connected to the three routing areas. Router A advertises two routes: 192.168.10.0/24 and 192.168.100.1/32. Router C advertises two routes: 192.168.3.0/24 and 192.168.30.0/24. Router D advertises two routes: 192.168.4.0/24 and 192.168.40.0/24.

Networking topology for dynamic routing protocol redistribution



On Router B, the OSPF redistributes routes (type-1) in the RIP routing area and the BGP routes that carry the community attribute 11:11 in the BGP routing area. The RIP redistributes the route 192.168.10.0/24 in the OSPF routing area and advertises a default route to the RIP routing area. The metric of this route is set to 2.

Specific Configurations

When the routing protocol redistribute the routes among each other, the simple route filtering can be controlled by using the distribution list. However, different attributes must be set for different routes, which cannot be implemented by using the distribution list. In this case, a route-map must be used for control. The route-map provides more control functions than the distribution list, but the router configuration is more complex. Therefore, do not use the route-map if possible. The following examples use the route-map to match the community attribute of the BGP routes.

Configurations on Router A:

# Configure the network interface.

```
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ip address 192.168.10.1 255.255.255.0
Ruijie(config)# interface loopback 1
Ruijie(config-if-Loopback 1)# ip address 192.168.100.1 255.255.255.255
Ruijie(config-if-Loopback 1)# no ip directed-broadcast
Ruijie(config)# interface gigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)# ip address 192.168.12.1 255.255.255.0
```

# Configure the OSPF.

```
Ruijie(config)# router ospf 12
Ruijie(config-router)# network 192.168.10.0 0.0.0.255 area 0
Ruijie(config-router)# network 192.168.12.0 0.0.0.255 area 0
Ruijie(config-router)# network 192.168.100.0 0.0.0.255 area 0
```

Configurations on Router B:

# Configure the network interface.

```
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ip address 192.168.12.2 255.255.255.0
Ruijie(config)# interface gigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)# ip address 192.168.24.2
Ruijie(config)# interface Serial 1/0
Ruijie(config-Serial 1/0)# ip address 192.168.23.2 255.255.255.0
```

# Configure the OSPF and specify the type of routes to be redistributed.

```
Ruijie(config)# router ospf 12
Ruijie(config-router)# redistribute rip metric 100 metric-type 1 subnets
Ruijie(config-router)# redistribute bgp route-map ospfrm subnets
Ruijie(config-router)# network 192.168.12.0 0.0.0.255 area 0
```

# Configure the RIP and use the distribute list to filter the redistributed routes.

```
Ruijie(config)# router rip
Ruijie(config-router)# redistribute ospf 12 metric 2
Ruijie(config-router)# network 192.168.23.0
Ruijie(config-router)# distribute-list 10 out ospf
Ruijie(config-router)# default-information originate always
Ruijie(config-router)# no auto-summary
```

# Configure the BGP.

```
Ruijie(config)# router bgp 2
Ruijie(config-router)# neighbor 192.168.24.4 remote-as 4
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 192.168.24.4 activate
Ruijie(config-router-af)# neighbor 192.168.24.4  send-community
```

# Configure the route-map.

```
Ruijie(config)# route-map ospfrm
Ruijie(config-route-map)# match community cl_110
```

# Define the access list.

```
Ruijie(config)# access-list 10 permit 192.168.10.0
```

# Define the community list.

```
Ruijie(config)# ip community-list standard cl_110 permit 11:11
```

Configurations on Router C:

# Configure the network interface.

```
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ip address 192.168.30.1 255.255.255.0
Ruijie(config)# interface gigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)# ip address 192.168.3.1 255.255.255.0
Ruijie(config)# interface Serial 1/0
Ruijie(config-if-Serial 1/0)# ip address 192.168.23.3 255.255.255.0
```

# Configure the RIP.

```
Ruijie(config)# router rip
Ruijie(config-router)# network 192.168.23.0
Ruijie(config-router)# network 192.168.3.0
Ruijie(config-router)# network 192.168.30.0
```

Configurations on Router D:

# Configure the network interface.

```
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ip address 192.168.40.1 255.255.255.0
Ruijie(config)# interface gigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)# ip address 192.168.4.1 255.255.255.0
Ruijie(config)# interface gigabitEthernet 0/3
Ruijie(config-if-GigabitEthernet 0/3)# ip address 192.168.24.4 255.255.255.0
```

# Configure the BGP.

```
Ruijie(config)# router bgp 4
Ruijie(config-router)# neighbor 192.168.24.2 remote-as 2
Ruijie(config-router)# redistribute connected route-map bgprm
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 192.168.24.2 activate
Ruijie(config-router-af)# neighbor 192.168.24.2 send-community
```

# Configure the route-map.

```
Ruijie(config)# route-map bgprm
Ruijie(config-route-map)# set community 22:22
```

The OSPF routes learned by Router A:

```
O E1 192.168.30.0/24[110/101]via 192.168.12.2,00:04:07, gigabitEthernet 0/2
O E1 192.168.3.0/24[110/101]via 192.168.12.2,00:04:07, gigabitEthernet 0/2
O E1 192.168.23.0/24[110/101]via 192.168.12.2,00:04:07, gigabitEthernet 0/2
```

The RIP routes learned by Router C:

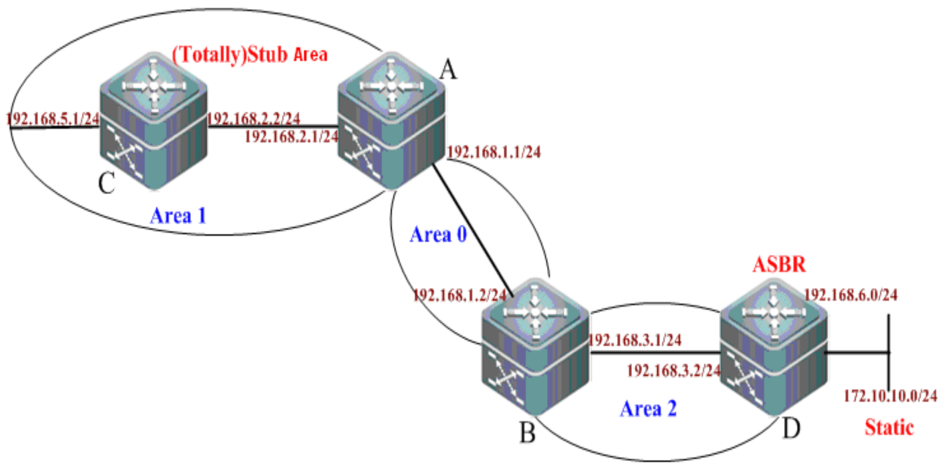
```
R    0.0.0.0/0 [120/1] via 192.168.23.2, 00:00:00, Serial 1/0
R    192.168.10.0/24 [120/2] via 192.168.23.2, 00:00:00, Serial 1/0
```

Example of OSPF (Totally) Stub Area Configuration

Networking Topology

The following figure shows the networking topology of an OSPF autonomous system. The entire autonomous system is divided into three areas: Area 0, Area 1, and Area 2. The network segment 172.10.10.0 is outside the routing area.

Networking topology for OSPF (Totally) Stub area configuration



Applications

Configure Router A and Router B as area border routers (ABR) and Router C as an intra-area router. Configure Router D as an ASBR and introduce one an external static route.

To reduce the size of the routing table inside the AS border and the number of routes exchanged, configure the specific area to be a (Totally) Stub area.

Routing information can be correctly transmitted in the OSPF autonomous system.

Configuration Tips

Do not configure the backbone area (Area 0) cannot be configured as a (Totally) Stub area, and there must be no ASBR exists in the (Totally) Stub area. That is, the external routes of the autonomous system cannot be propagated transmitted in this area. In this example, Area 1 is configured as the (Totally) Stub area.

When configuring an area as a Stub area, you must configure the **stub** command on all routers in this area. In this example, you need to configure this attribute on Router A and Router C.

When configuring an area as a Totally Stub area, you must configure the **stub** command on all routers (Router C) in this area and the **stub [no-summary]** command on the ABR (Router A).

Configuration Steps

The following information only shows how to configure an OSPF (Totally) Stub area. For other configurations, see "Example of Multi-Area OSPF Configuration" and "Example of OSPF Static Route Redistribution Configuration".

Step 1: Display the routing table of Router C when this router is in a normal area.

```
C#show ip route  ospf
O E2 172.10.10.0/24 [110/20] via 192.168.2.1, 4d,02:28:07, GigabitEthernet 0/3
                        //AS external route
O IA 192.168.1.0/24 [110/2] via 192.168.2.1, 4d,17:52:14, GigabitEthernet 0/3
O IA 192.168.3.0/24 [110/3] via 192.168.2.1, 4d,17:52:14, GigabitEthernet 0/3
O IA 192.168.6.0/24 [110/4] via 192.168.2.1, 4d,02:38:27, GigabitEthernet 0/3
```

In this case, the routing table contains AS external routes.

Step 2: Configure the Stub area

- Configurations on Router A:

```
A(config)#router ospf 1
A(config-router)#area 1 stub
```

- Configurations on Router C:

```
C(config)#router ospf 1
C(config-router)#area 1 stub
```

- Display the routing table of Router C when this router is in a stub area.

```
C#show ip route ospf
O*IA 0.0.0.0/0 [110/2] via 192.168.2.1, 00:00:32, GigabitEthernet 0/3
                                        //default route
O IA 192.168.1.0/24 [110/2] via 192.168.2.1, 00:00:32, GigabitEthernet 0/3
O IA 192.168.3.0/24 [110/3] via 192.168.2.1, 00:00:32, GigabitEthernet 0/3
O IA 192.168.6.0/24 [110/4] via 192.168.2.1, 00:00:32, GigabitEthernet 0/3
```

In this case, the routing table contains no AS external route. The original AS external route in the routing table has been replaced with a default route.

Step 3: Configure the Totally Stub area

- Configurations on Router A:

```
A(config)#router ospf 1
A(config-router)#area 1 stub stub no-summary
```

- Configurations on Router C:

```
C(config)#router ospf 1
C(config-router)#area 1 stub
```

- Display the routing table of Router C when this router is in a totally stub area.

```
C#show ip route ospf
```

```
O*IA 0.0.0.0/0 [110/2] via 192.168.2.1, 00:30:53, GigabitEthernet 0/3
```

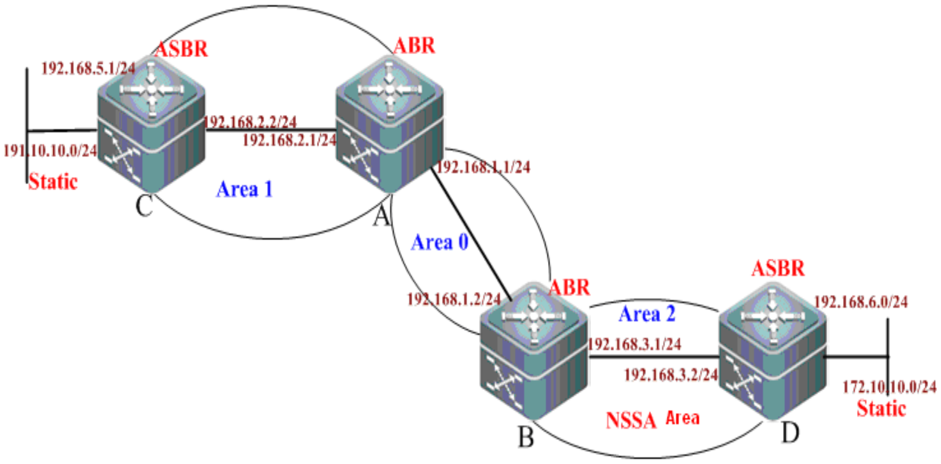
In this case, the routing table only contains one default route to the external area.

Example of OSPF NSSA Area Configuration

Networking topology

The following figure shows the networking topology of an OSPF autonomous system. The entire autonomous system is divided into three areas: Area 0, Area 1, and Area 2. The network segments 192.10.10.0 and 172.10.10.0 are outside the OSPF routing area.

Networking topology for OSPF NSSA area configuration



Applications

1. Configure Router A and Router B as area border routers (ABR). Configure Router C and Router D as ASBRs and introduce an AS external static route for Router C and Router D respectively.

2. Area 2 shall be configured as an NSSA area in order to reduce the size of routing table of the intra-area router and the number of routes exchanged. Meanwhile, prohibit Router B from sending summary LSAs (Type-3 LSA) to the NSSA area.

3. Routing information can be correctly transmitted in the OSPF autonomous system.

Configuration Tips

Tips for configuring the NSSA area are as follows:

1. The backbone area (Area 0) cannot be configured as the NSSA area.

2. The ASBRs can exist in the NSSA area, and certain number of AS external routes can be imported to the OSPF routing area.

3. When configuring an area as the NSSA area, you must use the area nssa command on all routers (Router B and D) connected to the NSSA area.

Configuration Steps

The following information only shows how to configure the NSSA area. For the basic OSPF configurations, see the above examples.

Step 1: Configure static route redistribution.

- Configurations on Router C:

! Configure a static route.

```
C(config)#ip route 191.10.10.0 255.255.255.0 192.168.5.2
```

! Redistribute the static route based on the OSPF.

```
C(config)#router ospf 1
C(config-router)#redistribute static subnets
```

- Configurations on Router D:

! Configure a static route.

```
D(config)#ip route 172.10.10.0 255.255.255.0 192.168.6.2
```

! Redistribute the static route based on the OSPF.

```
C(config)#router ospf 1
C(config-router)#redistribute static subnets
```

Step 2: Configure the NSSA.

- Configurations on Router B (ABR):

```
B(config)#router ospf 1
```

! Define the NSSA area and prohibit this ABR from sending summary LSAs (Type-3 LSA) to the NSSA area.

```
B(config-router)#area 2 nssa no-summary
```

- Configurations on Router D (ASBR):

```
D(config)#router ospf 1
D(config-router)#area 2 nssa
```

Verification

Step 1: Display the routing information when Area 2 is configured as a normal area.

- Display the routing table of Router D (ASBR).

```
D#show ip route
Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default
Gateway of last resort is no set
S    172.10.10.0/24 [1/0] via 192.168.6.2
O E2 191.10.10.0/24 [110/20] via 192.168.3.1, 00:00:21, GigabitEthernet 0/3
O IA 192.168.1.0/24 [110/2] via 192.168.3.1, 00:00:21, GigabitEthernet 0/3
O IA 192.168.2.0/24 [110/3] via 192.168.3.1, 00:00:21, GigabitEthernet 0/3
C    192.168.3.0/24 is directly connected, GigabitEthernet 0/3
C    192.168.3.2/32 is local host.
O IA 192.168.5.0/24 [110/4] via 192.168.3.1, 00:00:21, GigabitEthernet 0/3
C    192.168.6.0/24 is directly connected, GigabitEthernet 0/4
C    192.168.6.1/32 is local host.
```

- Display the OSPF routing table of Router B (ABR).

```
B#show ip route ospf
O E2 172.10.10.0/24 [110/20] via 192.168.3.2, 17:53:35, GigabitEthernet 0/2    O E2
191.10.10.0/24 [110/20] via 192.168.1.1, 00:57:46, GigabitEthernet 0/1
O IA 192.168.2.0/24 [110/2] via 192.168.1.1, 5d,15:39:01, GigabitEthernet 0/1
O IA 192.168.5.0/24 [110/3] via 192.168.1.1, 01:10:34, GigabitEthernet 0/1
O    192.168.6.0/24 [110/2] via 192.168.3.2, 17:53:36, GigabitEthernet 0/2
```

Step 2: Display the routing information about each router in the NSSA area when Area 2 is configured as an NSSA area.

- Display the OSPF routing table of Router B (ABR).

```
B#show ip route ospf
O N2 172.10.10.0/24 [110/20] via 192.168.3.2, 00:01:00, GigabitEthernet 0/2
O E2 191.10.10.0/24 [110/20] via 192.168.1.1, 01:11:26, GigabitEthernet 0/1
O IA 192.168.2.0/24 [110/2] via 192.168.1.1, 5d,15:52:41, GigabitEthernet 0/1
O IA 192.168.5.0/24 [110/3] via 192.168.1.1, 01:24:14, GigabitEthernet 0/1
O    192.168.6.0/24 [110/2] via 192.168.3.2, 00:01:01, GigabitEthernet 0/2
```

In this case, the ABR in the NSSA area has translated the AS external routes imported into this area into N2 (OSPF NSSA external type 2) routes and transmitted to other areas.

- Display the routing table of Router D (ASBR).

```
D#show ip route
Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default
Gateway of last resort is no set
S    172.10.10.0/24 [1/0] via 192.168.6.2
O IA 192.168.1.0/24 [110/2] via 192.168.3.1, 00:03:20, GigabitEthernet 0/3
O IA 192.168.2.0/24 [110/3] via 192.168.3.1, 00:03:20, GigabitEthernet 0/3
C    192.168.3.0/24 is directly connected, GigabitEthernet 0/3
```

```
C   192.168.3.2/32 is local host.
O IA 192.168.5.0/24 [110/4] via 192.168.3.1, 00:03:20, GigabitEthernet 0/3
C   192.168.6.0/24 is directly connected, GigabitEthernet 0/4
C   192.168.6.1/32 is local host.
```

In this case, the AS external routes imported into other areas cannot reach this area when Router D is in an NSSA area.

Step 3: Display the routing information of the NSSA area when configuring the attribute of the NSSA area to be no-summary on Router B (ABR).

```
D#show ip route
Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default
Gateway of last resort is 192.168.3.1 to network 0.0.0.0
O*IA 0.0.0.0/0 [110/2] via 192.168.3.1, 00:00:40, GigabitEthernet 0/3
S   172.10.10.0/24 [1/0] via 192.168.6.2
C   192.168.3.0/24 is directly connected, GigabitEthernet 0/3
C   192.168.3.2/32 is local host.
C   192.168.6.0/24 is directly connected, GigabitEthernet 0/4
C   192.168.6.1/32 is local host.
```

In this case, the routing table contains a default route which replaces the inter-area route.

Step 4: Display the OSPF routing information on routers in other areas. Key point: Note whether there is any AS external route imported into the NSSA area.

```
SwitchA#show ip route ospf
O E2 172.10.10.0/24 [110/20] via 192.168.1.2, 02:08:08, GigabitEthernet 0/1
O E2 191.10.10.0/24 [110/20] via 192.168.2.2, 03:18:35, GigabitEthernet 0/2
O IA 192.168.3.0/24 [110/2] via 192.168.1.2, 5d,17:59:01, GigabitEthernet 0/1
O   192.168.5.0/24 [110/2] via 192.168.2.2, 03:31:25, GigabitEthernet 0/2
O IA 192.168.6.0/24 [110/3] via 192.168.1.2, 02:08:09, GigabitEthernet 0/1
```

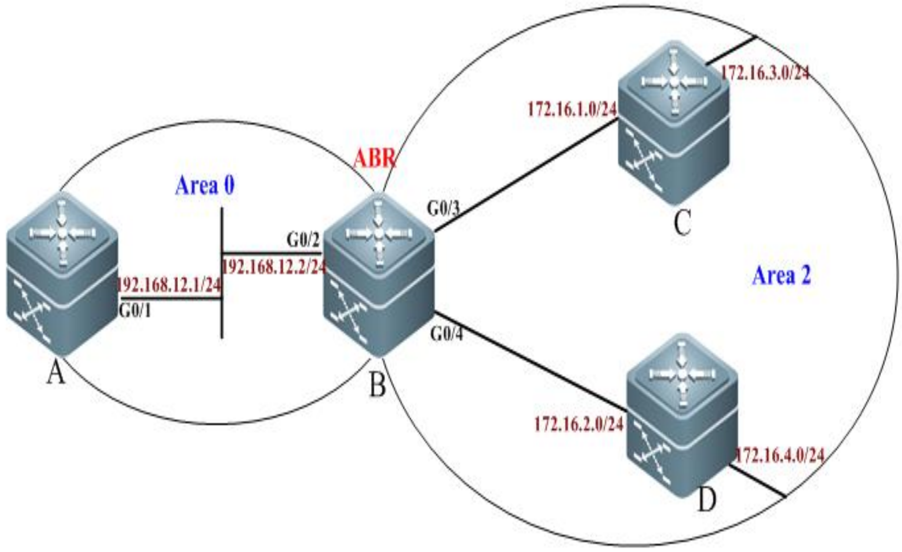
In this case, the routing table of Router A contains an AS external route imported into the NSSA area.

Example of OSPF Inter-area Route Aggregation Configuration

Networking Topology

The following figure shows the topological topology of an OSPF autonomous system, in which the network segment 192.168.12.0/24 belongs to Area 0 and the network segments 172.16.1.0/24, 172.16.2.0/24, 172.16.3.0/24, and 172.16.4.0/24 belong to Area 2.

Networking topology for OSPF inter-area route aggregation configuration



Applications

To reduce the size of routing table, configure Router B so that Router B only advertises the summary route of four network segments (172.16.1.0/24, 172.16.2.0/24, 172.16.3.0/24, and 172.16.4.0/24) instead of separately advertising the routes of these four network segments.

Configuration Tips

1. Since the network segments 172.16.1.0/24, 172.16.2.0/24, 172.16.3.0/24, and 172.16.4.0/24 are consecutive addresses, you can configure route aggregation on the area border router (Router B) to alleviate route calculation. Use this command **area range** to configure the route aggregation between the OSPF inter-areas".

2. During route aggregation, the aggregated route range may exceed the actual network range in the routing table. Routing loop may incur or load on the router may increase if packets are sent to a network that is beyond the aggregated route range. So you need to add a "discard" route into the routing table on the ABR (Router B) or ASBR. Use the inter-area route aggregation command area range to add the discard route. This function is enabled by default.

3. The aggregated route address of 172.16.1.0/24, 172.16.2.0/24, 172.16.3.0/24, and 172.16.4.0/24 is 172.16.0.0/21. Routes falling within this range will not be advertised to other areas by the ABR.

Configuration Steps

Step 1: Configure the IP address for interfaces.(omitted)

Step 2: Configure the basic OSPF functions.

- Configure Router A.

```
A(config)#router ospf 1
A(config)# network 192.168.12.0 0.0.0.255 area 0
```

- Configure Router B.

```
B(config)#router ospf 1
```

```
B(config-router)#network 192.168.12.0 0.0.0.255 area 0
B(config-router)#network 172.16.1.0 0.0.0.255 area 2
B(config-router)#network 172.16.2.0 0.0.0.255 area 2
```

- Configure Router C.

```
C(config)#router ospf 1
C(config-router)#network 172.16.1.0 0.0.0.255 area 2
C(config-router)#network 172.16.3.0 0.0.0.255 area 2
```

- Configure Router D.

```
D(config)#router ospf 1
D(config-router)#network 172.16.2.0 0.0.0.255 area 2
D(config-router)#network 172.16.4.0 0.0.0.255 area 2
```

- Display the OSPF routing table of Router A.

```
A#show ip route ospf
O IA 172.16.1.0/24 [110/2] via 192.168.12.2, 00:06:47, GigabitEthernet 0/1
O IA 172.16.2.0/24 [110/2] via 192.168.12.2, 00:06:47, GigabitEthernet 0/1
O IA 172.16.3.0/24 [110/3] via 192.168.12.2, 00:06:47, GigabitEthernet 0/1
O IA 172.16.4.0/24 [110/3] via 192.168.12.2, 00:06:19, GigabitEthernet 0/1
```

In this case, the detailed routing information about Area 2 is advertised to Area 0.

Step 3: Configure the inter-area route aggregation on the ABR (Router B).

```
B(config)#router ospf 1
B(config-router)#area 2 range 172.16.0.0 255.255.248.0
```

Step 4: On ABR (Router B), configure to control the addition of the aggregated route entry into the core routing table. This function is enabled by default.

```
B(config-router)# discard-route internal
```

Verification

- After configuring route aggregation, display the OSPF routing table of Router A.

```
A#show ip route ospf
O IA 172.16.0.0/21 [110/2] via 192.168.12.2, 00:01:04, GigabitEthernet 0/1
```

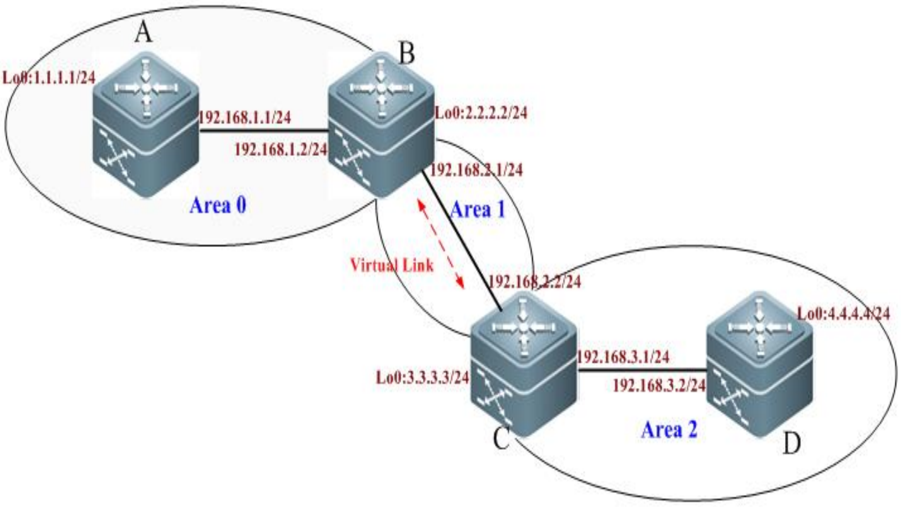
In this case, only the aggregated routes are advertised. Specific routes will not be advertised by the ABR to other areas. The size of the routing table is decreased substantially.

Example of OSPF Virtual Link Configuration

Networking Topology

The following figure shows an OSPF routing area. The network segment 192.168.1.0 belongs to Area 0. The network segment 192.168.2.0 belongs to Area 1. The network segment 192.168.3.0 belongs to Area 2. Due to the limitation of physical conditions, other specific areas cannot be deployed around the backbone area. As shown in the following figure, Area 2 is not directly connected to Area 0.

Networking topology for OSPF virtual link configuration



Applications

Through configuration, Router D shall be able to receive routes of the network segments 192.168.1.0/24 (Area 0) and 192.168.2.0/24 (Area 1). Meanwhile, Router B shall be able to learn the routes of the network segment 192.168.3.0/24 (Area 2).

Details about IP address assignment are shown as follows:

Router name	Router ID	Interface address
A	1.1.1.1	Gi0/1: 192.168.1.1/24
B	2.2.2.2	Gi0/1: 192.168.1.2/24 Gi0/3: 192.168.2.1/24
C	3.3.3.3	Gi0/3: 192.168.2.2/24 Gi0/5: 192.168.3.1/24
D	4.4.4.4	Gi0/5: 192.168.3.2/24

Configuration Tips

When the OSPF routing area is composed of multiple areas, each area must be directly connected to the backbone area (Area 0). Otherwise, these areas cannot be interconnected. If there is no direct physical link, create virtual links to logically connect each area to the backbone area. Configuration tips are shown as follows:

- Configure the IP address for the interfaces. (Omitted)
- Configure the basic OSPF functions.
- Configure OSPF virtual links

The virtual link must be configured on ABRs. This example configures virtual links on Router B and Router C.

Use the **area** *area-id* **virtual-link** *router-id* command to configure virtual links on the ABRs. The router-id refers to the identifier of a peer device.

Configuration Steps

Step 1: Configure the basic OSPF functions.

➢ Configurations on Router A:

! Create an OSPF routing process and specify the IP address range associated with this routing process and the OSPF area to which these IP addresses belong.

```
A(config)#router ospf 1
A(config-router)#network 192.168.1.0 0.0.0.255 area 0
A(config-router)#exit
```

! Configure the loopback IP 1.1.1.1 as the router ID of Router A.

```
A(config)#interface loopback 0
A(config-Loopback 0)#ip address 1.1.1.1 255.255.255.0
```

➢ Configurations on Router B:

! Create an OSPF routing process and specify the IP address range associated with this routing process and the OSPF area to which these IP addresses belong.

```
B(config)#router ospf 1
B(config-router)#network 192.168.1.0 0.0.0.255 area 0
B(config-router)#network 192.168.2.0 0.0.0.255 area 1
B(config-router)#exit
```

! Configure the loopback IP 2.2.2.2 as the router ID of Router B.

```
B(config)#interface loopback 0
B(config-Loopback 0)#ip address 2.2.2.2 255.255.255.0
```

➢ Configurations on Router C:

! Create an OSPF routing process and specify the IP address range associated with this routing process and the OSPF area to which these IP addresses belong.

```
C(config)#router ospf 1
C(config-router)#network 192.168.2.0 0.0.0.255 area 1
C(config-router)#network 192.168.3.0 0.0.0.255 area 2
C(config-router)#exit
```

! Configure the loopback IP 3.3.3.3 as the router ID of Router C.

```
C(config)#interface loopback 0
C(config-Loopback 0)#ip address 3.3.3.3 255.255.255.0
```

➢ Configurations on Router D:

! Create an OSPF routing process and specify the IP address range associated with this routing process and the OSPF area to which these IP addresses belong.

```
D(config)#router ospf 1
D(config-router)#network 192.168.3.0 0.0.0.255 area 2
```

```
D(config-router)#exit
```

! Configure the loopback IP 4.4.4.4 as the router ID of Router D.

```
D(config)#interface loopback 0
D(config-Loopback 0)#ip address 4.4.4.4 255.255.255.0
```

- Display the OSPF routing table of Router A.

```
A#show ip route ospf
O IA 192.168.2.0/24 [110/2] via 192.168.1.2, 00:32:48, GigabitEthernet 0/1
```

Since Area 2 is not directly connected to Area 0, the routing table of Router A contains no routing information about Area 2

Step 2: Configure OSPF virtual links.

- Configure Router B.

```
B(config)#router ospf 1
B(config-router)#area 1 virtual-link 3.3.3.3
```

- Configure Router C.

```
C(config)#router ospf 1
C(config-router)#area 1 virtual-link 2.2.2.2
```

Verification

- Display the OSPF routing table of Router B.

```
B#show ip route
Codes:  C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default
Gateway of last resort is no set
C    2.2.2.0/24 is directly connected, Loopback 0
C    2.2.2.2/32 is local host.
C    192.168.1.0/24 is directly connected, GigabitEthernet 0/1
C    192.168.1.2/32 is local host.
C    192.168.2.0/24 is directly connected, GigabitEthernet 0/3
C    192.168.2.1/32 is local host.
O IA 192.168.3.0/24 [110/2] via 192.168.2.2, 00:02:49, GigabitEthernet 0/3
```

In this case, after the virtual link is configured, Router B has successfully learned the routes of the network segment 192.168.3.0/24 (Area 2).

- Display the OSPF routing table of Router D.

```
D#show ip route
Codes:  C - connected, S - static, R - RIP, B - BGP
```

```
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default
Gateway of last resort is no set
C    4.4.4.0/24 is directly connected, Loopback 0
C    4.4.4.4/32 is local host.
O IA 192.168.1.0/24 [110/3] via 192.168.3.1, 00:04:45, GigabitEthernet 0/5
O IA 192.168.2.0/24 [110/2] via 192.168.3.1, 00:05:02, GigabitEthernet 0/5
C    192.168.3.0/24 is directly connected, GigabitEthernet 0/5
C    192.168.3.2/32 is local host.
```

In this case, after the virtual link is configured, Router D has successfully learned the routes of the network segments 192.168.1.0/24 (Area 0) and 192.168.2.0/24 (Area 1).

- Display the OSPF routing table of Router A.

```
A#show ip route ospf
O IA 192.168.2.0/24 [110/2] via 192.168.1.2, 00:51:22, GigabitEthernet 0/1
O IA 192.168.3.0/24 [110/3] via 192.168.1.2, 00:07:58, GigabitEthernet 0/1
```

In this case, after the virtual link is configured, Router A has successfully learned the routes of the network segment 192.168.3.0/24 (Area 2).

- Display the OSPF virtual link information about Router B.

```
B#show ip ospf 1 virtual-links
Virtual Link VLINK0 to router 3.3.3.3 is up
  Transit area 0.0.0.1 via interface GigabitEthernet 0/3
  Local address 192.168.2.1/32
  Remote address 192.168.2.2/32
  Transmit Delay is 1 sec, State Point-To-Point,
  Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
    Hello due in 00:00:03
Adjacency state Full
```

- Display the OSPF virtual link information about Router C.

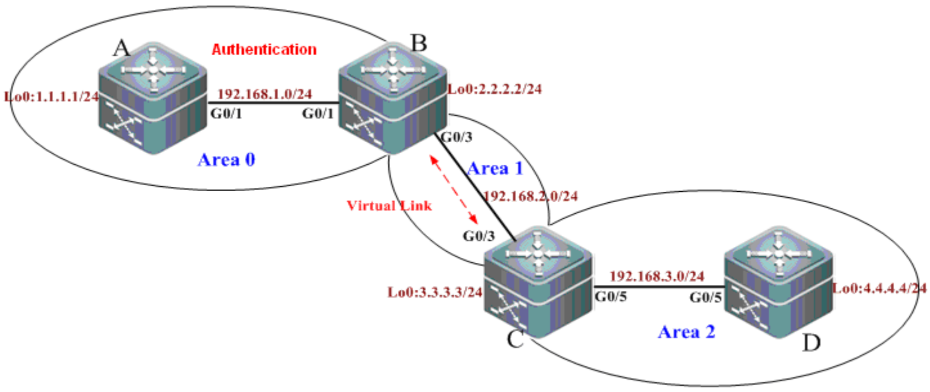
```
C#show ip ospf 1 virtual-links
Virtual Link VLINK0 to router 2.2.2.2 is up
  Transit area 0.0.0.1 via interface GigabitEthernet 0/3
  Local address 192.168.2.2/32
  Remote address 192.168.2.1/32
  Transmit Delay is 1 sec, State Point-To-Point,
  Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
    Hello due in 00:00:00
    Adjacency state Full
```

Example of OSPF Authentication Configuration

Networking Topology

The following figure shows an OSPF routing area. The network segment 192.168.1.0 belongs to Area 0. The network segment 192.168.2.0 belongs to Area 1. The network segment 192.168.3.0 belongs to Area 2. Due to the limitation of network structures, Area 2 is connected to Area 0 through virtual links.

Networking topology for OSPF authentication configuration



Applications

1. To prevent the device from learning unauthenticated and invalid routes and advertising valid routes to unauthenticated devices, it is required to configure area authentication in the backbone area (Area 0), with the authentication type being MD5.

2. Router D shall be able to learn routes of the network segments 192.168.1.0/24 (Area 0) and 192.168.2.0/24 (Area 1). Meanwhile, Router B shall be able to learn the routes of the network segment 192.168.3.0/24 (Area 2).

Configuration Tips

To configure the OSPF area authentication, configure the area authentication on all routers in the same area with the same authentication type. This example enables the area authentication in Area 0, namely all routers (Router A and Router B) in Area 0 shall be configured with the same authentication type.

When OSPF virtual links are used to connect a non-backbone area (Area 2) with a backbone area, if ID authentication is enabled in the backbone area (Area 0), the identity authentication shall also be configured on the ABR (Router C) in the non-backbone area.

Tips for configuring the OSPF area authentication are shown as follows:

8) In OSPF route configuration mode, specify the authentication type for the area.

9) Configure the authentication type and key on the interface.

Configuration Steps

The following information only shows how to configure the OSPF area authentication. For other configurations, see "Example of OSPF Virtual Link Configuration".

- **Configure Router A.**

Step 1: In OSPF route configuration mode, specify Area 0 to enable the MD5 authentication.

```
A(config)#router ospf 1
A(config-router)#area 0 authentication message-digest
A(config-router)#exit
```

Step 2: Configure the authentication type and key on the interface.

```
A(config)#interface gigabitEthernet 0/1
A(config-if-GigabitEthernet 0/1)#ip ospf message-digest-key 1 md5 hello
```

- **Configure Router B.**

Step 1: In OSPF route configuration mode, specify Area 0 to enable the MD5 authentication.

```
B(config)#router ospf 1
B(config-router)#area 0 authentication message-digest
B(config-router)#exit
```

Step 2: Configure the authentication type and key on the interface.

```
B(config)#interface gigabitEthernet 0/3
B(config-if-GigabitEthernet 0/3)#ip ospf message-digest-key 1 md5 hello
```

- **Configure Router C.**

! Enable the identity authentication of the backbone area (Area 0) on Router C.

```
C(config)#router ospf 1
C(config-router)#area 0 authentication message-digest
```

Verification

Step 1: Display the OSPF information about the routers when the authentication is enabled only on Router A and Router B. (disabled on Router C)

! Display the virtual link configurations of Router B.

```
B#show ip ospf virtual-links
Virtual Link VLINK0 to router 3.3.3.3 is up
  Transit area 0.0.0.1 via interface GigabitEthernet 0/3
  Local address 192.168.2.1/32
  Remote address 192.168.2.2/32
  Transmit Delay is 1 sec, State Point-To-Point,
  Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
    Hello due in 00:00:09
Adjacency state Down
```

In this case, the adjacency state is down.

! Display the virtual link configurations of Router C.

```
C#show ip ospf virtual-links
Virtual Link VLINK0 to router 2.2.2.2 is up
  Transit area 0.0.0.1 via interface GigabitEthernet 0/3
  Local address 192.168.2.2/32
  Remote address 192.168.2.1/32
  Transmit Delay is 1 sec, State Point-To-Point,
  Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
    Hello due in 00:00:08
Adjacency state Down
```

In this case, the adjacency state is down.

! Display the OSPF routing information about Router A.

```
A#show ip route ospf
O IA 192.168.2.0/24 [110/2] via 192.168.1.2, 00:10:59, GigabitEthernet 0/1
```

In this case, Router A has failed to learn the routes of Area 2.

Step 1: Display the OSPF information about the routers after the authentication is enabled on Router A and Router B and the identity authentication of Area 0 is enabled on Router C.

! Display the virtual link configurations of Router B.

```
B#show ip ospf virtual-links
Virtual Link VLINK0 to router 3.3.3.3 is up
  Transit area 0.0.0.1 via interface GigabitEthernet 0/3
  Local address 192.168.2.1/32
  Remote address 192.168.2.2/32
  Transmit Delay is 1 sec, State Point-To-Point,
  Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
    Hello due in 00:00:01
Adjacency state Full
```

In this case, the adjacency state is full.

! Display the virtual link configurations of Router C.

```
C#show ip ospf virtual-links
Virtual Link VLINK0 to router 2.2.2.2 is up
Transit area 0.0.0.1 via interface GigabitEthernet 0/3
Local address 192.168.2.2/32
Remote address 192.168.2.1/32
Transmit Delay is 1 sec, State Point-To-Point,
Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
Hello due in 00:00:00
Adjacency state Full
```

In this case, the adjacency state is full.

! Display the OSPF routing information about Router A.

```
A#show ip route ospf
O IA 192.168.2.0/24 [110/2] via 192.168.1.2, 00:21:30, GigabitEthernet 0/1
O IA 192.168.3.0/24 [110/3] via 192.168.1.2, 00:03:18, GigabitEthernet 0/1
```

In this case, Router A has successfully learned the routes of Area 2.

Step 3: Display general OSPF information about Router A.

```
A#show ip ospf
 Routing Process "ospf 1" with ID 1.1.1.1
 Process uptime is 18 hours 22 minutes
 Process bound to VRF default
 Conforms to RFC2328, and RFC1583 Compatibility flag is enabled
 Supports only single TOS(TOS0) routes
 Supports opaque LSA
 Enable two-way-maintain
 Initial SPF schedule delay 1000 msecs
 Minimum hold time between two consecutive SPFs 5000 msecs
 Maximum wait time between two consecutive SPFs 10000 msecs
 Initial LSA throttle delay 0 msecs
 Minimum hold time for LSA throttle 5000 msecs
 Maximum wait time for LSA throttle 5000 msecs
 Lsa Transmit Pacing timer 40 msecs, 10 LS-Upd
 Minimum LSA arrival 1000 msecs
 Pacing lsa-group: 240 secs
 Number of incoming current DD exchange neighbors 0/5
 Number of outgoing current DD exchange neighbors 0/5
 Number of external LSA 0. Checksum 0x000000
 Number of opaque AS LSA 0. Checksum 0x000000
 Number of non-default external LSA 0
 External LSA database is unlimited.
 Number of LSA originated 2
 Number of LSA received 244
 Log Neighbor Adjacency Changes: Enabled
  Number of areas attached to this router: 1: 1 normal 0 stub 0 nssa
    Area 0 (BACKBONE)
        Number of interfaces in this area is 1(1)
        Number of fully adjacent neighbors in this area is 1
        Area has message digest authentication
        SPF algorithm last executed 17:24:38.030 ago
        SPF algorithm executed 11 times
        Number of LSA 7. Checksum 0x032955
```

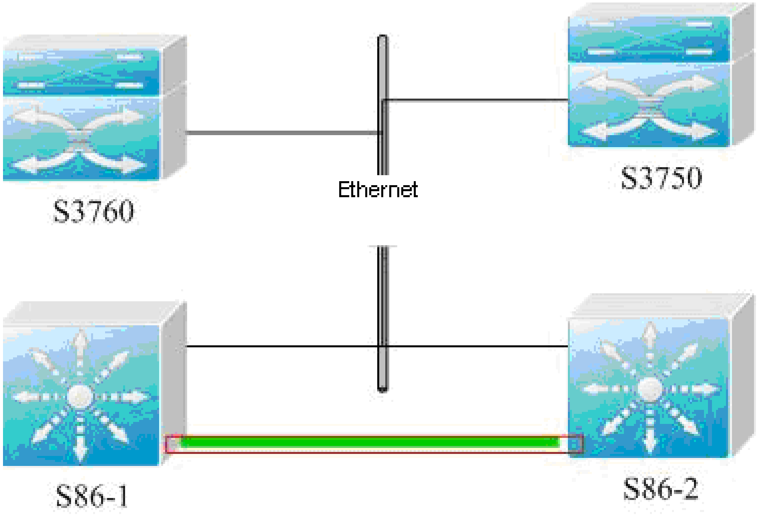
The above information shows that the area authentication has been enabled.

Example of OSPF GR Configuration

Configuration Requirements

The following figure shows that two S86 high-end switches have the GR Restart capability and are equipped with primary and secondary engines to support redundant backup at the control plane. S86-1 establishes the OSPF adjacency relationship with S86-2, S3760, and S3750. The OSPF GR capability is supported by all devices. The connection layout is shown as follows:

OSPF GR configuration



It is required that two S86 devices shall support non-stop packet forwarding to enhance the reliability of core devices.

Specific Configurations

Configure S3760.

```
Ruijie(config)# router ospf 1
Ruijie(config-router)# graceful-restart helper strict-lsa-checking
```

Configure S3750.

```
Ruijie(config)# router ospf 1
Ruijie(config-router)# graceful-restart helper strict-lsa-checking
```

Configure S86-1.

```
Ruijie(config)# router ospf 1
Ruijie(config-router)# graceful-restart
Ruijie(config-router)# graceful-restart helper strict-lsa-checking
```

Configure S86-2.

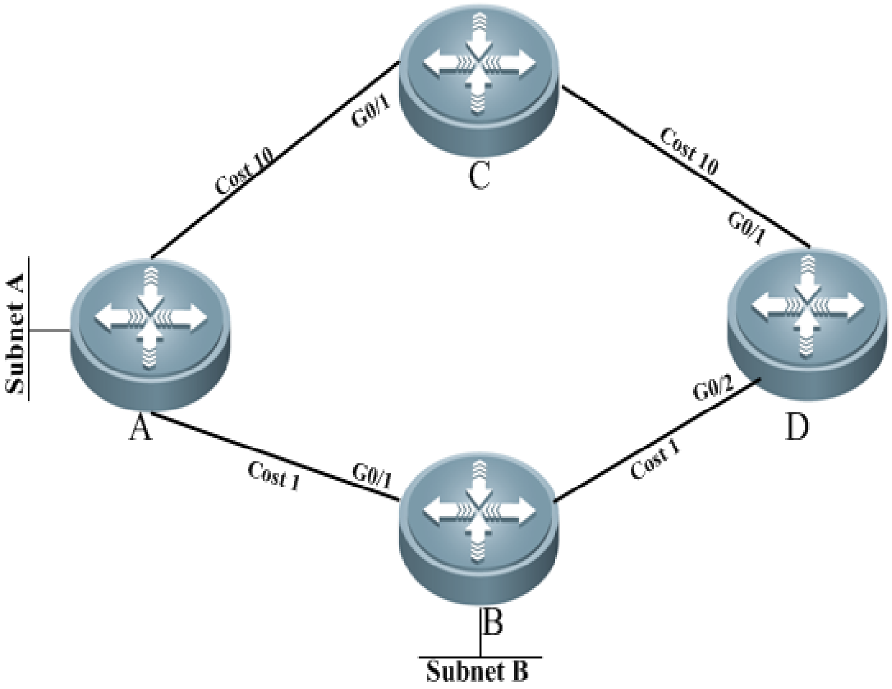
```
Ruijie(config)# router ospf 1
Ruijie(config-router)# graceful-restart
Ruijie(config-router)# graceful-restart helper strict-lsa-checking
```

Example of OSPF Stub Router Configuration

Configuration Requirements

Four routers form an OSPF routing area. The connection layout is shown in the following figure. According to the rule for optimal routing, the route from D to subnet A passes B. It is expected that the route passes C by changing configurations of B only.

OSPF Stub Router configuration



It is required that B only transmit routes to Subnets B and C transmit other routes.

Specific Configurations

Configure IP addresses and OSPF processes on the four routers, and make the following configurations after the adjacency relationship have been established successfully.

Configurations on D:

# Configure the Ethernet interface.

```
interface gigabitEthernet 0/1
ip ospf cost 10
interface gigabitEthernet 0/2
ip ospf cost 1
```

Configurations on C:

# Configure the Ethernet interface.

```
interface gigabitEthernet 0/1
ip ospf cost 10
```

Configurations on B:

# Configure the Ethernet interface.

```
interface gigabitEthernet 0/1
ip ospf cost 1
```

Configure the OSPF routing protocol.

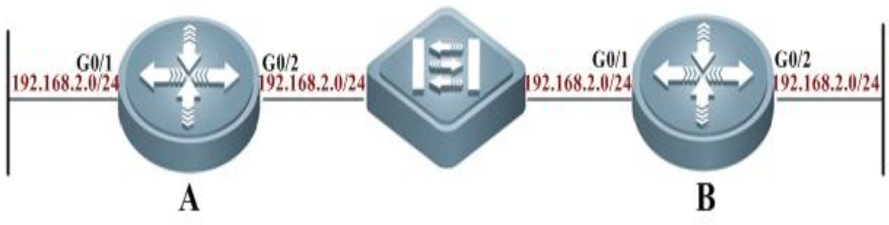
```
router ospf 1
max-metric router-lsa
```

Example of OSPF Fast Convergence Configuration

Configuration Requirements

Routers A and B are interconnected through a layer-2 switch. Run the OSPF protocol on them to establish routes. The following figure shows details about IP address assignment and connection layout.

OSPF fast convergence configuration



After link failure between B and the layer-2 switch occurs, A shall be able to detect adjacency changes within 1 second and quickly respond to the network changes.

Specific Configurations

The Fast Hello function reduces the time for detecting adjacency changes to less than 1 second. Meanwhile, the LSA fast convergence function facilitates to adaptation to the swift network changes.

Configurations on A:

# Configure the Ethernet interface.

```
interface gigabitEthernet 0/1
ip address 192.168.1.1 255.255.255.0
interface gigabitEthernet 0/2
ip address 192.168.2.1 255.255.255.0
ip ospf dead-interval minimal hello-multiplier 5
```

# Configure the OSPF routing protocol.

```
router ospf 1
network 192.168.1.0 0.0.0.255 area 0
network 192.168.2.0 0.0.0.255 area 0
```

```
timers arrival-time 100
timers throttle lsa all 0 100 500
```

Configurations on B:

# Configure the Ethernet interface.

```
interface gigabitEthernet 0/1
ip address 192.168.3.1 255.255.255.0
interface gigabitEthernet 0/2
ip address 192.168.2.2 255.255.255.0
ip ospf dead-interval minimal hello-multiplier 5
```

# Configure the OSPF routing protocol.

```
router ospf 1
network 192.168.2.0 0.0.0.255 area 0
network 192.168.3.0 0.0.0.255 area 0
timers arrival-time 100
timers throttle lsa all 0 100 500
```

Configuring OSPFv3

OSPFV2 (RFC2328, OSPFv2) runs under the IPv4. The RFC5340 describes OSPFV3, the extension of OSPFv2 that provides support for IPv6 routes. This document briefly describes the OSPFv3 protocol and its configuration.

Before learning this document, you must know the OSPFv2 protocol and related configuration.

The OSPFv3 protocol extends the OSPFv2 protocol with the main operating mechanisms and most configuration the same as the OSPFv2.

Overview

As an Interior Gateway Protocol (IGP), the OSPF runs among the layer 3 devices within an Autonomous System (AS).

Unlike a vector distance protocol, the OSPF is a link-state protocol. By exchanging various types of link-state advertisements (LSAs) recording link state between devices, it synchronizes link state information between devices and then calculates OSPF route entries through the Dijkstra algorithm.

The OSPFv3 is described in the RFC5340 and supports the IPv6. This section describes the differences from the OSPFv2 in implementation.

LSA Association Change
Interface Configuration
Router ID Configuration
Authentication Mechanism Configuration

LSA Association Change

Just as described above, the OSPF is a link-state protocol and its implementation is based on LSAs. Through LSAs, we can know the topologies of networks and address information. In contrast to the IPv4, the IPv6 uses 128-bit IP addresses. The design of LSAs is modified accordingly. Firstly, the LSA types are described as follows:

Router-LSAs (Type 1)

Each device generates this type of LSAs by itself. They describe the states of its links in specified areas and the cost spent in reaching the links. In contrast to the OSPFv2, the Router-LSAs of the OSPFv3 only indicate the state information of links. They do not record the information about the network addresses connected to routers. The information will be acquired by newly added types of LSAs. Additionally, in the OSPFv2, only one Router-LSA is allowed to be generated for each device in each area. While in the OSPFv3, multiple Router-LSAs are allowed to be generated. Thus, when performing the SPF calculation, we must consider all the Router-LSAs generated by the device. Router-LSAs and Network-LSAs describe the link topology of areas together.

Through the flag bits on Router-LSAs, we can know whether the routers are Area Border Routers (ABR), AS boundary routers (ASBR) or those at one end of a virtual link.

Network-LSAs (Type 2)

Network-LSAs only exist in broadcast networks or NBMA networks and are generated by DRs (Designated Routers) in a network. They describe the information about all the routers connected in specified areas on a network. Like Router-LSAs, Network-LSAs also only indicate the link-state information and do not record the network address information. Network-LSAs and Router-LSAs describe the link topology of areas together.

Inter-Area-Prefix-LSAs (Type 3)

They are generated for an area by the ABRs in the area and used to describe the network information about reaching other areas. They replace type 3 summary-LSAs in OSPFv2. In contrast to the OSPFv2, they use a prefix structure to describe the destination network information.

Inter-Area-Router-LSAs (Type 4)

They are generated for an area by the ABRs in the area, used to describe the path information about reaching the ASBRs in other areas, and replace type 4 summary-LSAs in OSPFv2.

AS-external-LSAs (Type 5)

This type of LSAs is generated by ASBRs and used to describe the network information about reaching outside the AS. Usually, the network information is generated through other routing protocols. In contrast to the OSPFv2, it uses a prefix structure to describe the destination network information.

NSSA-LSA (Type 7)

Their function is same as that of type 5 AS-external-LSAs. However, they are generated by ASBRs in the NSSA area.

Link-LSAs (Type 8)

In the OSPFv3, the newly added LSA type is generated by each device for each connected link and describes the local link address of the device in the current link and all set IPv6 address prefix information.

Intra-Area-Prefix-LSAs (Type 9)

It is a newly added LSA type in the OSPFv3 and provides additional address information for Router-LSAs or Network-LSAs. Therefore, it plays two roles:

- Associating network-LSAs and recording the prefix information of a transit network.
- Associating router-LSAs and recording the prefix information on all Loopback interfaces, point-to-point links, point-to-multipoint links, virtual links and stub networks of the router in the current area.

Other major changes associated with LSA:

LSA flooding scope

In the OSPFv2, the LSA flooding occurs inside areas and ASs. In the OSPFv3, flooding occurs also in local links. Type 8 Link-LSAs is the type that can flood only inside a local link.

Handling an unknown LSA type

This is an improvement of OSPFv3 based on OSPFv2.

In the OSPFv2, database synchronization is necessary in the initial establishment of the adjacency relationship. If there is an unrecognizable LSA type in the database description message, this relationship cannot be established properly. If there is an unrecognizable LSA type in a link-state updating message, then the type of LSAs will be dropped.

In the OSPFv3, it is allowed to receive an unknown LSA type. By using the information recorded in the LSA header, we can determine how to handle the unrecognizable LSA type received.

Interface Configuration

In the OSPFv3, the changes based on interface configuration are as follows:

In order for an interface to run OSPFv3, enable the OSPFv3 directly in the interface configuration mode. For OSPFv2, however, run the **network** command in the OSPF route configuration mode.

If an interface runs OSPFv3, all the addresses on the interface will run IPv6. In the OSPFv2,however, all the addresses are enabled via the **network** command.

In the environment where the OSPFv3 runs, a link can support multiple OSPF entities and different devices connecting this link can run one of these OSPF instances. The OSPFv3 adjacency can only be established between the devices with the same instance ID. The OSPFv2 does not support this function.

Router ID Configuration

RFC5340 specifies the OSPFv3 Router ID is in the format of 32-bit IPv4 address but not the IPv6 address.

By default, the methods of electing OSPFv3 Router ID are the same as the OSPFv2 process . The automatic election method is adopted. Firstly, the largest IPv4 address for the loopback interface is elected as the Router ID. if the loopback interface of IPv4 addresses has not been configured, OSPFv3 process will select the largest IPv4 address for other interfaces as the Router ID. With multiple OSPFv3 processes running on the device, the OSPFv3 process selects the Router ID with the highest priority from the unselected IPv4 addresses in the above way. Different Router IDs are for the different processes.

If the IPv4 addresses available for the Router ID selection are insufficient, the OSPFv3 process will fail to auto-obtain the Router ID. You can use the **router-id** command to configure a Router ID to enable the OSPFv3 process.

The Router ID for each router in the AS must be unique. With multiple OSPFv3 processes running on the same device, the Router ID for each process must also be unique.

Authentication Mechanism Configuration

OSPFv2 itself supports two authentication modes: plain text authentication and key authentication based on MD5. Authentication fields have been removed from OSPFv3 packet headers. OSPFv3 does away its support for authentication entirely, instead relying on IPsec framework offered by IPv6. When OSPFv3 runs on IPv6, OSPFv3 requires the IPv6 authentication header (AH) or IPv6 encapsulating security payload (ESP) to ensure integrity and confidentiality of routing exchanges.

Configure authentication commands to enable IP AH, which only provides authentication on data integrity and consistency. Configure encryption commands to enable IP ESP, which covers AH functions and ensures confidentiality. Namely, authentication and encryption are performed simultaneously.

OSPFv3 authentication configuration can be based on an interface, an area or a virtual link. If you want to achieve higher security, configure different IPsec authentications on every interface. Area configuration is effective for all interfaces except the virtual link within this area. If area configuration and interface configuration are both performed, IPsec of interface configuration has a higher priority.

Basic Configuration of OSPFv3

The OSPFv3 protocol of Ruijie Network has the following features:

Supports multi-instance OSPF;

Supports network type setting;

Supports virtual links;

Supports passive interfaces;

Supports an interface to select a participant OSPF instance;

Supports stub area;

Supports route redistribution;

Supports route aggregation;

Supports timer setting;

Supports link detection using BFD mechanism

To be implemented:

Supports NSSA areas;

Supports authentication. The OSPFv3 will use the IPSec authentication mechanism.

Default OSPFv3 Configuration:

Router ID		Undefined
Interface Configuration	Interface type	Broadcast network
	Interface cost	Undefined
	Hello message sending interval	10 seconds
	Dead interval of adjacent device	4 times of the hello interval.
	LSA sending delay	1 seconds
	LSA retransmitting interval	5 seconds
	Priority	1
	MTU check of database description messages	Enabled
Virtual Link	Virtual Link	Undefined
	Hello message sending interval	10 seconds
	Dead interval of adjacent device	4 times the hello interval.
	LSA sending delay	1 seconds
	LSA retransmitting interval.	5 seconds
	Fast Hello function	Disabled
Area Configuration	Area	Undefined
	Default router cost for stub areas	1
Routing information Aggregation	Inter-area route aggregation	Off
	External route aggregation	Off
Management Distance	Intra-area route	110
	Inter-area route	110
	External route	110
Auto cost generation		Enabled The default cost reference is 100 Mbps.

Shortest path first (SPF) timer	Time from receiving the topology change to running next SPF calculation :5 seconds The least interval between two calculations: 10 seconds
Route redistribution	Off
Route filtering	Off
Passive interface	Off

Enabling OSPFv3

Perform the following steps in the privileged mode to enable the OSPFv3:

Command	Function
configure terminal	Enter the global configuration mode
ipv6 router ospf *process-id*	Start an OSPFv3 routing process and enter the OSPFv3 configuration mode.
router-id *router-id*	Configure the Router ID used for OSPFv3 running on this device.
interface interface-id	Enter the interface configuration mode
ipv6 ospf process-id **area** *area-id* **[instance** *instance-id***]**	Enable the OSPFv3 on the interface. instance-id：Set the interface instance ID that participates the OSPFv3. The interfaces of different devices connected to the same network can choose different OSPFv3 instances to participate.
copy running-config startup-config	Save the configuration.

The OSPFv3 instance ID and process ID are different. OSPFv3 process ID is valid for the device itself only, not influencing the interaction with other routers. While the OSPFv3 instance ID influences the interaction with other routers. Only the devices with the same instance ID can set up the OSPFv3 neighbor relationship.

First enable the interface to participate in the OSPFv3 and then configure the OSPFv3 process in the interface configuration mode. Once the process is configured, the interface will automatically participate in the corresponding process. Currently, our products can support up to 32 OSPFv3 processes.

Configuring OSPFv3 Parameters on the Interface

You can modify the interface parameters in the interface configuration mode according to the actual application.

To configure the OSPFv3 interface parameters, execute the following commands in the interface configuration mode:

Command	Function
ipv6 ospf *process-id* **area** *area-id* [**instance** *instance-id*]	Set the interface to participate in the OSPFv3 routing process.
ipv6 ospf network {**broadcast** | **non-broadcast** | **point-to-point** | **point-to-multipoint** [**non-broadcast**]} [**instance** *instance-id*]	Set the network type of an interface. The default is the broadcast network type.
ipv6 ospf neighbor *ipv6-address* {[**cost** *<1-65535>*] | [**poll-interval** *<0-2147483647>* | **priority** *<0-255>*]} [**instance** *instance-id*]	(Optional) Set the OSPFv3 neighbor.
ipv6 ospf cost *cost* [**instance** *instance-id*]	(Optional) Define the interface cost.
ipv6 ospf hello-interval *seconds* [**instance** *instance-id*]	(Optional) Set the interval for sending the Hello packets on the interface. For all nodes in adjacency on the network, this value must be identical.
ipv6 ospf dead-interval *seconds* [**instance** *instance-id*]	(Optional) Set the adjacency dead-interval on the interface. For all nodes in adjacency on the network, this value must be identical.
ipv6 ospf transmit-delay *seconds* [**instance** *instance-id*]	(Optional) Set the delay in sending LSA on the interface.
ipv6 ospf retransmit-interval *seconds* [**instance** *instance-id*]	(Optional) Set the interval for retransmitting LSA on the interface.
ipv6 ospf priority *number* [**instance** *instance-id*]	(Optional) Set the priority of the interface for elect the DR and BDR.
ipv6 ospf authentication ipsec spi *spi* [**md5** | **sha1**] [**0** | **7**] *key*	(Optional) Sets the same interface authentication parameters on both sides.. *spi*: security parameter index within the ragne from 256 to 4294967295. **md5**: specifies md5 authentication mode. **sha1**: specifies sha1 authentication mode. **0**: specifies the key to be displayed as plain text. **7**: specifies the key to bedisplayed as cipher text. *key*: authentication key.

Command	Function
ipv6 ospf encryption ipsec spi *spi* **esp** *null* [**md5** | **sha1**] [**0** | **7**] *key*	(Optional) Sets the same interface authentication parameters on both sides.. *spi*: security parameter index within the ragne from 256 to 4294967295. **null**: specifies null encryption mode. **md5**: specifies md5 authentication mode. **sha1**: specifies sha1 authentication mode. **0**: specifies the key to be displayed as plain text. **7**: specifies the key to bedisplayed as cipher text. *key*: authentication key.

Use the **no** form of the above command to invalidate the configuration.

You can modify the parameter settings according to the actual needs. But note that some parameter settings must be consistent with those of neighbors otherwise no adjacency can be established. These parameters include the following: **instance**, **hello-interval**, **dead-interval**, **authentication** and **encryption**

Configuring OSPFv3 Area Parameter

The OSPF protocol applies the concept of “hierarchical structure”, allowing a network to be divided into a group of parts connected through a “backbone” in a mutual independence way. These parts are called Areas. The backbone part is called Backbone Area and always indicated by the numerical value 0 (or 0.0.0.0).

By using this hierarchical structure, each device is allowed to keep the link state database in the area where it resides and the topology inside the area is invisible to the outside. In this way, the link state database of each device can be always in a reasonable size, the route calculation time is not too much and the number of packets is not too big.

In the OSPF, the following types of special areas have been defined to meet actual needs:

stub Area.

If an area is at the end of the whole network, then we can design the area as a stub area.

A stub area cannot learn the external routing information of an AS (type 5 LSAs). In practical application, external routing information takes a great proportion in the link state database. Therefore, the devices inside a stub area will learn very little routing information, thus reducing the system resources for running the OSPF protocol.

A device inside a stub area can reach outside of an AS through the default route entry (type3 LSA) generated from the default routing information published by Area Border Routers in the stub area.

NSSA area (Not-So-Stubby Area)

NSSA is the extension of the stub area. By preventing from flooding type 5 LSAs to the devices in the NSSA, it reduce the consumption of device resources. However, unlike a stub area, it allows a certain amount of external routing information of the AS to enter an NSSA in other ways, namely, inject into the NSSA in the form of type 7 LSAs.

So far, the NSSA area functions of the OSPFv3 have not be implemented.

To configure the OSPFv3 area parameters, execute the following commands in the OSPFv3 configuration mode:

Command	Function
area *area-id* **stub** [**no-summary**]	Configure a stub area. no-summary: configure the area to a totally stub area, preventing the area border router in the stub area from sending type3 and type4 LSAs to the stub area.
area *area-id* **default-cost** *cost*	Configure the cost of the default route sent to a stub area.

Use the **no** form of the above command to invalidate the configuration.

You can configure the parameter **default-cost** after the configuration of the stub area is made.If the stub area is changed into an ordinary area, the default-cost configuration will be deleted automatically.

Configuring OSPFv3 Virtual Link

In the OSPF, all areas must be connected to the backbone area to ensure the communication with other areas. If some areas cannot be connected to the backbone area, virtual links are required to connect the backbone area.

To establish a virtual link, execute the following commands in the OSPFv3 configuration mode:

Command	Function
area *area-id* **virtual-link** *router-id* [**hello-interval** *seconds*] [**dead-interval** *seconds*] [**transmit-delay** *seconds*] [**retransmit-interval** *seconds*] [**instance** *instance-id*] [**authentication ipsec spi** *spi* [**md5** | **sha1**] [**0** | **7**] *key*] [**encryption ipsec spi** *spi* **esp null** [**md5** | **sha1**] [**0** | **7**] *key*]	Configure a virtual link. By default, the virtual link is not configured. *area-id:* the ID for the area where the virtual link is. *router-id:* the router-id for the virtual link neighbor. *spi*: security parameter index within the ragne from 256 to 4294967295. **null**: specifies null encryption mode. **md5**: specifies md5 authentication mode. **sha1**: specifies sha1 authentication mode. **0**: specifies the key to be displayed as plain text. **7**: specifies the key to bedisplayed as cipher text. *key*: authentication key. Other parameters have the same meanings as the interface parameters.

Use the **no** form of the command to invalidate the configuration.

It is not allowed to create a virtual link in the stub area .A virtual link can be taken as a special interface, so its configuration are the same as that of a normal interface. You must ensure that the configuration of **instance, hello-interval**, **dead-interval**, **authentication** and **encryption** configured at the two ends of the virtual link are identical.

Configuring OSPFv3 Route Aggregation

Without route aggregation, each device on the network has to maintain the routing information to every network.By aggrgating some information together, route aggregation can alleviate the burden on the L3 device and network bandwidth. As the size of a network is growing, the importance of route aggregation increases..

Ruijie's L3 devices support two types of route aggregation configuration: inter-area route aggregation and external route aggregation.

Configuring Inter-area Route Aggregation

The ABR in an area needs to advertise the routes in an area to other areas. If the route addresses are continual, the ABR aggregates the routing information and then advertises it.

To configure the inter-area route aggregation, execute the following commands in the OSPFv3 configuration mode:

Command	Function
area *area-id* **range** *ipv6-prefix*/*prefix-length* [**advertise** | **not-advertise**]	Configure inter-area route aggregation. *area-id*: ID of the area for aggregation. *ipv6-prefix/prefixlength*: Set the ipv6 prefix of the aggregated route. **advertise|not-advertise**: Advertise the summary-LSA created by aggregation or not.

Use **no area** *area-id* **range** *ipv6-prefix /prefix-length* to remove the inter-area aggregation configured.

Configuring External Route Aggregation

The route aggregation is allowed when redistributing the generated Type-5 LSA on the ASBR.

To configure the external route aggregation, execute the following commands in the OSPFv3 configuration mode:

Command	Function
summary-prefix *ipv6-prefix* / *prefix-length* [**not-advertise** | **tag** *tag-value*]	Configure external route aggregation. *ipv6-prefix/prefixlength*: Set the ipv6 prefix of the aggregated route. **not-advertise**: Not advertise the LSA created by aggregation. *tag-value*: The valid range is *<0-4294967295>*, used to specify the tag value for the LSA created by aggregation.

Use **no summary-prefix** *ipv6-prefix*/*prefix-length* to remove the external route aggregation configured.

Configuring Bandwidth Reference Value of OSPFv3 Interface Metric

The metric for the OSPF protocol is a bandwidth value based on the interface. The cost value of the interface is calculated based on its bandwidth.

For example, if the bandwidth reference value of an interfaces is 100 Mbps and the bandwidth of the network interfaces is 10Mbps, the automatically calculated interface cost is 100/10=10.

Currently, the default reference value of the network interface bandwidth of our products is 100Mbps.

To modify the reference value of the OSPFv3 interface bandwidth, execute the following commands in the OSPFv3 configuration mode:

Command	Function
auto-cost [**reference-bandwidth** *ref-bw*]	Configure the bandwidth reference value for interface metric, in Mbps.

You can run the **ipv6 ospf cost** *cost-value* command in the interface configuration mode to set the cost for a specified interface, which takes precedence over the one calculated based on bandwidth reference value.

Configuring MTU Check of DD Packets Received on OSPFv3 Interfaces

When the OSPFv3 receives the DD(Database Description) packets, it checks whether the MTU for the neighbor interface is the same as the MTU for its own interface. If the former is larger than the latter, the adjacency relationship cannot be established.

By default, this function of MTU check is disabled. To enable the MTU check on an interface, execute the following command in the interface configuration mode:

Command	Function
no ipv6 ospf mtu-ignore [**instance** *instance-id*]	Enable the MTU check on the interface when receiving database description (DD) packets.

By default, the MTU check function of the interface is disabled.

Configuring OSPFv3 Default Route

In the OSPFv3 protocol, the default route can be generated in many ways.

As described in section "Configuring OSPFv3 Area Parameters", the default route represented by Type-3 LSA will be automatically generated in a stub area.

You can configure a default route represented by Type 5 LSA and advertise it to the whole OSPF AS.

Execute the following command in the OSPFv3 configuration mode:

Command	Function
default-information originate [always] [metric *metric-value***] [metric-type** *type-value***] [route-map** *map-name***]**	Configure the generation of a default route. **always:** With this parameter configured, no matter what the condition the system routing is in, a default route LSA is always generated. With this parameter not configured, only when the default routing existd in the core routing table, the default route LSA is generated and advertised. *metric:* Initial metric value of the route. The valid range is 0-16777214. **metric-type:** The external routing type corresponding to the default routing. **route-map:** the corresponding route-map rule to set the generated LSA.

Use **no default-information originate** to remove the default routing generated.

This command cannot be configured on the devices in a stub area.

Once configured, the device automatically becomes the ASBR.

Configuring OSPFv3 Routing Redistribution

Routing information redistribution allows the routing information of a routing protocol to be redistributed to another routing protocol.

To configure the OSPFv3 route redistribution, execute the following commands in the OSPFv3 configuration mode:

Command	Function
redistribute {**bgp** | **connected** | **isis** [*area-tag*] | **ospf** *process-id* | **rip** | **static**} [{**level-1** | **level-1-2** | **level-2**} | **match** {**internal** | **external** [**1**|**2**]} | **metric** *metric-value* | **metric-type** {*1*|*2*} | **route-map** *route-map-name* | **tag** *tag-value*]	Redistribute the routing information of other routing protocols. And set the conditions of redistribution. At present, the OSPFv3 supports redistribution of static, connect, rip, bgp, isis and ospf routes. When redistributing ISIS routes, you can configure the level parameter to redistribute the ISIS routes at the specified level. When redistributing OSPF routes, you can configure the match parameter to redistribute the OSPF routes of the specific sub type.
default-metric *number*	Configure the default metric for route redistribution.

Use the **no** redistribute *protocol* to disable the routing information redistribution.

- The isis parameter is not supported by S8600 and S12000 series in v10.4(3b17).

Configuring OSPFv3 Timer

After receiving the notice of network topology changes, the OPSPFv3 routing process will wait for a period of time before starting the SPF calculation. The SPF calculation delay is configurable, you can also use the command to configure the minimum and maximum interval between two SPF calculations.

To configure the OSPFv3 routing calculation timer, execute the following command in the routing process configuration mode:

Command	Function
timers throttle spf *spf-delay spf-holdtime spf-max-waittime*	Configure the OSPFv3 timer of routing calculation, in ms.

The parameter *spf-delay* refers to the delay from the topology change to the beginning of the SPF calculation.

The parameter *spf-holdtime* refers to the minimum interval of the first and the second SPF calculations triggered. Afterwards, the next SFP holdtime shall at least be twice as the last interval till the interval reaches the configured *spf-max-waittime*. If the SPF calculation intervals have exceeded the minimum value, it will re-calculate the SPF calculation interval from the *spf-holdtime.*

In normal conditions, when the link changes occassionally, reducing the *spf-delay* and *spf-holdtime* value can speed up the OSPF convergence. Setting a large *spf-max-waittime* avoids high CPU consumption by OSPF due to the continuous link fluctuation.

For example, **timers throttle spf** *1000 5,000 100,000*

If the topology keeps changing, the SPF calculation intervals(the SPF calculation interval increases by the binary exponential backoff algorithm, but cannot exceed the max-wait-time) are 1s, 6s, 16s, 36s, 76s, 156s, 256s, 256+100, ……

To configure the delay and holdtime for OSPFv3 routing calculation only, execute the following command in the routing process configuration mode:

Command	Function
Ruijie (config-router)# timers spf *spf-delay spf-holdtime*	Configure the routing calculation timer in second.

The **timers spf** and **timers throttle spf** commands are overwritten, and the one configured later is valid. With both commands not configured, the default value is **timers throttle spf.**

The function of the command **timers throttle spf** has covered the function of **timers spf**, and is even stronger. It is recommended to use the **timer throttle spf** command.

Configuring OSPFv3 Passive Interface

To prevent other Layer 3 devices in the network from learning the routing information of this device, you can set a network interface to a passive interface in the routing protocol configuration mode

For the OSPFv3 protocol, if a network interface is configured as a passive network interface, then this network interface will receive/send no OSPF message.

To configure an OSPFv3 passive interface, execute the following command in the OSPFv3 configuration mode:

Command	**Function**
passive-interface {**default** | *interface-type interface-number* }	Configure a passive interface. default: with this parameter configured, all interfaces will be set as the passive interfaces. Interface: set the specified interface as the passive interface. Combining **passive-interface default** and **no passive-interface *interface*** can specify some interfaces as non-passive interfaces and the others as passive interfaces.

Use the command **no passive-interface** {*interface-id* | **default**} to remove the passive interface setting.

Configuring OSPFv3 Authenticated Encryption

Authenticated encryption is configured to avoid learning unauthenticated encryption and invalid routes, and prevent valid routes from being announced to the unauthenticated encryption device. On a broadcast network, authenticated encryption can also help avoid the possibility of specifying the unauthenticated encryption device to ensure stability and invasion-resistance of the routing system.

Run the following demands to configure OSPFv3 authenticated encryption in routing process configuration mode or interface configuration mode:

Command	**Function**
area *area-id* authentication ipsec spi *spi* [**md5** | **sha1**] [**0** | **7**] *key*	Enables authentication on the area. Sets authentication mode and key.
area *area-id* **encryption ipsec spi** *spi* **esp null** [**md5** | **sha1**] [**0** | **7**] *key*	Enables authenticated encryption on the area. Sets encrypted authentication mode and key.
ipv6 ospf authentication ipsec spi *spi* [**md5** | **sha1**] [**0** | **7**] *key*	Enables authentication on the interface. Sets authentication mode and key.
ipv6 ospf encryption ipsec spi *spi* **esp null** [**md5** | **sha1**] [**0** | **7**] *key*	Enables authenticated encryption on the interface. Sets encrypted authentication mode and key.

Use the **no** form of this command to disable configuration.

Note

Connected interfaces within the same area must be configured with the same authenticated encryption parameters. Authenticated encryption configured on the area is effective for all interfaces (except the virtual link) within this area but authenticated encryption configured on the interface has a higher priority.

Authenticated encryption parameters configured on two ends of the virtual link must be the same. All *spi* parameters must be unique.

Please refer to *configuring OSPFv3 virtual link* section for virtual link authentication configuration.

Configuring the OSPFv3 Route Management Distance

The route management distance, representing the reliability of the route source, is used to compare the priorities for different routing protocols. The valid range for the management distance is 0-255. The smaller the management distance is, the higher the route priority is, and the higher the route source reliability is.

By default, the OSPFv3 route management distance is 110. You can set different management distances for different OSPFv3 routes, the intra-area, inter-area and external routes.

To change the OSPFv3 route management distance, execute the following command in the routing process configuration mode:

Command	**Function**
distance {*distance* | **ospf** { **intra-area** *distance* | **inter-area** *distance* | **externa**l *distance* }}	Modify the OSPFv3 route management distance.

The management distance must be used to compare the priorities of the different routes originated from different OSPFv3 processes.

Configuring the OSPFv3 BFD

Refer to relevant sections in BDF Configuration Guide for the OSPFv3 BFD configuration.

OSPFv3 Debugging & Monitoring

OSPFv3 supports a large range of debugging and monitoring commands.

OSPFv3 Debugging Commands

Use the following commands to enable the OSPFv3 process debugging in the privileged configuration mode:

Command	Function
debug ipv6 ospf events	Show the OSPFv3 event information.
debug ipv6 ospf ifsm	Show the state machine events and changes of an egress interface.
debug ipv6 ospf lsa	Show the related OSPFv3 LSA information.
debug ipv6 ospf nfsm	Show state machine events and changes of a neighbor.
debug ipv6 ospf nsm	Show the related OSPFv3 and NSM module information.
debug ipv6 ospf packet	Show the OSPFv3 packet information.
debug ipv6 ospf route	Show the OSPF routing calculation and addition information.

Use the **undebug** form of the above commands to disable the above **debug** commands.

The **debug** commands are provided for technicians.

Running a **debug** command will affect the performance of the system in a certain extent. Therefore, after running a **debug** command, use an **undebug** command to disable the debug command.

OSPFv3 Monitoring Commands

Use the following commands to enable the OSPFv3 process monitoring in the privileged configuration mode:

Command	Function
show ipv6 ospf	Show the OSPFv3 process information.
show ipv6 ospf [*process-id*] **database** [**isa-type** [**adv-router** *router-id*]]	Show the database information of the OSPF process.
show ipv6 ospf interface *[interface-type interface-number]*	Show the interface information of the OSPFv3 process.
show ipv6 ospf [*process-id*] **neighbor** [*interface-type interface-number* [**detail**]] *[neighbor-id*] [**detail**]	Show the neighbor information of the OSPFv3 process.
show ipv6 ospf [*process-id*] **route**	Show the OSPFv3 routing information.
show ipv6 ospf [*process-id*]**summary-prefix**	Show the OSPFv3 external route summary information
show ipv6 ospf [*process-id*] **topology** [**area** *area-id*]	Show each area topology of the OSPFv3.
show ipv6 ospf [*process-id*] **virtual-links**	Show the virtual link information of the OSPFv3 process.

OSPFv3 Configuration Examples

OSPFv3 Basic Configuration Example

The following configuration example shows the commands related to OSPF configuration.

Topological Diagram

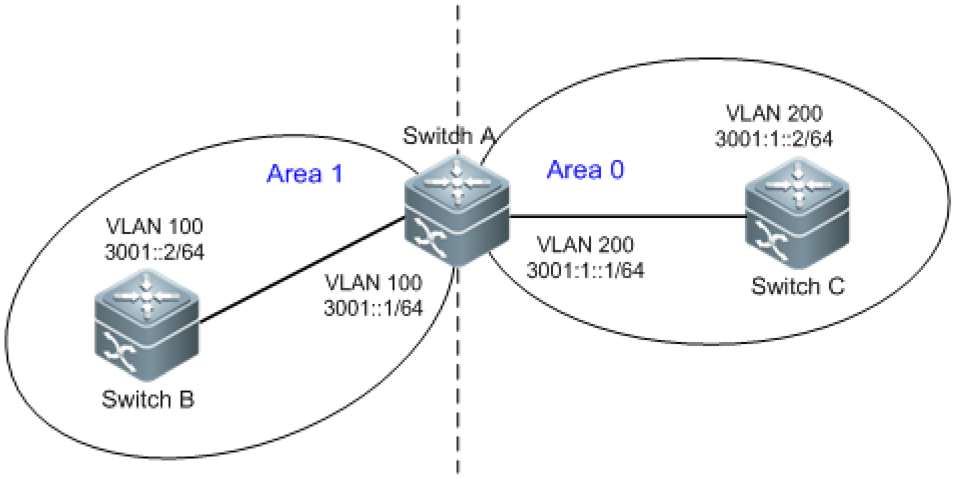


Figure 1 OSPFv3 basic configuration

SwitchA and SwitchB belong to Area 0, while Switch A and Switch C belong to Area 1. The intercommunication between three switches is realized via the vlan interface.

Application Requirements

Enable the OSPFv3 on all switches and divide them into two areas between which IPv6 packets can be communicated.

Configuration Tips

Key points

Configure Area0 and Area1, and enable OSPFv3 on the corresponding VLAN interface of the switch (interface vlan 100 or vlan 200 of SwtichA/SwitchB/SwitchC in this example)

Cautions

The router-id must be specified, or else the adjacency cannot be created. Automatic acquisition of router-id is supported in 10.4 and subsequent releases.

Vlan must be created first, or else the VLAN interface cannot join OSPFv3.

Configuration Steps

Configuring SwitchA

Step 1, Create a VLAN and set the IPv6 address

```
SwitchA# config terminal
```

Enter configuration commands, one per line.   End with CNTL/Z.

! Create and configure interface vlan100

```
SwitchA(config)# vlan 100
SwitchA(config-vlan)#exit
SwitchA(config-vlan)#interface vlan 100
SwitchA(config-if-VLAN 100)#ipv6 enable
SwitchA(config-if-VLAN 100)#ipv6 address 3001::1/64
SwitchA(config-if-VLAN 100)#exit
```

! Create and configure interface vlan200

```
SwitchA(config)#vlan 200
SwitchA(config-vlan)#interface vlan 200
SwitchA(config-if-VLAN 200)#ipv6 enable
SwitchA(config-if-VLAN 200)#ipv6 address 3001:1::1/64
SwitchA(config-if-VLAN 200)#exit
```

Step 2, Create an OSPFv3 process and specify the router-id

```
SwitchA(config)#ipv6 router ospf  10
SwitchA(config-router)#router-id 1.1.1.1
Change router-id and update OSPFv3 process! [yes/no]:y
SwitchA(config-router)#exit
```

Step 3, Enable OSPFv3 on interface vlan 100, with the area being Area0

```
SwitchA(config)#interface vlan 100
SwitchA(config-if-VLAN 100)#ipv6 ospf 10 area 0
SwitchA(config-if-VLAN 100)#exit
```

Step 4, Enable the OSPFv3 on interface vlan 200, with the area being Area1

```
SwitchA(config)#interface vlan 200
SwitchA(config-if-VLAN 200)#ipv6 ospf 10 area 1
SwitchA(config-if-VLAN 200)#end
```

Configuring SwitchB

Step 1, create a VLAN and configure the IPv6 address

SwitchB# conf

Enter configuration commands, one per line.   End with CNTL/Z.

! Create and configure interface vlan100

```
SwitchB(config)# vlan 100
SwitchB(config-vlan)#interface vlan 100
SwitchB(config-if-VLAN 100)#ipv6 enable
SwitchB(config-if-VLAN 100)#ipv6 address 3001::2/64
SwitchB(config-if-VLAN 100)#exit
```

Step 2, Create an OSPFv3 process and specify the router-id

```
SwitchB(config)#ipv6 router ospf 10
SwitchB(config-router)#router-id 2.2.2.2
Change router-id and update OSPFv3 process! [yes/no]:y
SwitchB(config-router)#exit
```

Step 3, Enable the OSPFv3 on interface vlan 100, with the area being Area0

```
SwitchB(config)#interface vlan 100
SwitchB(config-if-VLAN 100)#ipv6 ospf 10 area 0
SwitchB(config-if-VLAN 100)#end
```

Configuring SwitchC

Step 1, create a VLAN and configure the IPv6 address

SwitchC#configure terminal

Enter configuration commands, one per line. End with CNTL/Z.

! Create and configure interface vlan200

```
SwitchC(config)#vlan 200
SwitchC(config-vlan)#interface vlan 200
SwitchC(config-if-VLAN 200)#ipv6 enable
SwitchC(config-if-VLAN 200)#ipv6 address 3001:1::2/64
SwitchC(config-if-VLAN 200)#exit
```

Step 2, Create an OSPFv3 process and specify the router-id

```
SwitchC(config)#ipv6 router ospf 10
SwitchC(config-router)#router-id 3.3.3.3
Change router-id and update OSPFv3 process! [yes/no]:y
SwitchC(config-router)#exit
```

Step 3, Enable the OSPFv3 on interface vlan 200, with the area being Area1

```
SwitchC (config)#interface vlan 200
SwitchC (config-if-VLAN 200)#ipv6 ospf 10 area 1
SwitchC (config-if-VLAN 200)#end
```

Verifying configuration

Step 1: Verify whether the configuration are correct. Pay attention: whether the router-id is specified, whether the OSPFv3 is enabled on the interface, and whether such parameters as OSPFv3 timer are identical in the same area.

Configuring SwitchA

```
vlan 100
!
vlan 200
!
```

```
interface VLAN 100
 no ip proxy-arp
 ipv6 address 3001::1/64
 ipv6 enable
 ipv6 ospf 10 area 0
!
interface VLAN 200
 no ip proxy-arp
 ipv6 address 3001:1::1/64
 ipv6 enable
 ipv6 ospf 10 area 1
!
ipv6 router ospf 10
 router-id 1.1.1.1
```

Configuring SwitchB

```
vlan 100
!
interface VLAN 100
 no ip proxy-arp
 ipv6 address 3001::2/64
 ipv6 enable
 ipv6 ospf 10 area 0
!
ipv6 router ospf 10
 router-id 2.2.2.2
```

Configuring SwitchC:

```
vlan 200
!
interface VLAN 200
 no ip proxy-arp
 ipv6 address 3001:1::2/64
 ipv6 enable
 ipv6 ospf 10 area 1
!
ipv6 router ospf 10
 router-id 3.3.3.3
```

Step 2: Display OSPFv3 neighbors. Pay attention: whether the adjacencies have been created.

```
SwitchA#show ipv6 ospf neighbor
OSPFv3 Process (10), 2 Neighbors, 2 is Full:
Neighbor ID   Pri  State      Dead Time   Instance ID   Interface
2.2.2.2       1   Full/BDR    00:00:37    0            VLAN 100
3.3.3.3       1   Full/DR     00:00:34    0            VLAN 200
```

The information displayed on SwitchB and SwitchC is similar to the information displayed on SwitchA.

Step 3: Display OSPFv3 routes and ping IPv6 address in another area. Pay attention: whether all the IPv6 routes are learned and whether the routes can be pinged.

```
SwitchC#show ipv6 route
IPv6 routing table name is Default(0) global scope - 7 entries
Codes: C - Connected, L - Local, S - Static, R - RIP, B - BGP
      I1 - ISIS L1, I2 - ISIS L2, IA - ISIS interarea, IS - ISIS summary
      O - OSPF intra area, OI - OSPF inter area,  OE1 - OSPF external type 1, OE2 - OSPF external
type 2
      ON1 - OSPF NSSA external type 1, ON2 - OSPF NSSA external type 2
      [*] - NOT in hardware forwarding table
L     ::1/128  via Loopback, local host
OI    3001::/64  [110/2] via FE80::21A:A9FF:FE15:4CB9, VLAN 200
C     3001:1::/64  via VLAN 200, directly connected
L     3001:1::2/128  via VLAN 200, local host
L     FE80::/10  via ::1, Null0
C     FE80::/64  via VLAN 200, directly connected
L     FE80::21A:A9FF:FE01:FB1F/128  via VLAN 200, local host
```

```
SwitchC#ping ipv6 3001::2
Sending 5, 100-byte ICMP Echoes to 3001::2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/10 ms
```

The information displayed on SwitchA and SwitchB is similar to the information displayed on SwitchC.

OSPFv3 Redistribution Configuration Example

Configuration Requirements

There are three devices which are connected as shown in Figure 2.

- Enable the OSPFv3 protocol on RouterA; Enable BGP protocol and configure the static route on RouterC; For RouterB, redistribute the static route redistributed on RouterC to the OSPFv3 domain. Set the specified community attributes for the static route redistributed to BGP on RouterC and redistribute BGP route with the specified community attributes to the OSPFv3 domain on RouterB.

- Configure the external route summary on RouterB: aggregate the routes within the range of 2001:db8:77::/48 and advertise the summary to the OSPFv3 domain.

- To speed up the convergence, set the SPF calculation delay, holdtime and max-waittime for RouterA and RouterB to 5ms, 1000ms and 90000ms respectively.

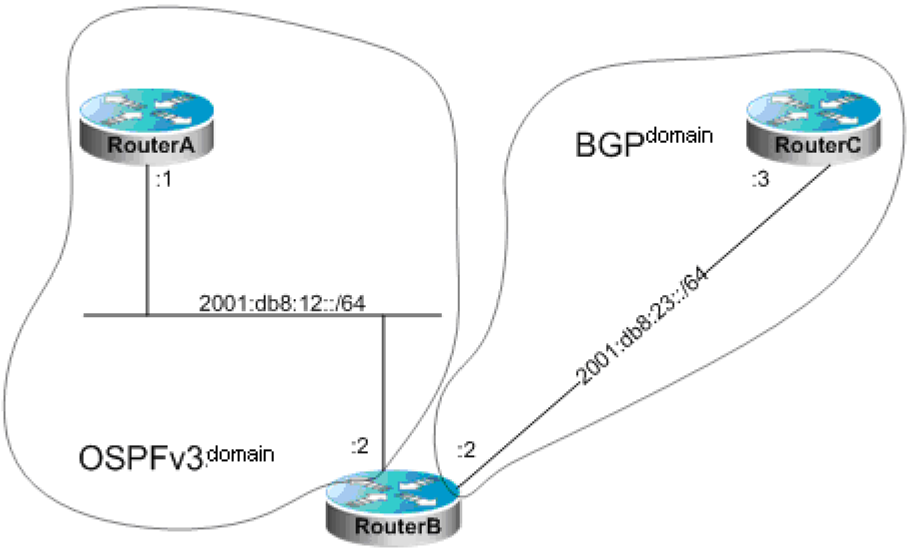

Figure 2 OSPFv3 Redistribution Configuration Example

Configuration Details

Router A configuration:

# Configure the network interface

```
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# ipv6 enable
Ruijie(config-if)# ipv6 address 2001:db8:12::1/64
Ruijie(config-if)# ipv6 ospf 12 area 0
```

# Configure OSPFv3

```
Ruijie(config)# ipv6 router ospf 12
Ruijie(config-router)# router-id 1.1.1.1
Ruijie(config-router)# timers throttle spf 5 1000 90000
```

Router B Configuration:

# Configure the network interface

```
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# ipv6 enable
Ruijie(config-if)# ipv6 address 2001:db8:12::2/64
Ruijie(config-if)# ipv6 ospf 12 area 0
Ruijie(config)# interface gigabitEthernet 0/2
Ruijie(config-if)# ipv6 enable
Ruijie(config-if)# ipv6 address 2001:db8:23::2/64
```

# Configure OSPFv3

```
Ruijie(config)# ipv6 router ospf 12
Ruijie(config-router)# router-id 2.2.2.2
Ruijie(config-router)# redistribute bgp route-map ospfrm
Ruijie(config-router)# timers throttle spf 5 1000 90000
Ruijie(config-router)# summary-prefix 2001:db8:77::/48
```

# Configure BGP

```
Ruijie(config)# router bgp 2
Ruijie(config-router)# neighbor 2001:db8:23::3 remote-as 3
Ruijie(config-router)# address-family ipv6
Ruijie(config-router-af)# neighbor 2001:db8:23::3 activate
```

# Configure route-map

```
Ruijie(config)# route-map ospfrm
Ruijie(config-route-map)# match community cl_110
```

# Define community list

```
Ruijie(config)# ip community-list standard cl_110 permit 22:22
```

Router C Configuration:

# Configure the network interface

```
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# ipv6 enable
Ruijie(config-if)# ipv6 address 2001:db8:23::3/64
```

# Configure BGP

```
Ruijie(config)# router bgp 3
Ruijie(config-router)# neighbor 2001:db8:23::2 remote-as 2
Ruijie(config-router)# address-family ipv6
Ruijie(config-router-af)# redistribute static route-map bgprm
Ruijie(config-router-af)# neighbor 2001:db8:23::2 activate
Ruijie(config-router-af)# neighbor 2001:db8:23::2 send-community
```

# Configure static route

```
Ruijie(config)# ipv6 route 2001:db8:77:88::/64 null 0
Ruijie(config)# ipv6 route 2001:db8:77:99::/64 null 0
```

# Configure route-map

```
Ruijie(config)# route-map bgprm
Ruijie(config-route-map)# set community 22:22
```

Example of Stub Area Configuration

Typology Diagram

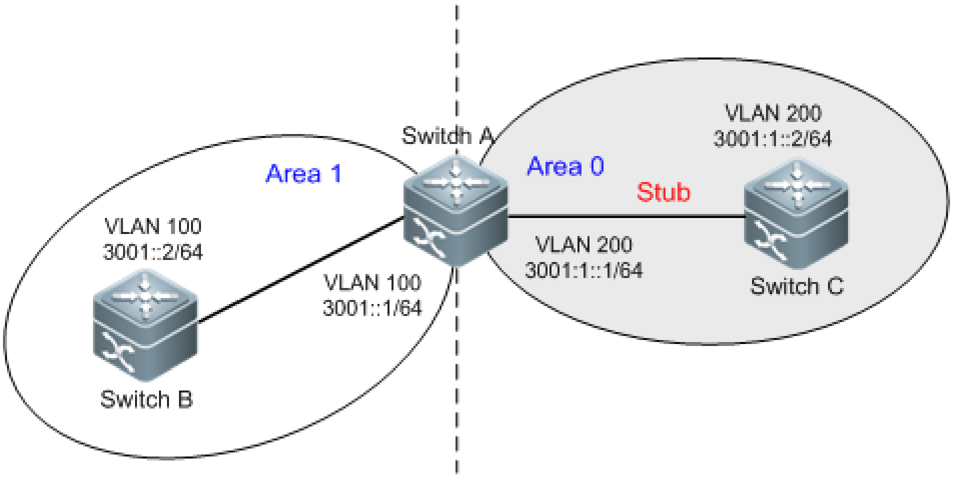

Figure 3 OSPFv3 stub area (the same as Figure 1)

Application Requirements

Configure Area 1 as a stub area in order to reduce the system overhead of switches in this area.

Configuration tips

Use the parameter of "stub no-summary" on the area border router (ABR) (Switch A in this example)

Use the parameter of "stub" on the non-area-border router (Switch C in this example)

Configuration Steps

Configuring SwitchA

Step 1: Enable OSPFv3 basic configuration, as in the OSPFv3 basic configuration example.

Step 2: Configure stub no-summary

```
SwitchA# conf
Enter configuration commands, one per line.  End with CNTL/Z.
SwitchA(config)#ipv6 router ospf 10
SwitchA(config-router)#area 1 stub no-summary
SwitchA(config-router)#exit
```

Configuring SwitchC

Step 1: Enable OSPFv3 basic configuration, as in the OSPFv3 basic configuration example.

Step 2: Configure stub

```
SwitchC# conf
Enter configuration commands, one per line.  End with CNTL/Z.
SwitchA(config)#ipv6 router ospf 10
SwitchA(config-router)#area 1 stub
SwitchA(config-router)#exit
```

Verifying configuration

Step 1: Verify whether the configuration are correct. While making sure the OSPFv3 basic configuration are correct, pay attention to the differences in stub parameters between ABR and the other router.

SwitchA Configuration

```
vlan 100
!
vlan 200
!
interface VLAN 100
 no ip proxy-arp
 ipv6 address 3001::1/64
 ipv6 enable
 ipv6 ospf 10 area 0
!
interface VLAN 200
 no ip proxy-arp
 ipv6 address 3001:1::1/64
 ipv6 enable
 ipv6 ospf 10 area 1
!
ipv6 router ospf 10
 router-id 1.1.1.1
area 1 stub no-summary
!
```

SwitchC Configuration

```
vlan 200
!
interface VLAN 200
 no ip proxy-arp
 ipv6 address 3001:1::2/64
 ipv6 enable
 ipv6 ospf 10 area 1
!
ipv6 router ospf 10
```

```
 router-id 3.3.3.3
area 1 stub
!
```

Step 2: Display OSPFv3 neighbors. Pay attention: whether the adjacencies have been created.

```
SwitchA#show ipv6 ospf neighbor
OSPFv3 Process (10), 2 Neighbors, 2 is Full:
Neighbor ID   Pri  State       Dead Time   Instance ID   Interface
2.2.2.2       1    Full/BDR    00:00:37    0             VLAN 100
3.3.3.3       1    Full/DR     00:00:34    0             VLAN 200
```

Similar information will be displayed on SwitchC.

Step 3: Display OSPFv3 routes. Pay attention: whether the default route is generated, and whether the inter-area route exists

```
SwitchC #show ipv6 route
IPv6 routing table name is Default(0) global scope - 7 entries
Codes: C - Connected, L - Local, S - Static, R - RIP, B - BGP
  I1 - ISIS L1, I2 - ISIS L2, IA - ISIS interarea, IS - ISIS summary
  O - OSPF intra area, OI - OSPF inter area,  OE1 - OSPF external type 1, OE2 - OSPF external
type 2
ON1 - OSPF NSSA external type 1, ON2 - OSPF NSSA external type 2
      [*] - NOT in hardware forwarding table
OI    ::/0  [110/2] via FE80::21A:A9FF:FE15:4CB9, VLAN 200
L     ::1/128  via Loopback, local host
C     3001:1::/64  via VLAN 200, directly connected
L     3001:1::2/128  via VLAN 200, local host
L     FE80::/10  via ::1, Null0
C     FE80::/64  via VLAN 200, directly connected
L     FE80::21A:A9FF:FE01:FB1F/128  via VLAN 200, local host
```

Example of OSPFv3 DR Election Configuration

Typology Diagram

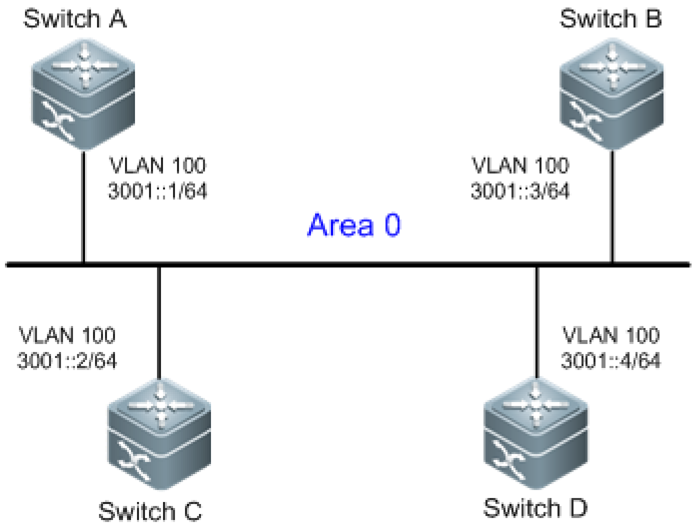

Figure 4 OSPFv3 DR election

SwitchA, SwitchB, SwitchC and SwitchD are in the same area (Area 0) and are interconnected via vlan 100. Switch A and Switch B are devices with the best configuration and the highest stability on the network

Application Requirements

Corresponding requirements: By adjusting the parameter **priority**, configure SwitchA as the DR and SwitchB as the BDR in order to avoid network route flap.

Configuration Tips

Configuration tips

Configure the priority of the interface of expected DR (Switch A in this example) to the highest (150 in this example) and the priority of the interface of BDR (Switch B) to the second highest (50 in this example)

Cautions

The default priority of interface is 1, and DR/BDR can be determined according to the router-id. Generally, the router with the largest router-id will be the DR, and the router with the second largest router-id will be the BDR.

Configuration Steps

Configuring SwitchA

Step 1, create a VLAN and configure the IPv6 address

```
SwitchA# conf

Enter configuration commands, one per line.   End with CNTL/Z.
```

! Create and configure interface vlan100

```
SwitchA(config)# vlan 100
SwitchA(config-vlan)#exit
SwitchA(config)#interface vlan 100
SwitchA(config-if-VLAN 100)#ipv6 enable
SwitchA(config-if-VLAN 100)#ipv6 address 3001::1/64
SwitchA(config-if-VLAN 100)#exit
```

Step 2, Create an OSPFv3 process and specify the router-id

```
SwitchA(config)#ipv6 router ospf 10
SwitchA(config-router)#router-id 1.1.1.1
SwitchA(config-router)#exit
```

Step 3, Enable the OSPFv3 on interface vlan 100, with the area being Area0 and the priority being 150

```
SwitchA(config)#interface vlan 100
SwitchA(config-if-VLAN 100)#ipv6 ospf 10 area 0
SwitchA(config-if-VLAN 100)# ipv6 ospf priority 150
SwitchA(config-if-VLAN 100)#end
```

Configuring SwitchB

Step 1, create a VLAN and configure the IPv6 address

SwitchB# conf

Enter configuration commands, one per line.   End with CNTL/Z.

! Create and configure interface vlan100

```
SwitchB(config)# vlan 100
SwitchB(config-vlan)#exit
SwitchB(config)#interface vlan 100
SwitchB(config-if-VLAN 100)#ipv6 enable
SwitchB(config-if-VLAN 100)#ipv6 address 3001::2/64
SwitchB(config-if-VLAN 100)#exit
```

! Create an OSPFv3 process and specify the router-id

```
SwitchB(config)#ipv6 router ospf 10
SwitchB(config-router)#router-id 2.2.2.2
SwitchB(config-router)#exit
```

Step 2, Enable the OSPFv3 on interface vlan 100, with the area being Area0 and the priority being 50

```
SwitchB(config)#interface vlan 100
SwitchB(config-if-VLAN 100)#ipv6 ospf 10 area 0
SwitchB(config-if-VLAN 100)# ipv6 ospf priority 50
SwitchB(config-if-VLAN 100)#end
```

Configuring SwitchC

Step 1, create a VLAN and configure the IPv6 address

SwitchC# conf

Enter configuration commands, one per line.   End with CNTL/Z.

! Create and configure interface vlan100

```
SwitchC(config)#vlan 100
SwitchC(config-vlan)#exit
SwitchC(config)##interface vlan 100
SwitchC(config-if-VLAN 100)#ipv6 enable
SwitchC(config-if-VLAN 100)#ipv6 address 3001::3/64
SwitchC(config-if-VLAN 100)#exit
```

Step 2, Create an OSPFv3 process and specify the router-id

```
SwitchC(config)#ipv6 router ospf 10
SwitchC(config-router)#router-id 3.3.3.3
SwitchC(config-router)#exit
```

Step 3, Enable OSPFv3 on interface vlan 100, with the area being Area0 and the priority using the default value.

```
SwitchC(config)#interface vlan 100
SwitchC(config-if-VLAN 100)#ipv6 ospf 10 area 0
SwitchC(config-if-VLAN 100)#end
```

Configuring SwitchD

Step 1, create a VLAN and configure the IPv6 address

SwitchD# conf

Enter configuration commands, one per line. End with CNTL/Z.

! Create and configure interface vlan100

```
SwitchD(config-vlan)#vlan 100
SwitchD(config-vlan)#exit
SwitchD(config)#interface vlan 100
SwitchD(config-if-VLAN 100)#ipv6 enable
SwitchD(config-if-VLAN 100)#ipv6 address 3001::4/64
SwitchD(config-if-VLAN 100)#exit
```

Step 2, Create an OSPFv3 process and specify the router-id

```
SwitchD(config)#ipv6 router ospf 10
SwitchD(config-router)#router-id 4.4.4.4
SwitchD(config-router)#exit
```

Step 3, Enable OSPFv3 on interface vlan 100, with the area being Area0 and the priority using the default value.

```
SwitchD(config)#interface vlan 100
SwitchD(config-if-VLAN 100)#ipv6 ospf 10 area 0
SwitchD(config-router)#end
```

Verifying configuration

Step 1: Verify whether the configuration are correct. Pay attention: whether the OSPF basic parameters and interface priority are correct

SwitchA Configuration:

```
vlan 100
!
interface VLAN 100
 no ip proxy-arp
 ipv6 address 3001::1/64
 ipv6 enable
 ipv6 ospf 10 area 0
ipv6 ospf priority 150
!
ipv6 router ospf 10
 router-id 1.1.1.1
```

SwitchB Configuration

```
vlan 100
!
interface VLAN 100
 no ip proxy-arp
 ipv6 address 3001::2/64
 ipv6 enable
 ipv6 ospf 10 area 0
ipv6 ospf priority 50
!
ipv6 router ospf 10
 router-id 2.2.2.2
```

SwitchC Configuration

```
vlan 100
!
interface VLAN 100
 no ip proxy-arp
 ipv6 address 3001::3/64
 ipv6 enable
 ipv6 ospf 10 area 0
!
ipv6 router ospf 10
 router-id 3.3.3.3
```

SwitchD Configuration:

```
vlan 100
!
interface VLAN 100
 no ip proxy-arp
 ipv6 address 3001::4/64
 ipv6 enable
 ipv6 ospf 10 area 0
!
ipv6 router ospf 10
 router-id 4.4.4.4
```

Step 2: Display OSPFv3 neighbors. Pay attention: whether the adjacencies have been created, and whether each switch plays the correct role.

```
SwitchD#show ipv6 ospf neighbor
Neighbor ID  Pri   State    Dead Time   Interface ID    Interface
3.3.3.3      1   2WAY/DROTHER  00:00:33    4196         Vlan100
1.1.1.1      150   FULL/DR     00:00:35    4196           Vlan100
2.2.2.2      50   FULL/BDR     00:00:35    4196           Vlan100
```

Adjacencies before priority configuration are shown below. We can see that DR/BDR can be specified by adjusting the priority.

```
SwitchA#show ipv6 ospf neighbor
OSPFv3 Process (10), 3 Neighbors, 2 is Full:
Neighbor ID  Pri   Stat      Dead Time   Instance ID   Interface
2.2.2.2       1    Full/BDR       00:00:33    0            VLAN 100
3.3.3.3       1    2-Way/DROther   00:00:35   0            VLAN 100
4.4.4.4       1    Full/DR        00:00:33    0            VLAN 100
```

Configuration Example of OSPFv3 Multiple Instances on One Link

Topological Diagram

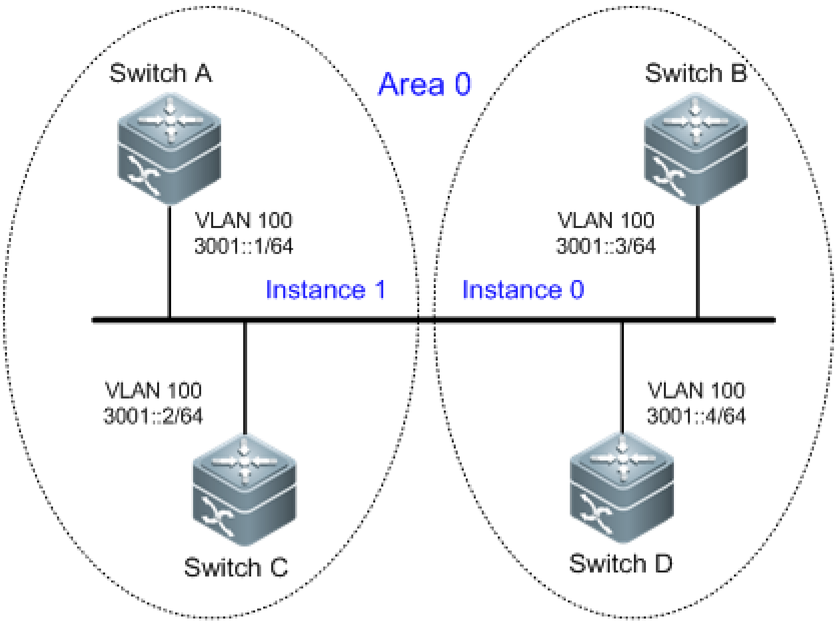

Figure 1-5 Multiple instances on one link

SwitchA, SwitchB, SwitchC and SwitchD are in the same area (Area 0) and are interconnected via vlan 100.

Application Requirements

On a broadcast link, especially within a vlan, adjacencies will be established among all the switches. This may result in increased system overhead and network oscillation.

Application requirements: Switches in the same area are divided into several groups, and OSPFv3 adjacencies can only be established between switches belonging to the same group.

Configuration Tips

Key points

By configuring multiple instances on the same link (the link on interface vlan100 in this example), adjacency establishment by group can be implemented (in this example, SwitchA and SwitchB form a group, with instance ID being 1; SwitchC and SwitchD form a group, with instance ID being 0).

Cautions

By default, the instance ID of the interface is 0. In this example, you only need to configure the instance ID on Switch A and Switch B.

Configuration Steps

Configuring SwitchA

Step 1, Create a VLAN and configure the IPv6 address

SwitchA# conf

Enter configuration commands, one per line. End with CNTL/Z.

! Create and configure interface vlan100

```
SwitchA(config)# vlan 100
SwitchA(config-vlan)#interface vlan 100
SwitchA(config-if-VLAN 100)#ipv6 enable
SwitchA(config-if-VLAN 100)#ipv6 address 3001::1/64
SwitchA(config-if-VLAN 100)#exit
```

Step 2, Create an OSPFv3 process and specify the router-id

```
SwitchA(config)#ipv6 router ospf 10
SwitchA(config-router)#router-id 1.1.1.1
SwitchA(config-router)#exit
```

Step 3, Enable the OSPFv3 on interface vlan 100, with the area being Area0 and the instance ID being 1

```
SwitchA(config)#interface vlan 100
SwitchA(config-if-VLAN 100)#ipv6 ospf 10 area 0 instance 1
SwitchA(config-if-VLAN 100)# end
```

Configuring SwitchB

Step 1, Create a VLAN and configure the IPv6 address

SwitchB# conf

Enter configuration commands, one per line. End with CNTL/Z.

! Create and configure interface vlan100

```
SwitchB(config)# vlan 100
SwitchB(config-vlan)#interface vlan 100
SwitchB(config-if-VLAN 100)#ipv6 enable
SwitchB(config-if-VLAN 100)#ipv6 address 3001::2/64
SwitchB(config-if-VLAN 100)#exit
```

Step 2, Create an OSPFv3 process and specify the router-id

```
SwitchB(config)#ipv6 router ospf 10
SwitchB(config-router)#router-id 2.2.2.2
SwitchB(config-router)#exit
```

Step 3, Enable the OSPFv3 on interface vlan 100, with the area being Area0 and the instance ID being 1

```
SwitchB(config)#interface vlan 100
SwitchB(config-if-VLAN 100)#ipv6 ospf 10 area 0 instance 1
SwitchB(config-if-VLAN 100)# end
```

Verifying Configuration

Step 1: Verify whether the configuration is correct. Pay attention: whether the instance ID for establishing adjacency between switches is correct.

SwitchA Configuration:

```
vlan 100
!
interface VLAN 100
 no ip proxy-arp
 ipv6 address 3001::1/64
 ipv6 enable
 ipv6 ospf 10 area 0 instance 1
!
ipv6 router ospf 10
 router-id 1.1.1.1
```

SwitchB Configuration:

```
vlan 100
!
interface VLAN 100
 no ip proxy-arp
 ipv6 address 3001::2/64
 ipv6 enable
ipv6 ospf 10 area 0 instance 1
!
ipv6 router ospf 10
 router-id 2.2.2.2
```

SwitchC Configuration:

```
vlan 100
!
interface VLAN 100
 no ip proxy-arp
 ipv6 address 3001::3/64
 ipv6 enable
 ipv6 ospf 10 area 0
!
```

```
ipv6 router ospf 10
 router-id 3.3.3.3
```

SwitchD Configuration:

```
vlan 100
!
interface VLAN 100
 no ip proxy-arp
 ipv6 address 3001::4/64
 ipv6 enable
 ipv6 ospf 10 area 0
!
ipv6 router ospf 10
 router-id 4.4.4.4
```

Step 2: Display the instance ID of the interface link and reconfirm that the switches in the same group have the same instance ID

```
SwitchA#show ipv6 ospf interface vlan 100
VLAN 100 is up, line protocol is up
  Interface ID 4196
  IPv6 Prefixes
    fe80::21a:a9ff:fe15:4cb9/64 (Link-Local Address)
    3001::1/64
  OSPFv3 Process (10), Area 0.0.0.0, Instance ID 1
    Router ID 1.1.1.1, Network Type BROADCAST, Cost: 1
    Transmit Delay is 1 sec, State BDR, Priority 1
    Designated Router (ID) 2.2.2.2
      Interface Address fe80::2d0:f8ff:fe22:88b1
    Backup Designated Router (ID) 1.1.1.1
      Interface Address fe80::21a:a9ff:fe15:4cb9
    Timer interval configured, Hello 10, Dead 40, Wait 40, Retransmit 5
      Hello due in 00:00:08
    Neighbor Count is 1, Adjacent neighbor count is 1
  Hello received 7 sent 8, DD received 3 sent 5
  LS-Req received 1 sent 1, LS-Upd received 5 sent 4
  LS-Ack received 3 sent 3, Discarded 0
```

```
SwitchB#show ipv6 ospf interface vlan 100
VLAN 100 is up, line protocol is up
  Interface ID 4196
  IPv6 Prefixes
    fe80::2d0:f8ff:fe22:88b1/64 (Link-Local Address)
    3001::2/64
  OSPFv3 Process (10), Area 0.0.0.0, Instance ID 1
    Router ID 2.2.2.2, Network Type BROADCAST, Cost: 1
```

```
   Transmit Delay is 1 sec, State DR, Priority 1
   Designated Router (ID) 2.2.2.2
     Interface Address fe80::2d0:f8ff:fe22:88b1
   Backup Designated Router (ID) 1.1.1.1
     Interface Address fe80::21a:a9ff:fe15:4cb9
   Timer interval configured, Hello 10, Dead 40, Wait 40, Retransmit 5
     Hello due in 00:00:05
   Neighbor Count is 1, Adjacent neighbor count is 1
  Hello received 16 sent 21, DD received 10 sent 8
  LS-Req received 2 sent 2, LS-Upd received 10 sent 9
  LS-Ack received 6 sent 6, Discarded 0
```

Step 3: Display OSPFv3 neighbors. Pay attention: whether the adjacencies have been created, and whether the adjacencies are established only between the switches in the same group.

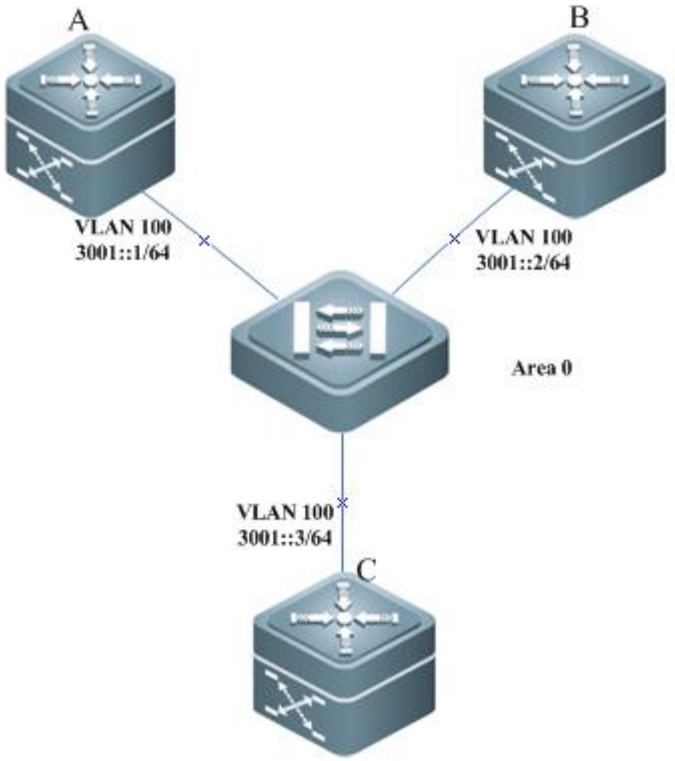
```
SwitchA#show ipv6 ospf neighbor
OSPFv3 Process (10), 1 Neighbors, 1 is Full:
Neighbor ID  Pri State     Dead Time   Instance ID   Interface
2.2.2.2       1   Full/DR   00:00:39     1           VLAN 100
```

```
SwitchB#show ipv6 ospf neighbor
OSPFv3 Process (10), 1 Neighbors, 1 is Full:
Neighbor ID  Pri  State       Dead Time   Instance ID   Interface
1.1.1.1       1   Full/BDR    00:00:34    1            VLAN 100
```

Configuration Example of OSPFv3 Authenticated Encryption

Topological Diagram

Figure 1-6 Encrypted authentication instance



Application Requirements

The OSPFv3 protocol runs on Device A, B and C, which belong to the same area. Connected interfaces establish adjacency only if the same authenticated encryption is configured on them.

The interfaces connecting Device A and B are configured with the same authentication parameters. Device C is not configured with authentication. Device A establishes adjacency with Device B and no adjacency with Device C.

Configuriation Tips

According to the topological requirements, the OSPFv3 protocol is configured to run on Device A, B and C, which belong to the same area

The Interfaces connecting Device A and B are configured with the same authentication parameters.

Configuration Steps

- Configuring Switch A

Step1, Enable the same OSPFv3 basic configuration on Device A, B and C as OSPFv3 basic configuration example.

Step2. Configure authentication parameters on interfaces connecting Device A and B.

```
Ruijie(config)# vlan 100
Ruijie(config-vlan)# exit
Ruijie(config)# interface vlan 100
Ruijie(config-if-vlan 100)# ipv6 address 3001::1/64
Ruijie(config-if-vlan 100)# ipv6 ospf 1 area 0
Ruijie(config-if-vlan 100)# ipv6 ospf authentication ipsec spi 400 md5
aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa
Ruijie(config-if-vlan 100)# exit
```

- Configuring Switch B

Step1, Enable the same OSPFv3 basic configuration on Device A, B and C as OSPFv3 basic configuration example.

Step2. Configure authentication parameters on interfaces connecting Device A and B.

```
Ruijie(config)# vlan 100
Ruijie(config-vlan)# exit
Ruijie(config)# interface vlan 100
Ruijie(config-if-vlan 100)# ipv6 address 3001::2/64
Ruijie(config-if-vlan 100)# ipv6 ospf 1 area 0
Ruijie(config-if-vlan 100)# ipv6 ospf authentication ipsec spi 400 md5
aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa
Ruijie(config-if-vlan 100)# exit
```

- Configuring Switch C

Step1, Enable the same OSPFv3 basic configuration on Device A, B and C as OSPFv3 basic configuration example.

Step2. Configure authentication parameters on interfaces connecting Device A and B.

```
Ruijie(config)# vlan 100
Ruijie(config-vlan)# exit
Ruijie(config)# interface vlan 100
Ruijie(config-if-vlan 100)# ipv6 address 3001::2/64
Ruijie(config-if-vlan 100)# ipv6 ospf 1 area 0
Ruijie(config-if-vlan 100)# ipv6 ospf authentication ipsec spi 400 md5
aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa
Ruijie(config-if-vlan 100)# exit
```

Verifying Configuration

- Step 1: Run the **show ipv6 ospf neighbor** command on Device A, B and C. It is shown that each two devices establish adjacency.
- Step 2: Neighbors.are shown only on Device A and B. Device C shows no neighbor. Run the **debug ipv6 ospf packet** command. Device A and B can receive packets from each other while Device C cannot receive packets.

```
Ruijie#show ipv6 ospf neighbor
OSPFv3 Process (1), 1 Neighbors, 1 is Full:
Neighbor ID   Pri   State      Dead Time   Instance ID   Interface
2.2.2.2      1    Full/BDR   00:00:37    0           VLAN 100

Ruijie#show ipv6 ospf neighbor
OSPFv3 Process (1), 1 Neighbors, 1 is Full:
Neighbor ID   Pri   State      Dead Time   Instance ID   Interface
1.1.1.1      1    Full/BDR   00:00:37    0           VLAN 100

Ruijie#show ipv6 ospf neighbor
```

```
OSPFv3 Process (1), 0 Neighbors, 0 is Full:
```

Configuring BGP

About BGP

The border gateway protocol (BGP) is an exterior gateway protocol (EGP) used for routers to communicate with one another in different autonomous systems. The protocol is designed to exchange information about network reachability among these autonomous systems (AS) and eliminate loops based on the characteristics of the BGP protocol.

The BGP protocol relies on the TCP protocol for reliable packet transmission.

A router which operates on the BGP protocol is referred to as a “BGP Speaker”, and BGP Speakers that have set up a BGP session are referred to as “BGP Peers”.

There are two modes of BGP session: IBGP (Internal BGP) and EBGP (External BGP). The IBGP refers to a BGP session in an AS, while the EBGP refers to a BGP session between different ASs. To summarize, the EBGP exchanges routing information among different ASs. The IBGP transmits routing information in an AS.

The BGP protocol has the following features:

- Supports BGP-4
- Supports path attributes
  - ✓ ORIGN Attribute
  - ✓ AS_PATH Attribute
  - ✓ NEXT_HOP Attribute
  - ✓ MULTI_EXIT_DISC Attribute
  - ✓ LOCAL-PREFERENCE Attribute
  - ✓ ATOMIC_AGGREGATE Attribute
  - ✓ AGGREGATOR Attribute
  - ✓ COMMUNITY Attribute
  - ✓ ORIGINATOR_ID Attribute
  - ✓ CLUSTER_LIST Attribute
  - ✓ AS4_PATH Attribute
  - ✓ AS4_AGGREGATOR Attribute
  - ✓ Connector Attribute
- Supports BGP peer groups
- Supports loopback interface
- Supports MD5 authentication of TCP
- Supports the synchronization of BGP and IGP
- Supports the aggregation of BGP routes
- Supports BGP route flap dampening
- Supports BGP routing reflector
- Supports AS confederation
- Supports BGP soft reset
- Supports BGP Graceful Restart (defined in RFC4724)

Enabling the BGP Protocol

To enable the BGP protocol, execute the following commands in privileged EXEC mode:

Command	**Function**
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)# **ip routing**	Enables the routing function (if the switch is disabled).
Ruijie(config)# **router bgp** *as-number*	Enables the BGP and configures the AS number. The range of *AS-number* is 1 to 65535.
Ruijie(config-router)# **bgp router-id** *router-id*	(Optional) Configures the ID used when this switch runs the BGP protocol.
Ruijie(config-router)# **end**	Returns to privileged EXEC mode.
Ruijie# **show run**	Shows current configuration.
Ruijie# copy running-config startup-config	Saves the configuration.

Use the **no router bgp** command to disable the BGP protocol**.**

Default BGP Configuration

The BGP protocol is not enabled by default.

After the BGP protocol is enabled, the default BGP configuration is shown as follows:

Feature		**Default Setting**
Router ID		To configure a loopback interface, select the maximum address from loopback interface addresses. Otherwise, select the maximum interface address from the directly connected interface.
Synchronization of BGP and IGP		Enabled
Generation of Default Route		Disabled
Multi hops of EBGP	Status	Off
	Number of hops	255
TCP MD5 Authentication		Disabled
Timer	Keepalive Time	60 seconds
	Holdtime	180 seconds
	ConnectRetry Time	120 seconds
	AdvInterval(IBGP)	15 seconds
	AdvInterval(EBGP)	30 seconds
Path Attribute	MED	0
	LOCAL_PREF	100
Route Aggregate		Off
Route Flap Dampening	Status	Off
	Suppress Limit	2000
	Half-life-time	15 minutes
	Reuse Limit	750

Feature		Default Setting
	Max-suppress-time	4*half-life-time
Route Reflector	Status	Off
	Cluster ID	Undefined
	Route among reflection clients	Enabled
AS Confederation		Off
Soft Reset		Off
Traceful Restart		Disabled
Management Distance	External-distance	20
	Internal-distance	200
	Local-distance	200

Injecting Routing Information into the BGP Protocol

The BGP protocol has no routing information when running for the first time. There are two ways to inject routing information to the BGP:

Manually inject routing information to the BGP by using the **network** commands.

Inject routing information to the BGP from the IGP protocol through interaction with the IGP protocol.

The BGP will advertise the injected routing information to its neighbors. This section outlines the manual injection of routing information. For injecting routing information from the IGP protocol, refer to the *Configuration of BGP and IGP Interaction* in related sections.

To manually inject network information advertised by the BGP Speaker to other BGP Speaker, execute the following commands in BGP configuration mode:

Command	Function
Router(config-router)# **network** *network-number* **mask** *network-mask*[**route-map** *map-tag*]	Configures the network whose routing information will be injected into the BGP routing table.

Use the **no network** *network-number* **mask** *network-mask* command to remove the configuration. To cancel the used route-map, reconfigure it by using the r*oute-map not added* option. If the configured network information comes under standard class A, class B or class C network address, the mask option of this command cannot be used.

In BGP4+, you can use this command in IPv6 address family configuration mode to configure IPv6 routes.

Caution

- The **network** command is used to inject IGP routes into the routing table of BGP, and the advertised networks can be direct-connected, static and dynamic routes.
- For the external gateway protocol (EGP), the **network** command indicates the network to be advertised. This is different from the internal gateway protocol (IGP, such as OSPF and RIP). The IGP uses the **network** commands to determine where the routing update message will be sent to.

Sometimes, you may need to use an IGP route rather than an EBGP route. This can be done by using the **network backdoor** command. Execute the following operations in BGP configuration mode:

Command	Function
Ruijie(config-router)# **network** *network-number* **mask** *network-mask* **backdoor**	Sets the backdoor route.

Use the **no network** *network-number* **mask** *network-mask* **backdoor** command to remove the configuration.

Caution

By default, the distance for network information management learned from the BGP Speakers which have established the EBGP connection is 20. Set the distance by using the **network backdoor** command as 200. As such, identical network information learned from the IGP presents a higher priority. The networks learned from the IGP are considered as backdoor networks, and will not be advertised.

Controlling Route Advertisement

The BGP protocol can control the routes advertised to the core routing table by using the **table-map** command. If a route is matched, the command modifies its attribute and advertises it. If a route is not matched or denied, the command advertises it without modifying its attribute.

By default, the **table-map** command advertises all routes without modifying their attributes.

To configure the **table-map** command, execute it in BGP configuration mode or IPv4 address family confiugration mode:

Command	Function
Router(config-router)# **table-map** *route-map-name*	Configures table-map. route-map-name indicates the name of the route-map you want to associate.

Use the **no table-map** command to remove the configuration.

For the configuration of the **table-map** command to take effect immediately, run the **clear ip bgp** [vrf *vrf-name*] **table-map** command to update the core routing table. The **clear ip bgp** [vrf *vrf-name*] **table-map** command will clear but add the routes in the core routing table. Instead, it uses the table-map to advertise route update messages without causing forwarding oscillation..

The **table-map** command supports the following options: rules-match, as-path/community/ip address/ip next-hop/metric/origin/route-type, set, metric/tag/next-hop.

Controlling the Route Redistribution from IBGP to IGP

The BGP protocol controls the redistribution of routes learnded from the IBGP protocol to IGP protocol by using the **bgp redistribute-internal** command. The routes learned from the EBGP protocol or confederation can be redistriubted to the IGP protocol.

This command is enabled by default in either VRF or global mode. Specifically, routers learned from the IBGP can be redistributed to the IGP protocol.

To redistribute a route to the IGP protocol (inclding RIP/OSPF/ISIS), execute the following command in BGP configuration mode, IPv4/IPv6 address family configuration mode or IPv4 VRF address family configuraiton mode:

Command	Function
Router(config-router)# **bgp-redistirbute-internal**	Redistributes IBGP routes to the IGP protocol.

Use the **no bgp redistribute-internal** command to remove the configuration.

Configuring BGP Peer (Group) and Its Parameters

Since the BGP is an external gateway protocol (EGP), it is necessary for a BGP Speaker to know who its peer (BGP Peer) is.

As mentioned in the overview of the BGP protocol, two modes can be used to set up the connection among BGP Speakers: IBGP (Internal BGP) and EBGP (External BGP). The protocol determines which connection will be established among BGP Speakers by using the AS of BGP Peer and BGP Speakers.

The BGP protocol supports IPv4 and IPv6. To check IPv6 function, verify whether the **address-family ipv6** command is executed in BGP configuration mode. Otherwise, IPv6 is not supported. An IPv4 address represents an IPv4 neighbor. An IPv6 address represents an IPv6 neighbor. Note that you should activate neighbors in the right address family.

In general, BGP Speakers with EBGP connection should be physically connected. BGP Speakers with IBGP connection, however, can be located anywhere within an AS.

To configure the BGP peer, execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **neighbor** {*address* | *peer-group-nam*e } **remote-as** *as-number*	Configures the BGP peer. *address* indicates the IP addresses of the BGP peer. *peer-group-name* indicates the name of the BGP peer group.

Command	Function
	The range of *as-number* is 1 to 65535.

Use the **no neighbor** {*address*|*peer-group-name*} to delete one peer or peer group.

The BGP Speakers have some configurations in common (including the executed routing policy). To simplify configuration and improve efficiency, it is recommended that you use the BGP peer group.

To configure the BGP peer group, execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **neighbor** *peer-group-name* **peer-group**	Creates a BGP peer group.
Ruijie(config-router)# **neighbor** *peer-group-name* **remote-as** *as-number*	(Optional) Configures the BGP peer group. The range of *as-number* is 1 to 4294967295.
Ruijie(config-router)# **neighbor** *address* **peer-group** *peer-group-name*	(Optional) Sets the BGP peer as the member of the BGP peer group.

Use the **no neighbor** *address* **peer-group** to delete some members of the BGP peer group.

Use the **no neighbor** *peer-group-name* **peer-group** to delete the entire peer group.

Use the **no neighbor** *peer-group-name* **remote-as** to delete all members of the BGP peer group and AS numbers of the peer group.

To configure the peer of the BGP Speakers or the optional parameter of the BGP peer group, execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router-af)# **neighbor** {*address* | *peer-group-name*} **activate**	(Optional) Activates the address family of the neighbor so that the router can exchange routing information with the address family.
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **update-source** *interface*	(Optional) Configures the network interfaces to establish the BGP session with specified BGP peer (group).
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **ebgp-multihop** [*ttl*]	(Optional) Allows you to establish a BGP session among non-direct-connected EBGP peers (group). The range of TTL is 1 to 255, the EBGP is one hop by default, and the IBGP is 255 hops by default.
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **password** *string*	(Optional) Enables the TCP MD5 authentication when the connection is established among specified BGP peer (group), and configures the password.
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **times** *keepalive holdtime*	(Optional) Configures the Keepalive and Holdtime value to establish a connection with the specified BGP peer (group). The range of the *keepalive* is 0 to 65535 seconds, 60 seconds by default. The range of the *holdtime* is 0 to 65535 seconds, 180 seconds by default.
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **advertisemet-interval** *seconds*	(Optional) Configures the minimal time interval of sending the routing update message to the specified BGP peer (group). The range of advertisement-interval is 1 to 600 seconds, 15

Command	Function
	seconds for the IBGP peer by default, and 30 seconds for the EBGP peer by default.
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **default-originate** [**route-map** *map-tag*]	(Optional) Configures the router to send a default route to the specified BGP peer (group).
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **next-hop-self**	(Optional) Configures the router to set the next routing information as this BGP speaker when the route is distributed to the specified BGP peer (group).
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **remove-private-as**	(Optional) Configures the router to delete the private AS number in the AS path attribute when distributing the routing information to the EBGP peer (group).
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **send-community**	(Optional) Configures the router to send the community attribute to the specified BGP peer (group).
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **maximum-prefix** *maximum* [**warning-only**]	(Optional) Limits the number of the messages received from the specified BGP peer (group).
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **distribute-list** *access-list-name* {**in** | **out**}	(Optional) Configures the router to implement the routing police according to the access control list when routing information is received from and sent to the specified BGP peer (group).
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **prefix-list** *prefix-list-name* {**in** | **out**}	(Optional) Configures the router to implement the routing policy according to the prefix list when the routing information is received from and sent to specified BGP peer (group).
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **route-map** *map-tag* {**in** | **out**}	(Optional) Configures the router to implement the routing policy according to the route-map when the routing information is received from and sent to the specified BGP peer (group).
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **filter-list** *path-list-name* {**in** | **out**}	(Optional) Configures the router to implement the routing policy according to the AS path list when the routing information is received from and sent to the specified BGP peer (group).
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **unsuppress-map** *map-tag*	(Optional) Configures the router to selectively advertise the routing information suppressed by the **aggregate-address** command previously when it is distributed to the specified BGP peer.
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **soft-reconfiguration** inbound	(Optional) Restarts the BGP session and reserve the unchanged routing information sent by the BGP peer (group).
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **route-reflector-client**	(Optional) Configures this switch as the route reflector and specify its client.
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **shutdown**	(Optional) Disables the BGP peer (group).

Use the **no** form of the above commands to disable the configurations.

If a peer does not support **remote-as**, each of its members can use the **neighbor remote-as** command to configure it independently.

By default, each member of the BGP peer group will inherit all its configurations. However, each member can support the optional configurations without affecting the output update independently to replace the unified configuration of the BGP peer group.

Caution

Each member of the BGP peer group can support the optional configurations without affecting the output update independently to replace the unified configuration of the BGP peer group. That is to say, each member of the BGP peer group will inherit the following configurations: **remote-as**, **update-source**, **local-as**, **reconnect-interval**, **times**, **advertisemet-interval**, **default-originate**, **next-hop-self**, **password remove-private-as**, **send-community**, **distribute-list out**, **filter-list out**, **prefix-list out**, **route-map out**, **unspress-map**, **route-reflector-client.**

The **neighbor update-source** command can be used to select any valid interface for establishing a TCP connection. This command is designed mostly to provide available Loopback interfaces, which increase the stability of the connection to the IBGP Speaker.

By default, direct physical connection with BGP peers is required for establishing an EBGP connection. To establish the EBGP peers among non-direct-connected external BGP Speakers, the **neighbor ebgp-multihop** command can be used.

Caution

To avoid route loop and oscillation, the EBGP peers who need multiple hops for BGP connection must have non-default routes to each other.

For the sake of security, you can set the authentication for the BGP peers (group) which will establish the connection based on the MD5 algorithm. The authentication password for the BGP peer should be identical. The process of enabling the MD5 authentication on a BGP peer is shown as follows:

Command	Function
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **password** *string*	Enables the TCP MD5 authentication and set the password when the BGP connection with the BGP peer is established.

Use the **no neighbor** {*address* | *peer-group-name*} **password** command to disable the BGP peer (group) from MD5 authentication.

Use the **neighbor shutdown** command to disable the valid connection established with the BGP peer (group), and delete all routing information related to the BGP peer (group).

Caution

To break the connection established with the specified BGP peer (group) and reserve the configuration information set for this specified BGP peer (group), use the **neighbor shutdown** command. If such configuration information is no longer required, use the **no neighbor** [**peer-group**] command.

Configuring the Management Policy

Whenever the routing policy (including the **neighbor distribute-list**, **neighbor route-map**, **neighbor prefix-list and neighbor filter-list)** changes, you need implement the new routing policy. The traditional way is to break and re-establish the BGP session.

This product supports implementing a new routing policy without ending the BGP session by using soft reset for BGP effectively.

To facilitate the description of BGP soft reset, the following section will refer to the routing policy that affects the input routing information as the input routing policy (such as the **In-route-map** and **In-dist-list**) and the policy that affects the output routing information as the output routing policy (such as the **Out-route-map** and **Out-dist-list**).

If the output routing policy changes, execute the following commands in BGP configuration mode:

Command	Function
Ruijie# **clear ip bgp** {* | peer *address* | **peer-group** *peer-group-name* | **external**} **soft out**	Soft-resets the BGP session and executes the routing policy without resetting the BGP session.

A change in input routing policy changes complicates operations compared with the output routing policy, because the output routing policy is based on the routing table of this BGP Speaker. The implementation of the input routing policy is based on the routing information received from a BGP peer. To reduce memory consumption, the local BGP Speaker will not retain the original routing information received from BGP peers.

To modify the input routing policy if necessary, save the original routing information for each specified BGP peer in this BGP Speaker by using the **neighbor soft-reconfiguration inbound** command. The aim is to provide the original foundation of routing information to modify the input routing policy.

At present, the standard implementation method is referred to as the “Route Refresh Performance”, which can support modifying the routing policy without storing the original routing information. This product supports the feature.

If the input routing policy changes, execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **soft-reconfiguration inbound**	Restarts the BGP session and reserve the unchanged routing information from the BGP peer (group). This command may consume more memory. If both parties support route refreshing performance, this command becomes unnecessary.
Ruijie# clear **ip bgp** {* | *peer-address* | **peer-group** *peer-group-name* | **external**} **soft in**	Soft-resets the BGP session and executes the routing policy without resetting the BGP session.

You can determine whether the BGP peer supports route refreshing performance by the **show ip bgp neighbors** command. If so, you need to execute the **neighbor soft-reconfiguration inbound** command when the input routing policy changes.

Configuring Synchronization between BGP and IGP

The routing information can be transmitted to another AS through the local AS only when it passes through this AS and reaches another AS. The routing information will be advertised to all the routers in the local AS. Otherwise, if some routers running the IGP protocol within this AS have not learned this routing information, data packets may be discarded, because these routers do not know this route when these packets traverses this AS, which may cause a route black hole.

The BGP-IGP synchronization is designed to ensure all routers within this AS can learn the outgoing routing information. Simply, the BGP Speakers redistribute all of the routes learned by the BGP protocol to the IGP protocol to ensure that the routers within the AS learn such routing information.

The BGP-IGP synchronization mechanism can be cancelled in two situations:

10) There is no routing information passing through the local AS (In general, this AS is an end AS).

11) All routers within this AS run the BGP protocol and a full connection is established among all BGP Speakers (An adjacent relationship is established between any two BGP Speakers).

Caution

By default, synchronization is disabled. Enable synchronization when not all the routers are running BGP when traversing an AS.

To enable synchronization of BGP speakers, execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **synchronization**	Enables synchronization of BGP and IGP.

Execute the **no synchronization** command to disable the synchronization mechanism.

Configuring Interaction between BGP and IGP

To inject the routing information generated by the IGP protocol into the BGP protocol, execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **redistribute** [**connected** | **rip** | **static**] [**route-map** *map-tag*] [**metric** *metric-value*]	(Optional) Redistributes static route, direct route and the routing information generated by RIP.
Ruijie(config-router)# **redistribute ospf** *process-id* [**route-map** *map-tag*] [metric *metric-value*] [**match internal external** [**1** | **2**] **nssa-external** [**1** |**2**]]	(Optional) Redistributes the routing information generated by OSPF.
Ruijie(config-router)# **redistribute isis** [*isis-tag*] [**route-map** *map-tag*] [**metric** *metric-value*] [**level-1**| **level-1-2**| **level-2**]	(Optional) Redistributes the routing information generated by ISIS.

By default, distribution of a default route is disabled. To enable this function, execute the following command:

Command	Function
Ruijie(config-router)# **default-information originate**	Redistributes the default route.

Configuring BGP Timer

The BGP uses the Kepalive timer to maintain an effective connection with the peers, and takes the Hldtime timer to determine whether the peers are valid. By default, the value of the Kepalive timer is 60s, and the value of the Holdtime timer is 180s. When a BGP session is established between BGP Speakers, both parties will negotiate with the Holdtime timer and the one with a smaller value will be selected. The selection of the Keepalive timer is based on the smaller one between 1/3 of the negotiated Holdtime timer and the configured Keepalive timer.

To adjust the value of the BGP timer based on all peers, execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **timers bgp** *keepalive holdtime*	Adjusts the keepalive and holdtime values of BGP based on all peers. The range of the *keepalive* is 0 to 65535 seconds, and 60 seconds by default. The range of the *holdtime* is 0 to 65535 seconds, 180 seconds by default.

Certainly, you can adjust the value of the BGP timer based on the specified peers, and execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **times** *keepalive holdtime*	Configures the Keepalive and Holdtime value to establish a session with the specified BGP peer (group). The range of the keepalive is 0 to 65535 seconds, 60 seconds by default. The range of the holdtime is 0 to 65535 seconds, 180 seconds by default.

Use the **no** form of the right command to clear the value of configured timer.

Configuring BGP Path Attributes

AS_PATH Attribute

The BGP protocol controls the distribution of routing information in the following ways:

- IP address by using the **neighbor distribute-list** and **neighbor prefix-list** commands
- AS_PATH Attribute (refer to this section)
- COMMUNITY Attribute (refer to the COMMUNITY Attribute configuration)

You can use the AS path-based access control list to control the distribution of the routing information, where the AS path-based ACL will use Regular Expression to resolve the AS path.

To configure the AS path-based distribution of routing information, execute the following commands in privileged EXEC mode:

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **ip as-path access-list** *path-list-name* {**permit** | **deny**} *as-regular-expression*	(Optional) Defines an AS path list.
Ruijie(config)# **ip routing**	Enables the routing function (if disabled)

Command	Function
Ruijie(config)# **router bgp** *as-number*	Enables the BGP and configures this AS number to enter BGP configuration mode.
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **filter-list** *path-list-name* {**in** | **out**}	(Optional) Implements the routing policy according to the AS path list when the routing information is received from and sent to the specified BGP peer (group).
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **route-map** *map-tag* {**in** | **out**}	(Optional) Implements the routing policy according to the route-map when the routing information is received from and sent to the specified BGP peer (group). In route-map configuration mode, you can use the match as-path to operate the AS path attribute based on the AS path list, or take the set as-path to operate the AS attribute value.

The BGP protocol will not consider the length of the AS path when selecting the optimal path as specified in RFC1771. In general, the shorter the AS path, the higher its priority. Hence, we take the length of the AS path as the optimal path. You can determine whether to consider the length of the AS path when selecting the optimal path according to actual condition.

If you wish to ignore the length of the AS path when selecting the optimal path, execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **bgp bestpath as-path ignore**	Compares the length of the AS path when selecting the optimal path.

Caution

Within the AS, all BGP Speakers consider the length of the AS path as consistent when selecting the optimal path. Otherwise, the optimal path information selected by different BGP Speakers will be different.

NEXT_HOP Attribute

To set the next hop as the local BGP Speaker for sending the routing information to the specified BGP peer, you can use the **neighbor next-hop-self** command, which is mainly used in non-mesh networks, such as frame relay and X.25. Execute the follwing commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **next-hop-self**	Sets the next hop as the local BGP speaker for distributing the routing information to the specified BGP peer (group).

You can also modify the next hop of the specified path by using the **set next-hop** command of Route-map.

Caution

This command is not recommended for a fully meshed network such as Ethernet, because it may cause additional hops and incur unnecessary overhead.

MULTI_EXIT_DISC Attribute Configuration

The BGP takes the MED value as the foundation for priority comparision of the paths learned from the EBGP Peers. The smaller the MED value, the higher the path priority.

By default, the protocol only compares it with the MED value for the path of the peers from the same AS when the optimal path is selected. If you hope to compare it with the MED value for the path of the peers from different ASs, execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **bgp always-compare-med**	Compares with the MED value for the path of different ASs.

By default, it will not compare with the MED value for the path of the peers for other ASs within the AS when the optimal path is selected. If you hope to compare with the MED value for the path of the peers from different AS confederations, execute the following commands in the BGP configuration mode.

Command	Function
Ruijie(config-router)# **bgp bestpath med confed**	Compares with the MED value for the path of the peers from other ASs within the confederation.

By default, if a path with an undefined MED attribute is received, the MED value of this path will be taken as 0. The smaller the MED value, the higher the path priority. The MED value of this path reaches the highest priority. If you want the MED attribute for the path with undefined MED attribute to present the lowest priority, execute the following command in BGP configuration mode:

Command	Function
Ruijie(config-router)# **bgp bestpath med missing-as-worst**	Sets the priority of the path whose MED attribute is not set as the lowest.

By default, they are compared with each other in the sequence the paths are received when the optimal path is selected. If you want to first compare with the path of the peers from the same AS, execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **bgp deterministic-med**	Compares first with the path of the peers from the same AS. By default, they will be compared with by the receiving sequence. The later received path will be compared with first.

LOCAL_PREF Attribute Configuration

The BGP takes the LOCAL_PREF as the foundation for priority comparision of the path learned from the IBGP peers. The larger the LOCAL_PREF value, the higher the path priority.

The BGP Speakers will add the local preference when they send the received external routes to the IBGP peers. To modify the local preference, execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **bgp default local-preference** *value*	Changes the default local preference. The range of the value is 0 to 4294967295, 100 by default.

You can also modify the local preference of the specified path by using the **set local-preference** command of Route-map.

COMMUNITY Attribute Configuration

COMMUNITY Attribute provides another way to control the distribution of the routing information.

The community is a set of destinations. The purpose is to implement the community-based routing policy so as to simplify the configuration for the distribution of the routing information in the BGP Speakers.

Each destination may have more than one community, and the manager of the AS can define the community destination.

By default, all destinations belong to the Internet community carried in the community attribute of the path.

At present, totally four common community attributes are predefined:

- **Internet**: Indicates the Internet community, and all paths are in this community.
- **no-export**: Indicates this path will not be exported to BGP peers.
- **no-advertise**: Indicates this path will not be advertised to BGP peers.
- **local-as**: Indicates this path will be advertised only in the local AS or the AS confederation if it is configured.

You can control the receiving, priority and distribution of the routing information by using the community attribute.

The BGP supports up to 32 COMMUNITY attributes for every route. When configuring the **route-map** command, you can set up to 32 COMMUNITY attributes for the parameters **match** and **set COMMUNITY.**

The BGP Speakers can set, add or modify the community attribute value when they learn, issue or redistribute a route. The aggregated path includes the community attribute of all aggregated paths when route aggregation is carried out.

To configure the community attribute-based distribution of routing information, execute the following commands in privileged EXEC mode:

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.

Command	Function
Ruijie(config)# **ip community-list standard** *community-list-name* {p**ermit** | **deny**} *community-number*	(Optional) Creates the community list. The *community-list-name* is the name of the community list. The community-number is the concrete value of the community list in the range 1 to 4,294,967,295, or the well-known community attribute such as Internet, local-AS, no-advertise and no-export.
Ruijie(config)# **ip routing**	Enables the routing function (if disabled).
Ruijie(config)# **router bgp** *as-number*	Enables the BGP and configure this AS number to enter into BGP configuration mode.
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **send-community**	(Optional) Configures the router to send the community attribute to the specified BGP peer (group).
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **route-map** *map-tag* {**in** | **out**}	(Optional) Configures the router to implement the routing policy according to the route-map when the routing information is received from and sent to the specified BGP peer (group). In the route-map configuration mode, you can use the match community-list [exact] and set community-list delete to operate the community attribute by the community list, or use the set community command to operate the community attribute value directly.

Other Related Configuration

By default, if two paths with identical path attributes are received from different EBGP peers during the selection of the optimal path, we will select the optimal path based on the path receiving sequence. You can select the path with a smaller router ID as the optimal path by using the following commands.

Command	Function
Ruijie(config-router)# **bgp bestpath compare-routerid**	Allows the BGP to compare with the router ID when the optimal path is selected.

Selecting the Optimal Path for BGP

Optimal route selection forms an important part of the BGP protocol. The following section describes the selection process of the BGP route protocol in detail:

- An invalid routing table entry is not allowed in the selection of optimal routes.

Caution Invalid entries include those unreachable for the next hop and those in oscillation.

- Select the route with the high LOCAL_PREF attribute value.
- Select the route generated by the local BGP speaker.

The route generated by the local BGP speaker includes the one generated by the **network, redistribute, aggregate** command.

- Select the route with the shortest AS length.
- Select the route with the lowest ORIGIN attribute.
- Select the route with the smallest MED value.
- The EBGP path has a higher priority than the IBGP path and the AS confederation, and the priority is identical for the IBGP path and the AS confederation.
- Select the route with the smallest IGP metric to reach the next hop.
- Select the route received earlier from the EBGP routes.
- Select the route which advertises that the router ID of the BGP speaker is small.
- Select the route with the greater cluster length.
- Select the route: the value of neighbor address for which is high.

Caution

Discussed above is the process of select the optimum route under the default configuration. You can change the selection process of the route by the CLI command. For instance, you can use the **bgp bestpath as-path ignore** command to make step 4 part of the process of invalidating the optimal route. Use the bgp bestpath compare-routerid command to invalidate Step 9 of the selection.

Configuring BGP Route Aggregation

Since the BGP-4 supports CIDR, aggregated entries can be created to downsize the BGP routing table. Certainly, BGP aggregated entries can be added to the BGP routing table only when there is a valid path within the aggregation scope.

To configure the BGP route aggregation, execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **aggregate-address** *address mask*	(Optional) Configures the aggregated address.
Ruijie(config-router)# **aggregate-address** *address mask* **as-set**	(Optional) Configures the aggregated address, and remain the AS path information of the path within the scope of the aggregated address.
Ruijie(config-router)# **aggregate-address** *address mask* **summary-only**	(Optional) Configures the aggregated address and only advertise the aggregated path.
Ruijie(config-router)# **aggregate-address** *address mask* **as-set summary-only**	(Optional) Configures the aggregated address, and remain the AS path information of the path within the scope of the aggregated address. At the same time, only the aggregated path is advertised.

Use the **no** form of the above commands to disable the configuration.

Caution

By default, the BGP will advertise all routing information both before and after aggregation. If you want to advertise only the aggregated path information, use the **aggregate-address summary-only** command.

Configuring Route Reflector for BGP

To speed up the convergence of routing information, all BGP Speakers within one AS will usually establish the full connection (The adjacent relationship is established between any two BGP Speakers). Too many BGP Speakers within the AS may increase the resource overhead of the BGP Speakers, raise the configuration workload and complexity of network administrators, and reduce the network scalability.

Therefore, route reflector and AS confederation are preferrably used to reduce the connections of the IBGP peers within an AS.

The route reflector provides a way to reduce the connections of the IBGP peer within the AS. One BGP Speaker is set as the route reflector, which divides the IBGP peer within this AS into two types, such as client and non-client.

The rule to implement the route reflector within the AS is shown as follows:

- Configure the route reflector and specify its client, so the route reflector and other clients form a cluster. The route reflector establishes the connection with clients.
- The clients of the route reflector within one cluster should not establish the connection with other BGP Speakers of other clusters.
- Within an AS, a full connection is established among the IBGP peer of non-clients. The IBGP peer of non-clients involves the following scenarios: among several route reflectors within one cluster, among the route reflector within the cluster and the BGP Speakers not involved in the route reflector function out of the cluster (In general, the BGP Speakers don’t support the route reflector function), among the route reflector within the cluster and the route reflector of other cluster.

The following rules applies when the route reflector receives one route:

- The route update received from the EBGP Speaker will be sent to all clients and non-clients.
- The route update received from the clients will be sent to other clients and all non-clients.
- The route update received from the IBGP non-clients will be sent to all its clients.

To configure the BGP route reflector, execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **route-reflector-client**	Configures this product as the route reflector and specifies its clients.

In general, one group is only configured with one reflector. In this case, the Router ID of the route reflector can be used to identify this cluster. To increase the redundancy, you can set more than one route reflector within this cluster. You must configure the cluster ID, so that one route reflector can identify the route update from other route reflectors of this cluster.

Caution To set several route reflectors for one cluster, you need to configure a cluster ID for this cluster.

To configure the cluster ID of the BGP, execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **bgp cluster-id** *cluster-id*	Configures the cluster ID of the route reflector.

In general, it is not necessary to establish a connection between the clients of the route reflector within the cluster, as the route reflector will reflect the routes among clients. However, this function can be disabled if a full connection is established among all clients.

To disable the function of reflecting the client routes, execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **no bgp client-to-client reflection**	Disables route reflection on clients.

Configuring Route Flap Dampening for BGP

Route flap means that a route changes between the valid status and the invalid status. The route flap usually causes instable routes to be transmitted on the Internet, thus resulting an unstable network. BGP route flap dampening provides a way to reduce route flap by monitoring the routing information of EBGP peers.

The route flap dampening of BGP uses the following terminologies:

- Route Flap: A route changes between the valid status and the invalid status.
- Penalty: The route flap dampening-enabled BGP Speakers will add a penalty for the route each time when a route flaps. The penalty will be accumulated to exceed the suppress limit.
- Suppress Limit: When the penalty of a route exceeds this value, the route will be suppressed.
- Half-life-time: The time elapsed when the penalty is reduced to half of its value.
- Reuse Limit: When the penalty of the route is lower than this value, route suppression is released.
- Max-suppress-time: The maximum amount of time the route can be suppressed.

Overview of route flap dampening: The BGP Speakers will add a penalty for the route each time when a route flaps. The penalty is accumulated. Once the penalty value reaches the suppress limit, the route will be suppressed. When the half-life-time is reached, the penalty value is reduced to half of its value. Once the penalty value is reduced to the reuse limit, the route will be activated again. A route can be suppressed for the maximum suppress time.

To configure the route flap dampening of the BGP, execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **bgp dampening**	Enables the route flap dampening of the BGP protocol.
Ruijie(config-router)# **bgp dampening** *half-life-time reuse suppress max-suppress-time*	(Optional) Configures the parameters of the route flap dampening. half-life-time: in the range of 1 to 45minutes, 15minutes by default. reuse: in the range of 1 to 20000, 750 by default. suppress: in the range of 1 to 20000, 2000 by default. max-suppress-time: in the range of 1 to 255 minutes, 4*half-life-time by default.

To monitor the route flap dampening information if necessary, execute the following commands in privileged EXEC mode:

Command	Function
Ruijie# **show ip bgp dampening flap-statistics**	(Optional) Shows the flap statistics information of all routers.
Ruijie# **show ip bgp dampening dampened-paths**	(Optional) Shows the dampened statistics.

To clear the route flap dampening information or the dampened routes, execute the following commands in BGP configuration mode:

Command	Function
Ruijie# **clear ip bgp flap-statistics**	(Optional) Clears flap statistics about all un-dampened route.
Ruijie# **clear ip bgp flap-statistics** address mask	(Optional) Clears flap statistics about the specified route (excluding the dampened routes).
Ruijie# **clear ip bgp dampening** [*address mask*]	(Optional) Clears flap statistics about all routes, and releases the suppressed routes.

Configuring AS Confederation for BGP

Confederation provides a way to reduce the connections of the IBGP peer within the AS.

One AS is divided into multiple sub ASs that can form a confederation by setting a unified confederation ID (namely, confederation AS number). An external confederation is still considered an AS and only the AS number of the confederation is visible. Within the confederation, the full IBGP peer connection is still established among the BGP Speakers, and the EBGP connection is established among the BGP Speakers within the sub AS. Although the EBGP connection is established among BGP Speakers within the sub ASs, the path attribute information of NEXT_HOP, MED and LOCAL_PREF remains intact when the information is exchanged.

To implement the AS confederation, execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **bgp confederation identifier** *as-number*	Configures the AS confederation number. The range of *as-number* is 1 to 4294967295.
Ruijie(config-router)# **bgp confederation peers** *as-numbe* [as-number..]	Configures other sub AS numbers within the AS confederation. The range of *as-number* is 1 to 4294967295.

Use the **no** form of the above commands to disable the configuration.

Configuring BGP Management Distance

The management distance indicates the reliability of the routing information resource, within the range of 1 to 255. The larger the value of the management distance, the lower the reliability is.

The BGP sets different management distances for different information sources that have been learned, such as External-distance, Internal-distance and Local-distance.

- **External-distance:** The management distance of the route learned from the EBGP peers.
- **Internal-distance:** The management distance of the route learned from the IBGP peers.
- **Local-distance:** The management distance of the route learned from the peers. However, the optimal one can be learned from the IGP. In general, these routes are indicated by the **Network Backdoor** command.

To modify the management distance of the BGP protocol, execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **distance bgp** *external-distance internal-distance local-distance*	Configures the management distance. The range of the distance is 1 to 255. For the default configuration: *external-distance* *20* *internal-distance* *200* *local-distance* *200*

Use the **no** form to restore the default management distance of the BGP protocol.

Caution

It is not recommended that you change the management distance of the BGP route. If the change is necessary, please make sure:

■ The External-distance is lower than the management distance of other IGP route protocol (OSPF and RIP).

■ The Internal-distance and Local-distance is higher than the management distance of other IGP route protocol.

Configuring BGP Route Update Mechanism

The BGP route update mechanism comprises two parts: timing scanning update and event trigger update. The former means that the timer is used in the BGP to start the scanning mechanism periodically to update the routing table. The latter means that when BGP configuration or the next hop of BGP route changes, the BGP protocol starts the scanning mechanism to update the routing table.

To configure the BGP route update mechanism, execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **bgp scan-rib disable**	Enables the event trigger mechanism. By default, the timing scanning update mechanism is used.
Ruijie(config-router)# **bgp scan-time** *scan-time*	(Optional) Sets the scanning interval. *scan-time*: In the range of 5 to 60 seconds, 60 seconds by default

You can also configure this command in IPv4/IPv6/VPNv4/IPv4 vrf address family mode.

Use the **no** form to remove the configuration.

Caution

When you run the **bgp scan-rib disable** command to enable the event trigger mechanism, the synchronization should be disabled and the BGP next hop trigger mechanism should be enabled. When synchronization is enabled or the BGP next hop trigger mechanism is disabled, the BGP updates the routing table in timing scanning mode.

Configuring BGP Nexthop Trigger Update Mechanism

The BGP next hop trigger update mechansim improves the converge of BGP routes. It monitors the next hop of BGP routes to speed up converge in stable network topology.

By default, the BGP next hop trigger update mechansim is enabled. After establishing connections with neighbors, the BGP will automatically monitor the next hops of the routes learned from neighbors. When the next hop changes, the BGP will receive a notification of updating the routing tble. This can reduce the time to check the change of next hop for better converge of BGP routes.

If the function is disabled, scan-timer will periodically scan updates to the next hope of BGP.

To configure the BGP next hop trigger update mechanism, execute the following commands in BGP configuration mode:

Command	Function
Ruijie(config-router)# **bgp nexthop trigger enable**	Enables the function of triggering the next BGP route. This function is enabled by default.
Ruijie(config-router)# **bgp nexthop trigger delay** ***delay***-*time*	(Optional) Sets the delay of the BGP next hop trigger update. *delay-time*: In the range of 0 to 100 seconds, 5 seconds by default

You can also configure this command in IPv4/IPv6/VPNv4/IPv4 vrf address family mode.

Use the **bgp nexthop trigger enable** command to restore the setting to the default value.

The **bgp nexthop trigger enable** command and the bgp scan-time command control the same timer. When the timing scanning mechanism is enabled (bgp scan is enabled by default. The **bgp scan-rib disable** command is used to disable **bgp scan**）， the time of larger than 60 seconds set by the **bgp nexthop trigger enable** command does not take effect because the timing scanning mechanism is always activated before the delay time.

Caution

In an unstable network (the next hop changes frequently), especially when there are a large number of routes, this function carries out unnecessary route calculation and consumes more CPU resources. In this case, it is recommended that you disable the BGP next hop trigger update mechanism.

Configuring BGP GR

GR (Graceful Restart) can ensure continuous data forwarding during the resetting of the BGP protocol. Currently, Ruijie supports GR during active and standby switching on its high-end devices to ensure service continuity.

Working Mechanism of GR

12) Standard

RFC4724: Graceful Restart Mechanism for BGP, which is represented by BGP GR later.

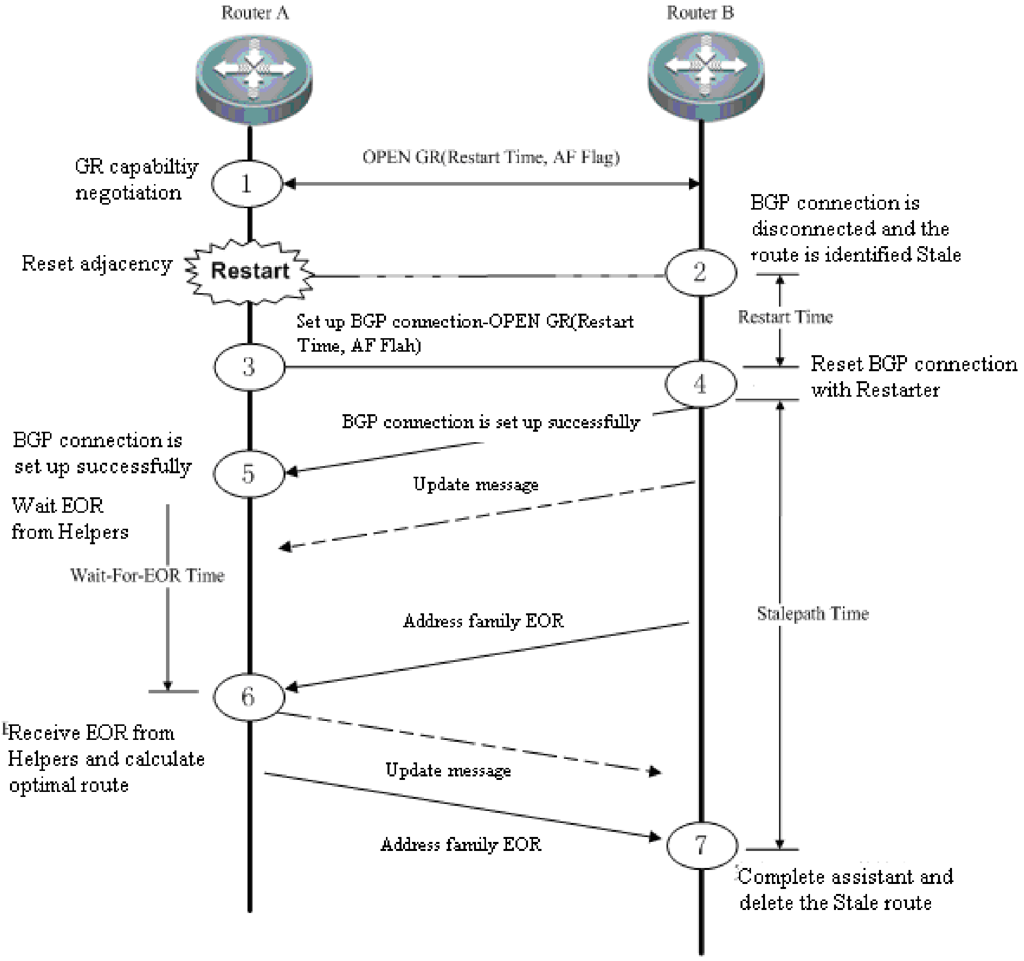
13) Working mechanism

RFC4724 is a standard GR protocol that IETF especially defines for the BGP protocol. This document outlines the principles of BGP GR, including:

- Graceful Restart Capability is added to the OPEN message of the BGP protocol, indicating that the BGP supports GR. The GR capability is negotiated by neighbors during the initiation of BGP connection.
- GR Restarter and GR Helper. GR Restarter means that the router restarts the BGP protocol, which can ensure continuous route forwarding when the route control panel fails. GR Helper is the BGP neighbor of the GR Restarter that assists the GR Restarter in BGP GR for continous forwarding across the network.
- In the update message, EOR (End-of-RIB) is added to indicate that the route message update is complete.

The following ffigure illustrates the process of BGR GR.

Figure 1 Process of graceful restart for BGP



Router A
Router B

Wait-For-EOR Time
Stalepath Time
Address family EOR
6
Receive EOR from Helpers and calculate optimal route
Update message
Address family EOR
7
Complete assistant and delete the Stale route

Initially, the BGP protocol establishes a adjacency and negotiates respective GR capability with the GR Capability field of the OPEN message. At a point, the device reboots and the BGP session is disconnected. The neighbor detects disconnection. With GR supported, the BGP neighbor keeps the route of the GR Restarter valid but identifies it in Stale (aged, not updated) state. The GR Restarter reboots and re-establishes connection with the GR Helper and waits the route update message and EOR label from the GR Helper. After receiving an EOR label from all neighbors, the BGP Restarter calculates routes and update the routing table, and begins to send update routes to the GR Restarter. Upon the receipt of these routes, the GR Helper removes the Stale tag from these routes and then deletes the routes (these routes have not been updated) tagged with Stale after receiving the EOR label from the BGP Restarter, calculates routes and updates the routing table.

Some key timers are defined to assist the implemetation of BGP GR:

- **Restart-Timer**: The GR Restarter notifies the GR Helper of restart time that the GR Helper needs to wait before reestablishing the BGP connection. You can modify this value by using the **bgp graceful-restart restart-time** command.
- **Wait-For-EOR Timer**: Time the GR Restarter needs to wait for the EOR label of all GR Helpers. After receiving the EOR label of all GR Helpers or the timer expires, the GR Restarter calculates optimal routes and updates the routing table. You can modify this value by using the **bgp update-delay** command.
- **StalePath Timer**: Time the GR Helper needs to wait before receiving the EOR label from the GR Restarter after reestablishing the connection with the GR Restarter. During this period, the GT Helper keeps alive the route of the

GR Restarter. It will delete the rotue tagged with Stale after receiving the EOR lable or the StalePath timer expires. You can modify this value by using the **bgp graceful-restart stalepath-time** command.

Implementation of BGP GR

Implementation of BGP GR is not an independent process. All BGP peers are necessary to enable BGP GR capability for normal operation. Failed GR may cause a temporary route black hole or loop and affect the network operation. Consequently, it is recommended that you ensure the GR capability is negotiatied successfully by using the **show ip bgp neighbors** command. To enable BGP GR, exeucte the **bgp graceful-restart** command in BGP route configuration mode.

Configuring BGP GR Capability

BGP GR capability is an extended capability of the BGP protocol, which is disabled by default. When enabling GR, the BGP reestablishes the connection with its neighbor and negotiates GR capability. The GR is enabled only when both sides support GR capability.

To enable the GR capability, execute the following commands:

Command	Function
Ruijie # **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *500*	Enters BGP configuration mode.
Ruijie(config-router)# **bgp graceful-restart**	Enables GR.
Ruijie(config-router)# **end**	Returns to privileged EXEC mode.
Ruijie # **show running-config**	Shows the configuration.
Ruijie # **write**	(Optional) Saves the configuration.

☑ All the BGP-enabled products support this command.

Caution

The **bgp graceful-restart** command does not take effect for established BGP connections. Namely, the BGP connection will not negotiate GR capability immediately when it is in Established status. In this case, you need to forcibly restart the peer to renegotiate the GR capability, for instance, **clear ip bgp 192.168.195.64**. This is to prevent the restart of neighboring relations for capability renegotiation when GR is enabled or disabled, as renegotiation may cause network oscillation. Therefore, you can decide whether to restart neighbors.

Supporting BGP GR capability does not mean a device can serve as the GR Restarter for graceful restart, which also depends on the hardware. The GR Restarter device of Ruijie Networks needs to support dual-engine redundant hot backup.

Configuring BGP GR Timer

After the GR capability is enabled, the BGP automatically configures relevant timers with default values. By default, the Restart Timer is 120s, the Wait-For-EOR Timer is 120s and the StalePath Timer is 360s.

To configure these timers, execute the following commands:

Command	Function
Ruijie # **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *500*	Enters BGP configuration mode.
Ruijie(config-router)# **bgp graceful-restart**	Enables GR capability.
Ruijie(config-router)# **bgp graceful-restart restart-time** *150*	Sets the Restart Timer to 150s.
Ruijie(config-router)# **bgp update-delay** *150*	Sets the Wait-For-EOR Timer to 150s.
Ruijie(config-router)# **bgp graceful-restart stalepath-time** *400*	Sets the StalePath Timer to 400s.
Ruijie(config-router)# **end**	Returns to privileged EXEC mode.
Ruijie # **show running-config**	Shows the configuration.
Ruijie # **write**	(Optional) Saves the configuration.

☑ All the BGP-enabled products support this command.

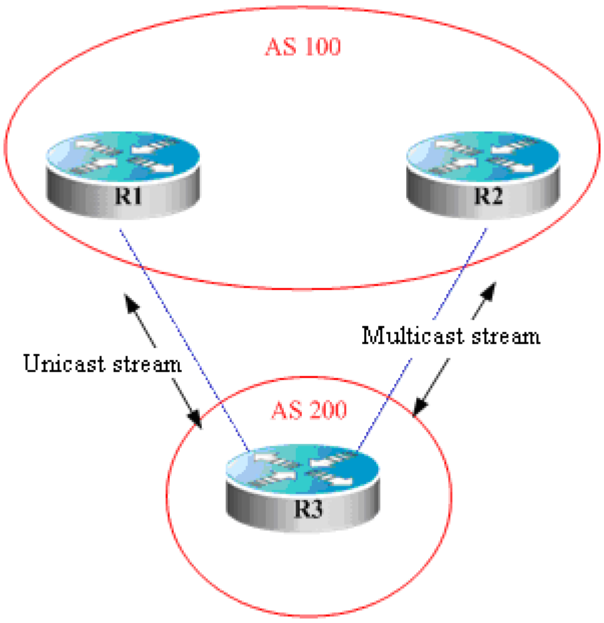
⚠ Caution

The restart time configured by using the **bgp graceful-restart restart-time** command should not exceed the Hold time of the BGP peer. Otherwise, the Hold Time will be used as the restart time and be notified to the peer for GR capability negotiation.

Configuring BGP Multicast

The BGP multicast route is used for multicast RFC check. In general, the multicast forwarding topology is similar to the unicast forwarding topology. You can design different multicast topologies by using BGP multicast, which is used for the multicast topology between ASs, as shown in the following figure.

Figure 2



There are two routers in AS100. In terms of design, unicast streams are sent to R1 and multicast streams to R2. In this case, MPBGP is required between R2 and R3.

Step 1: Enable BGP on R1, R2 and R3 and establish neighbors among them.

Take R3 as an example. Configures R1 and R2 as its BGP neighbors.

Command	Function
Ruijie # **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *200*	Enters BGP configuration mode with the AS number of 200.
Ruijie(config-router)# **neighbor** *R2* **remote-as** *100*	Configures R2 as the BGP neighbor with the AS number of 100.
Ruijie(config-router)# **neighbor** *R1* **remote-as** *100*	Configures R1 as the BGP neighbor with the AS number of 100.

Step 2: Since R3 does not need to transmit multicast routes with R1, disable the multicast address of R1.

Command	Function
Ruijie(config-router)# **address-family ipv4 multicast**	Enters the IPv4 multicast address family configuration mode.
Ruijie(config-router-af)# **no neighbor** *R1* **active**	Disable the multicast address of R1.

Step 3: Since R2 needs to transmit multicast rotues with R1, enable the multicast address of R2.

Command	Function
Ruijie(config-router)# **address-family ipv4 multicast**	Enters IPv4 multicast address family configuration mode.
Ruijie(config-router-af)# **neighbor** *R2* **active**	Enables the multicast address of R2.

Step 4: Import the routes that R3 needs to advertise to R2 in multicast address family mode.

Routes are imported by using **redistribute**, network advertising, and aggregate route publishing. They are configured in a multi-address family, for example:

Command	Function
Ruijie(config-router)# **address-family ipv4 multicast**	Enters IPv4 multicast address family configuration mode.
Ruijie(config-router-af)# **redistribute ospf** 1	Redistributes OSPF routes.

Caution

During the process of redistribution, the routes imported are unicast routes. For instance, the **redistribute ospf 1** command imports OSPF unicast routes. This is because that multicast routes depend on the egress of unicast routes for the establishment of a multicast spanning tree.

Configuring BGP Local AS

This function configures a local AS different from the real AS (rotuer BGP AS) for one peer, which is equivalent to virtualizing an AS. When the real AS changes, you still can establish a BGP connection without modifying the BGP configuration of the peer. Local AS applies to AS migration and converge of large networks without affecting the configurations of the devices in other interconencted ASs.

When establishing the BGP connection, the local device will advertise the local AS number to the peer in an OPEN message. The peer checks whether the AS number matches the local one and rejects the BGP connection if there is a difference. By default, the local AS of the BGP connection is the real BGP AS. With this function, the local device replaces the real AS with the configured one to establish a BGP connection.

By default, no peer is configured with Local AS. The Local AS of the peer is real AS over BGP. To configure a local AS for one peer, execute the following commands:

Command	Function
Ruijie # **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *500*	Enters BGP configuration mode.
Ruijie(config-router)# **neighbor** *192.168.195.64* **remote-as** *100*	Configures the peer.
Ruijie(config-router)# **neighbor** *192.168.195.64* **local-as** *300*	Configures AS 300 as the local AS for the peer

The local AS function applies only to EBGP peers, instead of IBGP peers, confederation EBGP peers. Meanwhile, there are some limitations as described below:

- The local AS cannot be configured as the remote peer.
- Local AS cannot be configured for one member of the peer group.
- The local AS cannot be configured as the real BGP AS.
- The local AS cannot be configured as the AS number of the confederation if the device is a member of the confederation.

For details about the **neighbor** *peer-address* **local-as** *as-num* command, refer to the *Command Reference*.

Monitoring BGP

You can use the **Shows** commands to view the BGP route table, buffer and database. Execute the follwing commands in privileged EXEC mode:

Command	**Function**
Ruijie# **show ip bgp**	Shows the information on all BGP routes.
Ruijie# **show ip bgp** {*network* | *network-mask* } [longer-prefixes]	Shows the BGP routing information of the specified destination.
Ruijie# **show ip bgp prefix-list** *prefix-list-name*	Shows the BGP routing information of the specified matching against the prefix list.
Ruijie# show **ip bgp community** [**exact**] *community-number*	Shows the BGP routing information including the specified community.
Ruijie# **show ip bgp community-list** *community-lister-number* [exact]	Shows the BGP routing information which matches against the specified community list.
Ruijie# **show ip bgp filter-list *path-list***-*number*	Shows the BGP routing information which matches against the specified AS path list.
Ruijie# **show ip bgp regexp** *as-regular-expression*	Shows the BGP routing information of the specified regular expression which matches against the AS path attribute.
Ruijie# **show ip bgp dampening dampened-paths**	Shows the suppressed flap statistics information.
Ruijie# **show ip bgp dampening flap-statistics**	Shows the flap statistics information of all routes with the flap record.
Ruijie# **show ip bgp neighbors** [*address*] [**received-routes** | **routes** | **advertised-routes** | **received]**	Shows the information of the BGP peer.
Ruijie# **show ip bgp summary**	Shows the configuration of the BGP router and the information about the peer.
Ruijie# show **ip bgp peer-group** [*peer-group-name*]	Shows the configuration of the BGP peer group.

Protocol Independent Configuration

route-map Configuration

The BGP protocol follows the Route-map policy. For detailed configurations, refer to the Protocol Independent Configuration.

Regular Expression Configuration

The regular expression is a formula used to match the string based on a template. The regular expression is used to evaluate the text data and return a true or false value, that is to say, it determines whether the expression can describe this data correctly.

Description of Control Characters for Regular Expression

The BGP path attribute uses the regular expression. The following table describes the use of the special characters for the regular expression:

Characters	Signs	Special Functions
Period	.	Matched with any single character.
Asterisk	*	Matched with none or any sequence of the string.
Plus	+	Matched with one or any sequence of the string.
Interrogation Mark	?	Matched with none or one sign of the string.
Plus Sign	^	Matched with the starting of the string.
Dollar	$	Matched with the end of the string.
Underlining	_	Matched with the comma, bracket, the starting and end of the string and blank.
Square Brackets	[ ]	Matched with the single character within the specified scope.

Application Example of Regular Expression

Run the **show ip bgp** command on the device:

```
Ruijie# show ip bgp
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal
Origin codes: i - IGP, e - EGP, ? - incomplete
Status Network           Next Hop     Metric  LocPrf  Path
------ ------------------  ---------------   ---------  ---------  -------------------
*>  211.21.21.0/24   110.110.110.10  0     1000   200 300
*>  211.21.23.0/24   110.110.110.10  0     1000   200 300
*>  211.21.25.0/24   110.110.110.10  0     1000   300
*>  211.21.26.0/24   110.110.110.10  0     1000   300
*> 1.1.1.0/24      192.168.88.250  444        0   606
*> 179.98.0.0      192.168.88.250  444        0   606
*> 192.92.86.0     192.168.88.250  8883        0   606
*> 192.168.88.0    192.168.88.250  444         0   606
*> 200.200.200.0   192.168.88.250  777         0   606
```

Use the regular expression in the **show** command:

```
Ruijie# show ip bgp regexp _300_
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal
Origin codes: i - IGP, e - EGP, ? - incomplete
Status Network        Next Hop          Metric  LocPrf  Path
------ ------------------  ---------------   ---------  ---------  -------------------
*>  211.21.21.0/24  110.110.110.10  0     1000   200 300
*>  211.21.23.0/24  110.110.110.10  0     1000   200 300
*>  211.21.25.0/24  110.110.110.10  0     1000   300
*>  211.21.26.0/24  110.110.110.10  0     1000   300
```

BGP Load Protection Configuration

Too many BGP routes may overload a switch, especially a switch with a small memory size. BGP load protection can prevent unforeseen switch problems caused by switch resource usage.

Limiting BGP Routes

To limit BGP routes, configure the maximum number of routes in the BGP address-family mode. Configure the maximum number of routes learned from a BGP neighbor.

Use the following commands to configure the maximum number of routes learned from a BGP neighbor:

Command	Function
Ruijie(config)# **router bgp** *as-num*	Enters BGP configuration mode.
Ruijie(config-router)#**neighbor** {*address* | *peer-group-name*} **remote**-as *as-num*	Configures the BGP neighbor.
Ruijie(config-router)# **neighbor** {*address* | *peer-group-name*} **maximum-prefix** *maximum* [**threshold**] [**warning-only**]	Configures the maximum number of routes learned from the BGP neighbor.

Use the following commands to configure the maximum number of routes in the specified BGP address-family mode:

Command	Function
Ruijie(config)# **router bgp** *as-num*	Enters BGP configuration mode.
Ruijie(config-router)#**address-family ipv4 unicast**	Enters the BGP ipv4 unicast address-family mode.
Or： Ruijie(config-router)#**address-family ipv4** vrf *vrf-name*	Enters the BGP ipv4 VRF address-family mode.
Or： Ruijie(config-router)#a**ddress-family vpnv4 unicast**	Enters the BGP VPNV4 address-family mode.
Ruijie(config-router)# **maximum-prefix** *maximum*	Configures the maximum number of routes in the specified BGP address-family mode.

Configuring Overflow Memory-lack

BGP can be in the overflow state when the memory is insufficient. In OVERFLOW mode, BGP generates a default route to the NULL interface. A newly learned route will be discarded if it is not a default route in the current routing table. In general, the routes BGP learned in the overflow state are dropped, and the system memory stays in a steady state to protect the network from routing loops. In other words, BGP is safe and also preferred in OVERFLOW state.

Use the following commands to move BGP into the overflow state:

Command	Function
Ruijie(config)# **router bgp** *as-num*	Enters BGP configuration mode.
Ruijie(config-router)# **overflow memory-lack**	Brings BGP into the overflow state when memory is running short.

Note

By default, BGP switches to OVERFLOW state automatically when the memory is running short. Use the **no overflow memory-lack** command for the BGP to exit the OVERFLOW state.

Caution

In OVERFLOW state, BGP supports the **clear bgp** { *addressfamily* | **all** } * command. Alternatively, you can disable and re-enable BGP to exit the OVERFLOS state. When the memory becomes sufficient, BGP exits the OVERFLOW state automatically.

BGP Configuration Examples

The following section lists BGP configurations.

Configuring BGP Neighbor

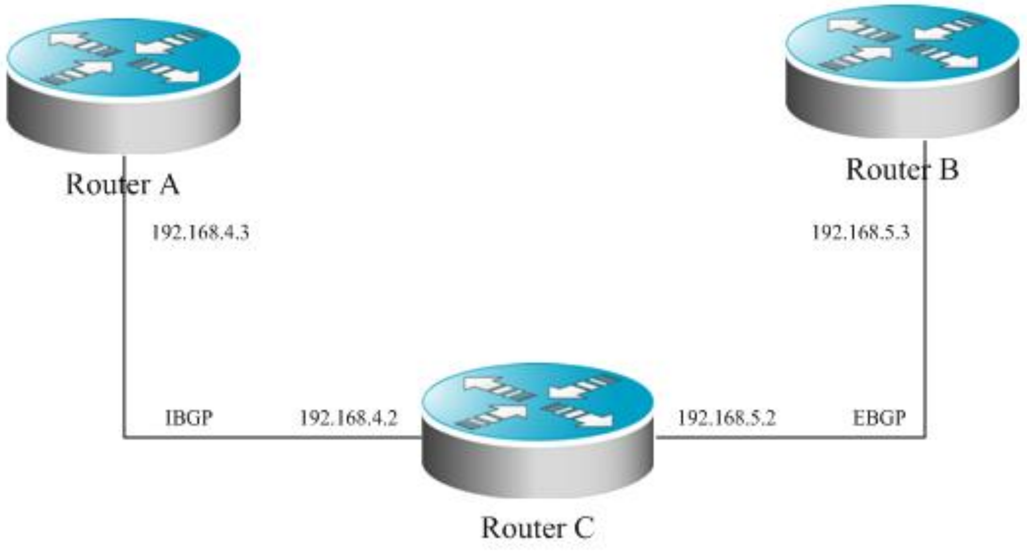
The following section shows how to configure a BGP neighbor. Use the **neighbor remote-as** command to configure the BGP neighbor. Configuration details are shown as follows:

```
router bgp 109
neighbor 131.108.200.1 remote-as 167
neighbor 131.108.234.2 remote-as 109
neighbor 150.136.64.19 remote-as 99
```

Configure one IBGP peer 131.108.234.2 and two EBGP peers 131.108.200.1 and 150.136.64.19.

The following example shows how to configure the BGP neighbor. For the relationship among routers and the assignment of IP addresses, see the figure.

Figure 3



This example shows the BGP configuration of different routers:

Router A configuration:

```
!
router bgp 100
 neighbor 192.168.4.2 remote-as 100
```

Router B configuration:

```
!
router bgp 100
 neighbor 192.168.4.3 remote-as 100
 neighbor 192.168.5.3 remote-as 200
```

Router C configuration:

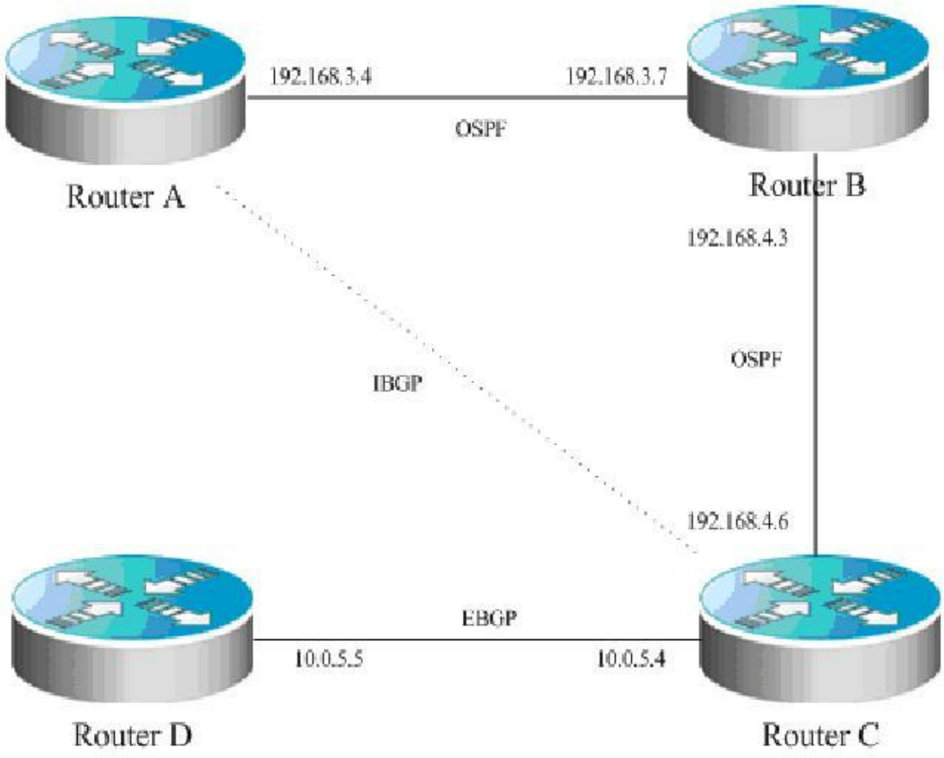
```
!
router bgp 200
 neighbor 192.168.5.2 remote-as 100
```

Configuring BGP Synchronization

Use the **synchronization** command to configure synchronization in BGP routing configuration mode, and use the **no synchronization** command to cancel the configured synchronization.

The following example shows the function of synchronization. The following figure illustrates the relationship between devices and the assignment of IP addresses:

Figure 4



In the figure, route p in router A is sent to router C based on the IBGP adjacency. If router C is configured with BGP synchronization, it is necessary for the router to wait for the IGP (this example uses the OSPF protocol) to receive the same routing information p, and send the route p to the EBGP neighbor, router D. If router C is configured asynchronously, it is not necessary for the BGP to wait for the IGP to receive the route p, and send the route p to the EBGP neighbor router D.

Configuring Neighbors to Use as-Path Filter

Configure the **as-path access-list** command for filtering first in configuration mode. Enter BGP route configuration mode after configuration, and use the **neighbor filter-list** command to apply the configured as-path access list among the BGP neighbors to filter AS paths.

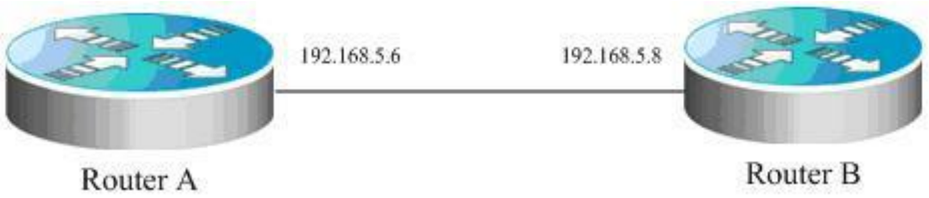
The configurations are detailed below:

```
router bgp 200
neighbor 193.1.12.10 remote-as 100
neighbor 193.1.12.10 filter-list 2 out
neighbor 193.1.12.10 filter-list 3 in
ip as-path access-list 2 permit _200$
ip as-path access-list 2 permit ^100$
ip as-path access-list 3 deny _690$
ip as-path access-list 3 permit .*
```

This configuration indicates that only the routes permitted by the **as-path access-list** *2* can be advertised to the neighbor 193.1.12.10. The advertised routes from the neighbor 193.1.12.10 can be received only when they are permitted by the **as-path access-list** *3.*

The following figure provides a configuration eaxmple that shows the relationship and IP addresses of devices:

Figure 5



Do AS path-based filter on Router A.

The following example shows the configuraitons of different devices:

Router A configuration:

```
!
ip as-path access-list 4 deny ^300_
ip as-path access-list 4 permit .*
ip as-path access-list 5 deny ^450_65_
ip as-path access-list 5 permit .*
!
router bgp 100
 bgp log-neighbor-changes
 neighbor 192.168.5.8 remote-as 200
 neighbor 192.168.5.8 filter-list 5 in
 neighbor 192.168.5.8 filter-list 4 out
```

Router B configuration:

```
!
router bgp 200
 bgp log-neighbor-changes
 neighbor 192.168.5.6 remote-as 100
```

Configuring Route Aggregation

Use the **aggregate-address** command to configure an aggregated route in route configuration mode. When any route falls within the configured range, this aggregated route will become active.

The configuration is detailed as follows:

```
router bgp 100
aggregate-address 193.0.0.0 255.0.0.0
```

Configure one aggregate route:

```
router bgp 100
aggregate-address 193.0.0.0 255.0.0.0 as-set
```

The **as-path** segment of the aggregated route is an collection of **ASs**:

```
router bgp 100
aggregate-address 193.0.0.0 255.0.0.0 summary-only
```

The aggregated route is not advertised.

Configuring Confederation

When configuring a confederatin, you need to use the **bgp confederation identifier** command to configure the AS number for external connection, and use the **bgp confederation peers** command to configure confederation members.

The configuration is detailed as follows:

```
router bgp 6003
bgp confederation identifier 666
bgp confederation peers 6001 6002
neighbor 171.69.232.57 remote-as 6001
neighbor 171.69.232.55 remote-as 6002
neighbor 200.200.200.200 remote-as 701
```

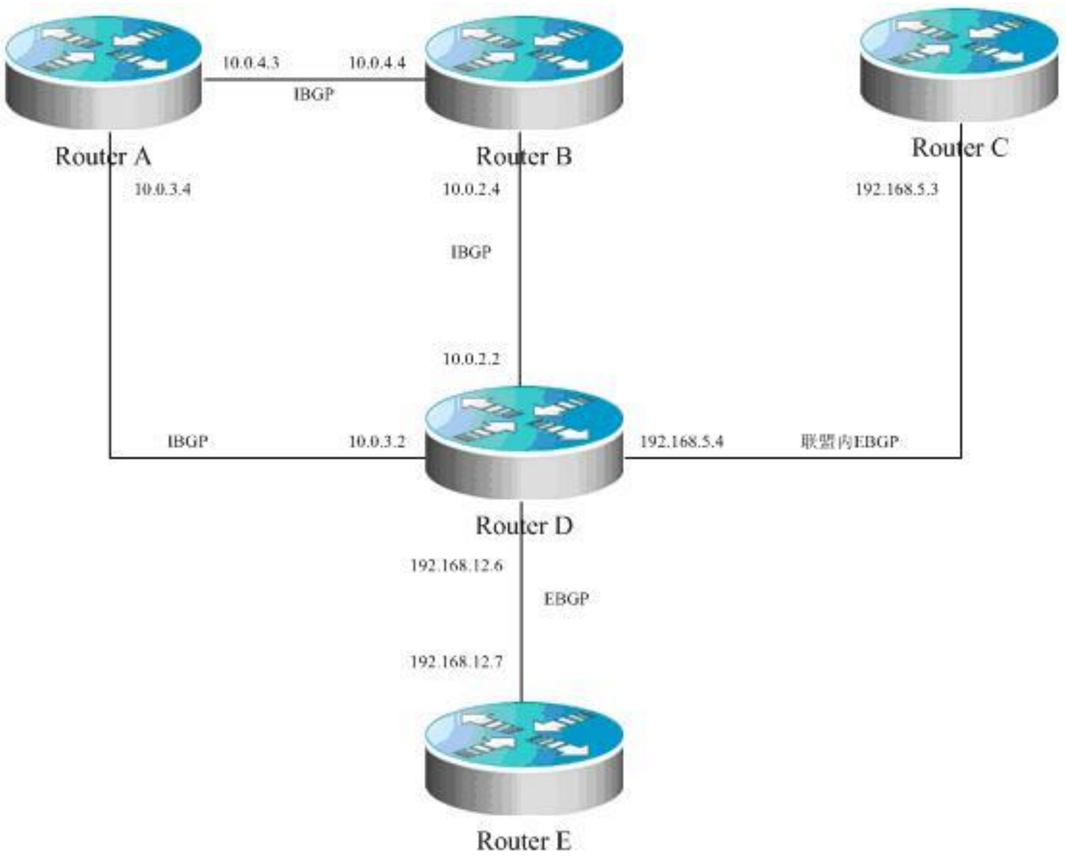
The configuration of peer 200.200.200.200 outside the confederation is shown as follows:

```
router bgp 701
neighbor 171.69.232.56 remote-as 666
neighbor 200,200,200,205 remote-as 701
```

For the configuration, the first device is in the confederation, while the second device is outside the confederation. Therefore, they are EBGP neighbors.

The following example shows their relastionship and IP addresses:

Figure 6



The following example shows the configurations of different devices:

Router A configuration:

```
!
router bgp 65530
 bgp confederation identifier 100
 bgp confederation peers 65531
 bgp log-neighbor-changes
 neighbor 10.0.3.2 remote-as 65530
 neighbor 10.0.4.4 remote-as 65530
```

Router B configuration:

```
!
router bgp 65530
 bgp confederation identifier 100
 bgp log-neighbor-changes
 neighbor 192.168.5.4 remote-as 65530
```

Router C configuration

```
!
router bgp 65531
 bgp confederation identifier 100
 bgp confederation peers 65530
 bgp log-neighbor-changes
 neighbor 10.0.3.2 remote-as 65530
 neighbor 10.0.4.4 remote-as 65530
```

Router D configuration:

```
!
router bgp 65530
 bgp confederation identifier 100
 bgp confederation peers 65531
 bgp log-neighbor-changes
 neighbor 10.0.2.4 remote-as 65530
 neighbor 10.0.3.4 remote-as 65530
 neighbor 192.168.5.3 remote-as 65531
 neighbor 192.168.12.7 remote-as 200
```

Router E configuration:

```
!
router bgp 200
 bgp log-neighbor-changes
 neighbor 192.168.12.6 remote-as 100
```

Configuring Route Reflector

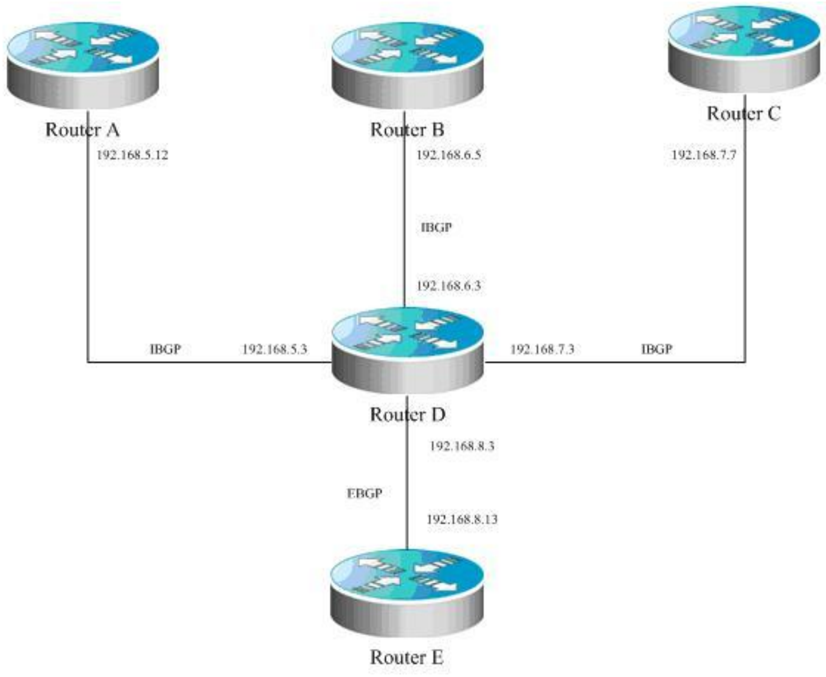
When a route reflector is configured, use the **bgp client-to-client reflection** command to enable the route reflection function on the device. If there are more than one route reflector within one cluster, use the **bgp cluster-id** command to configure the cluster ID of the reflector, and use the **neighbor route-reflector-client** command to add the peer to the client for route reflection.

The configuration is detailed as follows:

```
router bgp 601
bgp cluster-id 200.200.200.200
neighbor 171.69.232.56 remote-as 601
neighbor 200,200,200,205 remote-as 701
neighbor 171.69.232.56 route-reflector-client
```

The following example shows the relastionship between and IP addresses of the devices:

Figure 7



In this example, Router D is a route reflector. The following section shows the configurations of different devices:

Router A configuration:

```
!
router bgp 100
 bgp log-neighbor-changes
 neighbor 192.168.5.3 remote-as 100
 neighbor 192.168.5.3 description route-reflector server
```

Router B configuration:

```
!
router bgp 100
 bgp log-neighbor-changes
 neighbor 192.168.6.3 remote-as 100
 neighbor 192.168.6.3 description route-reflector server
```

Router C configuration:

```
!
router bgp 100
 bgp log-neighbor-changes
 neighbor 192.168.7.3 remote-as 100
 neighbor 192.168.7.3 description not the route-reflector server
```

Router D Configuration:

```
!
router bgp 100
```

```
 bgp log-neighbor-changes
 neighbor 192.168.5.12 remote-as 100
 neighbor 192.168.5.12 description route-reflector client
 neighbor 192.168.5.12 route-reflector-client
 neighbor 192.168.6.5 remote-as 100
 neighbor 192.168.6.5 description route-reflector client
 neighbor 192.168.6.5 route-reflector-client
 neighbor 192.168.7.7 remote-as 100
 neighbor 192.168.7.7 description not the route-reflector client
 neighbor 192.168.8.13 remote-as 200
```

Router E configuration:

```
!
router bgp 500
 bgp log-neighbor-changes
 neighbor 192.168.8.3 remote-as 100
```

Configuring Peergroup

This section uses the configuration of **peergroup** for IBGP and EBGP as an example.

Configuring IBGP peergroup

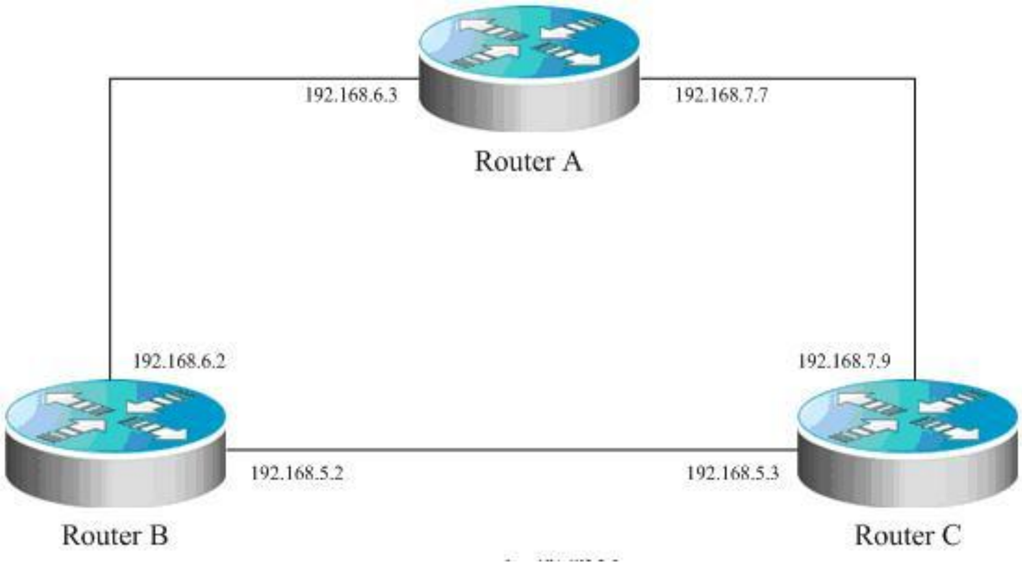
Use the **neighbor** *internal* **peer-group** command to create a peer group named *internal*, and configure a remote AS, and other options for the peer group. Use the **neighbor** *A.B.C.D* **peer-group** *internal* command to add peers A.B.C.D into the peer group.

The configuration commands are described as follows:

```
router bgp 100
neighbor internal peer-group
neighbor internal remote-as 100
neighbor internal update-source loopback 0
neighbor internal route-map set-med out
neighbor internal filter-list 1 out
neighbor internal filter-list 2 in
neighbor 171.69.232.53 peer-group internal
neighbor 171.69.232.54 peer-group internal
neighbor 171.69.232.55 peer-group internal
neighbor 171.69.232.55 filter-list 3 in
```

The following example shows the relastionship between and IP addresses of the devices:

Figure 8



Router A configuration

```
!
router bgp 100
 bgp log-neighbor-changes
 neighbor ibgp-group peer-group
 neighbor ibgp-group description peer in the same as
 neighbor 192.168.6.2 remote-as 100
 neighbor 192.168.6.2 peer-group ibgp-group
 neighbor 192.168.6.2 description one peer in the ibgp-group
 neighbor 192.168.7.9 remote-as 100
 neighbor 192.168.7.9 peer-group ibgp-group
```

Router B configuration:

```
!
router bgp 100
 bgp log-neighbor-changes
 neighbor ibgp-peer peer-group
 neighbor ibgp-peer remote-as 100
 neighbor ibgp-peer route-map ibgp-rmap out
 neighbor 192.168.5.3 peer-group ibgp-peer
 neighbor 192.168.5.3 route-map set-localpref in
 neighbor 192.168.6.3 peer-group ibgp-peer
```

Router C configuration:

```
!
router bgp 100
 bgp log-neighbor-changes
 neighbor ibgp-group peer-group
 neighbor 192.168.5.2 remote-as 100
 neighbor 192.168.5.2 peer-group ibgp-group
 neighbor 192.168.7.7 remote-as 100
 neighbor 192.168.7.7 peer-group ibgp-group
```

Configuring EBGP peergroup

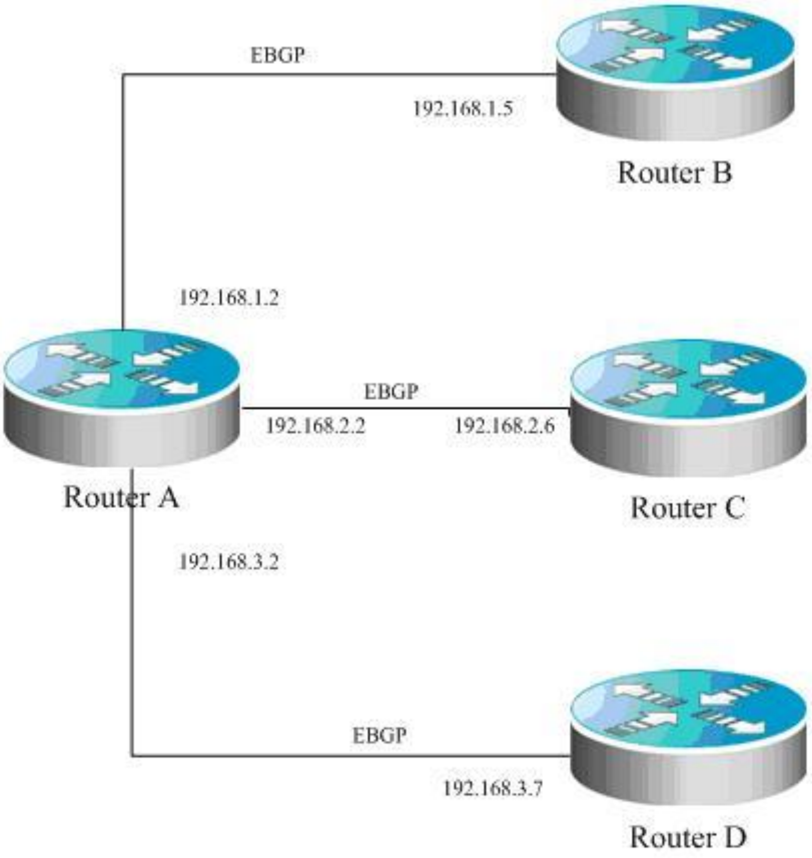
Use the **neighbor** *A.B.C.D* **remote-as** *num* command to configure an EBGP peer. Use the **neighbor** *external* **peer-group** command to create a peer group named **external**, and apply the **neighbor** *A.B.C.D* **peer-group** *external* command to add the peers A.B.C.D into the peer group *external*.

Here is an example of the specific configuration:

```
router bgp 100
neighbor external-peers peer-group
neighbor external-peers route-map set-metric out
neighbor external-peers filter-list 99 out
neighbor external-peers filter-list 101 in
neighbor 171.69.232.90 remote-as 200
neighbor 171.69.232.90 peer-group external-peers
neighbor 171.69.232.100 remote-as 300
neighbor 171.69.232.100 peer-group external-peers
neighbor 171.69.232.110 remote-as 400
neighbor 171.69.232.110 peer-group external-peers
neighbor 171.69.232.110 filter-list 400 in
```

The following figure shows the configuration of peer-group:

Figure 9



The figure illustrates the relationship between devices and the assignment of IP address.

Router A configuration:

```
!
router bgp 100
 bgp log-neighbor-changes
 neighbor ebgp-group peer-group
 neighbor ebgp-group distribute-list 2 in
 neighbor ebgp-group route-map set-med out
 neighbor 192.168.1.5 remote-as 200
 neighbor 192.168.1.5 peer-group ebgp-group
 neighbor 192.168.2.6 remote-as 300
 neighbor 192.168.2.6 peer-group ebgp-group
 neighbor 192.168.2.6 distribute-list 3 in
 neighbor 192.168.3.7 remote-as 400
 neighbor 192.168.3.7 peer-group ebgp-group
!
```

Router B configuration:

```
!
router bgp 200
```

```
 bgp log-neighbor-changes
 neighbor 192.168.1.2 remote-as 100
!
```

Router C configuration:

```
!
router bgp 300
 bgp log-neighbor-changes
 neighbor 192.168.2.2 remote-as 100
!
```

Router D configuration:

```
!
router bgp 400
 bgp log-neighbor-changes
 neighbor 192.168.3.2 remote-as 100
!
```

Configuring TCP MD5

Use the CLI command **neighbor password** to configure TCP MD5 for the BGP connection in BGP configuration mode.

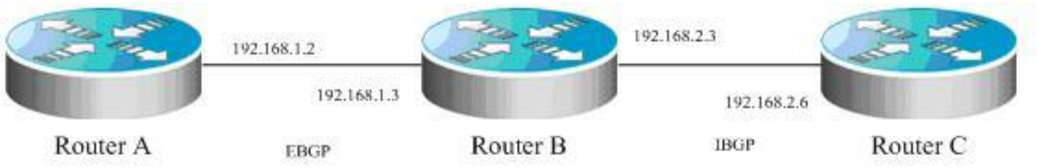
The configuration format is shown as follows:

```
router bgp 100
neighbor 171.69.232.54 remote-as 110
neighbor 171.69.232.54 password peerpassword
```

Configure the *password* of peer 171.69.232.54 as *peerpassword.*

The following figure shows the configuration of MD5 and IP addresses on different devices：

Figure 10



The AS of router A is 100, and the AS of router B and router C is 200. Router A establishes EBGP adjacency with router B and uses EBGP as the MD5 password. Router B establishes IBGP adjacency with router C and uses IBGP as the MD5 password.

router A configuration:

```
!
router bgp 100
 bgp log-neighbor-changes
 neighbor 192.168.1.3 remote-as 200
 eighbor 192.168.1.3 password ebgp
!
```

Router B configuration:

```
!
router bgp 200
 bgp log-neighbor-changes
 neighbor 192.168.1.2 remote-as 100
 neighbor 192.168.1.2 password ebgp
 neighbor 192.168.2.6 remote-as 200
 neighbor 192.168.2.6 password ibgp
!
```

Router C configuration:

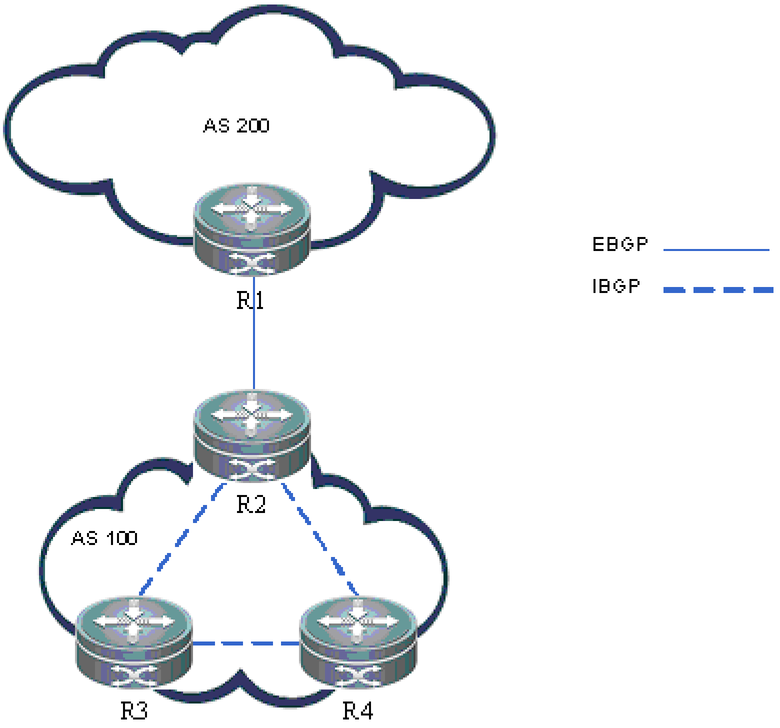
```
!
router bgp 200
 bgp log-neighbor-changes
 neighbor 192.168.2.3 remote-as 200
 neighbor 192.168.2.3 password ibgp
!
```

Configuring BGP GR

Networking Requirements

As shown in the following figure, R2 is the border device of AS100 and AS200. R1 is the access device of AS200. In AS100, R2, R3 run OSPF to offer IBGP connection for the BGP protocol. At the same time, IBGP connections are established between them. R2 establishes an EBGP conneciton with R1. R2, as the border device connecting AS100 and AS200, must be more reliable. R2 is configured to support dual-system redundant bakcup for continuous forwarding and graceful restart of routing protocols (OSPF and BGP in this example). The graceful restart of routing protocols involves adjacent devices. Hence, R1, 3 and R4 need to support the BGP GR capability, and R3 and R4 need to support the GR Helper of OSPF to support the OSPF GR capabiltiy. In this way, when one engine of R2 fails, the transmission of data is not interrupted and therefore reliability is enhanced.

Figure 11 BGP GR configuration example



Confiugration Precautions:

Before configuration, ensure that R2 can serve as the GR Restarter for graceful restart and the software on all devices support OSPF GR and BRP GR capability. If not, continuous data forwarding cannot be peformed when the backup engine takes over the work of the master engine in case of failures. Meanwhile, the BGP protocol depends on the BGP connection from OSPF. Hence, both the BGP and OSPF protocols should have GR enabled. Therefore, R2 must support OSPF GR.

14) R2 enables dual-eningle redundnat hot backup;

15) The software of all devices support OSPF GR and BGP GR capability

16) OSPF GR is enabled on R2

17) BGP GR is enabled on R2

18) BGP GR is enabled on neighbors to support the GR Helper of BGP

19) All BGP connections restart on R2 to negotitate GR capabitliy

Configuration Steps

20) Ensure that R2 enables dual-eningle redundnat hot backup

21) Ensure that the software of all devices supports OSPF GR and BGP GR capabilities.

Check that these devices support the configuration commands of BGP GR and OSPF GR. For details, refer to Step 3 and Step 4.

22) Enables OSPF GR on R2

```
Ruijie(config)# router ospf 1
Ruijie(config-router)# graceful-restart
```

23) Enable BGP GR on R2

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# graceful-restart
```

24) Enable BGP GR on neighbors to support the GR Helper of BGP

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# bgp graceful-restart
```

For BGP GR negotiation, both sides of the BGP connection must enable BGP GR. Hence, R2 needs to negotiate with its neighbors which serve as the GR Helper to assist BGP GR.

25) Restart all BGP connections on R2 to neotitate GR capabitliy

You must manually restart the BGP connection for GR capability renegotiation, because the **bgp graceful-restart** command cannot take effect immediately.

```
Ruijie# clear ip bgp *
```

Configuration Check

For R2 to enable continuous data forwarding during engine handover, check the negotiation of BGP GR and OSPF GR configration.

26) Ensure that BGP GR can negitate with all neighbors.

```
 Ruijie# show ip bgp neighbors
BGP neighbor is 192.168.195.183, remote AS 200, local AS 100, external link
Using BFD to detect fast fallover - BFD session state up
  BGP version 4, remote router ID 10.0.0.1
  BGP state = Established, up for 00:06:37
  Last read 00:06:37, hold time is 180, keepalive interval is 60 seconds
  Neighbor capabilities:
    Route refresh: advertised and received (old and new)
Address family IPv4 Unicast: advertised and received
Graceful restart: advertised and received
  Remote Restart timer is 120 seconds
  Address families preserved by peer:
    None
```

Graceful restart: advertised and received means BGP GR negotiation of the BGP connection is successful. Ensure that BGP GR can negotiate with all BGP connections.

27) Ensure that OSPF GR is enabled on R2.

```
Ruijie# show ip ospf
Routing Process "ospf 1" with ID 10.0.0.2
Process uptime is 4 minutes
Process bound to VRF default
Conforms to RFC2328, and RFC1583Compatibility flag isenabled
Supports only single TOS(TOS0) routes
Supports opaque LSA
This router is an ASBR (injecting external routing information)
SPF schedule delay 5 secs, Hold time between two SPFs 10 secs
LsaGroupPacing: 240 secs
Number of incomming current DD exchange neighbors 0/5
Number of outgoing current DD exchange neighbors 0/5
Number of external LSA 4. Checksum 0x0278E0
Number of opaque AS LSA 0. Checksum 0x000000
Number of non-default external LSA 4
External LSA database is unlimited.
Number of LSA originated 6
Number of LSA received 2
Log Neighbor Adjency Changes : Enabled
Graceful-restart enabled
Graceful-restart helper support enabled
Number of areas attached to this router: 1
Area 0 (BACKBONE)
```

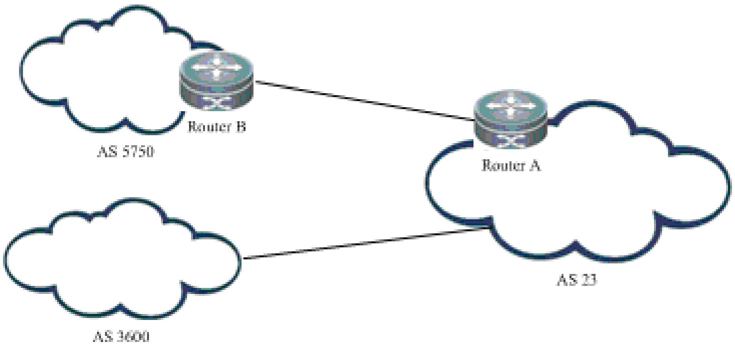
Graceful restart enabled means OSPF GR is enabled.

Configuring BGP Local AS

Networking requirements

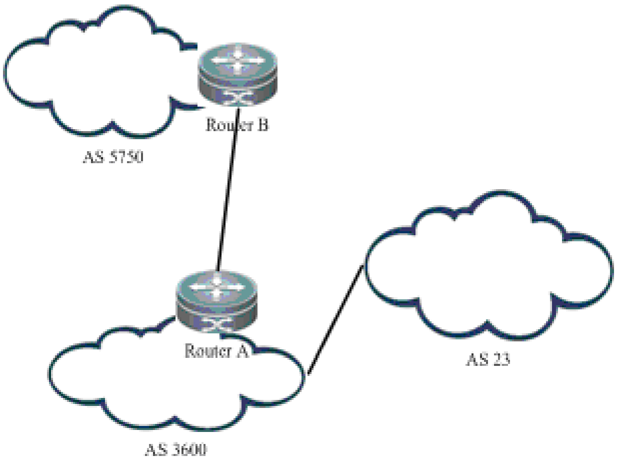
As shown in the following figure, Router A and its home network are located in AS 23, which connects AS 3600 through EBGP. The routing information of AS 5750 is transmitted to AS 3600 via AS 23.

Figure 12 Logical topology before AS migration



You must migrate Router A and its home network to AS 3600.

Figure 13 Logical topology after AS migration

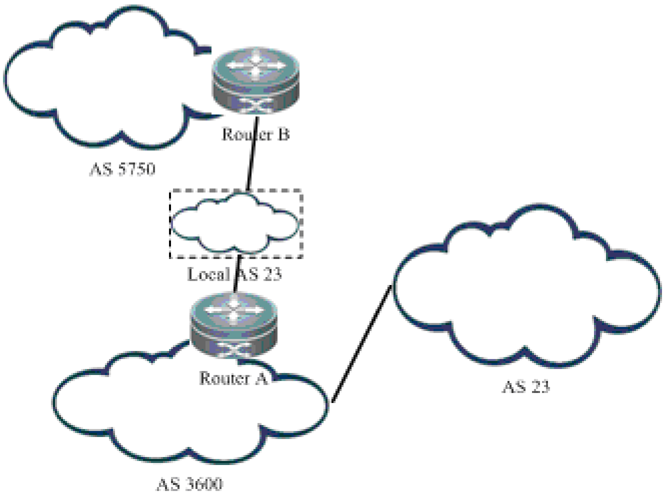


AS 23 and AS 3600 belong to one management domain. The configurations of these two ASs are modified after negotiation. At this point, Router A configures AS 3600 as the AS of the BGP protocol. In this case, you need to maintain the BGP connection between Router A and Router B, and modify related peer configuration on Router B of AS 5750. Sometimes Router B may not modify the configuration immediately. As a result, Router B cannot establish the BGP connection with Router A. On Router A, you can configure local AS for Router B to establish a BGP connection between them wihtout affecting the transmisison and calculation of routes.

Networking Topology

The following figure illustrates how to configure local AS for Router B.

Figure 14 Configuration of local AS



After configuration, a virtual AS 23 is set up between Router A and Router B. Router B considers that it is directly connected to AS 23 and can transmit routes to AS 23. This removes the need to modify Router B’s configuration. When AS 3600 reaches an agreement with AS 5750 in terms of management, Router B can modify the remote AS of Router A as AS 3600 and Router A deletes the corresponding local AS for migration of network in different ASs.

Configuration Steps

28) Enter BGP configuration mode

```
Ruijie-A(config)# router bgp 3600
```

29) Configures local AS for the peer

```
Ruijie-A(config-router)# neighbor 57.50.1.1 local-as 23 no-prepend replace-as dual-as
```

30) Delete local AS after Router B modifies its configuration

```
Ruijie-A(config-router)#no neighbor 57.50.1.1 local-as
```

Configuration Check

```
Use the show ip bgp neighbors command to verify the local AS used by a neighbor to establish
a BGP connection as follows:
Ruijie-A#show ip bgp neighbors 57.50.1.1
BGP neighbor is 57.50.1.1,  remote AS 5750, local AS 23(using Peer's Local AS, no-prepend,
replace-as, dual-as), external link
  BGP version 4, remote router ID 0.0.0.0
  BGP state = Idle
  Last read        , hold time is 180, keepalive interval is 60 seconds
  Received 0 messages, 0 notifications, 0 in queue
    open message:0 update message:0 keepalive message:0
    refresh message:0 dynamic cap:0 notifications:0
  Sent 0 messages, 0 notifications, 0 in queue
```

Detailed Configuration:

Router A configuration

```
router bgp 3600
neighbor 57.50.1.1 remote-as 5750
neighbor 57.50.1.1 local-as 23 no-prepend replace-as dual-as
neighbor 57.50.1.1 update-source loopback 0
neighbor 57.50.1.1 ebgp-multihop 255
```

Router B configuration

```
router bgp 5750
neighbor 36.0.1.1 remote-as 23
neighbor 36.0.1.1 update-source loopback 0
neighbor 36.0.1.1 ebgp-multihop 255
```

Configuring BGP MCE

About BGP MCE

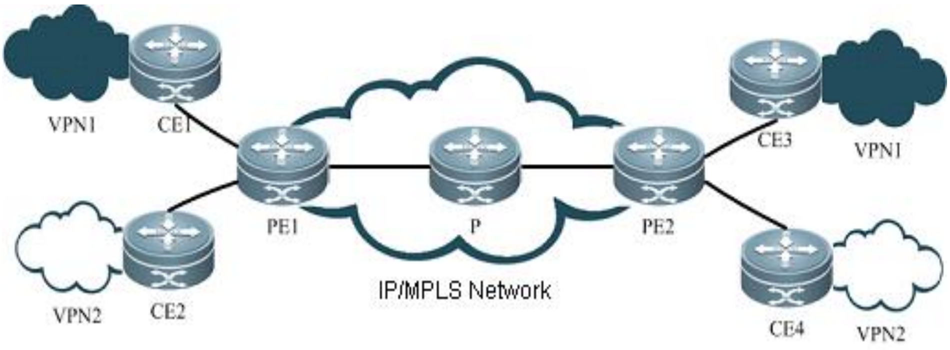
MCE Overview

MCE refers to Multi-CE. MCE enabled network devices can function as CEs of multiple VPN instances in a BGP/MPLS VPN network. This helps reduce the need for additional network equipment.

Working Principle of BGP MCE

With BGP/MPLS VPN, private network data can be securely transmitted in a public network through tunnels. However, in a typical BGP/MPLS VPN network, each VPN is connected to the PE through a CE, as shown in Figure 15:

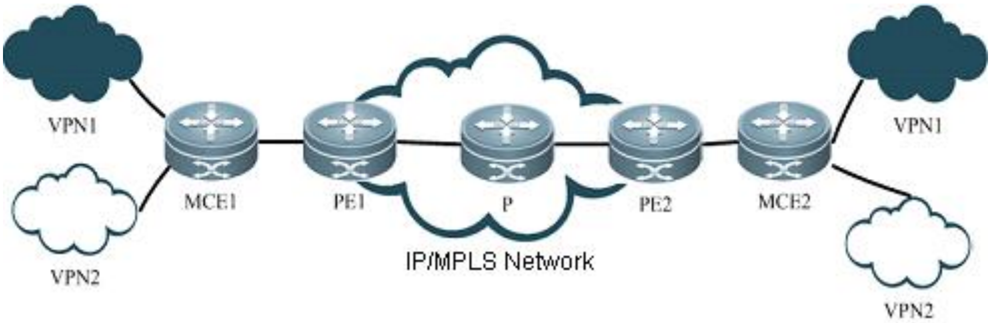
Figure 15 BGP/MPLS VPN network



As users’ demand surges for service segmentation and security, a private network may be divided into multiple VPNs, and the users of different VPNs are usually isolated from each other. As a result, equipment and maintenance costs may be increased by assigning a CE for each VPN, while data security cannot be guaranteed by sharing one CE and using the same routing entry among multiple VPNs. MCE can balance data security and networking cost. By binding the VLAN interfaces of a CE device to the VPNs, you can create and maintain a routing table for each of the VPNs (Multi-VRF). In this way, packets of different VPNs in the private network can be isolated. Moreover, the PE enables the routes of each VPN to be advertised to the corresponding remote PE. As such, packets of each VPN can be transmitted securely through the public network.

The following example shows how the MCE maintains routing entries of multiple VPNs and how the MCE exchanges VPN routes with PEs.

Figure 16 MCE functions



As shown in Figure 16, two VPN sites on the left side (VPN1 and VPN2) are connected to the MPLS backbone through an MCE device. Users of VPN1 and VPN2 need to establish VPN tunnels with remote VPN1 and VPN2 users. MCE enables routing tables to be created for VPN1 and VPN2 individually on the MCE device. VLAN-interface 2 can be bound to VPN1, and VLAN-interface 3 can be bound to VPN 2. When receiving routing information, MCE determines the source of information based on the number of the interface receiving the information and then maintains the corresponding VPN routing table. Meanwhile, you need to bind the MCE-connecting interfaces on PE1 to the VPNs in the same way as those on the MCE device. The MCE device is connected to PE1 through a trunk, which permits packets of VLAN2 and VLAN3 carrying VLAN tags. In this way, PE1 can determine the home VPN of a received packet according to the VLAN tag and passes the packet to the corresponding tunnel.

How does MCE device accurately transmit private routing information of multiple VPN instances to PEs? This involves two steps: routing information exchange between MCE and VPN site, and between MCE and PE. There are several ways to exchange routing information, such as static route, RIP, OSPF, ISIS and BGP. If BGP routing protocol is used to exchange routing information, BGP MCE applies. Specifically, BGP MCE allows BGP protocol to support VRF and enable BGP routing information exchange under VRF. We need to configure the BGP peer for each VRF instance on MCE and introduce IGP routing information of corresponding VPN. As each VPN is generally in different ASs, EBGP is therefore used to advertise routes.

Protocol Specification

NA.

Default Configurations

The following table describes the default configurations of BGP MCE.

Function	Default setting
VRF instance	No VRF instance is created by default.
BGP-VRF binding	No BGP-VRF binding by default

The following products support BGP MCE: the RSR30, RSR50 and RSR50E series of routers.

Configuring BGP MCE

Configuring VRF Instance and Route-related Attributes

Before configuring the BGP MCE, VRF instance and route-related attributes must be configured first:

Command	Function
Ruijie # **configure terminal**	Enters global configuration mode
Ruijie(config)# **ip vrf** *VRF1*	Creates a VRF named VRF1 and enters VRF mode.
Ruijie(config-vrf)# **rd** *rd-value*	Configures VRF RD value, which is identified using XX:XX format, such as RD 1:100. 1 refers to the AS ID of backbone network, while 100 is a user-defined numerical value.
Ruijie(config-vrf)# **route-target both** | **export** | **import**} *rt-value*	Configures the route export and import RT attribute of VRF.
Ruijie(config-vrf)# {**export** | **import**} **map** *map*	Configures the route map for import and export routes to support policy-based filtering of import and export routes.
Ruijie(config-vrf)# **exit**	Exits VRF mode and enters global configuration mode
Ruijie(config)# **interface vlan** ***2***	Enters VLAN 2 interface configuration mode.
Ruijie(config-if)# **ip vrf forwarding** *VRF1*	Associates interface with VRF instance of VRF2
Ruijie(config-if)# **ip address 172.16.25.18 255.255.255.0**	Configures IP address for VLAN 2
Ruijie(config-if)# **end**	Returns to privileged EXEC mode
Ruijie # **show running-config**	Verifies the configurations
Ruijie # **write**	(Optional) Saves configurations.

Configuring BGP Route Exchange between MCE and VPN Site

To use the BGP protocol to exchange routing information between MCE and VPN sites, you need to bind BGP to the corresponding VRF instance on MCE, and configure site device as EBGP neighbor, as shown below:

Command	Function
Ruijie # **configure terminal**	Enters global configuration mode
Ruijie(config)# **router bgp** ***23***	Enables the BGP protocol and enters BGP routing process mode
Ruijie(config-router)# **address-family ipv4 vrf** *VRF1*	Enters the IPv4 address family configuration mode of VRF1
Ruijie(config-router-af)# **neighbor** 172.16.25.57 **remote-as** 65531	Configures EBGP neighbor and learns routing information advertised by VPN site through BGP.
Ruijie(config-router-af)# **redistribute** *ospf 1*	Introduces the routing information of remote VPN as advertised by PE. We assume that MCE and PE exchange routing information through OSPF protocol.
Ruijie(config- router-af))# **end**	Returns to privileged EXEC mode.
Ruijie # **show running-config**	Verifies the configurations.
Ruijie # **write**	(Optional) Saves configurations.

BGP protocol must also be enabled on CE devices at a VPN site, allowing the site to exchange routing information with MCE devices through BGP protocol.

Configuring BGP Route Exchange between MCE and PE

To use the BGP protocol to exchange routing information between MCE and PE, bind BGP to the corresponding VRF instance on MCE, and configure PE device as EBGP neighbor, as shown below:

Command	Function
Ruijie # **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp *23***	Enables BGP protocol and enter BGP routing mode.
Ruijie(config-router)# **address-family ipv4 vrf** *VRF1*	Enters IPv4 address family configuration mode of VRF1.
Ruijie(config-router-af)# **neighbor** 172.16.25.157 **remote-as** 65532	Configures EBGP neighbor and study the routing information advertised by PE through BGP.
Ruijie(config-router-af)# **redistribute** *ospf 1*	Introduces the routing information of local VPN. We assume that MCE and local VPN site exchange routing information through OSPF protocol.
Ruijie(config- router-af))# **end**	Returns to privileged EXEC mode.
Ruijie # **show running-config**	Verifies the configurations.
Ruijie # **write**	(Optional) Saves configurations.

BGP protocol must also be enabled on the PE device, and MCE must be configured as EBGP neighbor, allowing PE to exchange routing information with the MCE device through BGP protocol.

Displaying Configurations

The "show" commands used in BGP MCE are similar to the "show" commands used in ordinary BGP. The following information is displayed: neighbor state, routing information and neighbor summary.

Command	Function
Ruijie # **show ip vrf**	Displays all VRF summary information on the device.
Ruijie # **show ip vrf detail [*VRF1*]**	Displays the detailed configurations of all VRFs or a specified VRF.
Ruijie # **show ip vrf interfaces** [*VRF1*]	Displays the interface binding information and state of all VRFs or a specified VRF.
Ruijie# show **ip bgp vrf** *VRF1* [**summary**| **neighbors**| *A.B.C.D*]	Displays the summary information, detailed information, specific routing information, and all routing information of BGP neighbor under VRF1. Similar to those "show" commands used in ordinary BGP, other sub-commands are not discussed herein.
Ruijie# **show bgp vpnv4 unicast** [**all** | **rd** *rd* | **vrf** *vrf-name*] [**neighbors** | **summary** | *A.B.C.D*]	This command is similar to the above command, but the routes displayed are different: "all" will display all vpn routes, "rd" will display vpn routes with a specified RD value, and "vrf" will display vpn routes under a specified VRF.

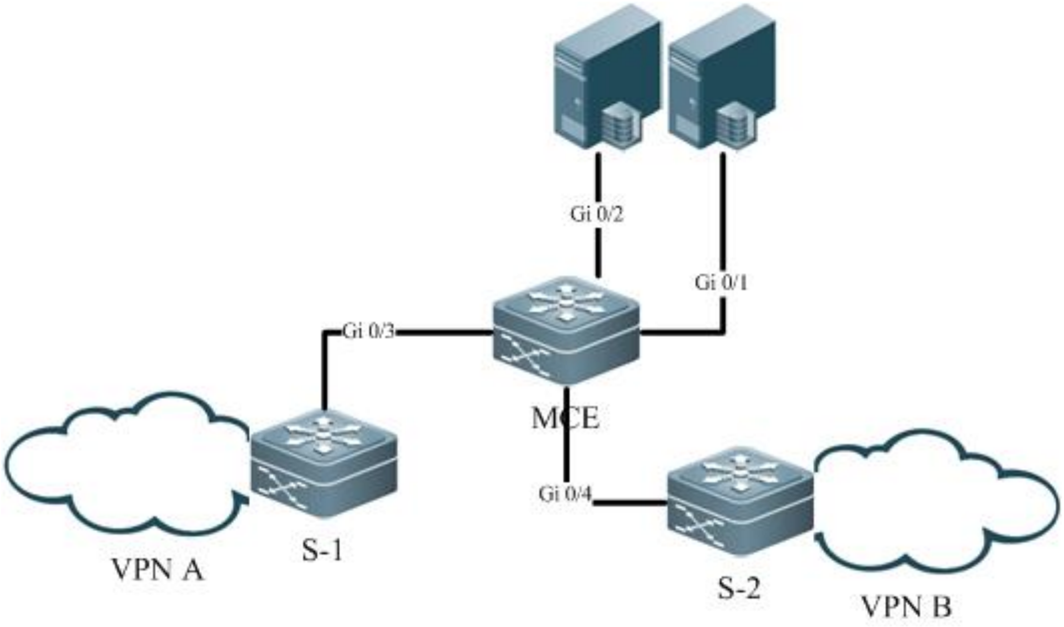
Typical BGP MCE Configuration Examples

Networking Requirements

A company needs to isolate the networks of two subsidiaries: A and B, and expects both subsidiaries to access the resource servers at the same time. OSPF protocol operates on the networks of subsidiary A and subsidiary B. An MCE device is used to isolate A and B. The device is directly connected with multiple resource servers.

Network Topology

Figure 17 Network topology of BGP MCE



S-1 is the convergence device on the network of subsidiary A; S-2 is the convergence device on the network of subsidiary B. S-1 and S-2 are both connected with the MCE device, with connecting interfaces belonging to different VRF instances and running the OSPF routing protocol. Gi 0/1 and Gi 0/2 of the MCE is directly connected with resource servers, and belong to another separate VRF instance.

Configuration Tips

We assume that OSPF protocol is running normally on VPN A connected directly with S-1 and VPN B connected directly with S-2. The following configurations are related to the MCE device.

31) Configure VRF instances and associate with interfaces to allow network isolation;

32) Configure OSPF routing protocol and associate with VRF, so that MCE can learn the routes to respective subsidiaries;

33) Configure BGP routing protocol and import OSPF routes and directly connected routes, allowing route exchange between different VRFs;

34) Configure the import and export route attributes of VRF instance, so that both subsidiaries can access the resource servers;

Configuration Steps

35) Configures VRF instances and associate with interfaces;

# Create three VRF instances: VRF1, VRF2 and VRF3

```
Ruijie# config terminal
Ruijie(config)# ip vrf VRF1
Ruijie(config-vrf)# rd 100:1
Ruijie(config-vrf)# exit
Ruijie(config)# ip vrf VRF2
Ruijie(config-vrf)# rd 100:2
Ruijie(config-vrf)# exit
Ruijie(config)# ip vrf VRF3
Ruijie(config-vrf)# rd 100:3
Ruijie(config-vrf)# exit
```

# Bind Gi0/1 and Gi0/2 to VRF3, Gi0/3 to VRF1 and Gi0/4 to VRF2

```
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-GigabitEthernet 0/1)#ip vrf forwarding VRF3
Ruijie(config-GigabitEthernet 0/1)#ip address 10.1.1.1 255.255.255.0
Ruijie(config)#interface gigabitEthernet 0/2
Ruijie(config-GigabitEthernet 0/2)#ip vrf forwarding VRF3
Ruijie(config-GigabitEthernet 0/2)#ip address 10.1.2.2 255.255.255.0
Ruijie(config)#interface gigabitEthernet 0/3
Ruijie(config-GigabitEthernet 0/3)#ip vrf forwarding VRF1
Ruijie(config-GigabitEthernet 0/3)#ip address 172.16.25.18 255.255.255.0
Ruijie(config)#interface gigabitEthernet 0/4
Ruijie(config-GigabitEthernet 0/4)#ip vrf forwarding VRF2
Ruijie(config-GigabitEthernet 0/4)# ip address 192.168.25.18 255.255.255.0
```

36) Configure OSPF routing protocol and associate with VRF;

# Create OSPF 1 and OSPF 2 and associate with VRF1 and VRF2

```
Ruijie# config terminal
Ruijie(config)# router ospf 1 vrf VRF1
Ruijie(config-router)# network 172.16.25.0 0.0.0.255 area 0
Ruijie(config-router)# exit
Ruijie(config)# router ospf 2 vrf VRF2
Ruijie(config-router)# network 192.168.25.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

37) Configure BGP protocol and import routes

# Configure BGP protocol and import OSPF routes to BGP VRF instance

```
Ruijie# config terminal
Ruijie(config)# router bgp 100
Ruijie(config-router)# address-family ipv4 vrf VRF1
Ruijie(config-router-af)# redistribute ospf 1
Ruijie(config-router-af)# exit
Ruijie(config-router)# address-family ipv4 vrf VRF2
Ruijie(config-router-af)# redistribute ospf 2
```

# Import the directly connected routes of VRF3 to BGP VRF3 instance

```
Ruijie(config-router)# address-family ipv4 vrf VRF3
Ruijie(config-router-af)# redistribute connect
```

38) Configure the import and export route attributes of VRF instance

# Configure the import route attribute of VRF1 as 100:3 and export attribute as 100:1

```
Ruijie(config)# ip vrf VRF1
Ruijie(config-vrf)# route-target import 100:3
Ruijie(config-vrf)# route-target export 100:1
Ruijie(config-vrf)# exit
```

# Configure the import route attribute of VRF2 as 100:3 and export attribute as 100:2

```
Ruijie(config)# ip vrf VRF2
Ruijie(config-vrf)# route-target import 100:3
Ruijie(config-vrf)# route-target export 100:2
Ruijie(config-vrf)# exit
```

# Configure the import route attribute of VRF3 as 100:1 and 100:2 and export attribute as 100:3

```
Ruijie(config)# ip vrf VRF2
Ruijie(config-vrf)# route-target import 100:1 100:2
Ruijie(config-vrf)# route-target export 100:3
Ruijie(config-vrf)# exit
```

Verification

Execute the following steps to verify configurations:

39) Verify the state of interfaces bound to VRF. Execute the **show ip vrf interface** command to verify interface binding information and the interface state.

40)

```
Ruijie#sh ip vrf interfaces
Interface           IP-Address     VRF                 Protocol
GigabitEthernet 0/1  10.1.1.1      VRF3               up
GigabitEthernet 0/2  10.1.2.1      VRF3               up
GigabitEthernet 0/3  172.16.25.18  VRF1               up
GigabitEthernet 0/4  192.168.25.18 VRF2               up
```

41) Verify whether OSPF protocol bindings are correct and whether OSPF protocol runs normally. Execute the **show ip ospf** command to verify whether the OSPF instance is properly bound to VRF;

42) Verify whether the routes imported by BGP instance are correct. Execute the **show ip bgp vrf** or **show bgp vpnv4 unicast** command to verify whether the imported routes are correct, as shown below:

```
Ruijie#sh ip bgp vrf VRF3
BGP table version is 1, local router ID is 10.14.219.1
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal, S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete
   Network        Next Hop          Metric  LocPrf     Weight Path
*> 10.1.1.0/24   0.0.0.0             0       32768      ?
*> 10.1.2.0/24   0.0.0.0            0       32768     ?
Total number of prefixes 2
```

43) Execute the **show ip bgp vrf** command to verify whether routes of other VRFs have been properly imported to local VRF. Execute the **show ip route vrf** command to verify whether routes are correct.

```
Ruijie#sh ip bgp vrf VRF3
BGP table version is 1, local router ID is 10.14.219.1
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal, S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete
   Network         Next Hop          Metric  LocPrf     Weight Path

```

Configuring BGP 4-Octet AS

About 4-octet AS

Overview

A traditional AS number consists of two octets within the range of 1-65535. The AS number defined by RFC4893 consists of four octets falling within the range of 1-4294967295 to ease the burden of AS number resources. According to RFC5396, a 4-octet AS number supports two representation formats: asplain and asdot+. The two representations take the same format. Specifically, the 4-octet AS number will be represented using decimal value. The asdot+ representation contains ([high order 2 octets.] low order 2 octets). The high order 2 octets are not displayed if the value is 0. In other words, the AS number of 65536 in asplain format will be represented as 1.0 in asdot+ format. In addition, the AS number of 65534 in asplain format will be represented as 65534 in asdot+ format (without displaying the 0 value).

Working Principle

The 4-octet AS number requires a BGP connection between an old bgp speaker supporting only 2-octet AS number and a new bgp speaker supporting 4-octet AS number. If the autonomous system for the new bgp speaker uses a 4-octet AS number, the old bgp speaker must use the reserved AS number of 23456 to replace the 4-octet AS number of new bgp speaker while creating a neighbor. In the packets sent from the new bgp speaker to the old bgp speaker, 23456 will replace the 4-octet AS number in the domain of "My Autonomous System". Meanwhile, in the UPDAT packets sent to the old bgp speaker, 23456 will replace the 4-octet AS number found in AS-PATH and AGGREGATOR attributes. These packets also carry the true 4-octet AS number reserved in the optional transitive attributes of AS4-PATH and AS4-AGGREGATOR. Therefore, the true AS-PATH attribute and AGGREGATOR attribute can be restored when this route reaches the next new bgp speaker.

In other cases, the true AS number of peer side is directly used to create a neighbor.

Protocol Specification

RFC 4893

RFC 5396

Default Configurations

By default, BGP protocol is not enabled. After BGP protocol is enabled, the decimal value is used by default to represent 4-octet AS numbers.

Configuring BGP 4-octet AS

Configuring BGP Instance with 4-octet AS Number

Command	Function
Ruijie # **configure terminal**	Enters global configuration mode
Ruijie(config)# **router bgp 65538**	Enables BGP protocol and configure device AS number as 65538
Ruijie(config)# **router bgp 1.2**	Uses asdot+ format 1.2 to represent four-octet AS number of 65538
Ruijie(config-router)# **end**	Returns to privileged EXEC mode.
Ruijie # **write**	(Optional) Saves configurations.

Configuring the Display Format of 4-octet AS Number

By default, the asplain format is used to display a 4-octet AS number. You can also configure the display format as asdot+. Meanwhile, after changing the display format of a 4-octet AS number, the 4-octet AS number in regular expression will be matched using asdot+ format.

Command	Function
Ruijie # **configure terminal**	Enters global configuration mode
Ruijie(config)# **router bgp 65538**	Enables BGP protocol and configures the device AS number as 65538
Ruijie(config-router)# **bgp asnotation dot**	Use the asdot+ format to display 4-octet AS number, namely 1.2
Ruijie(config-router)# **end**	Returns to privileged EXEC mode.
Ruijie # **clear ip bgp** *	Resets BGP protocol for re-matching the regular expression.
Ruijie # **write**	(Optional) Saves configurations.

After executing the **bgp asnotation dot** command, you must execute the **clear ip bgp *** command to reset BGP protocol, so that the regular expression can be rematched.

Displaying Configurations

Execute the **show** command to view the configuration of the 4-octet AS number. This command is similar to the **show** command used in BGP mode.

Command	Function
Ruijie # **show ip bgp summary**	Displays the connection state of all BGP neighbors.

Typical BGP 4-Octet AS Configuration Examples

Interconnection between 4-octet AS and 2-octet AS

Networking Requirements

44) A BGP connection is established between the router supporting 2-octet AS number and the router supporting 4-octet AS number (using 2-octet AS number);

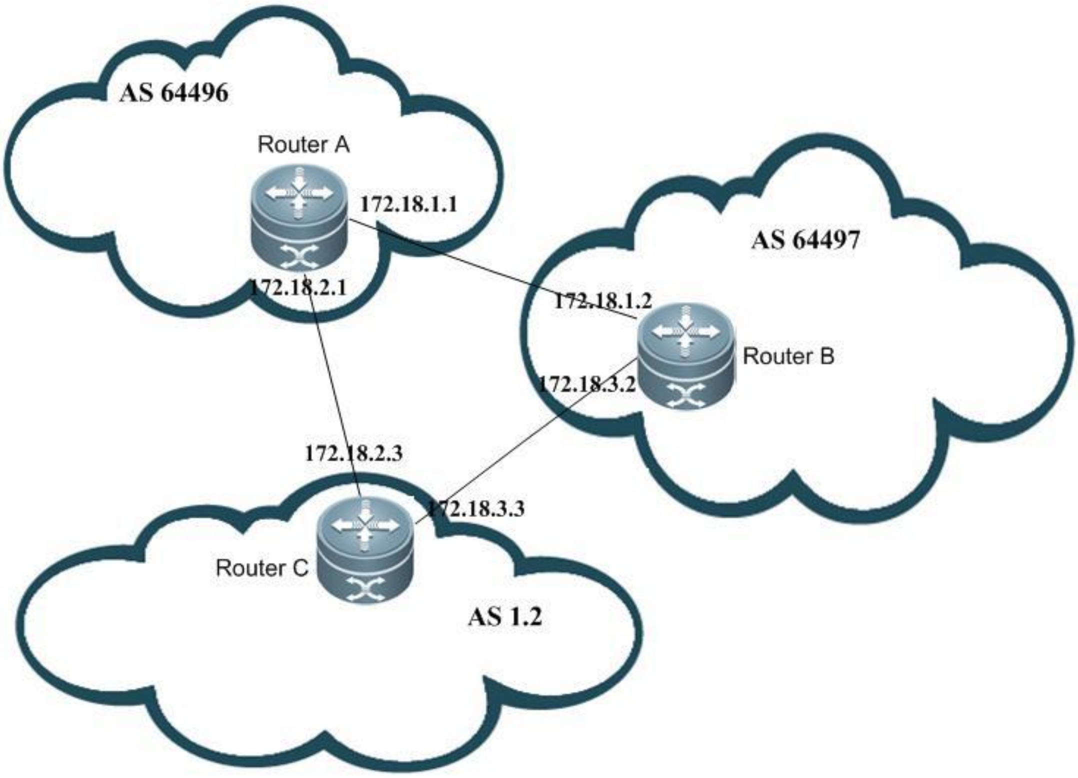
45) A BGP connection is established between the router supporting 2-octet AS number and the router supporting 4-octet AS number (using 4-octet AS number);

46) A BGP connection is established between routers supporting 4-octet AS number, with one router using 2-octet AS number and the other router using 4-octet AS number.

Network Topology

As shown in the figure below, Router A, Router B and Router C are edge routers of three autonomous systems, and BGP connections have been established between them. Router A only supports 2-octet AS numbers; Router B and Router C support 4-octet AS numbers. The autonomous system of Router A uses a 2-octet AS number of 64496; the autonomous system of Router B uses a 2-octet AS number of 64497; the autonomous system of Router C uses a 4-octet number of 1.2.

Figure 18 BGP 4-Octet AS configuration



Configuration Tips

47) Router A cannot recognize the 4-octet AS number of 1.2 used by the autonomous system of Router C. When a neighbor is created, the reserved AS number of 23456 must replace 1.2 during the configuration of remote-as.

48) Although Router B supports 4-octet AS numbers, it still uses a 2-octet AS number. Therefore, the AS number of the peer can be used as remote-as while neighbor interconnection is created between Router A and Router B.

49) Router B can recognize the 4-octet AS number used by the autonomous system of Router C. The AS number of the peer can be used as remote-as while a neighbor is created.

Configuration Steps

1. Router A

```
Ruijie# conf t
Ruijie(config)# router bgp 64496
Ruijie(config-router)# neighbor 172.18.1.2 remote-as 64497
Ruijie(config-router)# neighbor 172.18.2.3 remote-as 23456
```

2. Router B

```
Ruijie# conf t
Ruijie(config)# router bgp 64497
Ruijie(config-router)# neighbor 172.18.1.1 remote-as 64496
Ruijie(config-router)# neighbor 172.18.3.3 remote-as 1.2
```

# Use "bgp asnotation dot" command to change the display format of 4-octet AS number

```
Ruijie(config-router)# bgp asnotation dot
Ruijie(config-router)# end
Ruijie# clear ip bgp *
```

3. Router C

```
Ruijie# conft
Ruijie(config)# router bgp 1.2
Ruijie(config-router)# neighbor 172.18.2.1 remote-as 64496
Ruijie(config-router)# neighbor 172.18.3.2 remote-as 64497
```

Verification

50) Display the state of neighbor connection on Router A:

```
Ruijie# show ip bgp summary
BGP router identifier 172.18.1.1, local AS number 64496
BGP table version is 1, main routing table version 1
Neighbor       V         AS MsgRcvd MsgSent  TblVer  InQ OutQ Up/Down  Statd
172.18.1.2     4     64497      7      7      1    0    0 00:03:04     0
172.18.2.3     4     23456      4      4      1    0    0 00:00:15     0
```

51) Display the state of neighbor connection on Router B:

```
Ruijie# show ip bgp summary
```

```
BGP router identifier 172.18.3.2, local AS number 64497
BGP table version is 1, main routing table version 1
Neighbor       V          AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down  Statd
172.18.1.1     4      64496      7      7       1    0    0 00:03:04     0
172.18.3.2     4      65538      4      4       1    0    0 00:01:18     0
```

After executing "bgp notation dot" command, the following information will be displayed:

```
Ruijie# show ip bgp summary
BGP router identifier 172.18.3.2, local AS number 64497
BGP table version is 1, main routing table version 1
Neighbor       V          AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down  Statd
172.18.1.1     4      64496      7      7       1    0    0 00:00:04     0
172.18.3.2     4        1.2      4      4       1    0    0 00:00:16     0
```

52) Display the state of neighbor connection on Router C:

```
Ruijie# show ip bgp summary
BGP router identifier 172.18.3.3, local AS number 65538
BGP table version is 1, main routing table version 1
Neighbor       V          AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down  Statd
172.18.2.1     4      64496      7      7       1    0    0 00:00:15     0
172.18.3.2     4      65597      4      4       1    0    0 00:01:19     0
```

Configuring the BGP MDT Address Family

About the MDT Address Family

When using PIM-SSM to create Default-MDT during multicast VPN network configuration, configure a BGP MDT address family. Through routing based on the MDT address family, PE can discover other PE addresses and initiate the grating of SPT to other PEs (Configuration steps are detailed in "MD-SCG.doc").

Default Configurations

No address family is configured.

Configuring MDT address family

Configuring VRF Instance and Route-related Attributes

Before configuring the MDT address family, VRF instance and route-related attributes must be configured:

Command	Function
Ruijie # **configure terminal**	Enters global configuration mode
Ruijie(config)# **ip vrf** *VRF*	Creates a VRF named VRF1 and enters VRF mode.
Ruijie(config-vrf)# **rd** *rd-value*	Configures VRF RD value, which is identified using XX:XX format, such as RD 1:100. 1 refers to the AS ID of backbone network, while 100 is a numerical value specified by the user.
Ruijie(config-vrf)# **route-target** {**both** | **export** | **import**} *rt-value*	Configures route export and import RT attribute of VRF.
Ruijie(config-vrf)# {**export** | **import**} **map** *map*	Configures the route map for import and export routes, allowing policy-based filtering of import and export routes.
Ruijie(config-vrf)# **mdt default** *group-address*	Configures MDT group address of VRF.
Ruijie(config-vrf)# **exit**	Exit VRF mode and enter global configuration mode
Ruijie(config)# **interface** *IFNAME*	Enters interface configuration mode
Ruijie(config-if)# **ip vrf forwarding** *VRF*	Associates interface with VRF instance
Ruijie(config-if)# **ip address** *ip-address mask*	Configures an IP address for the interface
Ruijie(config-if)# **end**	Returns to privileged EXEC mode
Ruijie # **show running-config**	Verifies the configurations.
Ruijie # **write**	(Optional) Saves configurations.

Configuring MDT Address Family

The following part describes the steps of configuring an MDT address family:

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *asn-num*	Creates BGP and enters BGP configuration mode.
Ruijie(config-router)# **neighbor** *ip-address* **remote-as** *asn-number*	Configures BGP session.
Ruiije(config-router)# **neighbor** *ip-address* **update-source** *interface-name*	Configures the router to use interface address as the source address when MP-IBGP session is established. Usually, a Loopback interface address is used as the source address.
Ruiije(config-router)# **address**-**family ipv4** mdt	Enters MDT address family.
Ruijie(config-router-af)# **neighbor** *ip-address* **activate**	Activates the route to exchange MDT address family on BGP session.
Ruijie(config-router-af)# **neighbor** *ip-address* **next-hop-self**	Changes the next-hop route. This command can be executed on ASBR in OptionB.

Displaying Configurations

The BGP MDT address family can be viewed by executing the **show bgp ipv4 mdt** commands, as listed in the following table:

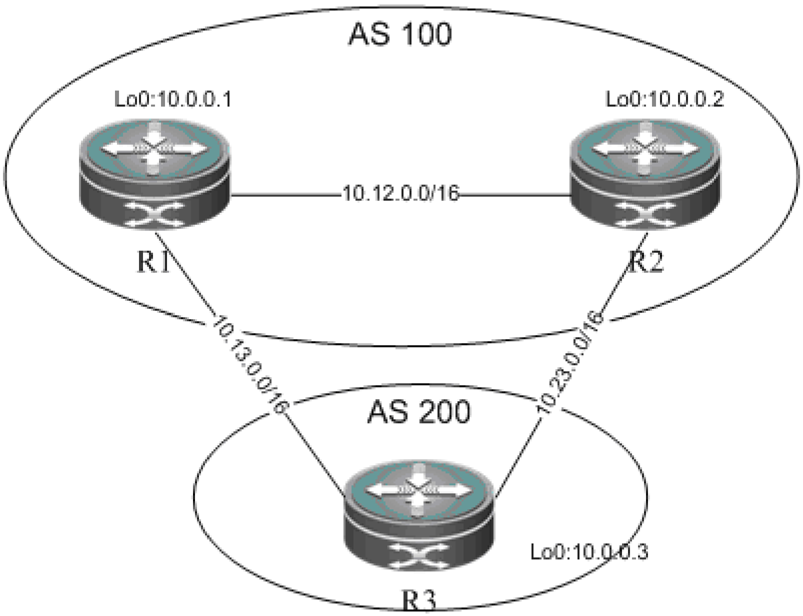
Command	Function
Ruijie # **show bgp ipv4 mdt all** [*ip-address* | neighbor [*ip-address*] | **summary**]	Displays all routes under all RDs, a specified route, neighbor information and summary information of the MDT address family.
Ruijie # **show bgp ipv4 mdt rd** *rd* [*ip-address*]	Displays all routes or a specified route under a specified RD of the MDT address family.

Typical Configuration Examples

Networking Requirements

R1 and R2 belong to the same AS. R3 belongs to another AS. Multicast VPN must be established between them, and BGP is used to transmit information about the MDT address family.

Network Topology



R1 and R2 belong to AS100. An IBGP connection is established between R1 and R2 to transmit routes of the MDT address family. R3 belongs to AS200 and establishes EBGP connections with R1 and R2 to transmit the MDT address family.

Configuration Tips

53) Configure VRF instances and associate with interfaces for network isolation;

54) Configure BGP routing protocol to advertise routes of the MDT address family

Configuration Steps

55) Configure VRF instances and associate with interfaces;

- R1

# Create a VRF instance named "VRF1"

```
Ruijie# config terminal
Ruijie(config)# ip vrf VRF1
Ruijie(config-vrf)# rd 100:1
Ruijie(config-vrf)# route-target both 123:123
Ruijie(config-vrf)# mdt default 232.1.1.1
Ruijie(config-vrf)# exit
```

# Associate Gi0/1 with VRF1

```
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-GigabitEthernet 0/1)# ip vrf forwarding VRF1
Ruijie(config-GigabitEthernet 0/1)# ip address 10.1.1.1 255.255.255.0
Ruijie(config-GigabitEthernet 0/1)# exit
```

```
R2 and R3 are configured to be the same as R1.
```

56) Configure the BGP routing protocol to advertise routes of the MDT address family

- R1

# Configure the MDT address family

```
Ruijie# configure terminal
Ruijie(config)# router bgp 100
```

# Configure R2 and R3 as BGP neighbors

```
Ruijie(config-router)# neighbor 10.0.0.2 remote-as 100
Ruijie(config-router)# neighbor 10.0.0.2 update-source loopback 0
Ruijie(config-router)# neighbor 10.13.0.3 remote-as 200
```

# Activate R2 and R3 under the MDT address family

```
Ruijie(config-router)# address-family ipv4 mdt
Ruijie(config-router-af)# neighobr 10.0.0.2 activate
Ruijie(config-router-af)# neighobr 10.13.0.3 activate
```

# Activate R2 and R3 under the VPNv4 address family

```
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighobr 10.0.0.2 activate
Ruijie(config-router-af)# neighobr 10.13.0.3 activate
```

# Bind VRF to BGP

```
Ruijie(config-router)# address-family ipv4 vrf VRFi
Ruijie(config-router)# exit
R2 and R3 are configured to be the same as R1.
```

Verification

Take the following steps to verify configurations:

57) Verify the state of interfaces bound to VRF. Execute the **show ip vrf interface** to verify interface binding information and state.

```
Ruijie#show ip vrf interfaces
Interface           IP-Address     VRF                Protocol
GigabitEthernet 0/1  10.1.1.1       VRF1               up
```

58) Ensure MDT routes exist in BGP protocol, as shown below:

```
Ruijie#show bgp ipv4 mdt all
BGP table version is 1, local router ID is 10.0.0.1
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal, S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete
   Network         Next Hop           Metric  LocPrf     Weight Path
Route Distinguisher: 100:1
```

```
*> 10.0.0.1/32   0.0.0.0             0       32768      ?
*>i10.0.0.2/32   10.0.0.2            0       100        ?
*> 10.0.0.3/32   10.13.0.3           0                200 ?
Total number of prefixes 3
```

Configuring BGP Multi-Path Load Balancing

Understanding BGP Multi-Path Load Balancing

Overview

Multi-path load balancing means data packets are equally forwarded from a number of paths to the same network, and multiple next hops are present in the routing table. Based on the type of equivalent route, BGP multi-path load balancing comes under the following two categories:

- EBGP load balancing: through routes from EBGP neighbors.
- IBGP load balancing: through routes from IBGP neighbors.

Caution The protocol currently does not support load balancing between IBGP and EBGP routes.

Currently, IPv4 and IPv6 protocol stacks support multi-path load balancing, a maximum number of 32 equivalent next hops. The BGP does not limit the number of equivalent routes. This also applies to IBGP and EBGP load balancing.

Working Principle

BGP selects the route with the highest priority from multiple routes that are contained in the BGP routing table and destined to the same network. If several routes have the same priority and are all optimal, BGP will select the only one based on comparison and advertises the route to the forwarding plane for data flow control. When multi-path load balancing is enabled, BGP will list the routes with the same priority as the only optimal route as equivalent routes and advertise the optimal route and its equivalent routes to the forwarding plane for load balancing. Equivalent routes have the same priority and basic attributes.

Protocol Specifications

N/A

Default Configuration

BGP load balancing is disabled.

Configuring BGP Multi-Path Load Balancing

Configuring EBGP Load Balancing

Command	Function
Ruijie # **configure terminal**	Enters global configuration mode.

Ruijie(config)# **router bgp** *as-number*	Enables BGP and specifies the *as-number* range (1 to 4294967295).
Ruijie(config-router)# **maximum-paths ebgp** *number*	Sets the number of equivalent routes that support EBGP multi-path load balancing. *number* ranges from 1 to 32.
Ruijie(config-router)# **end**	Returns to privilege mode.
Ruijie # **write**	(Optional) Saves configuration.

Configuring IBGP Load Balancing

Command	Function
Ruijie # **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *as-number*	Enables BGP and specifies the *as-number* range (1 to 4294967295).
Ruijie(config-router)# **maximum-paths ibgp** *number*	Sets the number of equivalent routes that support IBGP multi-path load balancing. *number* ranges from 1 to 32.
Ruijie(config-router)# **end**	Returns to privilege mode.
Ruijie # **write**	(Optional) Saves configuration.

Configuring AS-PATH Loose Comparison

By default, equivalent routes must have equal AS-PATH. This requirement is too strict in some cases. For load balancing, AS-PATH loose comparison is recommended. Under the AS-APTH loose comparison mode, equivalent routes only need to have equal AS-PATH and AS-PATH in addition to meeting other criteria.

Command	Function
Ruijie # **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *number*	Enables BGP and specifies the *as-number* range (1 to 4294967295).
Ruijie(config-router)# **bgp bestpath as-path multipath-relax**	Enables BGP AS-PATH loose comparison.
Ruijie(config-router)# **maximum-paths ibgp** *number*	Sets the number of equivalent routes that support IBGP multi-path load balancing. *number* ranges from 1 to 32.
Ruijie(config-router)# **end**	Returns to privilege mode.
Ruijie # write	(Optional) Saves configuration.

Checking Configuration

Use the **show** command to view information about equivalent routes.

Command	Function
Ruijie # **show ip bgp**	Displays BGP routing information.
Ruijie # **show ip route**	Checks information in the core routing table.

Typical Configuration Examples of BGP Multi-Path Load Balancing

Configuring IBGP Non-Equivalent Load Balancing

Networking Requirements

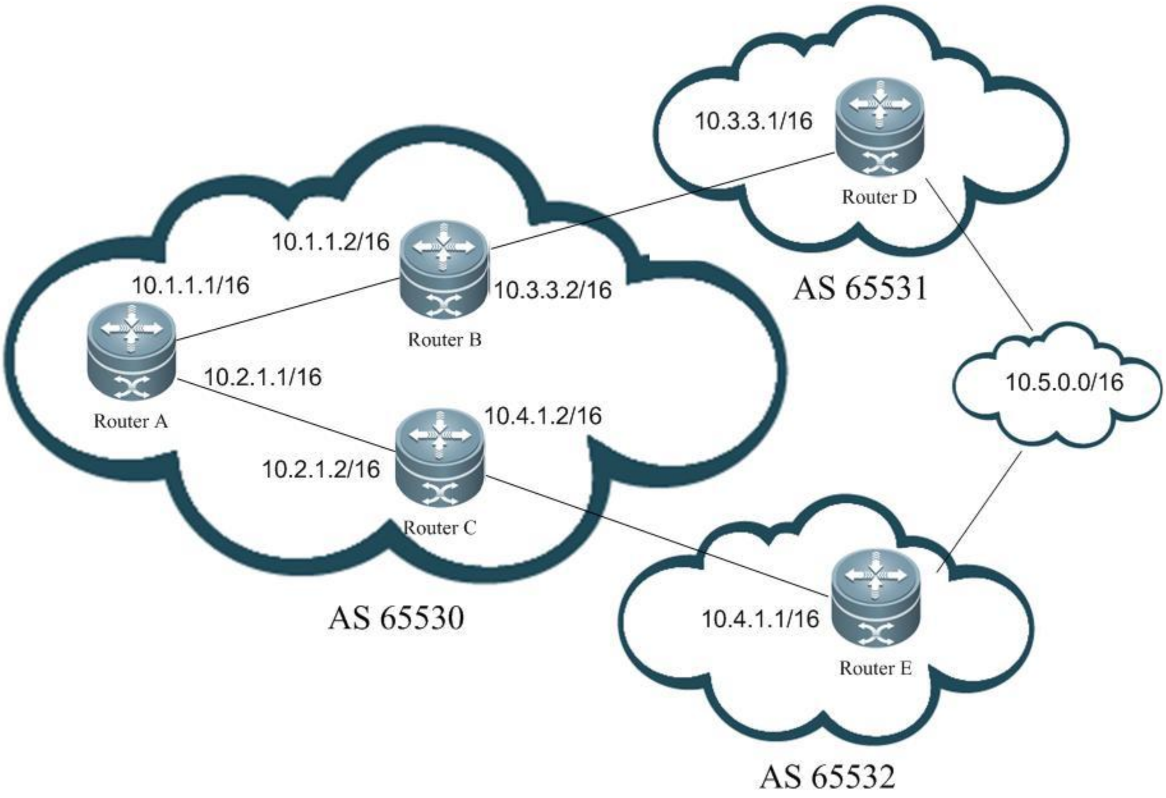
59) Achieves load balancing based on routes learned from IBGP neighbors;

60) Supports BGP AS-PATH loose comparison.

Network Topology

As shown in the following figure, Routers A, B and C belong to the same AS numbered 65530. Routers D and E belong to AS 65531 and 65532, which are linked by a BGP connection. AS 65531 and AS 65532 contain the route 10.5.0.0/16 with the same prefix and send the route to AS 65530. Router A learn the route 10.5.0.0/16 from Router B and Router C.

Figure 19 Configuring BGP ECMP



Configuration Precautions

61) Enables IBGP load balancing on Router A, and AS-PATH loose comparison.

62) Routers B and D, Routers C and E are connected to EBGP neighbors through a single hop.

63) Routers B and C consider Router A as IBGP neighbors.

Configuration Steps

64) Configuration on Router A

```
Ruijie# conf t
Ruijie(config)# interface fastEthernet 0/0
Ruijie(config-if-FastEthernet 0/0)# ip address 10.1.1.1 255.255.0.0
Ruijie(config-if-FastEthernet 0/0)# exit
Ruijie(config)# interface fastEthernet 0/1
Ruijie(config-if-FastEthernet 0/1)# ip address 10.2.1.1 255.255.0.0
Ruijie(config-if-FastEthernet 0/1)# exit
Ruijie(config)# ip route 10.3.0.0 255.255.0.0 10.1.1.2
Ruijie(config)# ip route 10.4.0.0 255.255.0.0 10.2.1.2
Ruijie(config)# router bgp 65530
Ruijie(config-router)# neighbor 10.1.1.2 remote-as 65530
Ruijie(config-router)# neighbor 10.2.1.2 remote-as 65530
Ruijie(config-router)# bgp maximum-paths ibgp 2
Ruijie(config-router)# bgp bestpath as-path multipath-relax
```

65) Configuration on Router B

```
Ruijie# conf t
Ruijie(config)# interface fastEthernet 0/0
Ruijie(config-if-FastEthernet 0/0)# ip address 10.1.1.2 255.255.0.0
Ruijie(config-if-FastEthernet 0/0)# exit
Ruijie(config)# interface fastEthernet 0/1
Ruijie(config-if-FastEthernet 0/1)# ip address 10.3.1.2 255.255.0.0
Ruijie(config-if-FastEthernet 0/1)# exit
Ruijie(config)# router bgp 65530
Ruijie(config-router)# neighbor 10.1.1.1 remote-as 65530
Ruijie(config-router)# neighbor 10.3.1.1 remote-as 65531
```

66) Configuration on Router C

```
Ruijie# conf t
Ruijie(config)# interface fastEthernet 0/0
Ruijie(config-if-FastEthernet 0/0)# ip address 10.2.1.2 255.255.0.0
Ruijie(config-if-FastEthernet 0/0)# exit
Ruijie(config)# interface fastEthernet 0/1
Ruijie(config-if-FastEthernet 0/1)# ip address 10.4.1.2 255.255.0.0
Ruijie(config-if-FastEthernet 0/1)# exit
Ruijie(config)# router bgp 65530
Ruijie(config-router)# neighbor 10.2.1.1 remote-as 65530
Ruijie(config-router)# neighbor 10.4.1.1 remote-as 65532
```

67) Configuration on Router D

```
Ruijie# conf t
Ruijie(config)# interface fastEthernet 0/0
Ruijie(config-if-FastEthernet 0/0)# ip address 10.3.1.1 255.255.0.0
Ruijie(config-if-FastEthernet 0/0)# exit
Ruijie(config)# interface loopback 1
Ruijie(config-if)#ip address 10.5.1.1 255.255.0.0
Ruijie(config-if-FastEthernet 0/1)# exit
Ruijie(config)# router bgp 65531
Ruijie(config-router)# neighbor 10.3.1.2 remote-as 65530
Ruijie(config-router)# redistribute connected
```

68) Configuration on Router E

```
Ruijie# conf t
Ruijie(config)# interface fastEthernet 0/0
Ruijie(config-if-FastEthernet 0/0)# ip address 10.4.1.1 255.255.0.0
Ruijie(config-if-FastEthernet 0/0)# exit
Ruijie(config)# interface loopback 1
Ruijie(config-if)#ip address 10.5.1.2 255.255.0.0
Ruijie(config-if-FastEthernet 0/1)# exit
Ruijie(config)# router bgp 65532
Ruijie(config-router)# neighbor 10.4.1.2 remote-as 65530
Ruijie(config-router)# redistribute connected
```

Checking Configuration

69) Check the status of neighbor connection on Router A:

```
Ruijie#show ip bgp summary
BGP router identifier 10.2.1.1, local AS number 65530
BGP table version is 9
2 BGP AS-PATH entries
0 BGP Community entries
3 BGP Prefix entries (Maximum-prefix:4294967295)
Neighbor       V   AS      MsgRcvd   MsgSent   TblVer   InQ   OutQ   Up/Down    State/PfxRcd
172.16.23.140   4   65530   29        25        8       0     0      00:18:48   2
172.16.23.141   4   65530   24        21        8       0     0      00:17:58   2
Total number of neighbors 2
```

70) Check BGP routes on Router A.

```
Ruijie#show ip bgp
BGP table version is 9, local router ID is 10.2.1.1
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
            S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete
   Network        Next Hop   Metric   LocPrf   Weight   Path
*>i10.3.0.0/16    10.3.1.1    0       100      0       65531 ?
*>i10.4.0.0/16    10.4.1.1    0       100      0       65532 ?
* i10.5.0.0/16    10.3.1.1    0       100      0       65531 ?
*>i              10.4.1.1   0       100      0       65532 ?
Total number of prefixes 3
```

71) Check BGP route 10.5.0.0 on Router A:

```
Ruijie#show ip bgp 10.5.0.0
BGP routing table entry for 10.5.0.0/16
Paths: (2 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  65532
    10.4.1.1 from 10.2.1.2 (172.16.24.1)
      Origin incomplete, metric 0, localpref 100, valid, internal, multipath, best
      Last update: Mon Mar 21 03:45:14 2011
  65531
    10.3.1.1 from 10.1.1.2 (172.16.25.1)
      Origin incomplete, metric 0, localpref 100, valid, internal, multipath
      Last update: Mon Mar 21 03:45:14 2011
```

72) Check routes in Router A’s core routing table:

```
Ruijie#show ip route
```

```
Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default
Gateway of last resort is no set
C    10.1.0.0/16 is directly connected, FastEthernet 0/0
C    10.1.1.1/32 is local host.
C    10.2.0.0/16 is directly connected, FastEthernet 0/1
C    10.2.1.1/32 is local host.
S    10.3.0.0/16 [1/0] via 10.1.1.2
S    10.4.0.0/16 [1/0] via 10.2.1.2
B    10.5.0.0/16 [200/0] via 10.3.1.1, 00:27:56
              [200/0] via 10.4.1.1, 00:27:56
```

Configuring BGP/MPLS VPN

Please refer to the section "BGP/MPLS L3VPN Configuration" in the "MPLS Configuration Guideline" for details.

Configuring BGP/MVPN

Please refer to the section "Multicast VPN Configuration" in the "Multicast VPN Configuration Guideline" for details.

Configuring BGP Fast-Reroute

BGP Fast-Reroute Overview

IP Fast-Reroute Overview

With high-speed development of IP technologies and application of various complex services, the requirements for network security and stability become increasingly higher. Especially, certain real-time services (audios and videos) are sensitive to network running status and may be largely affected by unstable networks. Therefore, more and more focus and importance are attached to network reliability. With these requirements, the IP Fast-Reroute function comes into being. It is intended to use a backup link to maintain data forwarding during route platform convergence after a faulty link is detected, in order to achieve the ideal targets of "zero delay" and "zero loss" in packet forwarding.

Working Principle of BGP Fast-Reroute

According to the description in RFC 4271, BGP uses a routing policy to select a best route for forwarding local data and advertises the route to neighbors. After the BGP Fast-Reroute function is used, BGP selects a backup route for each best route. After BFD Fast-Reroute detects that the master link is faulty, it switches the data to the originally calculated backup link for forwarding. After route convergence is completed, data is switched to the best route re-calculated for forwarding. In this way, BGP Fast-Reroute can avoid route disconnection due to a link fault before BGP route convergence is completed.

Default Configuration

BGP Fast-Reroute is disabled by default.

Configuring BGP Fast-Reroute

Enable BGP Fast-Reroute by using the following steps:

	Command	Description
Step 1	Ruijie# **configure terminal**	Enters global configuration mode.
Step 2	Ruijie(config)# **router bgp** *as-number*	Enters BGP routing configuration mode.
Step 3	Ruijie(config-router)# **address-family ipv4 unicast**	Enters the BGP IPv4 address family.
Step 4	Ruijie(config-router-af)# **bgp fast-reroute**	Enables BGP Fast-Reroute.
Step 5	Ruijie(config-router-af)#**exit**	Returns to BGP routing configuration mode.
Step 6	Ruijie(config-router)#**neighbor** *peer-address* **fall-over bfd**	Configures a BFD session with a BGP neighbor.
Step 7	Ruijie(config-router)#**exit**	Returns to global configuration mode.

	Command	Description
Step 8	Ruijie(config)#**bfd bind bgp peer-ip** *ip-address* **interface** *interface-type interface-index* **source-ip** *ip-address*	(Optional) Configure a BFD session when it is impossible to detect failure of the master link through a BFD session with a BGP neighbor. It is not recommended to use the two commands for configuring the BFD session at the same time.
Step 9	Ruijie(config)# **end**	Returns to privileged EXEC mode.
Step 10	Ruijie # **show running-config**	Verifies the configuration.
Step 11	Ruijie # **write**	(Optional) Saves the configuration.

Product Compatibility

All products that support BGP and IP Fast-Reroute support the above configuration commands.

Caution

BGP Fast-Reroute is subject to the following constraints:

1) BGP Fast-Reroute is supported only in the IPv4 Unicast and IPv4 VRF address families of BGP.

2) Only one backup route can be generated and the next hop of the backup route cannot be the same as that of the preferred route.

3) A backup next hop cannot be generated for an ECMP route.

4) In BGP IPv4 VRF configuration mode, BGP Fast-Reroute has a lower priority than VPN Fast-Reroute. That is, if VPN Fast-Reroute is enabled in VRF mode, BGP Fast-Reroute takes effect only when VPN Fast-Reroute fails to calculate a backup route.

Configuration Example

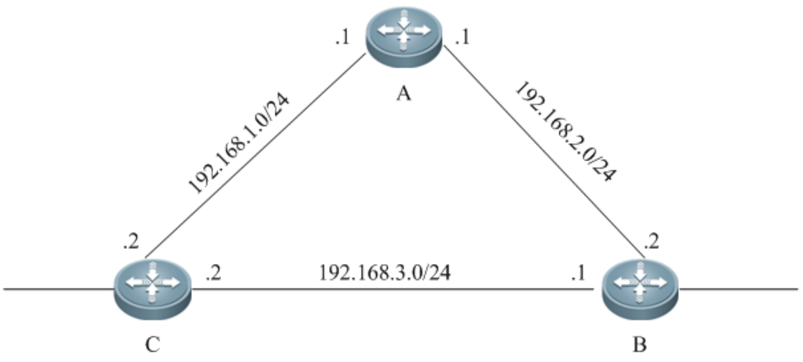
Configuring EBGP Fast-Reroute

Networking Requirements

As shown in the following figure, the three routers A, B and C belong to different autonomous areas (ASs). They are interconnected to each other through BGP. It is required that when the link between B and C is faulty, traffic can be fast switched to the link between C and A, and the traffic path is C→A→B.

Network Topology

Figure 0-1 EBGP Fast-Reroute



Configuration Steps

1) Configure router A.

```
Ruijie# conf t
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/1)# exit
Ruijie(config)# interface GigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)# ip address 192.168.2.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/2)# exit
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 192.168.1.2 remote-as 300
Ruijie(config-router)# neighbor 192.168.2.2 remote-as 200
Ruijie(config-router)# redistribute connect
```

2) Configure router B.

```
Ruijie# conf t
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ip address 192.168.3.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/1)# bfd interval 200 min_rx 200 multiplier 5
Ruijie(config-if-GigabitEthernet 0/1)# exit
Ruijie(config)# interface GigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)# ip address 192.168.2.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/2)# exit
Ruijie(config)# router bgp 200
Ruijie(config-router)# neighbor 192.168.3.2 remote-as 300
Ruijie(config-router)# neighbor 192.168.3.2 fall-over bfd
Ruijie(config-router)# neighbor 192.168.2.1 remote-as 100
Ruijie(config-router)# redistribute connect
```

3) Configure router C.

```
Ruijie# conf t
```

```
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ip address 192.168.1.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/1)# exit
Ruijie(config)# interface fastEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)# ip address 192.168.3.2 255.255.0.0
Ruijie(config-if-GigabitEthernet 0/2)# bfd interval 200 min_rx 200 multiplier 5
Ruijie(config-if-GigabitEthernet 0/2)# exit
Ruijie(config)# router bgp 300
Ruijie(config-router)# neighbor 192.168.1.1 remote-as 100
Ruijie(config-router)# neighbor 192.168.3.1 remote-as 200
Ruijie(config-router)# neighbor 192.168.3.1 fall-over bfd
Ruijie(config-router)# address-family ipv4 unicast
Ruijie(config-router-af)# bgp fast-reroute
Ruijie(config-router-af)# redistribute connect
```

Verification

4) Display the neighbor connection status on router C.

```
Ruijie# show ip bgp summary
BGP router identifier 10.10.10.10, local AS number 300
BGP table version is 12
4 BGP AS-PATH entries
0 BGP Community entries
3 BGP Prefix entries (Maximum-prefix:4294967295)

Neighbor       V        AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down  State/PfxRcd
192.168.1.1     4        100     76     77       12    12    0 00:59:27       3
192.168.3.1     4        200     30     30       12    12    0 00:19:03       3

Total number of neighbors 2
```

5) Display the BGP route on router C.

```
Ruijie# show ip bgp
BGP table version is 12, local router ID is 10.10.10.10
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
            S Stale, b - backup entry
Origin codes: i - IGP, e - EGP, ? - incomplete

  Network        Next Hop          Metric     LocPrf     Weight Path
*  192.168.1.0     192.168.3.1           0                    0 200 ?
*               192.168.1.1           0                    0 100 ?
*>              0.0.0.0              0               32768    ?
*> 192.168.2.0     192.168.3.1           0                    0 200 ?
*b              192.168.1.1           0                    0 100 ?
```

```
*  192.168.3.0    192.168.3.1            0                   0 200 ?
*                192.168.1.1            0                   0 100 200 ?
*>               0.0.0.0               0                32768    ?

Total number of prefixes 3
```

6) Display the BGP route 192.168.2.0 on router C.

```
Ruijie# show ip bgp 192.168.2.0
BGP routing table entry for 192.168.2.0/24

C    192.168.1.0/24 is directly connected, GigabitEthernet 1/9
C    192.168.1.2/32 is local host.
B    192.168.2.0/24 [20/0] via 192.168.3.1, 00:21:39
C    192.168.3.0/24 is directly connected, GigabitEthernet 1/11
C    192.168.3.2/32 is local host.
```

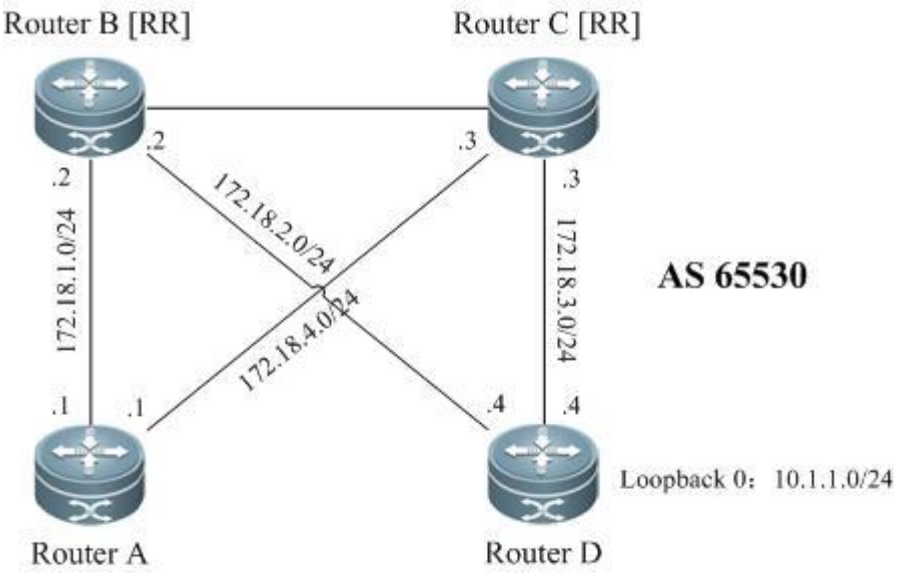
Configuring IBGP Fast-Reroute

Networking Requirements

As shown in the following figure, the router routers A, B, C and D belong to the same AS. B and C serve as the route reflectors and establish IBGP neighbors with A and D respectively. The route 10.1.1.0/24 advertised by D will be reflected to A through B and C at the same time. Normally, A prefers the link A->B->D to reach the network segment 10.1.1.0/24. It is required that when the link A->B->D is faulty, traffic can be fast switched to the link A->C->D.

Network Topology

Figure 0-2 IBGP Fast-Reroute



Configuration Steps

8) Configure router A.

```
Ruijie# conf t
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ip address 172.18.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/1)# bfd interval 200 min_rx 200 multiplier 5
Ruijie(config-if-GigabitEthernet 0/1)# exit
Ruijie(config)# interface GigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)# ip address 172.18.4.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/2)# exit
Ruijie(config)# router bgp 65530
Ruijie(config-router)# neighbor 172.18.1.2 remote-as 65530
Ruijie(config-router)# neighbor 172.18.4.3 remote-as 65530
Ruijie(config-router)# bgp fast-reroute
Ruijie(config-router)# exit
Ruijie(config)# bfd bind bgp peer-ip 172.18.2.4 interface GigabitEthernet 0/1 source-ip
172.18.1.1
```

9) Configure router B.

```
Ruijie# conf t
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ip address 172.18.1.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/1)# exit
Ruijie(config)# interface GigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)# ip address 172.18.2.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/2)# exit
Ruijie(config)# router bgp 65530
Ruijie(config-router)# neighbor 172.18.1.1 remote-as 65530
Ruijie(config-router)# neighbor 172.18.2.4 remote-as 65530
Ruijie(config-router)# address-family ipv4 unicast
Ruijie(config-router-af)# neighbor 172.18.1.1 route-reflector-client
Ruijie(config-router-af)# neighbor 172.18.2.4 route-reflector-client
Ruijie(config-router-af)# end
```

10) Configure router C.

```
Ruijie# conf t
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ip address 172.18.4.3 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/1)# exit
Ruijie(config)# interface GigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)# ip address 172.18.3.3 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/2)# exit
Ruijie(config)# router bgp 65530
Ruijie(config-router)# neighbor 172.18.4.1 remote-as 65530
Ruijie(config-router)# neighbor 172.18.3.4 remote-as 65530
Ruijie(config-router)# address-family ipv4 unicast
Ruijie(config-router-af)# neighbor 172.18.4.1 route-reflector-client
Ruijie(config-router-af)# neighbor 172.18.3.4 route-reflector-client
Ruijie(config-router-af)# end
```

11) Configure router D.

```
Ruijie# conf t
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ip address 172.18.2.4 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/1)# bfd interval 200 min_rx 200 multiplier 5
Ruijie(config-if-GigabitEthernet 0/1)# exit
Ruijie(config)# interface GigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)# ip address 172.18.3.4 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/2)# exit
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 10.1.1.1 255.255.255.0
Ruijie(config-if-Loopback 0)# exit
Ruijie(config)# router bgp 65530
Ruijie(config-router)# neighbor 172.18.2.2 remote-as 65530
Ruijie(config-router)# neighbor 172.18.3.3 remote-as 65530
Ruijie(config-router)# network 10.1.1.0 mask 255.255.255.0
Ruijie(config-router)# exit
Ruijie(config)# bfd bind bgp peer-ip 172.18.1.1 interface GigabitEthernet 0/1 source-ip
172.18.2.4
```

Verification

12) Display the neighbor connection status on router A.

```
Ruijie# show ip bgp summary
BGP router identifier 10.1.1.2, local AS number 300
BGP table version is 12
0 BGP AS-PATH entries

Configuring IS-IS

Understanding IS-IS Protocol

Overview

IS-IS (Intermediate System-to-Intermediate System) is a routing protocol defined in ISO10589. It was initially a dynamic routing protocol designed by ISO for CLNP (Connectionless Network Protocol). With IP getting more and more popular, IETF enables IS-IS to support IP in RFC1195 and develops IS-IS into Integrated IS-IS. After years of development, Integrated IS-IS has become a scalable, robust and easy-to-use IGP protocol, which is applicable to IP and ISO CLNS based dual-environment network.

As a link-state protocol, IS-IS has certain features shared by link-state protocols. It discovers and maintains adjacencies by sending Hello packets, and advertises its own link state by sending LSP (Link State PDU) to its neighbors. IS-IS has a two-level hierarchy (level 1 and level 2 routing), with all devices at the same level having the same LSDB, which stores the LSP generated by all devices at the same level. In this way, all devices at the same level are aware of the network topology of their level, and each device uses Dijkstra SPF algorithm to optimize route calculation, select path and achieve fast convergence.

Hierarchical Structure of IS-IS Network

Figure 1

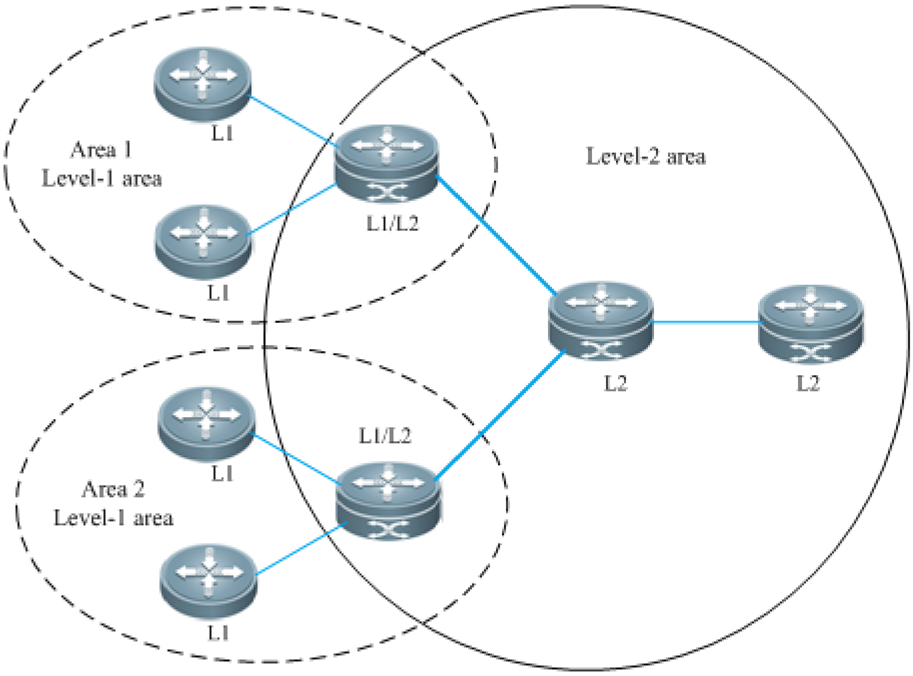

Figure 1 IS-IS hierarchy

This network is divided into Level-1 and Level-2. All nodes for exchanging information among devices in the same area form Level-1. All intra-area devices are aware of the network topology of entire area and carry out Inter-area data exchange. Level-1-2 devices are the boundary devices to connect different areas. Inter-area connection is achieved by connecting Level-2 devices, while the boundary devices of respective areas jointly form a backbone network (Level-2). Inter-area data exchange is carried out at level-2.

Level-1 devices only concern about the topology structure of the local area, including all nodes and next-hop devices reaching these nodes in the local area. Level-1 device accesses other areas through the Level-2 device, and forwards data packets in the destination network outside the area to the closest Level-2 device.

Address Encoding of IS-IS Protocol

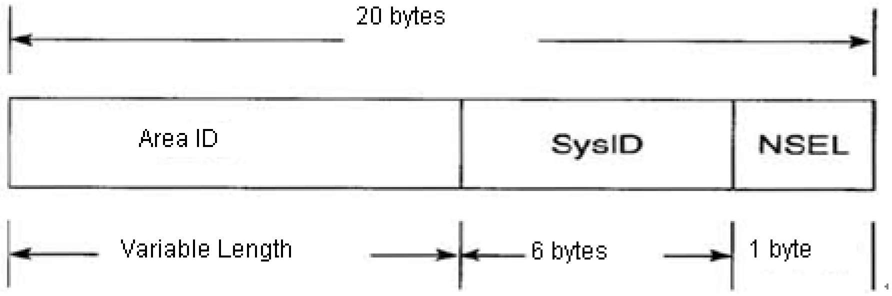

Figure 2 NET address format

IS-IS protocol address is called NET, which can be divided into three parts: Area address, System ID and NSAP selector. The total length of NSAP address ranges from 8 to 20 bytes.

The length reserved for area address is variable. The area ID is the length of route domain, and is fixed in the route domain. The length of area address ranges from 1 to 13 bytes.

The length of System ID is 6 bytes, and is unique in the autonomous system.

NSAP is the network selector, and is sometimes called SEL, with length being 1 byte. In IS-IS, SEL is usually set to 00 to represent the routing device.

IS-IS Packet Types

There are three types of packets:

- Link-state PDUs (LSP)
- IS-IS Hello PDUs

Sequence number PDUs (SNP)
Link-state PDUs (LSP) are used to advertise link-state logs within the area. They can be divided into: Level 1 Link State PDU and Level 2 Link State PDU. LSP will only be flooded at its own level.

IS-IS Hello PDUs (IIH PDU) are used to maintain adjacencies. Hello PDUs will send multicast MAC address to detect whether IS-IS is operated in other systems.

Sequence number PDUs (SNP) can be divided into CSNP and PSNP.

Complete sequence number PDU (CSNP) is used to synchronize LSDB. In a broadcast network, DIS will send CSNP packets once every 10 seconds by default. In a point-to-point network, CSNP packets will only be sent once after adjacency is formed.

Partial sequence number PDU (PSNP) is also used to synchronize LSDB.

DIS

DIS: Designated IS, the designated routing device in on the broadcast network, equivalent to the DR in OSPF.

Pseudonode: The pseudonode is generated by DIS and establishes contacts with all devices in the network.

DIS will model the multi-access link as a pseudonode to create pseudonode LSPs. All routing devices on the local network contact with the pseudonode, and no direct contact between them is allowed. The broadcast subnet and NBMA network are regarded as a pseudonode externally. All non-DIS devices on the network will report their link state to the DIS, which will report the link state on behalf of all ISs on the entire network. The reason to elect DIS is the same as the reason to elect DR in OSPF: to reduce unnecessary adjacencies and routing information exchange.

DIS is created through election. The DIS election in IS-IS is pre-emptive, which is different from DR in OSPF.

The result of DIS election can be controlled by configuring the "Priority" of interface. The one with the highest "Priority" value will be elected.

TLVs Supported by IS-IS

Currently, Ruijie IS-IS supports the following TLV codes:

TLV CODE	Description
Code=1	Area addresses
Code=2	Priority level information of IS neighbor
Code =3	ES neighbors
Code=6	MAC address of IS neighbor
Code=8	Padding
Code=9	LSP entries
Code=10	Authentication information
Code=14	Buffer size of source LSP
Code=22	Extended IS reachability
Code=128	IP internal reachability information
Code=129	Protocols supported
Code =130	IP external reachability information
Code=131	IDRP information
Code=132	IP interface address
Code=133	Authentication information

Code=135	Extended IP reachability TLV
Code=137	Dynamic host name
Code = 211	Graceful Restart
Code=232	IPV6 interface
Code =236	IPV6 IP Reachability TLV
Code =240	P2P 3-way handshake TLV

LSP Fragments Extension

IS-IS informs devices of link-state information by flooding LSP packets. The size of LSP packets is restricted by link MTU and cannot be extended. When the information to be informed exceeds the size of a LSP packet, IS-IS will create LSP fragments to carry new link-state information. According to the ISO standard, the LSP fragment is recognized by the 1-byte LSP Number. Therefore, the maximal number of LSP fragments produced by an IS-IS node is 256.

There are several reasons causing 256 fragments not enough:

- New TLV or Sub-TLV extended by new application, such as TE
- Constant expansion of network scale
- Informing routes with smaller chip or redistributing other routes to IS-IS.

When LSP fragments are filled, subsequent routing information and neighbor information will be discarded directly. There will be network anomaly, such as routing blackhole or routing loops. LSP fragments need to be extended to carry more link-state information to ensure normal operation of the network.

Definitions of fragments extension are listed as follows:

- Normal system-id: It refers to the current system ID defined by ISO, which is used to form adjacency and learn routes. “Nornal” differentiates this kind of system-id from additional system-id produced by fragments extension.
- Additional system-id: It is configured by the administrator and used to extend LAP, in comparison with normal system-id. Additional system-id does not appear in Hello packets for adjacency formation. Except that, additional system-id adopts the same rules as normal system-id, for example, it must be unique and cannot be repeated in the whole intra-area.
- Originating System: It refers to the routing device running the IS-IS protocol. It is in comparison with the virtual system identified by the additional system ID.
- Virtual System/Vritual IS: It refers to the system identified by additional system-id, which is used to generate extended LSP. RFC proposes this notion and differentiate it from the originating system. Every virtual system generates up to 256 LSP fragment packets. The administrator can configure several additional system IDs , which represent virtual systems, to generate more LSP fragment packets to meet the demand.
- Original LSP: The LSP packet is generated by the originating system. The system-id is normal system-id.
- Extended LSP: The LSP packet is generated by the virtual system. The system-id is additional system-id.

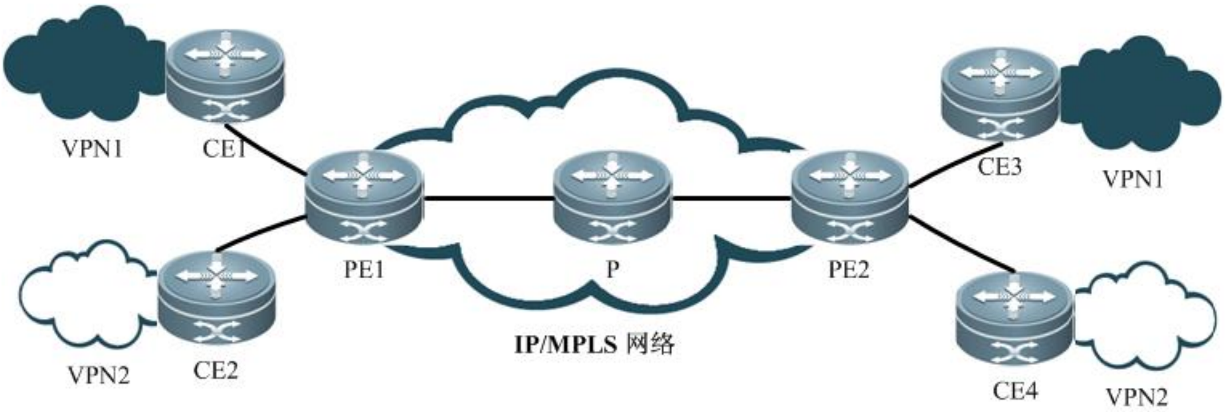
IS-IS can inform devices of more link-state information with extended LSP by setting additional system-id and enabling fragments extension. Every virtual system can be regarded as a virtual routing device which establishes adjacency with the originating system. The metric between them is 0. Extended LSP is the LSP packet released by the neighbor of originating system, namely the virtual system,

IS-IS VRF

VRF is short for VPN Routing and Forwading. It is mainly used to perform local routing, segregate data packets and address routing conflicts caused by VPNs using the same prefix. Most IPv4 and IPv6 VPNs are MPLS VPN. Combined with MPLS's advantage in service quality and security guarantee, MPLS VPN has become the preferred solution to enable interconnection among branches of enterprises and industries in different areas.

The following figure is a typical VRF networking application, which is to enable VPN segregation control by configuring VRF on PE devices.

Figure 1-3 Enabling VPN segregation control by configuring VRF on PE devices



As figure 1-3 shows, two site users (CE1 and CE3) under VPN1 should be able to visit each other. Two site users (CE2 and CE4) under VPN2 should be able to visit each other. VPN1 and VPN2 should not be able to visit each other for two reasons:

- The two VPNs belong to different users or departments. Mutual visit is prevented for security's sake.
- There may be the same IP address on VPN1 and VPN2.

CE is used to connect the user network to PE and exchange VPN routing information with PE: release local routes to PE and learn remote site routes from PE.

PE is used to learn routing from directly connected CE and exchange learned VPN routes with other PEs through BGP. The PE device is responsible for the access of VPN business.

The device P is a device that is not directly connected with CE on the operator network. The device is only required to support MPLS forwarding and cannot sense VPN.

The IS-IS routing protocol runs between PE and CE to enable VRF-based routes learning. PE and CE only learn routes within the same VPN to enable VPNs segregation control.

IS-IS Definitions

- ES: End System refers to non-router devices, such as host.
- IS: Intermediate System refers to router devices, the basic unit sending routing information and generating routes in the IS-IS protocol.
- ES-IS: End System-to-Intermediate System, an OSI protocol that defines how end systems (ES) and intermediate systems (IS) learn about each other.

- Domain: routing domain. In one routing domain, a group of ISs will exchange routing information through the same routing protocol.
- Area: a routing sub-domain. One routing domain can be divided into multiple areas.
- CSNP: Complete sequence number PDU, sent by DIS every 10 seconds on the broadcast network to synchronize link state.
- PSNP: Partial sequence number PDU, sent on the point-to-point link to acknowledge receipt of an LSP or on the broadcast network to request an LSP.
- ENPA: attached subnet point that provides subnet services.
- CLNP: Connectionless Network Protocol, an IP-alike OSI protocol to transmit data and error messages in the network layer.
- CNLS: Connectionless Network Service is the solution to unreliable connection which doesn't need the circuit to be established before data transmission.
- DIS: Designated Intermediate System, which is similar to the DR in OSPF. It floods LSPs to other devices on the LAN. Unlike OSPF, DIS forms adjacencies with other devices which also form adjacencies between each other.
- Hello: This packet is used to establish and maintain adjacencies.
- LSP: Link-state PDU, which is similar to the LSA in OSPF, but LSP doesn't rely on TCP/IP protocol information. There are different LSPs for different routes, such as L1 LSP and L2 LSP.
- NSEL: NSAP selector, sometimes also called SEL. It identifies a network service user, and is similar to the TCP/UDP port for upper-layer service in the IP protocol. In IS-IS, SEL is usually set to 00 to imply the routing device.
- NSAP: Network Service Access Point is the complete address for CLNS packets, including OSI address and high-level process, with structure containing area ID, System ID and SEL. A NSAP address with SEL being 00 implies the NET entity. It is similar to the combination of IP address and IP protocol number.
- SNPA: Sub-network Point of Attachment provides physical link and network layer services, and is similar to the MAC address in IP and DLCI, WAN and HDLC in FR.
- L1 router: The router inside an area. It only accepts relevant information from the local area. In order to reach other areas, a default route to the closest L2 must be saved in L1.
- L2 router: the trunk router between different areas. L1 cannot be directly connected with L2.
- L1/L2 router: The boundary router used to connected L1 router and L2 router, containing the databases of both L1 router and L2 routers. It is similar to the ABR in OSPF.
- Pseudonode: The identifier of broadcast subnet of LAN. Pseudonode makes broadcast media a virtual routing device, while every router acts as its interface. DIS manages the adjacency between router and pseudonode.
- NET: network entity title, a part of OSI address describing the area and system ID.
- Circuit: Circuit is the term for interface in IS-IS. NSAP and NET represent the entire device, while circuit represents the interface. For a point-to-point interface, the circuit ID is 1 byte long. For example, the circuit ID is 0x00 in HDLC; in a broadcast network such as LAN, the circuit ID is generally 7 bytes long combining the System ID, such as 1921.6800.0001.01.

To learn more details about IS-IS, please refer to ISO 10589 and RFC 1195.

Configuring IS-IS

The default configurations of IS-IS are given below:

Function	**Default setting**
Network interface	Interface metric: 10 Advertised Hello interval: 10 seconds Advertised CSNP interval: 10 seconds Minimal interval for LSP transmission: 33 milliseconds LSP retransmission interval: 5 seconds Hello multiplier number: 3 Priority for routing node election: 64 Circuit type: Level-1-2 Authentication password: none
System type	Level-1-2
Default route	Level-1 default route: enabled Level-2 default route: disabled.
LSP authentication password	NA
IS-IS GR	IS-IS GR Restarter: Disabled IS-IS GR Helper: Enabled
Summary-address	Undefined
Overload flag bit	Undefined
LSP checksum error	Enabled
Adjacency change logging	Disabled
LSP refresh interval	900 seconds
LSP lifetime	1200 seconds

Enabling IS-IS

Unlike other routing protocols, you need to first create an IS-IS routing process and specify the interfaces on which IS-IS shall be enabled.

Creating IS-IS Routing Process

Command	Function
Ruijie(config)# **router isis** [*tag*]	Starts IS-IS routing process, with tag being the name of IS-IS process.
Ruijie(config-router)# net areaAddress. SystemId.00	Configures the NET address of IS-IS.

- Create IS-IS route process:
- To run IS-IS routing protocol, first create IS-IS routing process in global configuration mode; you can also add "Tag" behind "router isis". This Tag refers to the name of IS-IS routing process. You can also choose not to configure the name of IS-IS routing process. You can configure different IS-IS routing processes by adding different Tags.
- Configure IS-IS protocol's system ID and area address:

- System ID is the only identifier of IS in an autonomous system. Therefore, System ID must be unique in the entire autonomous system. In IS-IS, each area can have one or multiple area addresses, and generally only one area address is needed. Area repartition can be done by configuring multiple area addresses. When configuring multiple area addresses for one IS, the System ID must be identical.

Example:

```
Ruijie(config-router)# net 49.0001.0000.0000.0001.00
```

In the above configuration command, the area address is 49.0001 and System ID is 0000.0000.0001.Dots in the numbers are for your convenience only.

Caution

Level-1 IS routing nodes in the same area must be configured with the same area address. Currently, the core routing table will not be sensitive to the IS-IS process generating the routing table.

Caution

By default, CPU protection is enabled on the switch. For packets corresponding to each destination group address of IS-IS (AllISSystems, AllL1ISSystems, AllL2ISSystems), there will be default limit in number when sent to the CPU. For example, the default limit is 400pps. If there are many adjacencies or if Hello packets are sent at short intervals, the IS-IS packets received by the switch may exceed the default limit, leading to the continual oscillation of adjacencies. In such a case, the limit for IS-IS packets must be raised by configuring such global commands of **cpu-protect type isis-is pps, cpu-protect type isis-l1is pps and cpu-protect type isis-l2is pps**.

Configuring IS-IS Protocol on the Interface

After global IS-IS protocol is enabled, you need to configure IS-IS protocol on the interface.

Use the following command to configure IS-IS protocol on the interface.

Command	Function
Ruijie(config-if)# ip router isis [tag]	Enables IPv4 IS-IS on the specified interface, with "tag" being the name of IS-IS process.
Ruijie(config-if)# **ipv6 router isis** [*tag*]	Enables IPv6 IS-IS on the specified interface, with "tag" being the name of IS-IS process.

Caution

When configuring IP address, the IP address must be in the same network segment as the IP address of adjacent interface.

Caution If the IP address is not in the same network segment as the IP address of adjacent interface, the adjacency cannot be established.

Caution If the interface needs to join the specified IS-IS process, the Tag name of this IS-IS process must be added after "ip router isis".

Caution By configuring the no ip routing command in global configuration mode, IS-IS will disable IPv4 routing function on all interfaces, namely "no ip router isis [tag]" will be executed automatically on all interfaces, while other IS-IS configurations will remain unchanged.

Caution When you configure the IPv6 address, the local link address will be configured by default

Caution If the IPv6 address or the IPv6 address of the adjacent interface does not have the local link address, the adjacency cannot be established.

Caution If you want to add the interface to the designated IS-IS process, attach the Tag of this IS-IS process to the end of **ipv6 router isis.**

Caution If the **no ipv6 unicast-routing** command is executed in global configuration mode, IS-IS will disable IPv6 routing on all interfaces. Namely, the **no ipv6 router isis** [*tag*] command is executed automatically on all interfaces while other IS-IS configurations remain unchanged.

Caution In order to avoid routing blackholes on the network where IPv4 and IPv6 coexist, if protocols supported by two devices or interfaces are not the same, adjacency will not be set up. In this case, please check whether the network topology has any problem. If there is no problem with the network topology and there are no routing blackholes, configure different instances to perform IPv4 and IPv6 routes learning.

Configuring IS-IS Hello Packets

Configuring the Advertised Hello Interval

IS-IS will periodically send Hello packets on the interface, while routing deviceswill discover and maintain adjacencies through the reception and sending of Hello packets. Complete the following configuration in interface configuration mode to set the Hello packet broadcast interval:

Command	Function

Ruijie(config-if)#**isis hello-interval** { **interval** | **minimal** } [**level-1** | **level-2**]	Configures the interval for sending Hello packets on the interface, in the range of 1 to 65535 seconds.

Use the command to change the interval for sending Hello packets. DIS in broadcast network will send Hello packets at an interval which is three times shorter than non-DIS. If IS is elected as DIS on this interface, the interface will send Hello packets every 3.3 seconds by default.

If the key word minimal is used, then the holdtime in Hello packets will be set to 1, and hello interval will be calculated based on the hello-multiplier. For example, if hello-multiplier is configured to 3 and the isis hello-interval minimal command is configured at the same time, the value of hello-interval shall be 1s/3 (333ms).

Caution

By default, CPU protection is enabled on the switch. For packets corresponding to each destination group address of IS-IS (AllISSystems, AllL1ISSystems, AllL2ISSystems), there will be default limit in number when sent to the CPU. For example, the default limit is 400pps. If there are many adjacencies or if Hello packets are sent at short intervals, the IS-IS packets received by the switch may exceed the default limit, leading to the continual oscillation of adjacencies. In such a case, the limit for IS-IS packets must be raised by configuring such global commands of cpu-protect type isis-is pps, cpu-protect type isis-l1is pps and cpu-protect type isis-l2is pps.

Configuring Hello Multiplier Number

IS-IS will periodically send the Hello packet on the interface, and advertise the adjacency hold time of the IS device in the header of the Hello packet. Neighbors will update adjacencies based on the holdtime field in the Hello packet header. The holdtime value in the Hello packet header equals to the hello-interval value multiplies the hello-multiplier value.

Complete the following configuration in interface configuration mode to set the Hello packet holdtime multiplier:

Command	**Function**
Ruijie(config-if)# **isis hello-multiplier multiplier-number** [**level-1** | **level-2**]	Configures Hello multiplier number on the interface.

Use the command to change the holdtime multiplier of Hello packets and the holdtime. The holdtime of Hello packets can also be changed by changing hello-interval or changing both of them.

Configuring Hello packet failure number

IS-IS protocol maintains relationships with adjacent routers by sending and receiving Hello packets. When the local router fails to receive a specific number of Hello packets from peers continuously, adjacent routers will be considered failed. The default number is three. Complete the following configuration in interface configuration mode to set the failure number of Hello packets:

Command	**Function**

Ruijie(config-if)# **isis hello-multiplier** *multiplier-number* [**level-1** | **level-2**]	Sets the number of failure Hello packets on the interface.

Configuring IS-IS LSP

Configuring LSP Minimal Transmission Interval

Complete the following configuration to set the minimum interval for sending LSP packets continuously by IS-IS on the interface:

Command	**Function**
Ruijie(config-if)# **isis lsp-interval** *interval*	Configures the minimal interval (1-4294967295 milliseconds) for sending LSPs on the interface.

Configuring LSP Retransmission Interval

On a point-to-point link, if the local router fails to receive any reply after sending LSPs for a while, it will assume that the LSPs sent formerly are lost or discarded. To ensure the reliability the LSP sending, the local routing device will retransmit the same LSPs. Complete the following configuration in interface configuration mode to set the packets retransmission interval:

Command	**Function**
Ruijie(config-if)# **isis retransmit-interval** *interval*	Configures the interval (1-65535 seconds) for retransmit LSPs on the point-to-point link.

Configuring LSP Refresh Interval

To ensure that each network node can maintain the latest LSP, LSP will periodically refresh the current LSP, and such interval is called LSP refresh interval. With this mechanism, LSPs can remain synchronized in the entire area. Complete the following configuration in IS-IS protocol configuration mode to set the LSP refreshing frequency:

Command	**Function**
Ruijie(config-router)# **lsp-refresh-interval** *interval*	Configures LSP refresh interval (1-65535 seconds).

Caution The lsp-refresh-interval shall be less than the max-lsp-lifetime.

Configuring LSP Lifetime

In LSP, there is a field value called LSP lifetime. When the routing device generates LSP, it will set the maximal lifetime in the field for this LSP. When the LSP is received by another routing decvice, the lifetime will decrease gradually, and the old LSP will be replaced if a new LSP is received. If no refreshed LSP is received and the LSP lifetime has decreased to 0, it will still be kept in the link-state database for 60 seconds. If no refreshed LSP is received within the 60 seconds, this LSP will be deleted from LSDB. With this mechanism, LSPs can remain synchronized in the entire area. Complete the following configuration in IS-IS protocol configuration mode to set the lifetime of LSPs generated by the router:

Command	Function
Ruijie(config-router)#**max-lsp-lifetime value**	Configures LSP lifetime (1-65535 seconds).

Caution The max-lsp-lifetime must be greater than lsp-refresh-interval.

Configuring LSP Fragments Expansion

The LSP fragments expansion function is enabled by setting additional system ID and enabling fragments expansion . Execute the following commands in IS-IS routing process configuration mode:

Command	Function
Ruijie(config-router)# **lsp-fragment-extend** [**level-1 | level-2**] [**compatible rfc3786**]	Enables fragments extension.
Ruijie(config-router)#**virtual-system** *system-id*	Sets additional system ID.

Configuring IS-IS SNP

Configuring the Advertised CSNP Interval

Complete Sequence Number PDUs (CSNP) are packets sent by DIS in the broadcast network to maintain link-state database synchronization. CSNPs are also periodic broadcast packets. Complete the following configuration in interface configuration mode to set the CSNP packet broadcasting interval:

Command	Function
Ruijie(config-if)# **isis csnp-interval** *interval* [**level-1** | **level-2**]	Configures the interval (0-65535 seconds) for sending CSNP packets on the interface.

Configure this command to change the interval for sending CSNP packets. By default, DIS on the broadcast network will send CSNP packets every 10 seconds.

For P2P interface network, CSNP packets will only be sent when adjacency is just established; if the interface is set mesh-groups, you can set sending CSNP packets periodically.

If csnp-interval is set to 0, no CSNP will be sent.

If **mesh-group** is required on the IS-IS interface, you need to configure a non-zero interval for sending VSNP packets to synchronize LSP by using the **isis csnp-interval** command so as to ensure complete LSP synchronization among adjacencies in the network.

Configuring IS-IS Level Type

IS-IS protocol supports two-level hierarchy, so as to manage route selection and achieve expandable route selection. Every level only maintains the topology structure of local area.

You can execute "is-type" command in IS-IS router configuration mode to configure IS-IS Level, or execute "circuit-type" command in the interface configuration mode to configure IS-IS Level of this interface. The default is-type and circuit-type are Level-1-2. If these two commands are configured simultaneously, the corresponding interface will only send Level PDUs with is-type being same as circuit-type.

Configuring System Type

You can configure the level of existing routing devices, which can be divided into Level-1 router (intra-area routing device), Level-2 (inter-area routing device) and Level-1-2 router (both an intra-area routing device and an inter-area routing device). If is-type is configured to Level-1 or Level-2-only, the IS-IS process will only process data at this level. Complete the following configuration in IS-IS protocol configuration mode to set Level of the router:

Command	Function
Ruijie(config-router)# **is-type** { **level-1** | **level-1-2** | **level-2-only** }	Configures system type.

Configuring the Interface Circuit Type

You can configure the type of the interface circuit. Complete the following configuration in interface configuration mode to set the type of the interface circuit:

Command	Function
Ruijie(config-if)# **isis circuit-type** { **level-1** | **level-1-2** | **level-2-only** }	Configures the interface circuit type.

If the circuit-type of "Level-1" or "Level-2-only" is configured, then IS-IS will only send PDUs of the same level.

Configuring IS-IS Authentication

You can configure IS-IS authentication to improve the security of IS-IS network. You can configure authentication for IS-IS in the different level ranges, which include IS-IS interface, IS-IS area and IS-IS route domain.

The interface authentication functions during adjacency formation. If two IS-IS devices are configured with different interface authentication passwords, the adjacency won't be formed, thus avoiding unauthorized or unauthenticated IS-IS devices from joining an IS-IS network in which authentication is required. The interface authentication password is encapsulated in the Hello packets.

IS-IS domain authentication and routing domain authentication are used to authenticate LSP, CSNP and PSNP packets, so as to avoid unauthorized or unauthenticated routing information from entering IS-IS link-state database. The authentication password is encapsulated in the corresponding LSP, CSNP and PSNP packets.

Currently, the following two kinds of authentication methods are provided: plain text authentication and MD5 authentication. The approach of plain text authentication can only guarantee limited security as the password carried by packets can be seen directly. The approach of MD5 authentication will provide better security as the password carried by packets has been encrypted using MD5 algorithm.

Configuring Interface Authentication

Configuring Interface Plain-text authentication

You can configure plain-text authentication password for IS-IS interface. The authentication password will be encapsulated in Hello packets sent on the interface; when Hello packets are received, consistency of the password will be examined.

IS-IS interface authentication should be configured in interface configuration mode. You can use the following command to configure interface plain-text authentication:

Command	**Function**
Ruijie(config)# **interface** *interface-name* Ruijie(config-if)# **isis password** *password* [**send-only**] [**level-1** | **level-2**]	Configures plain-text authentication password for Hello packets transmitted on the interface. When the send-only is specified, the authentication password is only applicable to the sent Hello packets rather than the received Hello packets. When Level is not specified, the authentication password configured is by default applicable to every Level. When configuring this command, if "isis authentication mode" has been executed, this command won't be configured successfully. Both commands can be used to configure IS-IS interface authentication, but this command has a lower priority level. To configure this command, you need to delete "isis authentication mode" command first.

You can also use the following commands to configure plain-text authentication for IS-IS interface:

Command	**Function**
Ruijie(config-if)# **isis authentication mode text** [**level-1** | **level-2**]	Use this command to specify the mode of IS-IS interface authentication. When Level is not specified, the authentication mode configured is by default applicable to every Level. When configuring this command, if "isis password password [level-1|level-2]" has been executed, the said command will be overwritten by this command. Both commands can be used to configure IS-IS interface authentication, but this command has a higher priority level.

Ruijie(config-if)# **isis authentication key-chain name-of-chain** [**level-1** | **level-2**]	Configures the key chain used by IS-IS interface authentication. When Level is not specified, the key chain configured is by default applicable to every Level. This command must be configured together with "isis authentication mode" command in order to achieve IS-IS interface authentication. Neither of them can be omitted.
Ruijie(config-if)# **isis authentication send-only** [**level-1** | **level-2**]	(Optional) The IS-IS interface authentication can only apply to the packets sent. No authentication will be performed on packets received. When Level is not specified, the send-only authentication mode configured is by default applicable to every Level. This command can be used to avoid network oscillation caused by the failure in temporary authentication. Before deploying IS-IS authentication for the entire network, configure this command for all devices; after configuring the aforementioned two commands for all devices, execute "no isis authentication send-only" command to restore the authentication of packets received, so as to carry out smooth authentication deployment and avoid network oscillation.

Configuring Interface Encryption Authentication

You can configure encryption authentication password for IS-IS interface. The authentication password will be encapsulated in Hello packets sent on the interface; when Hello packets are received, consistency of the password will be examined.

IS-IS interface authentication should be configured in interface configuration mode. You can use the following commands to configure interface encryption authentication:

Command	Function
Ruijie(config-if)# **isis authentication mode md5** [**level-1** | **level-2**]	Sets the IS-IS interface authentication mode. When Level is not specified, the set authentication mode applies to all Levels. If the isis password password [level-1 | level-2] command is previously configured, it will be covered by this command. The two commands can both configure IS-IS interface authentication. This command has a higher priority.
Ruijie(config-if)# **isis authentication key-chain** *name-of-chain* [**level-1** | **level-2**]	Sets key-chain used for IS-IS interface authentication. When Level is not specified, the set key-chain applies to all Levels. This command must be used together with the isis authentication mode command to authenticate IS-IS interface.

Ruijie(config-if)# **isis authentication send-only** [**level-1** | **level-2**]	(Optional) The IS-IS interface authentication can only apply to the packets sent. No authentication will be performed on packets received. When Level is not specified, the set authentication and password apply to all Levels. This command can be used to avoid network oscillation caused by the failure in temporary authentication during configuration of IS-IS authentication. Before deploying IS-IS authentication for the entire network, configure this command for all devices; after configuring the aforementioned two commands for all devices, use no isis authentication send-only command to restore the authentication of packets received, so as to carry out smooth authentication deployment and avoid network oscillation.

Configuring Area Authentication

Configuring Area Plain-text Authentication

You can configure plain-text authentication password for IS-IS area. The authentication password will be encapsulated in LSP, CSNP and PSNP packets in the area (Level-1); when the packets are received, consistency of the password will be examined.

IS-IS area authentication must be configured in IS-IS process mode. You can use the following command to configure IS-IS area plain-text authentication:

Command	Function
Ruijie(config-router)# **area-password** *password* [**send-only**]	Configures area (Level-1) plain-text authentication password. When send-only is specified, the authentication password is only applicable to the sent packets rather than the received packets. When configuring this command, if "authentication mode" has been executed, this command won't be configured successfully. Both commands can be used to configure IS-IS area authentication, but this command has a lower priority level. To configure this command, you need to delete "authentication mode" command first.

You can also use the following commands to configure plain-text authentication for IS-IS area:

Command	Function

Ruijie(config-router)# **authentication mode text level-1**	Use this command to specify the mode of IS-IS area authentication. When configuring this command, if "area-password password" has been executed, the said command will be overwritten by this command. Both commands can be used to configure IS-IS area authentication, but this command has a higher priority level.
Ruijie(config-router)# **authentication key-chain** *name-of-chain* **level-1**	Configures the key chain used by IS-IS area authentication. This command must be configured together with "authentication mode" command in order to perform IS-IS area authentication. Neither of them can be omitted.
Ruijie(config-router)# **authentication send-only level-1**	(Optional) The IS-IS area authentication can only apply to the packets sent. No authentication will be performed on packets received. This command can be used to avoid network oscillation caused by the failure in temporary authentication. Before deploying IS-IS authentication for the entire area, configure this command for all devices; after configuring the aforementioned two commands for all devices, execute "no authentication send-only" command to restore the authentication of packets received, so as to carry out smooth authentication deployment and avoid network oscillation.

Configuring Area Encryption Authentication

You can configure encryption authentication password for IS-IS area. The authentication password will be encapsulated in LSP, CSNP and PSNP packets in the area (Level-1); when the packets are received, consistency of the password will be examined.

IS-IS area authentication must be configured in IS-IS process mode. You can use the following commands to configure IS-IS area encryption authentication:

Command	Function
Ruijie(config-router)# **authentication mode md5 level-1**	Sets the IS-IS area authentication mode. If the area-password password command is previously configured, it will be covered by this command. The two commands can both configure IS-IS area authentication. This command has a higher priority.

Ruijie(config-router)# **authentication key-chain** *name-of-chain* **level-1**	Sets key-chain used for IS-IS area authentication. This command must be used together with the authentication mode command to authenticate IS-IS area authentication.
Ruijie(config-router)# **authentication send-only level-1**	(Optional) The IS-IS area authentication can only apply to packets sent. No authentication will be performed on packets received. This command can be used to avoid network oscillation caused by the failure in temporary authentication during configuration of IS-IS authentication. Before deploying IS-IS authentication for the entire area, configure this command for all devices; after configuring the aforementioned two commands for all devices, use no authentication send-only command to restore the authentication of packets received, so as to carry out smooth authentication deployment and avoid network oscillation.

Configuring the Routing Domain Authentication

Configuring Routing Domain Plain-text Authentication

You can configure plain-text authentication password for IS-IS routing domain. The authentication password will be encapsulated in LSP, CSNP and PSNP packets in Level-2; when the packets are received, consistency of the password will be examined.

IS-IS routing domain authentication must be configured in IS-IS process mode. You can use the following command to configure IS-IS routing domain plain-text authentication:

Command	**Function**
Ruijie(config-router)# domain-password password [send-only]	Configure routing domain (Level-2) plain-text authentication password. When send-only is specified, the authentication password is only applicable to the sent packets rather than the received packets. When configuring this command, if "authentication mode" has been executed, this command won't be configured successfully. Both commands can be used to configure IS-IS routing domain authentication, but this command has a lower priority level. To configure domain-password, you need to delete "authentication mode" command first.

You can also use the following commands to configure plain-text authentication for IS-IS routing domain:

Command	**Function**
Ruijie(config-router)# **authentication mode text level-2**	Use this command to specify the mode of IS-IS routing domain authentication. When configuring this command, if "domain-password password" has been executed, the said command will be overwritten by this command. Both commands can be used to configure IS-IS routing domain authentication, but this command has a higher priority level.
Ruijie(config-router)# **authentication key-chain** *name-of-chain* **level-2**	Configures the key chain used by IS-IS routing domain authentication. This command must be configured together with authentication mode command in order to achieve IS-IS routing domain authentication. Neither of them can be omitted.
Ruijie(config-router)# **authentication send-only level-2**	(Optional) The IS-IS routing domain authentication can only apply to the packets sent. Packets received will not be authenticated. This command can be used to avoid network oscillation caused by temporary authentication failure. Before deploying IS-IS authentication for the entire routing domain, configure this command for all devices; after configuring the aforementioned two commands for all devices, execute no authentication send-only command to restore the authentication of packets received, so as to carry out smooth authentication deployment and avoid network oscillation.

Configuring Routing Domain Encryption Authentication

You can configure encryption authentication password for IS-IS routing domain. The authentication password will be encapsulated in LSP, CSNP and PSNP packets in Level-2; when the packets are received, consistency of the password will be examined.

IS-IS routing domain authentication must be configured in IS-IS process mode. You can use the following commands to configure IS-IS routing domain encryption authentication:

Command	**Function**
Ruijie(config-router)# **authentication mode md5 level-2**	Sets the IS-IS routing domain authentication mode. If the domain-password password command is previously configured, it will be covered by this command. The two commands can both configure IS-IS routing domain authentication. This command has a higher priority.

Ruijie(config-router)# **authentication key-chain** *name-of-chain* **level-2**	Sets key-chain used for IS-IS routing domain authentication. This command must be used together with the authentication mode command to authenticate IS-IS routing domain authentication.
Ruijie(config-router)# **authentication send-only level-2**	(Optional) The IS-IS routing domain authentication can only apply to packets sent. No authentication will be performed on packets received. This command can be used to avoid network oscillation caused by the failure in temporary authentication during configuration of IS-IS authentication. Before deploying IS-IS authentication for the entire routing domain, configure this command for all devices; after configuring the aforementioned two commands for all devices, use no authentication send-only command to restore the authentication of packets received, so as to carry out smooth authentication deployment and avoid network oscillation.

Configuring IS-IS GR

IS-IS Graceful Restart (IS-IS GR) guarantees continuous data forwarding during the process of protocol restart. Currently, the high-end products of Ruijie can support IS-IS GR during main/standby switchover, so as to guarantee continuity of key services.

Operating Mechanism of IS-IS GR

- IS-IS GR Realization Standard

RFC5306: Restart Signaling for IS-IS

- RFC5306 operating mechanism

RFC5306 defines requirements, operating methods and issues to be noticed when executing GR; successful GR depends on two principles: 1) the network topology maintains stable; 2) the node maintains non-stop data forwarding during IS-IS protocol restart.

There are two roles in GR: Restarter and Helper. Accordingly, IS-IS GR can be functionally divided into IS-IS GR Restart Capability and IS-IS GR Help Capability. Devices with GR Restart Capability can send GR requests and proactively execute graceful restart, while devices with GR Help Capability can receive GR requests and help the neighbor to execute graceful restart. The process of GR starts with the sending of GR requests by Restarter. The neighbor devices will enter Help mode after receiving such GR requests and assist Restarter to rebuild link-state database while maintaining the adjacencies with Restarter. The main operating mechanism is shown below:

When proceeding with IS-IS GR, the device will advertise its neighbors to maintain their adjacencies, so that the other devices on the network will not perceive the network change. The topological relationships will remain unchanged, and the neighbors will not recalculate routes and update the forwarding table. On the other hand, the link-state database will be synchronized and restored under the aid of neighbors, so that routes and forwarding table remain unchanged after GR, ensuring continuity of data forwarding.

During graceful restart of Restarter, the following steps will be involved:

- GR Restarter advertises the GR Helpers of such restart

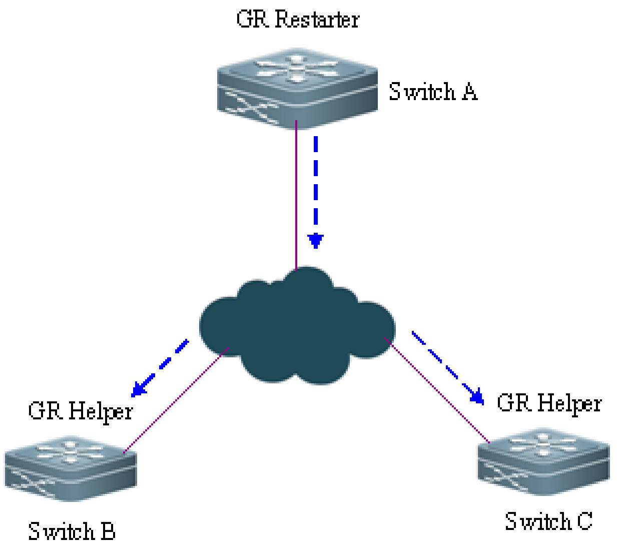


Figure 3 Restart of Restarter by advertising

As shown in Fig 3, Switch A is GR Restarter, Switch B and Switch C are GR Helpers of Switch A. Switch A sends GR requests to all its neighbors, as it needs to maintain the adjacencies during the process of GR. After receiving such requests, all neighbors will maintain the adjacencies with GR Restarter during the GR time (GR grace-period) advertised by the Restarter and send GR replies to Restarter.

- Restart of GR Restarter

As shown in Fig 4, when the GR Restarter proceeds with IS-IS restart, its IS-IS interface will undergo the process from Down to Up. Since the Helper is aware of the protocol restart state of Restarter, it will maintain its adjacency with GR Restarter and the routes acquired from GR Restarter during GR Time.

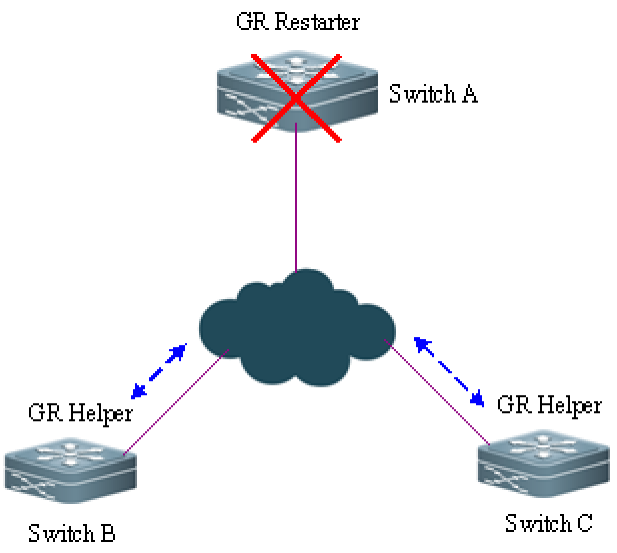

Figure 4 Restart of Restarter

- GR Restarter synchronizes with GR Helper and acquires the topology and routing information

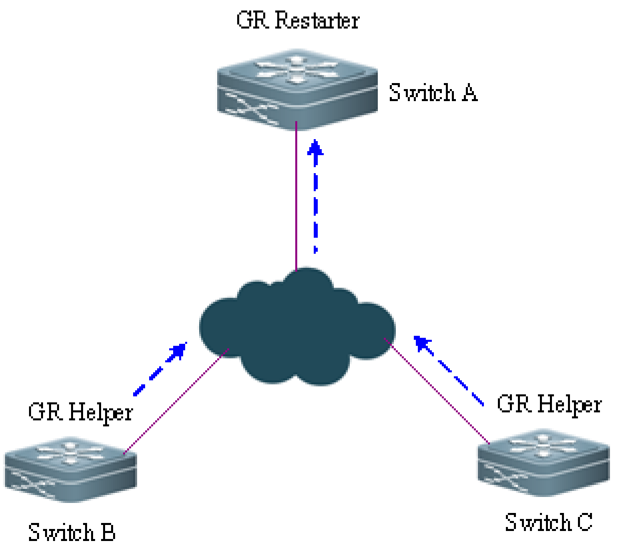

Figure 5 Database synchronization

As shown in Fig 5, after IS-IS protocol restart, GR Restarter will synchronize with GR Helper to acquire topology or routing information, and recalculate its own routing table accordingly. During this process, the forwarding table will not be updated by the routing table.

- GR Restarter completes database synchronization and graceful restart. All devices enter into IS-IS standard protocol interaction state.

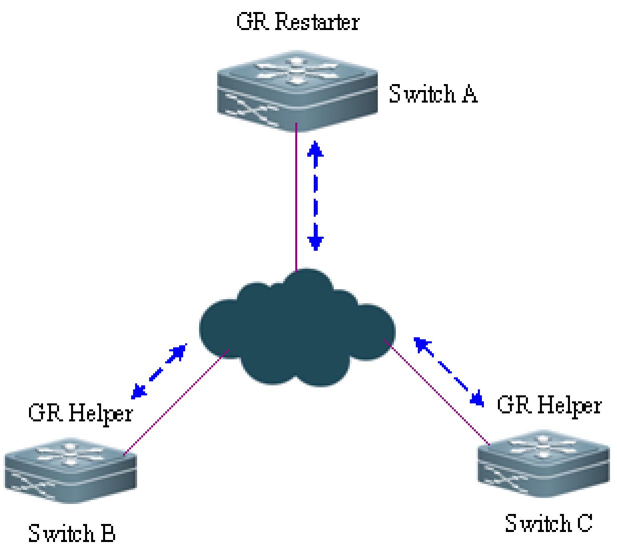

Figure 6 Completion of graceful restart

As shown in Fig 6, Restarter has completed data synchronization and all devices have entered into IS-IS standard protocol interaction state. By this time, the forwarding table will be updated by the routing table of Restarter and invalid entries will be deleted. Since the network maintains stable and Restarter has perfectly restored to the state before restart (completing graceful restart), its routing and forwarding tables will remain unchanged after the restart.

Use of IS-IS GR

GR of routing protocols is usually used to improve the system's reliability in the system that supports separation of the control panel and forwarding panel, thus realizing continued forwarding. IS-IS GR Restart capability depends on products.

When IS-IS GR Restarter capability is enabled, configure the IS-IS adjacency holdtime to no less than 40 seconds on devices with multiple management boards to ensure graceful restart of IS-IS triggered by switch of management boards. It can be achieved by configuring the isis hello-interval and isis hello-multiplier commands. If the holdtime value is less than 40 seconds, the holdtime value in the Hello packet header is set to 40 seconds by default.

The IS-IS GR Help capability only depends on software version. If the software supports IS-IS, the device is equipped with IS-IS GR Help capability.

Configuring IS-IS GR Restarter

To enable IS-IS graceful restart GR Restart capability, you must configure the graceful-restart command to enable graceful restart:

Command	Definition
Ruijie # **configure terminal**	Enters global configuration mode.
Ruijie (config)# **router isis**	Opens IS-IS and enters IS-IS configuration mode.
Ruijie(config-router)# **graceful-restart grace-period seconds**	(Optional) Configures the restart cycle GR Time (default value: 300 seconds).

Ruijie (config-router)# **end**	Returns to privileged mode.
Ruijie # **show isis graceful-restart**	Verifies the configuration.
Ruijie # **write**	(Optional) Save the configuration.

Configuring IS-IS GR Helper

IS-IS GR Help capability is enabled by default. You can also disable GR Help. The following example shows how to disable GR Help capability and re-enable it:

Command	Definition
Ruijie # **configure terminal**	Enters global configuration mode.
Ruijie (config)# **router isis**	Opens IS-IS and enters IS-IS configuration mode.
Ruijie(config-router)# **graceful-restart helper disable**	Disables IS-IS GR Restarter capability on the neighbor of Restarter. The capability is enabled by default.
Ruijie (config-router)# **no graceful-restart helper disable**	Re-enables IS-IS GR Help capability and restores it to the default action.
Ruijie (config-router)# **end**	Returns to privileged mode.
Ruijie # **show isis graceful-restart**	Verifies the configuration.
Ruijie # **write**	(Optional) Save the configuration.

Configuring Linkage between IS-IS and BFD

The IS-IS protocol detects neighbors through Hello packets. After BFD detection is enabled with IS-IS, BFD session is established for the UP neighbors to monitor the neighbor status, Once the BFD neighbor is DOWN, IS-IS performs immediate convergence. The convergence time is reduced to 1s from 30s(by default, IS-IS Hello packets sending interval is 10s on a point-to-point network, and the failure time of the neighbor device is three times of the interval, that is, 30s),

In normal cases, BFD send detecting packets to detect link state with intervals in milliseconds. When the link gets abnormal, for example, the link is disconnected, BFD can detect link anomaly quickly and inform IS-IS to delete neighbors and neighbors-reachable information in LSP packets. IS-IS performs routing calculation again to generate new a route, avoiding the abnormal link and achieving fast convergence, With the introduction of new technologies such as Multi-Service Transport Platform (MSTP), link is congestion-prone in peak periods of data communication. In congestion, BFD can detect link anomaly quickly and inform IS-IS to delete neighbors and neighbors-reachable information in LSP packets. Besides, BFD perform the link switch to avoid congestion. As the IS-IS neighbor detects that the interval to send Hello packets is 10s and the timeout period is 30s. When BFD detects anomaly, the router can receive IS-IS and establish IS-IS adjacency relation. The route restores to the congested link and performs BFD detection again. BFD repeats the process of detecting link anomaly and performing link switch, making the route switched to either the congested link or other links and causing congestion.

Anti-congestion is enabled to avoid routing congestion caused by link congestion. Thus in link congestion, the IS-IS neighbor remains but the neighbor-reachable information is deleted in LSP packets. The route is switched to the non-congested link. After the link restores to normal, or rather non-congested, the neighbor-reachable information in LSP packets is restored and the route is switched back, avoiding routing congestion.

When IS-IS enables anti- congestion, both the **bfd all-interfaces** [**anti-congestion**] and the **bfd up-dampening** commands must be configured on the interface. Configuring only one command may cause ineffective anti- congestion or other network anomalies.

Command	Definition
Ruijie(config-router)# **bfd all-interfaces** [**anti-congestion**]	Enables linkage between IS-IS and BFD on all interfaces.
Ruijie(config-if)# **isis bfd** [**disable** | **anti-congestion**]	Enables or disables linkage between IS-IS and BFD on the interface.

Note

The BFD session needs to be set on the interface before configuring IS-IS with BFD.

Note

When the interface is configured with the **bfd up-dampening** command, the **bfd all-interfaces** [**anti-congestion**] command must be enabled if IS-IS is used with BFD on the interface.

Note

The **bfd all-interfaces** [**anti-congestion**] command must be configured together with the **bfd up-dampening** command on the interface.

Note

IP routing may cause inconsistency between the specified interface and the actual outbound interface of BFD packets, therefore the BFD session cannot be established.

Note

If the specified interface is not the actual inbound interface of BFD packets, the BFD session cannot be established.

Configuring IS-IS OVERLOAD

If the OVERLOAD flag in a non-virtual LSP packet, IS-IS neighbors can be notified for not using a local node as a transit device.

Command	Function
Ruijie(config-router)# **set-overload-bit** [**on-startup** *seconds*] [**suppress** { [**interlevel**] [**external**] }] [**level-1** | **level-2**]	Sets the OVERLOAD flag.

The OVERLOAD flag is used in the following three cases:

- Device overload

If the overload (such as memory insufficiency and CPU full load) occurs on a local IS-IS node, the local routing table will be incomplete or contain no resource transit data. At this time, you can set the OVERLOAD flag in the LSP packet to notify the neighbors for not using the local node as a transit device.

In this case, the configuration does not carry the keyword on-startup, and the user must manually set or cancel the OVERLOAD flag. The user must manually cancel the OVERLOAD flag when the local IS-IS node recovers. Otherwise, the local IS-IS node will always stay in the OVERLOAD state.

- Instant black hole

In the scenario described in RFC3277, an instant black hole (instant blocked route) may occur after the IS-IS node is restarted because the IS-IS convergence speed is faster than that of BGP.

In this case, the configuration must carry the keyword on-startup. The IS-IS node automatically set or cancel the OVERLOAD flag based on the configuration. After the on-startup option is selected, an instant black hole occurs on the IS-IS node after it is restarted. Once a new neighbor relationship is created, the LSP packet carrying the OVERLOAD flag is sent for notifying the neighbor that there is an instant black hole on the local node and therefore do not use the local node as a transit device. When the specified period times out, the IS-IS node immediately sends the LSP packet where the OVERLOAD flag is canceled. This LSP packet notifies the neighbor that the instant black hole does not exist on the local node any more and therefore the neighbor can use the local node as a transit device.

- Requiring that the IS-IS node does not forward true data

The user may need the local IS-IS node to access the production network for experiments or other functions instead of forwarding true data on the network. At this time, the user can set the OVERLOAD flag in the LSP packet to notify the neighbors for not using the local node as a transit device.

In this case, the configuration does not carry the keyword on-startup, and the user must manually set or cancel the OVERLOAD flag. The user can configure the suppress function as required to suppress routing information carried in the LSP packet in the OVERLOAD state. If internal and external routes are suppressed, only the local directly-connected route is notified.

Configuring IS-IS VRF

Make sure VRF is configured before you binding the IS-IS instance to a VRF. To configure an IS-ISv6 neighbor, multi-protocol VRF must be configured and IPv6 must be enabled.

⚠ Caution The following restrictions should be noted for IS-IS and VRF bindings: 1. The IS-IS instances bound to a same VRF must be configured with different system IDs. While the IS-IS instances bound to different VRFs can share a system ID. 2. One IS-IS instance can be bound to only one VRF, and one VRF can be bound to multiple IS-IS instances. 3. When the VRF bound to an IS-IS instance changes, all the interfaces associated with the instance and the redistribution in routing process configuration mode will be removed accordingly.

Execute the following command to configure IS-IS VRF:

Command	Function
Ruijie(config-router)# **vrf** *vrf-name*	Binds an IS-IS instance to a VRF.

Configuring IS-IS SNMP

By default, SNMP software can perform MIB on the first IS-IS instance displayed by the system. If you want to perfom MIB on another instance, specify it manually.

Execute the following command in IS-IS routing process configuration mode to bind the instance used for IS-IS MIB operation:

Command	Function
Ruijie(config-router)# **enable mib-binding**	Binds the current instance to perform MIB.

There are 18 types of IS-IS packets. Based on different features, they are divided into several sets and each set includes several types of IS-IS TRAP packets. Enable IS-IS TRAP globally in global configuration mode (with the **snmp-server enable traps isis** command), specify the host receiving TRAP packets, and use this command to specify the types of IS-IS TRAP packets allowed to be sent in IS-IS routing process configuration mode. Then IS-IS packets can be transmitted.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)#**snmp-server enable traps isis**	Enables IS-IS TRAP globally.

Ruijie(config)#**snmp-server host** 10.1.1.1	Configures global SNMP host and receives IS-IS TRAP packets.
Ruijie(config)#**router isis**	Enters IS-IS routing pricess configuration mode
Ruijie(config-router)# **enable traps all**	Allows all IS-IS TRAP packets to be sent to the host 10.1.1.1.

Configuring Other IS-IS Parameters

Configuring IS-IS Interface Metric

You can configure the interface metric, which must be configured in interface configuration mode as follows:

Command	**Function**
Ruijie(config-if)# **isis metric metric** [**level-1**| **level-2**]	Configures the metric for the interface. This value is only effective when metric-style includes narrow mode.
Ruijie(config-if)# **isis wide-metric metric** [**level-1** | **level-2**]	Configures the wide-metric for the interface. This value is only effective when metric-style includes wide mode.

Configuring the Priority Level of the Specified Routing Node

In the broadcast network, IS-IS needs to elect a designed routing node (DIS) among all routing nodes. The designated router will then create Pseudonode and generate Pseudonode LSP. In the broadcast network, the DIS is elected by priority, and the user can configure different priority values for different Levels. You can set different priority for different Levels. Complete the following configuration in interface configuration mode to set router priority for election:

Command	**Function**
Ruijie(config-if)# **isis priority value** [**level-1** | **level-2**]	Configures the priority for designated router election on the interface.

Caution

The no isis priority command is used to restore the default priority no matter whether the parameter is followed. If you want to modify the configured priority, you can either use isis priority command with parameter specified to overwrite the configured command directly, or configure a new parameter after restoring the priority to the default value.

Configuring to Generate a Default Route

By default, L2 routers don't generate a default route. Execute the following command in IS-IS protocol configuration mode to generate a default route:

Command	**Function**

Ruijie(config-router)# **default-information originate** [*route-map map-name*]	Generates a Level-2 default route and publishes through LSP. If the route-map option is specified, the default route can be generated only when the condition in the route-map is matched.

Configuring Convergent Route

You can create a convergent route to represent a group of routes in the routing table. The process is called route convergence. One convergent route can include multiple routes in a Level. The interface metric of the convergent route is the smallest one of all routes. Complete the following configuration in IS-IS protocol configuration mode to set the route convergence:

Command	Function
Ruijie(config-router)#**summary-address ip-address net-mask** [**level-1** | **level-2** | **level-1-2**]	Sets convergent route.

Route convergence in IS-ISv6 protocol should be set in IS-ISv6 protocol configuration mode:

Command	Function
Ruijie(config-router)# **address-family ipv6 unicast** Ruijie(config-router-af)# **summary-prefix** *ipv6-prefix* / *prefix-length* [**level-1** | **level-2** | **level-1-2**]	Sets IS-IS IPv6 convergent route.

Configuring to Ignore LSP Authentication and Verification Errors

When local IS-IS receives LSP packet, the LSP packet needs to be verified and calculated. In addition, the calculation result is compared with the verification in the LSP packet. That is, the received LSP packet needs to be verified and authenticated. By default, if the calculation result is different from the verification in the LSP packet, the LSP packet is discarded and not processed. If you run the ignore-lsp- errors command to ignore the verification error, the LSP packet is processed normally even an error is verified. The configuration to ignore LSP authentication and errors must be performed in IS-IS protocol configuration mode:

Command	Function
Ruijie(config-router)#**ignore-lsp-errors**	Configures to Ignore LSP authentication and verification errors.

Configuring to Open Adjacent Event Output Switch

To log events when the IS-IS adjacency changes, you need to open the adjacent event output switch. Complete the following configuration in IS-IS protocol configuration mode to set the adjacent event output switch:

Command	Function
Ruijie(config-router)# **log-adjacency-changes**	Enable the logging of IS-IS adjacency change.

Configuring Route Redistribution

Route redistribution can redistribute one routing protocol's routing information to another routing protocol. Route redistribution must be configured in IS-IS configuration mode or IS-IS address-family ipv6 mode:

Caution

In case there are IS-IS Level-2 instances, all IS-IS Level-1 routes will by default be automatically redistributed into IS-IS Level-2 in these instances. Of course, you can also disable the redistribution from Level-1 into Level-2 by executing "no redistribute isis [tag] level-1 into level-2". You can also filter the redistributed Level-1 routes by executing "redistribute isis [tag] level-1 into level-2 {distribute-list access-list-name| route-map route-map-name}”.

Caution

2. Configure no redistritbue {bgp | ospf <1-65535> | rip | connected | static} to disable protocol redistribution. If no redistribute is followed by any other parameter, it means that this parameter is restored to the default setting instead of disabling protocol redistribution. For example: no redistribute bgp will disable bgp redistribution, while no redistribute bgp route-map aa will disable route-map aa filtering during redistribution instead of disabling bgp redistribution.

Caution

3. In the old version software developed by some manufacturers, after configuring metric-type as external, the metric of redistributed route will be added by 64 during route calculation, and the route will be selected according to metric value. This has violated the protocol. In actual applications, the external route may have higher priority than the internal route. During the intercommunication with such manufacturers, if this problem exists, relevant configurations of devices can be adjusted (such as metric or metric-type) to ensure internal routes have higher priority than the external routes.

Monitoring and Maintaining IS-IS

View IS-IS's link status database and transmission and reception of various packets and calculation of SPF through the following configuration and operation to confirm maintenance of IS-IS route.

Command	Function
Ruijie# **show isis** [*tag*] **database** [*FLAGS* | *LEVEL* | *LSPID*]	Displays IS-IS link-state database.
Ruijie# **show isis** [*tag*] **neighbors** [**detail**]	Displays IS-IS neighbors.
Ruijie# **show isis** [*tag*] **virtual-neighbors**	Displays IS-IS neighbors in virtual system.
Ruijie# **show isis** [*tag*] **interface** [*interface-type interface-number*]	Displays IS-IS interface information.
Ruijie# **show isis** [*tag*] **topology** [**l1** | **l2** | **level-1** | **level-2**]	Displays IS-IS connection topology.
Ruijie# **show isis** [*tag*] **ipv6 topology** [**l1** | **l2** | **level-1** | **level-2**]	Displays IS-IS IPv6 unicast topology.
Ruijie# **show isis** [*tag*] **counter**	Displays various statistics of IS-IS.
Ruijie# **show isis** [*tag*] **hostname**	Displays the mapping relation between the device hostname and System ID.
Ruijie# **show isis** [*tag*] **mesh-groups**	Displays the mesh group configurations on each interface.
Ruijie# **show isis** [*tag*] **graceful-restart**	Displays IS-IS GR status.
Ruijie# **show isis** [*tag*] **protocol**	Displays the IS-IS protocol.

For detailed explanation of commands, please refer to *IS-IS Commands*.

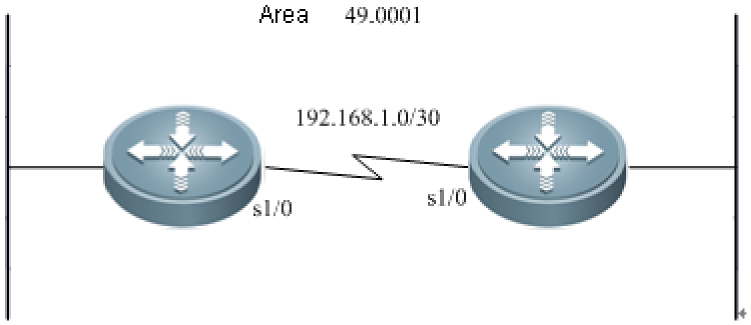
IS-IS Configuration Examples

IS-IS Point-to-Point Serial Link Configuration Example

- Requirement

The connection layout and IP address distribution are shown in Fig 7. A point-to-point network is configured between Device A and Device B.

Figure 7 IS-IS point-to-point serial link configuration



- Detailed configurations

Device A:

Configuring IS-IS routing protocol

```
Ruijie(config)# router isis
Ruijie(config-router)# net 49.0001.0000.0000.0001.00
```

Configuring the Ethernet interface

```
Ruijie(config)# interface GigabitEthernet 0/0
Ruijie(config-if)# ip address 10.1.1.1 255.255.255.0
Ruijie(config-if)# ip router isis
```

Device B:

Configuring IS-IS routing protocol

```
Ruijie(config)# router isis
Ruijie(config-router)# net 49.0001.0000.0000.0002.00
```

Configuring the Ethernet interface

```
Ruijie(config)# interface GigabitEthernet 0/0
Ruijie(config-if)# ip address 10.1.1.2 255.255.255.0
Ruijie(config-if)# ip router isis
```

Device C:

Configuring IS-IS routing protocol

```
Ruijie(config)# router isis
Ruijie(config-router)# net 49.0001.0000.0000.0003.00
```

Configuring the Ethernet port

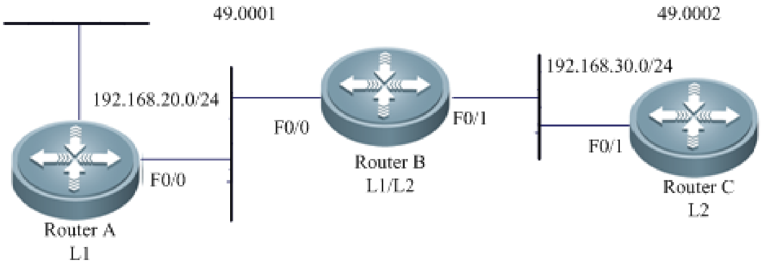
```
Ruijie(config)# interface GigabitEthernet 0/0
Ruijie(config-if)# ip address 10.1.1.3 255.255.255.0
Ruijie(config-if)# ip router isis
```

IS-IS Broadcast Multipoint Link Configuration Example

- Requirement

The connection layout and IP address distribution are shown in Fig 8. Device A, Device B and Device C are interconnected through Ethernet, running the IS-IS routing protocol. Device A is Level-1 node, Device B is Level1-2 node and Device C is Level-2 node. It is required that Hello packets between Device A and Device B, Level-1 LSP and SNP packets adopt plaintext authentication, Hello packets between Device B and Device C, Level-2 LSP and SNP packets adopt MD5 encryption authentication,

Figure 8 IS-IS broadcast multipoint link configuration



- Detailed configurations

Device A:

Configuring IS-IS routing protocol

```
Ruijie(config)# router isis
Ruijie(config-router)# net 49.0001.0000.0000.0001.00
```

Configuring Ethernet interface

```
Ruijie(config)# interface FastEthernet 0/0
Ruijie(config-if)# ip address 10.1.1.1 255.255.255.0
Ruijie(config-if)# ip router isis
```

Device B:

Configuring IS-IS routing protocol

```
Ruijie(config)# router isis
Ruijie(config-router)# net 49.0001.0000.0000.0002.00
```

Configuring Ethernet interface

```
Ruijie(config)# interface FastEthernet 0/0
Ruijie(config-if)# ip address 10.1.1.2 255.255.255.0
Ruijie(config-if)# ip router isis
```

Device C:

Configuring IS-IS routing protocol

```
Ruijie(config)# router isis
Ruijie(config-router)# net 49.0001.0000.0000.0003.00
```

Configuring Ethernet interface

```
Ruijie(config)# interface FastEthernet 0/0
Ruijie(config-if)# ip address 10.1.1.3 255.255.255.0
Ruijie(config-if)# ip router isis
```

IS-IS Authentication Configuration Example

- Requirement

Three devices are interconnected through Ethernet and run IS-IS routing protocol. The connection layout and IP address distribution are shown in Fig 9. Device A is a Level-1 router, Device B is a Level-1-2 router, and Device C is a Level-2 router. Hello packets exchanged between Device A and Device B shall be subject to plain-text authentication, and Level-1 LSP and SNP packets shall be subject to plain-text authentication. Hello packets exchanged between Device B and Device C shall be subject to MD5 encrypted authentication, and Level-2 LSP and SNP packets shall be subject to MD5 encrypted authentication.

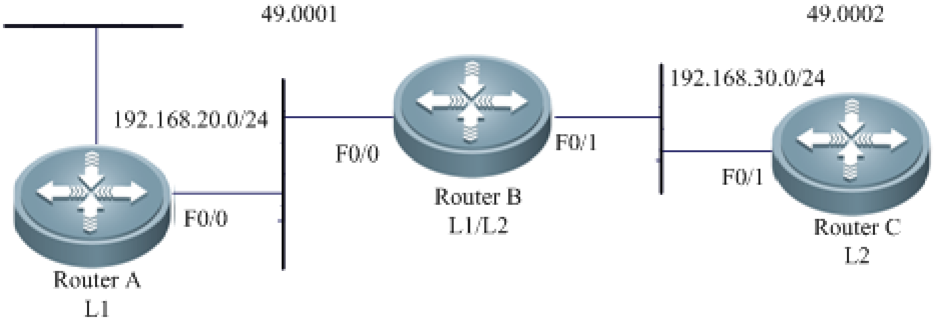


Figure 9 IS-IS authentication configuration

Detailed configurations

Device A:

Configuring IS-IS routing protocol

```
Ruijie(config)# router isis
Ruijie(config-router)# net 49.0001.0000.0000.0001.00
Ruijie(config-router)# is-type level-1
Ruijie(config-router)# area-password aa
```

Configuring Ethernet interface

```
Ruijie(config)# interface FastEthernet 0/0
Ruijie(config-if)# ip address 192.168.20.1 255.255.255.0
Ruijie(config-if)# ip router isis
Ruijie(config-if)# isis password cc
```

Device B:

Configuring the key chain used by IS-IS authentication:

```
Ruijie(config)# key chain kc1
Ruijie(config-keychain)# key 1
Ruijie(config-keychain-key)# key-string aa
Ruijie(config)# key chain kc2
Ruijie(config-keychain)# key 1
Ruijie(config-keychain-key)# key-string bb
Ruijie(config)# key chain kc3
Ruijie(config-keychain)# key 1
Ruijie(config-keychain-key)# key-string cc
```

Configuring IS-IS routing protocol

```
Ruijie(config)# router isis
Ruijie(config-router)# net 49.0001.0000.0000.0002.00
Ruijie(config-router)# authentication mode text level-1
Ruijie(config-router)# authentication key-chain kc1
Ruijie(config-router)# authentication mode md5 level-2
Ruijie(config-router)# authentication key-chain kc2
```

Configuring Ethernet interface

```
Ruijie(config)# interface FastEthernet 0/0
Ruijie(config-if)# ip address 192.168.20.2 255.255.255.0
Ruijie(config-if)# ip router isis
Ruijie(config-if)# isis authentication mode text
Ruijie(config-if)# isis authentication key-chain kc3
Ruijie(config)# interface FastEthernet 0/1
Ruijie(config-if)# ip address 192.168.30.2 255.255.255.0
Ruijie(config-if)# ip router isis
Ruijie(config-if)# isis authentication mode md5
Ruijie(config-if)# isis authentication key-chain kc3
```

Device C:

Configuring the key chain used by IS-IS authentication:

```
Ruijie(config)# key chain kc2
Ruijie(config-keychain)# key 1
Ruijie(config-keychain-key)# key-string bb
Ruijie(config)# key chain kc3
Ruijie(config-keychain)# key 1
Ruijie(config-keychain-key)# key-string cc
```

Configuring IS-IS routing protocol

```
Ruijie(config)# router isis
Ruijie(config-router)# net 49.0002.0000.0000.0002.00
Ruijie(config-router)# is-type level-2
Ruijie(config-router)# authentication mode md5 level-2
Ruijie(config-router)# authentication key-chain kc2
```

Configuring Ethernet interface

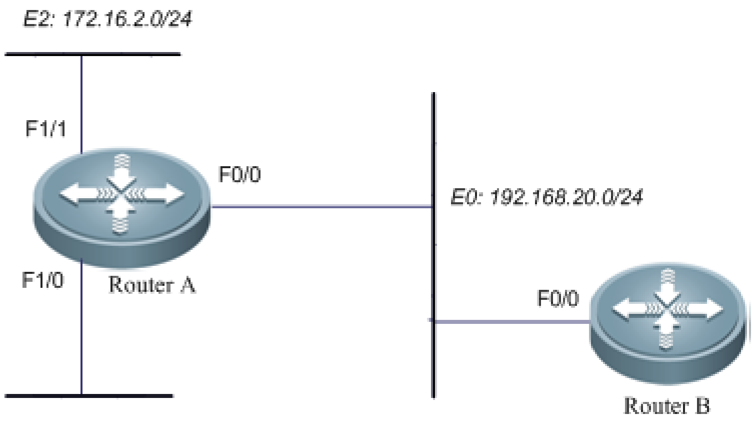
```
Ruijie(config)# interface FastEthernet 0/1
Ruijie(config-if)# ip address 192.168.30.3 255.255.255.0
Ruijie(config-if)# ip router isis
Ruijie(config-if)# isis authentication mode md5
Ruijie(config-if)# isis authentication key-chain kc3
```

IS-IS Route Summary

- Requirement

Two devices are connected through Ethernet. The IP address distribution and device layout are shown in Fig 10.

Figure 10 IS-IS route summary configuration



Requirement

1. Two devices run IS-IS route protocol.

2. Configure Router A, so that Router A only advertises the route of 172.16.0.0/22 instead of routes of 172.16.1.0/24 and 172.16.2.0/24.

■ Detailed configurations

Device A:

Configuring IS-IS routing protocol

```
Ruijie(config)# router isis
Ruijie(config-router)# net 49.0001.0000.0000.0001.00
Ruijie(config-router)# summary-address 172.16.0.0/16 level-1-2
```

Configuring Ethernet interface

```
Ruijie(config)# interface FastEthernet 0/0
Ruijie(config-if)# ip address 192.168.20.1 255.255.255.0
Ruijie(config-if)# ip router isis
Ruijie(config)# interface FastEthernet 1/0
Ruijie(config-if)# ip address 172.16.1.1 255.255.255.0
Ruijie(config-if)# ip router isis
Ruijie(config)# interface FastEthernet 1/1
Ruijie(config-if)# ip address 172.16.2.1 255.255.255.0
Ruijie(config-if)# ip router isis
```

Device B:

Configuring IS-IS routing protocol

```
Ruijie(config)# router isis
Ruijie(config-router)# net 49.0001.0000.0000.0002.00
```

Configuring Ethernet interface

```
Ruijie(config)# interface FastEthernet 0/0
Ruijie(config-if)# ip address 192.168.20.2 255.255.255.0
Ruijie(config-if)# ip router isis
```

Execute show ip route on Device B to see only one summary address:

```
Ruijie(config)# show ip route
i L1   172.16.0.0/16 [115/20] via 192.168.20.1, FastEthernet0/0
```

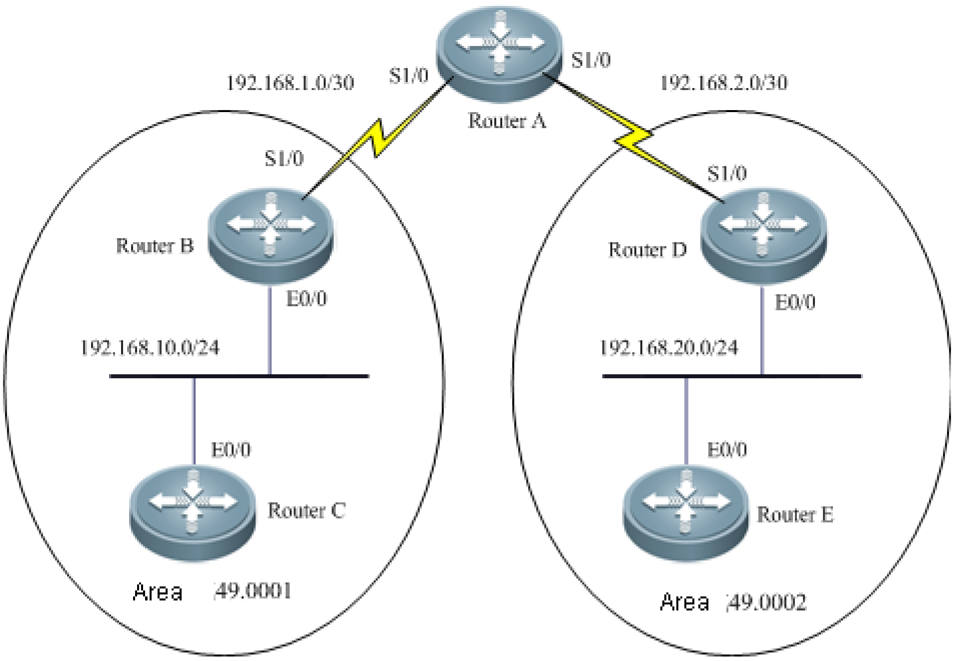
⚠ Caution If Level is no specified when summary-address is used, only Level-2 routes will be summarized by default.

IS-IS Level Configuration Example

- Requirement

See Fig 7 for allocation of IP addresses and connection of devices. P2P serial link connection is deployed between Device A and Device B and C respectively; Ethernet connection is deployed between Device B and Device C; Ethernet connection is deployed between Device D and Device E.

Figure 11 IS-IS level configuration



You need to configure IS-IS area route summary on Router A. Area route summary can only be configured on an area border device.

- Detailed configurations

Device A:

Configuring IS-IS routing protocol

```
Ruijie(config)# router isis
Ruijie(config-router)# net 50.0001.0000.0000.0001.00
Ruijie(config-router)# is-type level-2-only
```

Configuring serial link interface

```
Ruijie(config)# interface Serial 1/0
Ruijie(config-if)# ip address 192.168.1.1 255.255.255.252
Ruijie(config-if)# ip router isis
Ruijie(config)# interface Serial 1/1
Ruijie(config-if)# ip address 192.168.2.1 255.255.255.252
Ruijie(config-if)# ip router isis
```

Device B:

Configuring IS-IS routing protocol

```
Ruijie(config)# router isis
Ruijie(config-router)# net 49.0001.0000.0000.0002.00
```

Configuring Ethernet interface

```
Ruijie(config)# interface GigabitEthernet 0/0
Ruijie(config-if)# ip address 192.168.10.1 255.255.255.0
Ruijie(config-if)# ip router isis
```

Configuring serial link interface

```
Ruijie(config)# interface Serial 1/0
Ruijie(config-if)# ip address 192.168.1.2 255.255.255.252
Ruijie(config-if)# ip router isis
```

Device C:

Configuring IS-IS routing protocol

```
Ruijie(config)# router isis
Ruijie(config-router)# net 49.0001.0000.0000.0003.00
Ruijie(config-router)# is-type level-1
```

Configuring Ethernet interface

```
Ruijie(config)# interface GigabitEthernet 0/0
Ruijie(config-if)# ip address 192.168.10.2 255.255.255.0
Ruijie(config-if)# ip router isis
```

Device D:

Configuring IS-IS routing protocol

```
Ruijie(config)# router isis
Ruijie(config-router)# net 49.0002.0000.0000.0004.00
```

Configuring Ethernet interface

```
Ruijie(config)# interface GigabitEthernet 0/0
Ruijie(config-if)# ip address 192.168.20.1 255.255.255.0
Ruijie(config-if)# ip router isis
```

Configuring serial link interface

```
Ruijie(config)# interface Serial 1/0
Ruijie(config-if)# ip address 192.168.2.2 255.255.255.252
Ruijie(config-if)# ip router isis
```

Device E:

Configuring IS-IS routing protocol

```
Ruijie(config)# router isis
Ruijie(config-router)# net 49.0002.0000.0000.0005.00
Ruijie(config-router)# is-type level-1
```

Configuring Ethernet interface

```
Ruijie(config)# interface GigabitEthernet 0/0
Ruijie(config-if)# ip address 192.168.20.2 255.255.255.0
Ruijie(config-if)# ip router isis
```

IS-ISv6 Simplest Configuration

- Requirement

The connection layout and IPv6 address distribution are shown in Fig 12. Device A and Device B are interconnected through Ethernet.

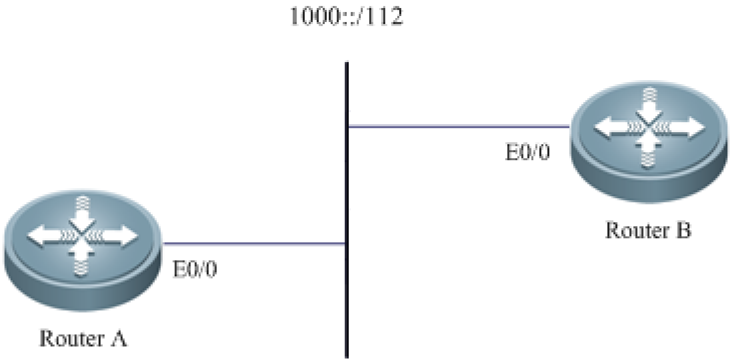


Figure 12 IS-ISv6 configuration

- Detailed configurations

Device A:

Configuring IS-IS routing protocol

```
Ruijie(config)# router isis
Ruijie(config-router)# net 49.0001.0000.0000.0001.00
```

Configuring Ethernet interface

```
Ruijie(config)# interface GigabitEthernet 0/0
Ruijie(config-if)# ipv6 address 1000 ::1/112
Ruijie(config-if)# ipv6 router isis
```

Device B:

Configuring IS-IS routing protocol

```
Ruijie(config)# router isis
Ruijie(config-router)# net 49.0001.0000.0000.0002.00
```

Configuring Ethernet interface

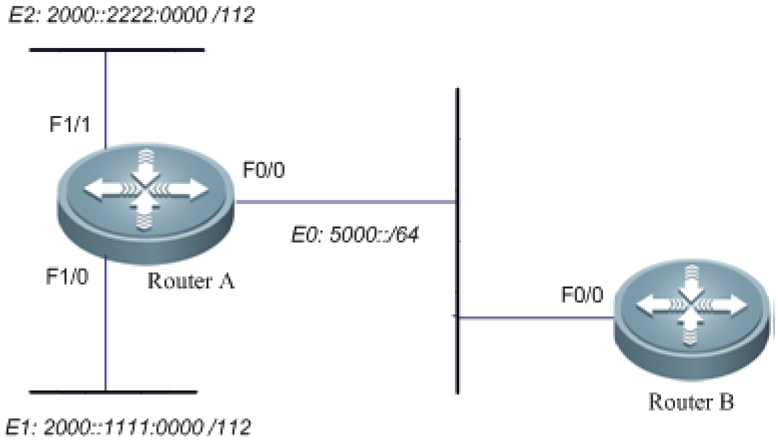
```
Ruijie(config)# interface GigabitEthernet 0/0
Ruijie(config-if)# ipv6 address 1000 ::2/112
Ruijie(config-if)# ipv6 router isis
```

IS-ISv6 Route Summary

- Requirement

Two devices are connected through Ethernet. See Fig 13 for allocation of IP addresses and connection of devices.

Figure 13 IS-ISv6 route summary configuration



Requirement

Two devices run IS-ISv6 route protocol.

Configure Router A, so that Router A only advertises the route of 2000::/96 instead of routes of 2000::1111:0/112 and 2000::2222::0/112.

Detailed configurations

Device A:

```
Configuring IS-IS routing protocol
Ruijie(config)# ipv6 unicast-routing
Ruijie(config)# router isis
Ruijie(config-router)# net 49.0001.0000.0000.0001.00
Ruijie(config-router)# address-family ipv6 unicast
Ruijie (config-router-af)# summary-prefix 2000::/96 level-1-2
Ruijie (config-router-af)# exit-address-family
Configuring Ethernet interface
Ruijie(config)# interface FastEthernet 0/0
Ruijie(config-if)# ipv6 address 5000::1/64
Ruijie(config-if)# ipv6 router isis
Ruijie(config)# interface FastEthernet 1/0
Ruijie(config-if)# ipv6 address 2000::1111:0001/112
Ruijie(config-if)# ipv6 router isis
Ruijie(config)# interface FastEthernet 1/1
Ruijie(config-if)# ipv6 address 2000::2222:0001/112
Ruijie(config-if)# ipv6 router isis
```

Device B:

```
Configuring IS-IS routing protocol
Ruijie(config)# ipv6 unicast-routing
Ruijie(config)# router isis
Ruijie(config-router)# net 49.0001.0000.0000.0002.00
Configuring Ethernet interface
Ruijie(config)# interface FastEthernet 0/0
Ruijie(config-if)# ipv6 address 5000::2/64
Ruijie(config-if)# ipv6 router isis
```

Execute "show ipv6 route" on Device B to see only one summary address:

```
Ruijie(config)# show ipv6 route
I1  2000::/96 [115/20]    via FE80::C800:1BFF:FEF8:1C, FastEthernet1/0
```

Caution

If Level is no specified when summary-prefix is used, only Level-2 routes will be summarized by default.

Configuring NHRP

Overview

Next Hop Resolution Protocol (NHRP) is defined by the IETF in RFC 2332. It is used to enable a source node (a host or router) on a non-broadcast multiple access (NBMA) network to obtain the Internet address and NBMA subnet address of "the next hop" destined to the destination node.

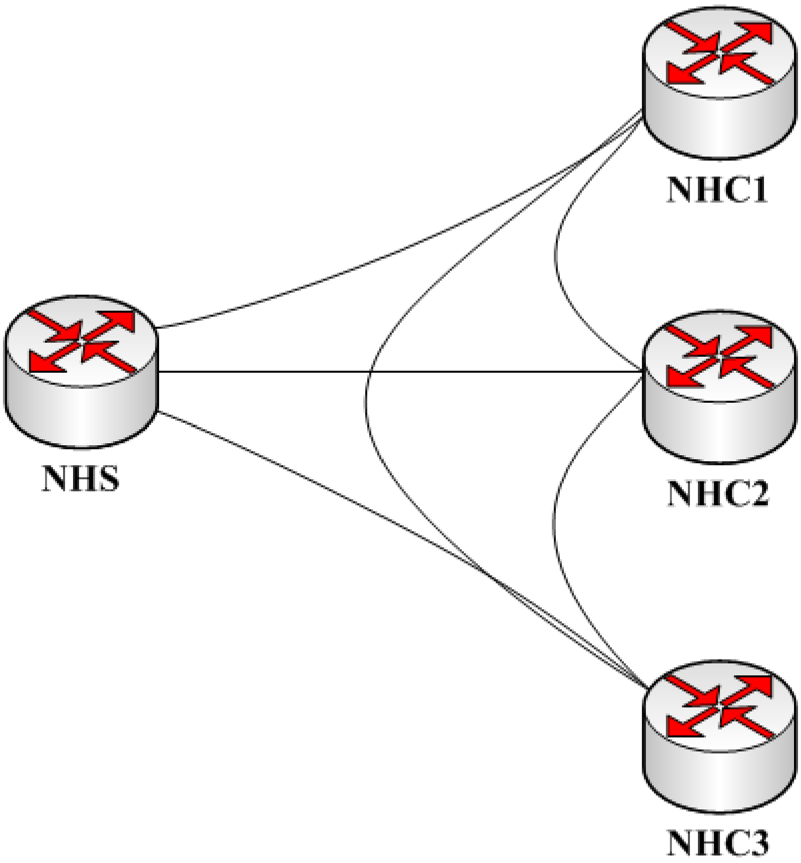
NHRP is a typical client/server protocol and comprises the Next Hop Server (NHS) and Next Hop Clients (NHCs). Each subnet comprises at least one NHS. One NHS can serve multiple subnets and receive request and resolution packets from multiple NHCs. Each end system is an NHC.

Working Principle

NHRP is similar to ARP that is used to complete resolution from IP addresses to MAC addresses. NHRP is used to complete resolution from internal VPN addresses to NBMA addresses (external addresses).

An NHS is used to maintain the NHRP database at the public IP address of each branch NHC. A branch NHC registers the IP address of its external port to the central router NHS through NHRP. The branch NHC can use a dynamic IP address. When the branch NHC wants to establish a direct tunnel with other branch NHCs, the branch NHC queries the NHRP database of the NHS for resolution to determine the real addresses of the other branch NHCs and make redundancy of the addresses to its own NHRP database. In this way, a branch NHC can dynamically join a network, which addresses the problem of establishing VPN tunnels through dynamic IP addresses. In addition, the branch NHC can directly exchange data with other branch NHCs by using the resolved addresses, rather than using the NHS for transmission, finally forming a mesh topology.

Figure 0-1 NHRP network topology



Negotiation packets of NHRP fall into the following types:

- NHRP Resolution Request: NHRP resolution request packet. For packets with uncertain mapping between IP addresses and NBMA addresses, an NHC sends a resolution request packet to the NHS for negotiation and obtain the mapping.
- NHRP Resolution Reply: NHRP resolution reply packet. After receiving the request, the NHS queries its cache table and sends the query result as the reply information to the NHC for address negotiation.
- NHRP Registration Request: NHRP registration request packet. After the NHC joins the network, the NHC needs to register the mapping between its IP address and NBMA address to the NHS in the current network. Therefore, the NHC sends a registration request packet to the NHS and registers itself to the NHS cache table.
- NHRP Registration Reply: NHRP registration reply packet. After receiving the registration request packet, the NHS stores the registration information into its cache table and sends an NHRP registration reply packet based on the registration result.
- NHRP Purge Request: NHRP purge request packet. When either NHRP party wants to purge the cache of a peer, the NHRP party will send an NHRP purge request packet.
- NHRP Purge Reply: NHRP purge reply packet. After receiving the NHRP purge request packet, the peer will send a reply packet to the purge requester based on the cache purge result.
- NHRP Error Indication: NHRP error indication packet. If a receiving error packet is generated during NHRP negotiation, this packet will be send to the original sender.

The two primary work processes of NHRP are the registration process and resolution process.

Registration Process

An NHC needs static cache, which is used to cache the mapping between the IP address and NBMA address of the NHS in the current network. The NHC generates and sends a registration request packet to the NHS. After receiving the packet, the NHS will generate dynamic cache, and generate and send a registration reply packet to the NHC for registration.

Resolution Process

When no NBMA address is found for the mapped IP address, the NHS and NHC will send a resolution request packet for negotiation about a proper address.

As shown in the figure above, HHC1 wants to ping the IP address of NHC2. The resolution negotiation process is as follows:

- When pinging packets, NHC1 queries the NBMA address mapped to the IP address of NHC2. Since no address is resolved, NHC1 sends a resolution request packet to the NHS.
- After receiving the resolution request packet, the NHS sends the corresponding registration cache entry of NHC2 to NHC1 as a resolution reply packet. In this way, NHC1 has learned the NBMA address mapped to the IP address destined to NHC2.
- After the ping packet reaches NHC2, NHC2 will send an ICMP reply packet. Since the source IP address of the ping packet is unresolved, NHC2 also sends a request packet to the NHS to resolve the correct address of NHC1 by following the method of NHC1.
- Then, data packets from NHC1 to NHC2 will be transmitted through the direct route between them, rather than be transmitted through the NHS, forming a mesh network.

If the NHRP resolution request is triggered by a data packet, NHC1 will select one of the following methods to process the data packet when waiting for an NHRP resolution response:

① Releases a data packet.

② Retains the data packet until the NHRP resolution response arrives and another optimum path is available.

③ Sends a data packet along the route.

Method ③ is the recommended default policy since it can resolve subnet-layer addresses as well as send data flows to destination sites.

Protocols and Standards

RFC 2332.

Default Configuration

NHRP is disabled by default.

Configuring NHRP

Enabling NHRP

The NHRP function can take effect on an interface only after it is enabled.

	Command	Description
Step 1	Ruijie(config)#**interface tunnel** *tunnel-number*	Enters a tunnel interface to start NHRP configuration.
Step 2	Ruijie(config-Tunnel *tunnel-number*)#**tunnel mode gre ip**	Configures the tunnel type as GRE. This type of tunnels is used to form a star topology. The tunnel type of the NHS must be MGRE.
	Or:	
	Ruijie(config-Tunnel *tunnel-number*)#**tunnel mode gre multipoint**	Configures the tunnel type as MGRE. This type of tunnels is used to form a mesh topology. The tunnel type of the NHS must be MGRE.
Step 3	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp network-id***nhrp-number*	Enables the NHRP function on a tunnel interface. *nhrp-number*: Indicates a 32-bit ID. <1-4294967295>.
	Ruijie(config-Tunnel *tunnel-number)*#**no ip nhrp network-id**	Disables the NHRP function.

Caution The NHRP function must be enabled on a tunnel interface and support only GRE and MGRE tunnels.

Example 1: Enable the NHRP function on a tunnel interface.

```
Ruijie(config)#interface tunnel1
Ruijie(config-Tunnel 1)#ip nhrp network-id1
```

Configuring Static IP-Address and NBMA-Address Mapping Cache

The IP-address and NBMA-address mapping cache of NHRP may be either static or dynamic. Static mapping cache can be manually configured whereas dynamic mapping cache is learned by sending protocol packets.

	Command	Description
Step 1	Ruijie(config)#**interface tunnel** *tunnel-number*	Enters a tunnel interface to start NHRP configuration.

	Command	Description
Step 2	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp map** *ip-address nbma-address*	Configures the IP-address and NBMA-address mapping cache on a tunnel interface. The cache is static and will not time out forever. The former address is an IP address and the latter address is an NBMA address.
	Or:	
	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp map** *ip-address***mask** *ip-mask nbma-address*	An IP address is a certain address or the IP address of a network segment, which should be configured with a mask.
	Ruijie(config-Tunnel *tunnel-number*)#**no ip nhrp map** *ip-address nbma-address*	Deletes the static configuration.
	Ruijie(config-Tunnel *tunnel-number*)#**no ip nhrp map** *ip-address* **mask***ip-mask nbma-address*	Deletes the static configuration.

Example 1: Configure static NHRP cache without a mask on a tunnel interface.

```
Ruijie(config)#interface tunnel 1
Ruijie(config-Tunnel 1)#ip nhrp map 55.1.1.1 11.1.1.1
```

Example 2: Configure static NHRP cache with a mask on a tunnel interface.

```
Ruijie(config)#interface tunnel 1
Ruijie(config-Tunnel 1)#ip nhrp map 55.1.1.0 mask 255.255.255.0 11.1.1.1
```

Configuring Destination Addresses of Broadcast and Multicast Packets

When a device needs to send broadcast and multicast packets, you need to specify the direction for sending the packets.

	Command	Description
Step 1	Ruijie(config)#**interface tunnel** *tunnel-number*	Enters a tunnel interface to start NHRP configuration.
Step 2	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp map multicast** *nbma-address*	Configures the NBMA addresses for sending broadcast and multicast packets through the tunnel. Multiple NBMA addresses can be configured.
	Or:	
	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp map multicast dynamic**	The sending direction can also be dynamically learned. After the dynamic learning command is configured, all NBMA addresses registered on the device can be used as the addresses for sending the broadcast packets.

Command	Description
Ruijie(config-Tunnel *tunnel-number*)#**no ip nhrp map multicast** *nbma-address*	Deletes the static configuration.
Ruijie(config-Tunnel *tunnel-number*)# **no ip nhrp map multicast dynamic**	Disables the configuration.

Caution This command is not supported by point-to-point GRE tunnels, but is supported only by MGRE tunnels.

Example 1: Configure a static address 11.1.1.1 for sending broadcast packets on a tunnel interface.

```
Ruijie(config)#interface tunnel 1
Ruijie(config-Tunnel 1)#ip nhrp map multicast 11.1.1.1
```

Example 2: Configure a dynamic address learning command for sending broadcast packets on a tunnel interface.

```
Ruijie(config)#interface tunnel 1
Ruijie(config-Tunnel 1)#ip nhrp map multicast dynamic
```

Configuring NHS

Configure a static address of an NHS to which a registration request packet needs to be sent on an NHC to trigger sending of the registration request.

	Command	Description
Step 1	Ruijie(config)#**interface tunnel** *tunnel-number*	Enters a tunnel interface to start NHRP configuration.
Step 2	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp map** *ip-address nbma-address*	Configures the static IP-address and NBMA-address mapping of the NHS.
Step 3	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp nhs** *nhs-address*	Configures the address of the NHS with which an NHC needs to register for sending a registration request packet.

Ruijie(config-Tunnel *tunnel-number*)#**no ip nhrp nhs** *nhs-address*	Disables the configuration.

Example 1: Configure the NHRP NHS address 11.1.1.1 on a tunnel interface.

```
Ruijie(config)#interface tunnel 1
Ruijie(config-Tunnel 1)#ip nhrp nhs11.1.1.1
```

Configuring Only the NHS Mode

Configure only the NHS mode in which no NHRP registration request packet will be sent.

Command	Description

Step 1	Ruijie(config)#**interface tunnel** *tunnel-number*	Enters a tunnel interface to start NHRP configuration.
Step 2	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp server-only**	Configures the tunnel interface only in the NHS mode.

Ruijie(config-Tunnel *tunnel-number*)#**no ip nhrp server-only**	Resets the default configuration.

Example 1: Configure only the NHS mode on a tunnel interface.

```
Ruijie(config)#interface tunnel 1
Ruijie(config-Tunnel 1)#ip nhrp server-only
```

Configuring Hold Time of NHRP Cache

Dynamic cache information obtained by NHRP through negotiation has hold time. The following commands are used to configure the hold time of NHRP cache.

	Command	Description
Step 1	Ruijie(config)#**interface tunnel** *tunnel-number*	Enters a tunnel interface to start NHRP configuration.
Step 2	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp holdtime** *seconds*	Configures the hold time of dynamic NHRP cache. The value of *seconds* ranges from 1 to 65,535. The default value is 7,200 seconds.

Ruijie(config-Tunnel *tunnel-number*)#**no ip nhrp holdtime**	Resets the default configuration.

Example 1: Configure the hold time of NHRP cache as 300 seconds on a tunnel interface.

```
Ruijie(config)#interface tunnel 1
Ruijie(config-Tunnel 1)#ip nhrp holdtime 300
```

Configuring NHRP Authentication

The NHRP information transferred in the same network can be authenticated with the following commands. Only NHRP information that can be successfully authenticated can be processed.

	Command	Description
Step 1	Ruijie(config)#**interface tunnel** *tunnel-number*	Enters a tunnel interface to start NHRP configuration.
Step 2	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp authentication***string*	Configures the NHRP authentication *string* of 8 bytes, which should be carried by the negotiation packet.
	Ruijie(config-Tunnel *tunnel-number*)#**no ip nhrp authentication**	Disables the configuration.

Example 1: Configure the NHRP authentication string as 123 on a tunnel interface.

```
Ruijie(config)#interface tunnel 1
Ruijie(config-Tunnel 1)#ip nhrp authentication 123
```

Configuring Conditions for NHRP to Trigger a Resolution Request

NHRP can control the conditions for triggering sending of resolution request packets so that certain packets cannot trigger sending of resolution requests.

	Command	Description
Step 1	Ruijie(config)#**access-list***access-list-number*	Configures an ACL rule.
Step 2	Ruijie(config)#**interface tunnel** *tunnel-number*	Enters a tunnel interface to start NHRP configuration.
Step 3	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp interest** *access-list-number*	Uses the ACL for matching. Negotiation can be performed only for packets matching the ACL. *access-list-number*: Indicates a standard or an extended ACL number, ranging from 1 to 199.
	Or:	
	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp interest none**	No ACL can be matched and negotiation cannot be triggered.

Step 1	Ruijie(config)#**interface tunnel** *tunnel-number*	Enters a tunnel interface to start NHRP configuration.
Step 2	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp use***usage-count*	Configures the packet count. NHRP negotiation can be triggered only after *usage-count* (number of packets) packets are sent. The value range is from 1 to 65,535 and the default value is 1.

Ruijie(config-Tunnel *tunnel-number*)#**no ip nhrp interest**	Disables the configuration.
Ruijie(config-Tunnel *tunnel-number*)# **no ip nhrp use**	Resets the default configuration.

Example 1: Configure an NHRP ACL rule on a tunnel interface to match ACL 100.

```
Ruijie(config)#access-list 100 permit ip any any
Ruijie(config)#interface tunnel 1
Ruijie(config-Tunnel 1)#ip nhrp interest 100
```

Example 2: Configure the NHRP delayed triggering command on a tunnel interface. Negotiation can be triggered only after 10 packets are sent.

```
Ruijie(config)#interface tunnel 1
Ruijie(config-Tunnel 1)#ip nhrp use 10
```

Configuring NHRP Redirection

When the central node forwards the mutual access traffic of branch nodes, the central node needs to enable the **ip nhrp redirect** function. After that, the central node will send the **ip nhrp redirect** message to the source branch node to enable the source branch to send an NHRP resolution request.

	Command	Description
Step 1	Ruijie(config)#**interface tunnel** *tunnel-number*	Enters a tunnel interface to start NHRP configuration.
Step 2	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp redirect**	Enables the NHRP redirection function on the NHS.

Example 1: Enable the **nhrp redirect** function on the tunnel 1 interface.

```
Ruijie(config)#interface tunnel 1
Ruijie(config-Tunnel 1)#ip nhrp redirect
```

Configuring the NHRP Shortcut Function

When forwarding mutual access traffic of branch nodes, the central node identifies whether the inbound and outbound interfaces for forwarding the packets belong to the same DMVPN. If yes, the central node will send a redirection packet to the source branch node. In this case, the source branch node needs to enable the **ip nhrp shortcut** function. The branch node can send a next-hop route resolution request packet only after receiving the redirection packet.

	Command	Description
Step 1	Ruijie(config)#**interface tunnel** *tunnel-number*	Enters a tunnel interface to start NHRP configuration.
Step 2	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp shortcut**	Enables the NHRP shortcut function on the NHS.

Example 1: Enable the **nhrp shortcut** function on the tunnel 1 interface.

```
Ruijie(config)#interface tunnel 1
Ruijie(config-Tunnel 1)#ip nhrp shortcut
```

Configuring the NHRP Group to Which an NHC Belongs

An NHC can configure an NHRP group to which it belongs and advertises the NHRP group to the NHS during registration so that the NHS executes the per-spoke flow rate-limit function.

	Command	Description
Step 1	Ruijie(config)#**interface tunnel** *tunnel-number*	Enters a tunnel interface to start NHRP configuration.
Step 2	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp group** *group-name*	Configures the NHRP group to which an NHC belongs.

Example 1: Configure the name of the NHRP group to which an NHC belongs as group-user-1.

```
Ruijie(config)#interface tunnel 1
Ruijie(config-Tunnel 1)#ip nhrp group group-user-1
```

Configuring Per-spoke Flow Rate-Limit on the NHS

You can limit the rates of flows forwarded by the NHS to each NHC. The same flow rate-limit policy will be applied to all NHCs registering to this *group*.

	Command	Description
Step 1	Ruijie(config)#**interface tunnel** *tunnel-number*	Enters a tunnel interface to start NHRP configuration.
Step 2	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp map group** *group-name***flow-label** *label-value*	Specifies the flow label corresponding to the NHRP group.

Example 1: Configure the flow label for the group named group-user-1 as 3.

```
Ruijie(config)#flow-limit output label 3 300000 3000 3000 conform-action  transmit
exceed-action drop
Ruijie(config)#interface tunnel 1
Ruijie(config-Tunnel 1)#ip nhrp map group group-user-1 flow-label 3
```

Configuring the Transmission Rate of NHRP Negotiation Packets

You can run the following commands to limit the transmission rate of NHRP negotiation packets.

	Command	Description
Step 1	Ruijie(config)#**interface tunnel** *tunnel-number*	Enters a tunnel interface to start NHRP configuration.
Step 2	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp max-send***pkt-count***every***interval*	Configures the transmission rate of NHRP negotiation packets as *pkt-count* per *interval* seconds. *pkt-count:* Indicates the number of packets sent. The value range is from 1 to 65,535 and the default value is **100**. *interval*: Indicates the interval for sending packets. The value range is from 10 to 65,535 and the default value is **10**.

Ruijie(config-Tunnel *tunnel-number*)#**noip nhrp max-send**	Disables the configuration.

Example 1: Configure the transmission rate of NHRP negotiation packets as 50 per 10 seconds on a tunnel interface.

```
Ruijie(config)#interface tunnel 1
Ruijie(config-Tunnel 1)#ip nhrp max-send 50every10
```

Configuring the Forward and Reverse Record Function

The forward record and reverse record extension fields are carried in NHRP request and reply packets, which are used to record the information about all NHSs before the request and reply packets reach the final NHS. This command is used to enable or disable the record function. The record function is enabled by default. The following commands are used to disable the function.

	Command	Description
Step 1	Ruijie(config)#**interface tunnel** *tunnel-number*	Enters a tunnel interface to start NHRP configuration.
Step 2	Ruijie(config-Tunnel *tunnel-number*)#**no ip nhrp record**	Disables the record function.

Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp record**	Enables the record function again.

Example 1: Disable the record function on a tunnel interface.

```
Ruijie(config)#interface tunnel 1
Ruijie(config-Tunnel 1)#no ip nhrp record
```

Configuring the Address for the NHRP Responder Field

An NHRP packet has the Responder Address extension field. This extension field is used to add the receiver's address information to this field of the reply packet when a request packet is received. This command is used to specify the address information in the Responder Address field.

	Command	Description
Step 1	Ruijie(config)#**interface tunnel** *tunnel-number*	Enters a tunnel interface to start NHRP configuration.
Step 2	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp responderinterface-name***interface-number*	Configures the first IP address of the specified interface as the address to be added to the Responder Address extension field of the NHRP reply packet.

Ruijie(config-Tunnel *tunnel-number*)#**no ip nhrp responder**	Disables the configuration.

Example 1: Add the address of the virtual-ppp1 interface to the Responder Address field on a tunnel interface.

```
Ruijie(config)#interface tunnel 1
Ruijie(config-Tunnel 1)#ip nhrp responder virtual-ppp 1
```

Configuring the Conditions for Sending NHRP Registration Request Packets

An NHC will send a registration request packet to the NHS to register its information. The following commands are used to control sending of the registration request packet.

	Command	Description
Step 1	Ruijie(config)#**interface tunnel** *tunnel-number*	Enters a tunnel interface to start NHRP configuration.

	Command	Description
Step 2	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp registration no-unique**	The **U** field is available in the NHRP registration request packet, indicating that the registration is unique. This command indicates that the registration is not unique. The value **0** of the **U** field indicates multiple registrations.
	Or:	
	Ruijie(config-Tunnel *tunnel-number*)#**ip nhrp registration timeout***seconds*	Configures the interval for sending two NHRP registration request packets. *seconds:* Indicates the interval for sending registration request packets, ranging from 1 to 65,535. The default value is 1/3 of the hold time.
	Ruijie(config-Tunnel *tunnel-number*)#**no ip nhrp registration no-unique**	Disables the configuration.
	Ruijie(config-Tunnel *tunnel-number*)#**no ip nhrp registration timeout**	Resets the default configuration.

Example 1: Configure NHRP registration requests not unique on a tunnel interface.

```
Ruijie(config)#interface tunnel1
Ruijie(config-Tunnel 1)#ip nhrp registration no-unique
```

Example 2: Configure the interval for sending NHRP registration requests as 10 seconds on the tunnel interface.

```
Ruijie(config)#interface tunnel 1
Ruijie(config-Tunnel 1)#ip nhrp registration timeout10
```

Enabling the NHRP Debug Command

Ruijie Network products provide the debug commands for monitoring and maintaining the NHRP module.

Command	Description
Ruijie#**debug nhrp**	Debugs the negotiation process of NHRP.
Ruijie#**debug nhrp cache**	Debugs cache management of NHRP.
Ruijie#**debug nhrp extension**	Debugs extension fields of NHRP.
Ruijie#**debug nhrp packet**	Debugs packet information display of NHRP.
Ruijie#**no debug nhrp**	Disables debugging by using the no command.
Ruijie#**no debug nhrp cache**	Disables debugging by using the no command.
Ruijie#**no debug nhrp extension**	Disables debugging by using the no command.
Ruijie#**no debug nhrp packet**	Disables debugging by using the no command.

Clearing NHRP Cache Information

Ruijie Network products provide the clear commands for clearing the IP-address and NBMA-address mapping table cache of the NHRP module.

Command	Description
Ruijie#**clear ip nhrp**	Clears all non-static cache information of NHRP.
Ruijie#**clear ip nhrp***ip-address*	Clears non-static NHRP cache of a specified IP-address without a mask.
Ruijie#**clear ip nhrp***ip-addressip-mask*	Clears non-static NHRP cache of a specified IP-address with a mask.

Clearing NHRP Packet Statistics

Ruijie Network products provide the clear commands for clearing NHRP packet statistics.

Command	Description
Ruijie#**clear ip nhrp counters**	Clears all NHRP packet statistics.
Ruijie#**clear ip nhrp counterstunnel***number*	Clears NHRP packet statistics of a specified tunnel interface.

Displaying

Ruijie Network products provide the show commands for displaying information of the NHRP configuration.

Command	Description
Ruijie#**show ip nhrp**	Displays all NHRP cache information.
Ruijie#**show ip nhrp brief**	Displays all NHRP cache information briefly.
Ruijie#**show ip nhrp dynamic**	Displays dynamic NHRP cache information.
Ruijie#**show ip nhrp incomplete**	Displays NHRP cache information about incomplete negotiation.
Ruijie#**show ip nhrp** *ip-address*	Displays NHRP cache information of a specified address.
Ruijie#**show ip nhrp multicast**	Displays the address for sending multicast packets.
Ruijie#**show ip nhrp nhs**	Displays NHS information.
Ruijie#**show ip nhrp static**	Displays static NHRP cache information.
Ruijie#**show ip nhrp summary**	Displays statistics about NHRP cache usage.
Ruijie#**show ip nhrp traffic**	Displays receiving and sending information of NHRP packets.
Ruijie#**show ip nhrpTunnel** *tunnel-number*	Displays NHRP cache information of a specified interface.

Example 1: Display all cache table information of NHRP. Two cache tables are available.

```
Ruijie#show ip nhrp
```

```
55.1.1.2/32 via 55.1.1.3, Tunnel 2 created 00:04:08, expire: 01:55:52
 Type: dynamic, Flags: router authoritative destination_stable unique Source_stable
 NBMA address: 11.1.1.2
 55.1.1.1/32 via 55.1.1.1, Tunnel 2 created 00:05:15, never expire
 Type: static, Flags: authoritative
 NBMA address: 11.1.1.1
```

Example 2: Display the NHRP cache table information in brief.

```
Ruijie# show ip nhrp brief
    Target      Via      NBMA    Mode   Intfc   Claimed
  55.1.1.1/32   55.1.1.1   11.1.1.1    static   Tu1     <   >
```

Example 3: Display the address information table for sending NHRP multicast packets.

```
Ruijie# show ip nhrp multicast
  I/F     NBMA address
  Tunnel2   1.1.1.1      Flags: static
  Tunnel2   2.2.2.2      Flags: static
```

Example 4: Display NHRP NHS table information.

```
Ruijie# show ip nhrp nhs
Tunnel 1  11.1.1.1   NO Responding
Tunnel 1  11.1.1.2   UP
```

Example 5: Display the NHRP cache table statistics.

```
Ruijie# show ip nhrp summary
 IP NHRP cache 0 entries, 0 bytes
 0 static  0 dynamic  0 incomplete
```

Example 6: Display the sending and receiving statistics about NHRP packets.

```
Ruijie# show ip nhrp traffic
Tunnel 1
  Sent: Total 0
        0 Resolution Request  0 Resolution Reply  0  Registration Request
        0 Registration Reply  0 Purge Request  0  Purge Reply
        0 Error Indication
  Rcvd: Total 0
        0 Resolution Request  0 Resolution Reply  0  Registration Request
        0 Registration Reply  0 Purge Request  0  Purge Reply
        0 Error Indication
```

Configuration Example

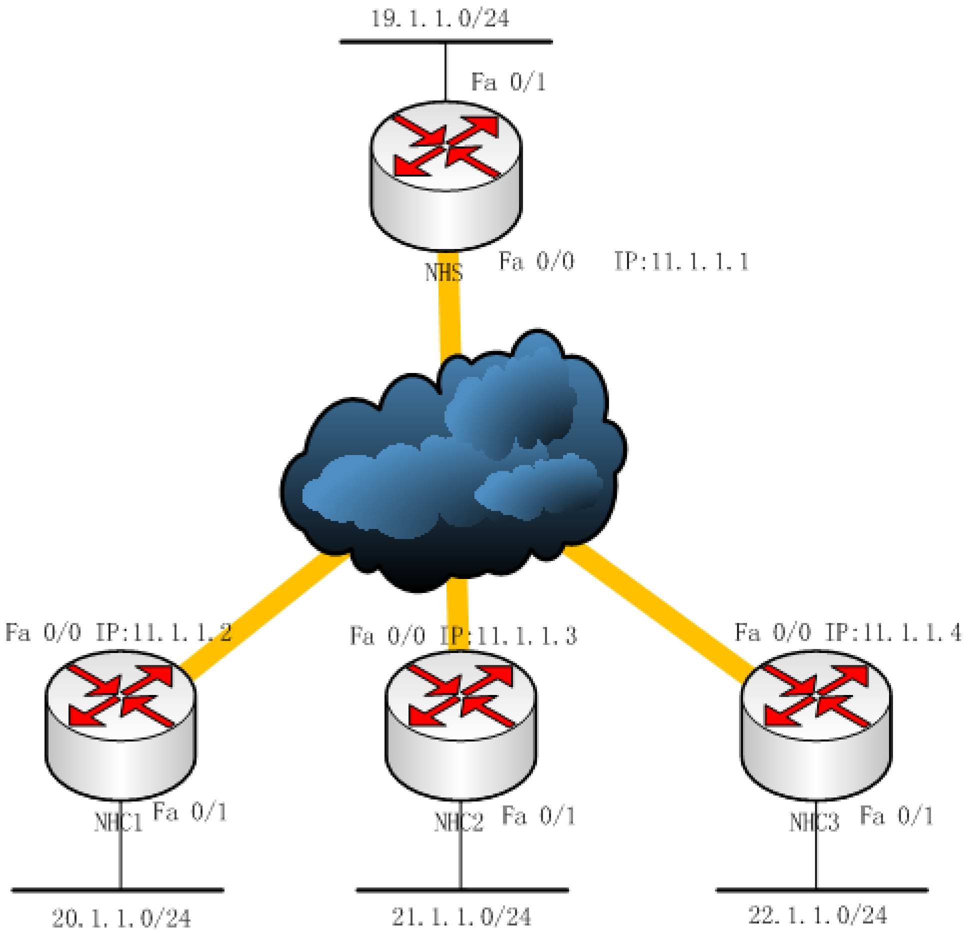
Configuring DMVPN

At present, NHRP is mainly used in a DMVPN (dynamic multi-point VPN) network. The IPSec, GRE and NHRP modules can be used together.

Networking Requirements

As shown in the following figure, four routers are needed. One router is used as the NHS and the other routers are used as the NHCs. They form a mesh topology.

Network Topology



DMVPN Network Topology

Configuration

If a mesh topology is needed, the three NHCs must be configured as MGRE tunnels. If a star topology is needed, the three NHCs must be configured as GRE tunnels.

Configuration Steps

Configuring NHS

/* Configure IPSEC. */

```

Security Configuration

18. Configuring RPL

Configuring ACLs

Overview

As part of Ruijie's security solution, an access control list (ACL) is used to provide a powerful traffic filtering function. Currently, Ruijie products support the following ACLs:

- Standard and extended IP ACLs
- IPv6 Extended ACLs

Depending on networks conditions, you can choose different ACLs to control data flows.

ACL Introduction

An ACL is also referred to as a firewall or packet filtering. ACLs permit or discard packets on interfaces of network devices by defining rules. According to application scopes, they can be divided into ACLs and QoS ACLs.

By filtering the data streams, you can restrict the communication data types in the network and restrict the users of the network and the device they can use. When data streams pass the switch, ACLs classify and filter them, that is, check the data streams input from the specified interface and determine whether to permit or deny them according to the matching conditions.

To sum up, the security ACL is used to control which data flow is allowed to pass through the network device. The QoS policy performs priority classification and processing for the data flow.

ACLs consist of a series of entries, known as Access Control Entry (ACE). Each entry has its matching condition and behavior.

ACL rules can be applied to the source addresses, destination addresses, upper layer protocols, time ranges or other information of data flows.

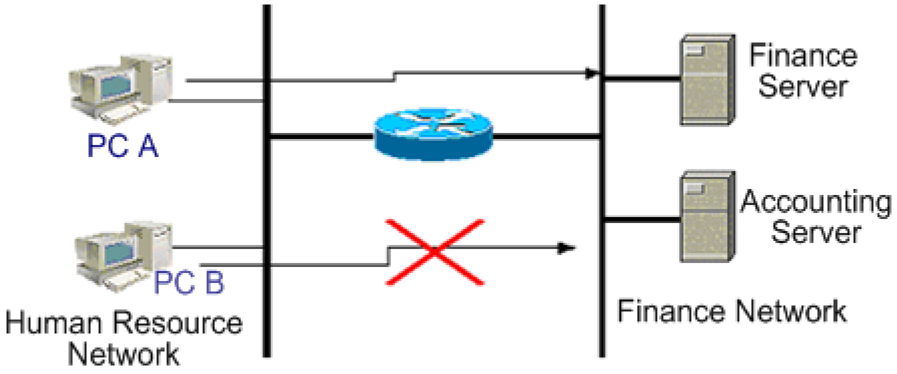
Why to Configure ACLs

There are many reasons why ACLs need to be configured. In most cases, ACLs are used to:

- Restrict route update: Control where the route update information is sent and received.
- Restrict network access: To ensure network security, provide users with access to desired services only (for example, if a user only needs webpage access and email services, other services such as Telnet are disabled), specify a time period in which access is permitted, or specify hosts which are allowed to access Internet.

In Figure 1, only host A is allowed to access Finance Network, while Host B is not.

Figure 1 Using ACLs to control network access



When to Configure Access Lists

Depending on your requirements, you can select the basic ACL or dynamic ACL. In general, the basic ACL can meet the security requirement. However, experienced hackers may use some software to forge source addresses and spoof the devices so as to gain access. Before the user can access the network, the dynamic ACL requires authentication so that the hackers are difficult to invade the network. So, in some sensitive areas the dynamic ACL can be used to ensure the network security.

Note

An inherent problem of all ACLs is spoofing, the behavior of providing spoofed source addresses to deceive switches. This cannot be avoided even you use the dynamic ACL. During the effective access period of an authenticated user, a hacker may use a spoofed user address and accesses the network. There are two methods to resolve the problem. One method is to set free time for a user to access the network as little as possible, making it hard for a hacker to attack the network. The other method is to use IPSEC to encrypt network data, ensuring that all the data entering switches is encrypted.

ACLs are usually configured in the following positions of network devices:

- Devices between the internal network and external network (such as the Internet)
- Devices at the border of two parts in a network
- Devices on the access control port

The execution of the ACL statements must follow the order in the table strictly. Starting from the first statement, once the header of a packet matches a conditional judge statement in the table, the following statements are ignored.

Input/Output ACL, Filtering Domain Template and Rule

When a device interface receives a message, the input ACL checks whether the message matches an ACE of the ACL input on the interface. When a device interface is ready to output a message, the output ACL checks whether the message matches an ACE of the ACL output on the interface.

When detailed filtering rules are formulated, all or some of the preceding eight items may be used. As long as the message matches one ACE, the ACL processes the message as the ACE defined (permit or deny). The ACE of an ACL identifies Ethernet messages according to some fields of Ethernet messages. The fields include the following:

Layer-2 fields:

- 48-bit source MAC address (all the 48 bits must be declared)
- 48-bit destination MAC address (all the 48 bits must be declared)
- 16-bit layer-2 type field

Layer 3 fields:

- Source IP address field (you can specify all the 32 bits of the IP address, or specify a type of streams of the defined subnet)
- Destination IP address field (you can specify all the 32 bits of the IP address, or specify a type of streams of the defined subnet)
- Protocol type fields

Layer-4 fields:

- You can specify one UDP source port, destination port, or both
- You can specify one UDP source port, destination port, or both

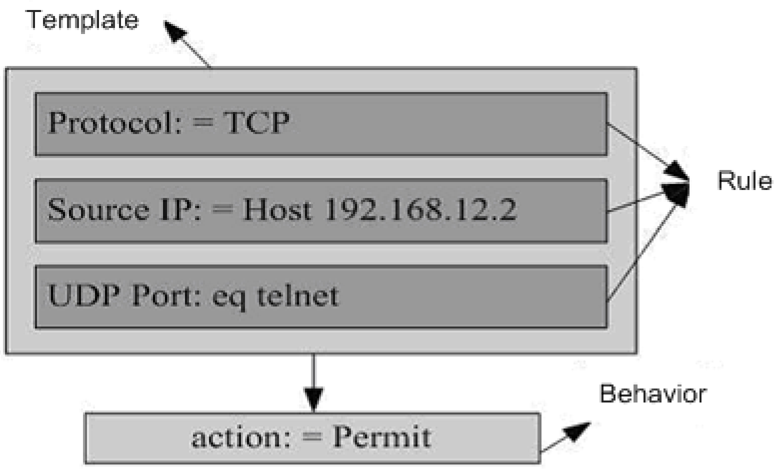
The filtering domain consists of the fields in the packets based on which the packets are identified and classified when you create an ACE. A filtering domain template is the definition formed by these fields. For example, when one ACE is generated, you want to identify and classify messages according to the destination IP field of a message. When another ACE is generated, you want to identify and classify messages according to the source IP address field of a message and the source port field of UDP. In this way, these two ACEs use different filtering domain templates.

Rules refer to the values of the ACE mask. For example, one ACE is:

```
permit tcp host 192.168.12.2 any eq telnet
```

In this ACE, the filtering domain template is a collection of the following fields: Source IP Address Fields, IP Protocol Fields and Destination TCP Port Fields. Corresponding values (rules) are respectively as follows: Source IP Address=Host 192.168.12.2; IP Protocol=TCP; TCP Destination Port=Telnet.

Figure 2 Analysis of the ACE: permit tcp host 192.168.12.2 any eq telnet



A filtering domain template can be the collection of L3 fields and L4 fields or the collection of multiple L2 fields. However, the filtering domain templates of a standard and extended ACL cannot be the collection of L2 and L3, L2 and 4, L2 and L3, or L4 fields.

Note

Caution

1. When associating SVI with the ACL at the outbound direction, you should note that:

Standard IP ACL and extended IP ACL are supported. There are some limits on matching the destination IP address and the destination MAC address with an ACL. If you need to match the destination IP address not in the subnet IP range of the associated SVI in the standard IP ACL and extended IP ACL, this ACL will not take effect. For example, the IP address of VLAN 1 is 192.168.64.1 and subnet mask of VLAN 1 is 255.255.255.0. Now you create an ACL with the ACE of **deny udp any 192.168.65.1 0.0.0.255 eq 255** and apply this ACL to the egress of VLAN 1. This ACL will not function for the destination IP address is not in the subnet IP range of VLAN 1. If the ACE is **deny udp any 192.168.64.1 0.0.0.255 eq 255**, this ACL will take effect.

Note

When applying an ACL, the labeled MPLS packet matching does not take effect if an ACE in the ACL (including the IP ACL) matches a non-L2 field (such as SIP and DIP).

Configuring IP Access List

To configure ACLs on a device, you must specify unique names or numbers for the ACLs of a protocol to uniquely identify each ACL within the protocol. The following table lists the protocols that can use numbers to specify ACLs and the number ranges of ACLs that can be used by each protocol.

Protocol	Number Range
Standard IP	1-99, 1300 - 1999
Extended IP	100-199, 2000 - 2699

Guide to Configuring IP ACLs

When you create an ACL, defined rules will be applied to all packets on a device. The device decides whether to forward or block a packet by judging whether the packet matches a rule.

Basic ACLs are classified into standard ACLs and extended ACLs. The typical rules defined in ACLs are as follows:

- Source address
- Destination address
- Upper layer protocol
- Time range

Standard IP ACLs (numbered from 1 to 99 and from 1300 to 1999) forward or block packets according to source addresses. Extended IP ACLs (numbered from 100 to 199 and from 2000 to 2699) use the above four combinations to forward or block packets. Other types of ACLs forward or block packets according to related codes.

A single ACL can use multiple separate ACL statements to define multiple rules. Where, all statements use the same number or name to bind these statements to the same ACL. However, the more the used statements are, the more difficult to read and understand an ACL.

Statement containing an implicit deny statement for all packets

The end of the ACL contains an implicit deny statement for all packets that it did not find a match for before reaching the end, as shown in the following example:

```
access-list 1 permit host 192.168.4.12
```

This ACL allows only the messages destined for host 192.168.4.12. This is because the ACL contains the following rule statement at the end: **access-list 1 deny any**

Here is another example:

```
access-list 1 deny host 192.168.4.12
```

If the ACL contains the only preceding statement, the messages from any host will be denied on the port.

Note

It is required to consider the routing update message when defining the ACL. Since the end of the ACL contains an implicit deny statement for all packets, this may cause all routing update messages blocked.

☑ If the inserted line cards do not include EA series, the ACEL associated with the outgoing direction of the AP port has no default deny ACE, which shall be configured manually as needed.

Order to Input Rule Sentences

Each added rule is appended to the ACL. If a statement is created, then you cannot delete it separately but delete the whole ACL. Therefore, the order of ACL statements is very important. When deciding whether to forward or block packets, a device compares packets and statements in order of statement creation time until It finds a matching statement.

If you have created a statement that allows all packets to pass, then the following statements will not be checked, as shown in the following example:

```
access-list 101 deny ip any any
access-list 101 permit tcp 192.168.12.0 0.0.0.255  eq  telnet any
```

Because the first rule statement denies all IP packets, the packets for accessing host 192.168.12.0/24 will be denied. Because the device discovers that the packets match the first rule statement, it will not check other rule statements.

Configuring IP ACLs

The configuration of the basic ACL includes the following steps:

- Define a basic ACL
- Apply the ACL to a specific interface.

There are two methods to configure a basic ACL.

Method 1: Run the following command in global configuration mode:

Command	Function
Ruijie(config)# **access-list id** {**deny** | **permit**} {**src** *src-wildcard* | **host src** | **any** | *interface idx*} [**time-range** *tm-rng-name*]	Defines an ACL .
Ruijie(config)# **interface** *interface*	Selects the interface to which the ACL is to be applied.
Ruijie(config-if)# ip access-group id { in | out } [unreflect]	Applies the ACL to the specific interface

Method 2: Run the following command in ACL configuration mode:

Command	Function
Ruijie(config)# **ip access-list** { **standard** | **extended** } { *id* | *name* }	Enters ACL configuration mode.
Ruijie (config-xxx-nacl)# [**sn**] { **permit** | **deny** } {**src** *src-wildcard* | **host src** | **any** } [**time-range** *tm-rng-name*]	Adds ACEs to the ACL. For details about the command, see command reference.
Ruijie(config-xxx-nacl)# **exit**	Exits ACL mode.
Ruijie(config)# **interface** *interface*	Selects the interface to which the ACL is to be applied.
Ruijie(config-if)# ip access-group *id* { in | out } [unreflect]	Applies the ACL to the specific interface.

Note

In method 1, an ACL can only be numbered. In method 2, an ACL can be numbered and named, and ACE priority can be specified if available. By default, the reflexive ACL is enabled on the IP ACL port. You can run the **unreflect** command to disable the reflexive ACL. (The operation principles of the reflexive ACL are described as follows:

a. The router automatically generates a temporary ACL according to the L3 and L4 information of the originating traffic in the internal network based on the principles. That is, the protocol is constant, while the source and destination IP addresses, and the source and destination ports are rigidly exchanged.

b. The router allows traffic to enter the internal network only when the L3 and L4 information of the returned traffic strictly matches the information in the temporary ACL previously created based on the outputting traffic.)

Displaying IP ACLs

To monitor ACLs, run the following command in privileged user mode:

Command	Function
Ruijie# **show access-lists** [*id* | *name*]	Queries the basic ACLs.

Configuring IPv6 Extended ACLs

Configuring IPv6 Extended ACLs

The configuration of an IPv6 ACL includes the following steps:

- Define an IPv6 ACL

- Apply the ACL to a specific interface (application particular case)

To configure a basic ACL, run the following command in ACL configuration mode:

Command	**Function**
Ruijie(config)# **ipv6 access-list** *name*	Enters ACL configuration mode.
Ruijie (config-ipv6-nacl)# [sn] **{permit | deny** } prot {*src-ipv6-prefix/prefix-len* | **host** *src-ipv6-addr* | **any**} *{dst-ipv6-pfix/pfix-len* | **any | host** *dst-ipv6-addr*} [**dscp** *dscp*] [**flow-label** *flow-labe*l] [**time-range** *tm-rng-name*]	Adds ACEs to the ACL. For details about the command, see command reference.
Ruijie(config-exp-nacl)# **exit**	Exits the access control list mode.
Ruijie(config)# **interface** *interface*	Selects the interface to which the ACL is to be applied.
Ruijie(config-if)# **ipv6 traffic-filter** *name* {**in** | **out**}	Applies the ACL to the specific interface.

Displaying Configuration of IPv6 Extended ACLs

To monitor ACLs, run the following command in privileged user mode:

Command	**Function**
show access-lists [*name*]	Queries the basic ACLs.

Configuring Extended Expert ACLs

To configure Expert extended ACLs on a device, you must specify unique names or numbers for the ACLs of a protocol to uniquely identify each ACL within the protocol. The following table lists the number range of the Expert ACLs.

Protocol	**Number Range**
Extended Expert ACL	2700-2899

Guide to Configuring Expert Extended ACLs

When you create an expert extended ACL, defined rules will be applied to all packets on a device. The device decides whether to forward or block a packet by judging whether the packet matches a rule.

The typical rules defined in Expert ACLs are as follows:

- All information in basic ACLs and MAC extended ACLs
- VLAN ID

Extended Expert ACLs (numbered from 2700 to 2899) are the syntheses of basic ACLs and MAC extended ACLs and can filter VLAN IDs.

A single expert ACL can use multiple separate ACL statements to define multiple rules. Where, all statements use the same number or name to bind these statements to the same ACL.

Configuring an Expert Extended ACL

The configuration of an expert ACL includes the following steps:

- Define an expert ACL
- Apply the ACL to a specific interface (application particular case)

There are two methods to configure an Expert ACL.

Method 1: Run the following command in global configuration mode:

Command	**Function**
Ruijie (config)# **access-list** *id* {**deny** | **permit**} [*prot* | {[*ethernet-type*] [**cos** *cos*]}] [**VID** *vid*] {**src** *src-wildcard* | **host** *src* | **interface** *idx*} {**host** *src-mac-addr* | **any**} {**dst** *dst-wildcard* | **host** *dst* | **any**}{**host** *dst-mac-addr* | **any**}] [**precedence** *precedence*] [**tos** *tos*] [**dscp** *dscp*] [**fragment**] [**time-range** *tm-rng-name*]	Defines an ACL. For details about the command, see command reference.
Ruijie(config)# **interface** *interface*	Selects the interface to which the ACL is to be applied.
Ruijie(config-if)# expert access-group *id* {in | out } [unreflect]	Applies the ACL to the specific interface.

Method 2: Run the following command in ACL configuration mode:

Command	**Function**
Ruijie(config)# **expert access-list extended** {*id*|*name*}	Enters ACL configuration mode.
Ruijie (config-exp-nacl)# [*sn*]{ **permit** | **deny** }[*prot* | {[*ethernet-type*] [**cos** *cos*]}] [**VID** *vid*] {**src** *src-wildcard* | **host** *src* | **interface** *idx*}{**host** *src-mac-addr* | **any**} {**dst** *dst-wildcard* | **host** *dst* | **any**} {**host** *dst-mac-addr* | **any**}][**precedence** *precedence*] [**tos** *tos*] [**dscp** *dscp*] [**fragment**] [**time-range** *tm-rng-name*]	Adds ACEs to the ACL. For details about the command, see command reference.
Ruijie(config-exp-nacl)# **exit**	Exit ACL mode.
Ruijie(config)# **interface** *interface*	Selects the interface to which the ACL is to be applied.
Ruijie(config-if)# **expert access-group** {*id*|*name*} {**in**|**out**} **[unreflect]**	Applies the ACL to the specific interface.

Note

In method 1, an ACL can only be numbered. In method 2, an ACL can be numbered and named, and ACE priority can be specified if available. In a version supporting ACE priority, method 2 can also specify the priorities of ACEs (using the [*sn*] option in a command).

☑ The router supports neither packet fragment filtering nor Expert ACLs.

Displaying Configuration of Expert Extended ACLs

To monitor ACLs, run the following command in privileged user mode:

Command	**Function**
show access-lists [*id* | *name*]	Queries the Expert ACLs.

Configuring MAC Extended ACLs

To configure MAC extended ACLs on a device, you must specify unique names or numbers for the ACLs of a protocol to uniquely identify each ACL within the protocol. The following table lists the range of the numbers that can be used to specify MAC ACLs.

Protocol	**Number Range**
MAC Extended Access List	700-799

Guide to Configuring MAC Extended ACLs

When a MAC ACL is created, the defined rules will be applied to all packets on a device. The device decides whether to forward or block a packet by judging whether the packet matches a rule.

The typical rules defined in MAC ACLs are as follows:

- Source MAC address
- Destination MAC address
- Ethernet protocol type
- Time-range

The MAC extended ACLs (numbered from 700 to 799) forward or block the packets based on the source and destination MAC addresses, and can also match Ethernet packets.

A single MAC ACL can use multiple separate ACL statements to define multiple rules. Where, all statements use the same number or name to bind these statements to the same ACL.

Configuring a MAC Extended ACL

The configuration of an MAC ACL includes the following steps:

- Define an MAC ACL
- Apply the ACL to a specific interface

There are two methods to configure an MAC ACL.

Method 1: Run the following command in global configuration mode:

Command	**Function**
Ruijie(config)# **access-list** id {**deny** | **permit**}{**any** | **host** *src-mac-addr*} {**any** | **host** dst-mac-addr} [*ethernet-type*] [**cos** *cos*]	Defines an ACL. For details about the command, see command reference.
Ruijie(config)# **interface** *interface*	Selects the interface to which the ACL is to be applied.
Ruijie(config-if)# **mac access-group** *id* { **in** | **out** }	Applies the ACL to the specific interface.

Method 2: Run the following command in ACL configuration mode:

Command	**Function**
Ruijie(config)# **mac access-list extended** {*id* | *name*}	Enters ACL configuration mode.

Ruijie (config-mac-nacl)# [sn] { **permit** | **deny** }{**any** | **host** *src-mac-addr*} {**any** | **host** *dst-mac-addr*} [*ethernet-type*] [**cos** *cos*]	Adds ACEs to the ACL. For details about the command, see command reference.
Ruijie(config-mac-nacl)# **exit** Ruijie(config)# **interface** *interface*	Exits ACL mode and selects the interface to which the ACL is to be applied.
Ruijie(config-if)# **mac access-group** {*id* | *name*} { **in** | **out**}	Applies the ACL to the specific interface.

Note

Method 1 only configures the numerical value ACL. Method 2 can configure the names and numerical value ACL, and specify the table entry priorities (in the devices that support ACE priorities).

☑ The route does not support MAC ACLs.

Displaying Configuration of MAC Extended ACLs

To monitor ACLs, run the following command in privileged EXEC mode:

Command	Function
show access-lists [*id* | *name*]	Queries the basic ACLs.

Other Related Configurations

Configuring ACEs by Priority

To embody the ACE priority, criteria is set up for each ACL so that ACEs in an ACL are arranged in a standard manner: using an ACE sequence number as the start point and making the sequence number grows at an increment:

- ACEs are arranged by sequence number in ascending order in the chain table.
- ACE arrangement starts from a sequence number. If no number is specified, it increases at an increment on the basis of the previous ACE number.
- To specify the sequence number of an ACE, insert the ACE and ensure that a new ACE can be inserted between two adjacent ACEs.
- The ACL specifies the start number and the increment.

The **ip access-list resequence** {*acl-id*| *acl-name*} *sn-start sn-inc* command is available. For details, see command reference.

Whenever the preceding command is run, the ACEs in the ACL will be sorted. For example, the ACEs in the ACL named **tst_acl** are numbered as follows:

In the beginning

```
ace1: 10
ace2: 20
ace3: 30
```

The ACEs are numbered as follows after "the **ip access-list resequence** *tst_acl 100 3*" command is run:

```
Ruijie(config)# ip access-list resequence tst_acl 100 3
ace1: 100
ace2: 103
ace3: 106
```

If you do not specify *sn-num* when adding ACE 4, ACE 4 is numbered as follows:

```
Ruijie(config-std-nacl)# permit …
ace1: 100
ace2: 103
ace3: 106
ace4: 109
```

If you set *seg-num* to **105** when adding ACE 5, ACE 5 is numbered as follows:

```
Ruijie(config-std-nacl)# 105 permit …
ace1: 100
ace2: 103
ace5: 105
ace3: 106
ace4: 109
```

The sequence number mechanism is designed to add ACEs by priority.

Delete ACEs

```
Ruijie(config-std-nacl)# no 106
ace1: 100
ace2: 103
ace5: 105
ace4: 109
```

It is also convenient to delete ACEs with a sequence number.

Configuring ACL Logging

When ACL Logging is enabled, if a packet matches a logging-enabled ACE and the matching speed reaches or even exceeds the configured logging threshold, the system generates a log within one logging interval to determine whether to permit or deny this packet.

Note

This function applies only to standard and extended IP ACLs and is optional.

Default configuration

The ACL logging function is disabled by default.

ACL Options are configured as follows:

Configure the ACL logging speed threshold. This threshold means the maximum speed an ACE is matched. When it is exceeded, a log is generated.

Command	Function
Ruijie(config)#**ip access-list log-update threshold** *threshold-value*	Configures the ACL logging threshold.

Configure the ACL logging interval, in milliseconds.

Command	Function
Ruijie(config)#**ip ccess-list logging interval** *interval-value*	Configures the ACL logging interval.

Enable ACE logging so that packets matching an ACE can be counted.

Command	Function
Ruijie(config)# **ip access-list extended** { *id* | *name* }	Enters ACL configuration mode.
Ruijie(config-ext-nacl)# [sn] {**permit** | **deny**} **protocol** *source source-wildcard destination destination-wildcard* [**precedence** *precedence*] [**tos** *tos*] [**fragment**] [**range** *lower upper*] [**time-range** *time-range-name*] [**option** *option*] [**log**]	Adds ACEs to the ACL. For details about the command, see command reference.
Ruijie(config-exp-nacl)# **exit**	Exits ACL configuration mode and selects the interface to which the ACL is to be applied.

Configuration example:

- Configure the permission and password for enabling the ACL logging function.

```
Ruijie> enable
Ruijie#
```

- Enter global configuration mode.

```
Ruijie# configure terminal
Ruijie(config)#
```

- Configure the ACL logging threshold and interval.

```
Ruijie(config)# ip access-list log-update threshold 1
Ruijie(config)# ip access-list logging interval 1
```

- Enter ACL configuration mode and enable logging on the desired ACE.

```
Ruijie(config-ext-nacl)# permit ip 99.9.9.0 0.0.0.255 any log
```

- Add a deny ACE and enable the logging function on the ACE.

```
Ruijie(config-ext-nacl)# deny ip any any log
```

- end

```
Ruijie(config-ext-nacl)# end
```

- The following log will be generated when the ACL logging threshold is reached or exceeded:

```
*Feb 20 14:10:48.747: %SEC-6-IPACCESSLOGNP: list s1 permitted 0 99.9.9.2 -> 99.9.9.1, 1 packet
```

```
*Feb 20 14:11:37.171: %SEC-6-IPACCESSLOGNP: list s1 permitted 0 99.9.9.2 -> 99.9.9.1, 2 packets
*Feb 20 14:42:51.207: %SEC-6-IPACCESSLOGNP: list s1 denied 0 90.9.9.2 -> 99.9.9.1, 1 packet
```

In privileged configuration mode, run the following commands to configure a global security tunnel:

Command	Function
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)#security global access-group *1*	Configures a global security tunnel.

In privileged configuration mode, execute the following commands to set an exception port:

Command	Function
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)#**interface** *idx*	Enters interface configuration mode.
Ruijie(config-if)# security uplink enable	Sets the interface as an exceptional port..

In privileged configuration mode, run the following commands to configure a security tunnel on the interface:

Command	Function
Ruijie# configure terminal	Enters global configuration mode.
Ruijie(config)#**interface** *idx*	Enters interface configuration mode.
Ruijie(config-if)# **security access-group** *1*	Configures a security tunnel on the interface.

The following example shows how to configure a security tunnel on a security port where IP/MAC binding is configured, so that IPX packets can pass:

Set port 4 as the security port and bind IP address and MAC address

```
Ruijie(config)#interface FastEthernet 0/4
Ruijie(config-if)#switchport port-security
Ruijie(config-if)#switchport port-security binding 0000.0000.0011 vlan 1 192.168.6.3
```

Only the packets whose source IP address is 192.168.6.3 and MAC address is 0000.0000.0011 can pass the device through port 4. To receive IPX packets, set a security tunnel as follows:

```
Ruijie#configure
Ruijie(config)#expert access-list extended safe_channel
Ruijie(config-exp-nacl)#permit ipx any any
Ruijie(config-exp-nacl)#exit
Ruijie(config)#security global access-group safe_channel
```

Or configure a security tunnel on the interface:

```
Ruijie#configure
Ruijie(config)#expert access-list extended safe_channel
Ruijie(config-exp-nacl)#permit ipx any any
Ruijie(config-exp-nacl)#exit
Ruijie(config)#interface FastEthernet 0/4
```

Ruijie(config-if)#**security access-group** *safe_channel*

IPX packets can pass through port 4 after a security channel is configured globally or on an interface.

Configuring ACL80

ACL 80 is also called the custom ACL, which is used to match the first 80 bytes of a packet. A packet consists of a series of byte flows. ACL 80 enables the user to filter packets according to the specified 16 bytes of the first 80 bytes in the packet.

Note

The SMAC/DMAC/SIP/DIP/ETYPE field of the packets is not specified. In other words, a packet is filtered only when the specified 16 bytes match ACL 80 in addition to these fields.

For any 16-byte field, it is possible to compare or not the configured value by bits. In other words, it allows setting any bit of those 16 bytes as 0 or 1. There are two factors in filtering any byte: filtering rule and filter domain template. The bits of the both are one-to-one corresponding. The filtering rule specifies the value of the field to be filtered. The filter domain template specifies whether to filter the related fields in the filtering rule (“1” indicates matching the bit in the corresponding filtering rule, 0 for not). Therefore, when it is time to match a bit, it is required to set 1 for the corresponding bit in the filter domain template. If the filter domain template bit is set as 0, no match will be done no matter what the corresponding bit is in the filtering rule.

For example,

```
Ruijie(config)# expert access-list advanced name
Ruijie(config-exp-dacl)# permit 00d0f8123456 ffffffffffff 0
Ruijie(config-exp-dacl)# deny 00d0f8654321 ffffffffffff 6
```

The user custom ACL matches any byte of the first 80 bytes in the layer-2 data frames according to the user definitions, and then performs corresponding processing for the packets. To use ACL 80 correctly, it is necessary to have in-depth knowledge about the structure of layer-2 data frames. The following illustrates the first 64 bytes in a layer-2 data frame (each letter indicates a hexadecimal number, and each two letters indicate a byte).

AA AA AA AA AA AA BB BB BB BB BB BB CC CC DD DD

DD DD EE FF GG HH HH HH II II JJ KK LL LL MM MM

NN NN OO PP QQ QQ RR RR RR RR SS SS SS SS TT TT

UU UU VV VV VV VV WW WW WW WW XY ZZ aa aa bb bb

The following table lists the meanings and offset values of each letter:

Letter	Meaning	Offset	Letter	Meaning	Offset
A	Destination MAC	0	O	TTL field	34
B	Source MAC	6	P	Protocol ID	35
C	VLAN tag field	12	Q	IP checksum	36
D	Data frame length field	14	R	Source IP address	38
E	DSAP field	18	S	Destination IP address	42
F	SSAP field	19	T	TCP source port	46
G	Ctrl field	20	U	TCP destination port	48
H	Org Code field	21	V	Sequence number	50
I	Encapsulated data type	24	W	Confirmation field	54

J	IP version No.	26	XY	IP header length and reservation bits	58
K	TOS field	27	Z	Reservation bit and flags bit	59
L	IP packet length	28	a	Windows size field	60
M	ID	30	b	Others	62
N	Flags field	32			

As shown in the preceding table, the offset of each field is the offset in the SNAP+tag 802.3 data frame. In ACL 80, the user can use two parameters, the rule mask and offset, to abstract any byte from the first 80 bytes of the data frame, and then compare it with the user defined rule to filter the matched data frame for corresponding processing. The user defined rule can be some fixed attributes of the data. For example, the user wants to filter all the TCP packets by defining the rule as “06”, rule mask as “FF” and offset as 35. Here, the rule mask and offset work together to abstract the contents of the TCP protocol ID field in the received data frame, and compare it with the rule to filter all TCP packets.

Caution

ACL 80 can be used to match Ethernet packets, 803.3 SNAP packets, and 802.311c packets. If the value for matching DSAP to the cnt1 field is set to AAAA03, it indicates to match the 803.3 SNAP packets. If the value is set to E0E003, it indicates to match the 803.311c packets. This field cannot be set to match Ethernet packets.

Caution

ACL 80 only match only the 16 bytes of a packet. If the 16 bytes are used, no fields other than the 16 bytes can be matched. For example:

```
Ruijie(config)# expert access-list advanced name
Ruijie(config-exp-dacl)# permit 11223344556677889900aabbccd deeff
ffffffffffffffffffffffffffffffff 50
```

Add another ACE:

```
Ruijie(config-exp-dacl)#permit 11223344556677889900aabbccd deeff
ffffffffffffffffffffffffffffffff 54
```

The configuration will fail because the 16 bytes are used by the first ACE. To match the second ACE, you must delete the first ACE.

Configuring IP Options Filtering

IP Options filtering is used to match options in the IP packet header by option value (0–255) or option name. If the IP options in a packet match all bits defined in ACEs, the packet is deemed to match the ACL. Users can set any values for IP options to filter packets with specified IP options.

Note

This feature applies only to named extended ACLs and is optional.

Configure IP Options filtering:

Command	Function
Ruijie(config)# **ip access-list extended** { *id* | *name* }	Enters ACL configuration mode.
Ruijie(config-ext-nacl)# [sn] {**permit** | **deny**} **protocol** *source source-wildcard destination destination-wildcard* [**precedence** *precedence*] [**tos** *tos*] [**fragment**] [**range** *lower upper*] [**time-range** *time-range-name*] [**option** *option*] [**log**]	Adds ACEs to the ACL. For details about the command, see command reference.
Ruijie(config-exp-nacl)# **exit**	Exits ACL configuration mode and selects the interface to which the ACL is to be applied.
Or	
Ruijie(config)# **interface** *interface*	Exits ACL configuration mode and selects the interface to which the ACL is to be applied.
Ruijie(config-if)# **ip access-group** {*id* | *name*} {**in** | **out**}	Applies the ACL to the specific interface.

Configuration example:

- Configure the permission and password for enabling the IP Option feature.

```
Ruijie> enable
Ruijie#
```

- Enter global configuration mode.

```
Ruijie# configure terminal
Ruijie(config)#
```

- Enter ACL configuration mode.

```
Ruijie(config)# ip access-list extended ip-options
Ruijie(config-ext-nacl)#
```

- Add ACEs.

```
Ruijie(config-ext-nacl)# permit ip any any option lsr
```

- Add deny ACEs.

```
Ruijie(config-ext-nacl)# deny ip any any option any-options
```

- end

```
Ruijie(config-ext-nacl)# end
```

- Display the configuration result.

```
Ruijie# show  access-list ip-options
ip access-lists extended ip-options
10 permit tcp any any option lsr
20 deny tcp any any option any-options
```

Configuring ACLs Based on the Time Range

You can make ACLs effective based on time, for example, ACLs take effect during certain periods in a week. For this purpose, you must first set a time range.

Time range implementation depends on the system clock. If you want to use this function, you must assure that the system has a reliable clock.

In privileged configuration mode, run the following commands:

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **time-range** *time-range-name*	Identifies a time range by using a meaningful display character string as its name
Ruijie(config-time-range)# **absolute** [**start time** *date*] **end time** *date*	Sets the absolute time range (optional). For details, see the time range configuration guide.
Ruijie(config-time-range)# **periodic day-of-the-week time to** [*day-of-the-week*] **time**	Sets the periodic time range (optional).
Ruijie# **show time-range**	Verifies the configuration.
Ruijie# **copy running-config startup-config**	Saves the configuration.
Ruijie(config)# **ip access-list extended** *101*	Enters ACL configuration mode.
Ruijie(config-ext-nacl)# **permit ip any any time-range** *time-range-name*	Configures a time range-based ACE.

Note

The length of the name should be 1-32 characters without any blank space.

You can set one absolute time range at most. The application based on time-ranges will be effective only in this time range.

You can set one or more intervals. If you have already set a running time range for **time-range**, the application takes effect at intervals in that time range.

The following example shows how to deny HTTP packets during the working hours in a week by using the time range-based ACLs:

```
Ruijie(config)# time-range no-http
Ruijie(config-time-range)# periodic weekdays 8:00 to 18:00
Ruijie(config)# end
Ruijie(config)# ip access-list extended limit-udp
Ruijie(config-ext-nacl)# deny tcp any any eq www time-range no-http
Ruijie(config-ext-nacl)# exit
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# ip access-group no-http in
Ruijie(config)# end
```

Example of time ranges:

```
Ruijie# show time-range
time-range entry: no-http(inactive)
```

```
periodic Weekdays 8:00 to 18:00
time-range entry: no-udp
periodic Tuesday 15:30 to 16:30
```

Configuring TCP Flag Filtering

The TCP Flag filtering feature provides a flexible mechanism. At present, TCP Flag filtering control supports the match-all option. Namely, when the TCP Flags in a received packet exactly match those defined in the ACE, the packet will be checked by the ACL rule. A user can define any combination of TCP Flags to filter some packets with specific TCP Flags.

For example,

```
permit tcp any any match-all rst
```

Allow the packets to pass if the TCP Flag is reset and other fields are set to 0.

Note

This feature is optional when the protocol number is set to TCP in naming ACLs and numerical value ACLs. MAC extended and IP standard ACLs do not support this function.

To configure TCP Flag filtering, run the following commands:

Command	Function
Ruijie(config)# **ip access-list extended** { *id* | *name* }	Enters ACL configuration mode
Ruijie(config-ext-nacl)# [sn] {**permit** | **deny**} **tcp** source source-wildcard [operator port] destination destination-wildcard [operator port] [**match-all** flag-name][**precedence** precedence]	Adds ACEs to the ACL. For details about the command, see command reference.
Ruijie(config-exp-nacl)# **exit**	Exits ACL configuration mode and selects the interface to which the ACL is to be applied.
Or	
Ruijie(config)# **interface** *interface*	Exits ACL configuration mode and selects the interface to which the ACL is to be applied.
Ruijie(config-if)# **ip access-group** {*id* | *name*} {**in** | **out**}	Applies the ACL to the specific interface

The following example explains how to configure TCP Flag filtering.

- Configure the permission and password for enabling the TCP Flag filtering function.

```
Ruijie> enable
Ruijie#
```

- Enter global configuration mode.

```
Ruijie# configure terminal
Ruijie(config)#
```

- Enter ACL configuration mode.

```
Ruijie(config)# ip access-list extended test-tcp-flag
Ruijie(config-ext-nacl)#
```

- Add an ACE.

```
Ruijie(config-ext-nacl)# permit tcp any any match-all rst
Ruijie(config-ext-nacl)# permit tcp host 1.1.1.1 any established
```

- Add a deny ACE.

```
Ruijie(config-ext-nacl)# deny tcp any any match-all fin
```

- end

```
Ruijie(config-ext-nacl)# end
```

- Show

```
Ruijie# show  access-list test-tcp-flag
ip access-lists extended test-tcp-flag
10 permit tcp any any match-all rst
20 deny tcp any any match-all fin
```

Configuring Comments

Comments on ACLs and ACEs are provided for easy query and understanding of ACL configuration.

Note Up to one ACL comment and 2048 ACE comments can be configured in one ACL.

Caution The length of each comment is 100 bytes.

☑ The ACE comment is supported on the router only.

In privileged configuration mode, run the following commands to configure an ACL comment:

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **ip access-list standard** *id*	Enters ACL configuration mode.
Ruijie(config-std-nacl)# **list-remark** *comment*	Comments the ACL.

You can also run the following commands to set an ACL comment:

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **access-list** *id* **list-remark** *comment*	Sets the ACL comment.

In privileged configuration mode, run the following commands to configure an ACE comment:

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **ip access-list standard** *id*	Enters ACL configuration mode.
Ruijie(config-std-nacl)# **remark** *comment*	Comment the ACE.

You can also run the following commands to set an ACE comment:

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **access-list** *id* **list-remark** *comment*	Sets the ACE comment.

The following example shows how to configure the ACL comment and the ACE comment:

```
Ruijie(config)#ip access-list standard 1
Ruijie(config-std-nacl)#remark ace_remark_permit_62_start
Ruijie(config-std-nacl)#permit 192.168.197.62 0.0.0.0
Ruijie(config-std-nacl)#remark ace_remark_permit_62_end
Ruijie(config-std-nacl)#list-remark acl_remark_foo
Ruijie(config-std-nacl)#end
Ruijie#write
Ruijie#show access-lists 1
ip access-list standard 1
 remark ace_remark_permit_62_start
 10 permit host 192.168.197.62
 remark ace_remark_permit_62_end
list-remark acl_remark_foo
Ruijie#
```

Configuring SVI Router ACLs

The ACLs applied to layer 3 interfaces are called Router ACLs, which apply only to the routing packets forwarded at layer 3.

To solve this problem, Ruijie switches are configured with a command for enabling SVI Router ACLs. After this function is enabled, security ACLs on SVIs apply only to layer 3 forwarding packets between VLANs.

Default Configuration

By default, SVI Router ACLs are disabled. SVI ACLs apply to both inter-VLAN layer 3 packets and intra-VLAN bridge-forwarded packets.

Configuring SVI Router ACLs

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie# **[*no*] svi router-acls enable**	Enables/Disables the SVI Router ACLs.

☑ This function is only supported on SS3000E, S5750, S8600 and S12000 series routers.

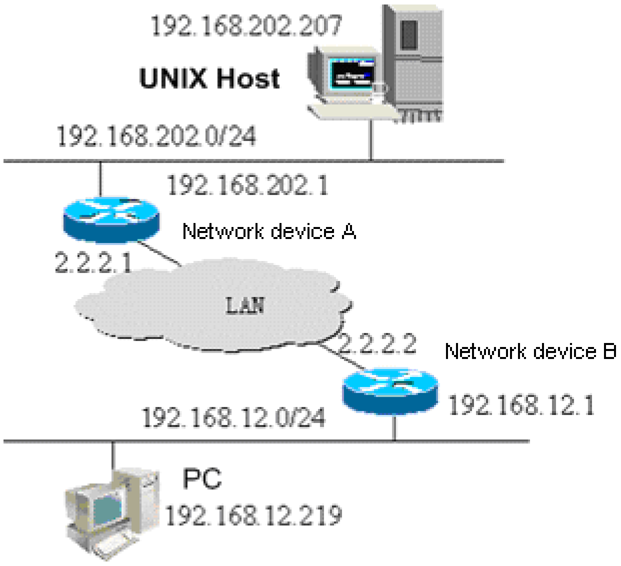
Configuration Examples

IP ACL Example

Configuration requirements:

There are two network devices A and B, as shown in Figure 1-3:

Figure 3 Basic ACL



It is required to implement the following security functions by configuring ACLs on device B.

Hosts on the 192.168.12.0/24 network segment can telnet the remote Unix host only in working hours and these host cannot ping the Unix server.

Device B is forbidden to access any services of hosts on the 192.168.202.0/24 network segment.

Note

This example shows a simplified topology of the banking system. Namely, only access from hosts on the LAN in a branch or outlet to the central host is allowed.

Equipment Configuration

Device B configuration:

```
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if)# ip address 192.168.12.1 255.255.255.0
Ruijie(config-if)# exit
Ruijie(config)# interface GigabitEthernet 0/2
Ruijie(config-if)# ip address 2.2.2.2 255.255.255.0
Ruijie(config-if)# ip access-group 101 in
Ruijie(config-if)# ip access-group 101 out
```

According to requirements, configure an extended ACL numbered 101

```
access-list 101 permit tcp 192.168.12.0 0.0.0.255 any eq telnet time-range check
Ruijie(config)# access-list 101 deny icmp 192.168.12.0 0.0.0.255 any
Ruijie(config)# access-list 101 deny ip 2.2.2.0 0.0.0.255 any
Ruijie(config)# access-list 101 deny ip any any
```

Configure the time range

```
Ruijie(config)# time-range check
Ruijie(config-time-range)# periodic weekdays 8:30 to 17:30
```

Note

For ACL 101, the last rule statement ”access-list 101 deny ip any any” is not needed, because the end of the ACL contains an implicit deny statement for all packets.

Device A configuration:

```
Ruijie(config)# hostname Ruijie
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if)# ip address 192.168.202.1 255.255.255.0
Ruijie(config)# interface GigabitEthernet 0/2
Ruijie(config-if)# ip address 2.2.2.1 255.255.255.0
```

IPv6 Extended ACL Configuration Example

It is required to implement the following security functions by configuring ACLs:

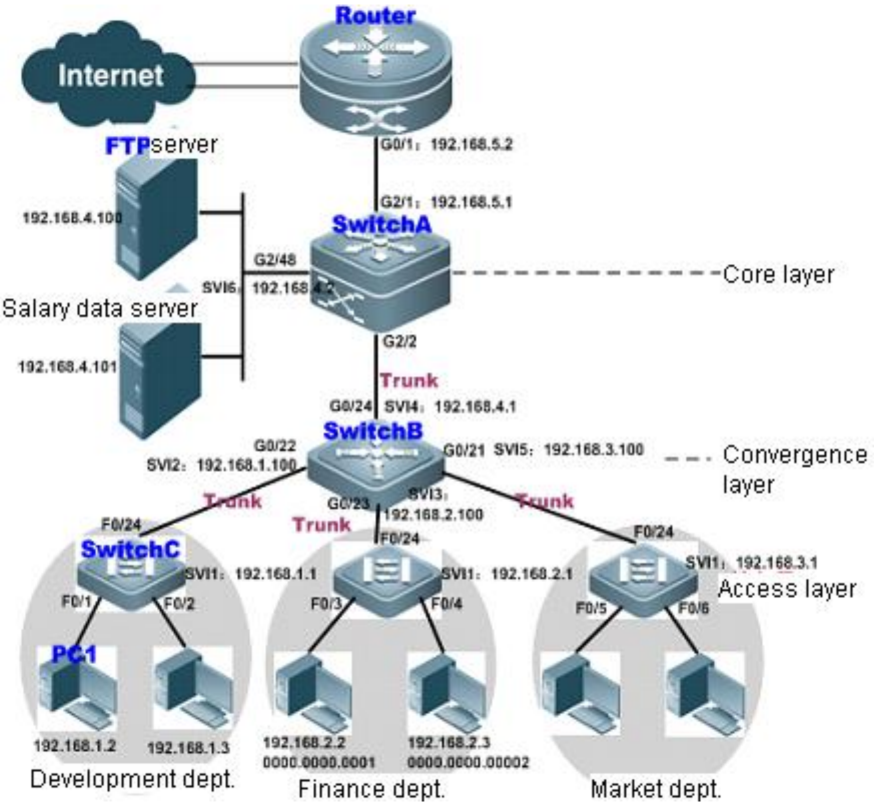
- The host whose IP address is 192.168.4.12 can access the gigabit 0/1 interface of a device.
- It cannot access other interfaces.

```
Ruijie> enable
Ruijie# config terminal
Ruijie(config)# ipv6 access-list v6-list
Ruijie(config-ipv6-nacl)# permit ipv6 ::192:68:4:12/24 any
Ruijie(config-ipv6-nacl)# deny ipv6 any any
Ruijie(config-ipv6-nacl)# exit
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# ipv6 traffic-filter v6-list in
Ruijie(config-if)# end
Ruijie# show access-lists
ipv6 access-list extended v6-list
petmit ipv6 ::192.168.4.12 any
deny any any
```

☑ An ACL cannot match all the preceding areas. Besides, the IPv6 ACL does not apply to packet fragments. Besides, when **sip** and **dip** of a packet match an ACL, **type code** or source and destination ports of ICMP is ignored.

Typical Application of Intranet ACL

Figure 5 Networking Diagram



The preceding diagram shows the typical topology of an Intranet:

The access switch (Switch C) connecting PCs of respective departments is connected to the convergence switch through Gigabit optical cable (trunk mode).

The convergence switch (Switch B) assigns one VLAN for each department and is connected to the core switch through 10G optical fiber cable (trunk mode).

The core switch (Switch A) is connected with multiple servers, such as FTP, HTTP server and etc, and is connected to Internet through firewall.

Application Requirements

The ACL application in this network has the following requirements:

Ports that are susceptible to viruses must be disabled to guarantee Intranet security.

Only the internal PCs can access the servers.

Only PCs within a department can access each other.

R&D personnel are forbidden to use Instant messaging software such as QQ and MSN in working hours (namely from 09:00 to 18:00).

Notes

- The viruses can be avoided by configuring extended ACLs on the router-connecting port (G2/1) of core switch (Switch A) to filter packets destined for relevant ports.
- As for the requirement that internal PCs can access the servers while external PCs are not allowed to access these servers, IP extended ACLs can be defined and applied to ports (G2/2, SVI2) of the core switch (Switch A) that connect with the convergence switch and server.
- As for the requirement that specific departments cannot access each other, IP extended ACLs can be applied to G0/22 and G0/23 of Switch B).
- Configuring time & IP based extended ACL can prevent R&D departments from suing QQ/MSN and other IM application during a specific period (applying time & IP based extended ACL to SVI2 of Switch B).

Configuration Steps

- Configure the core switch: Switch A

Step 1: Define the virus-blocking ACL "Virus_Defence".

Note

The worm viruses on the network will create a TFTP server on the local port of "udp/69" in order to transmit the binary virus program to other infected systems. While selecting the destination IP address, the worms will generally select the IP address of subnet to which the infected system belongs, and then randomly select the attack target on Internet as per certain algorithm. Once the connection is established, the worms will send attack data to TCP ports (135, 445, 593, 1025, 5554, 9995, and 9996), UDP ports (136, 445, 593, 1433, and 1434) and UDP/TCP ports (135, 137, 138, and 139) of targets. If the attack is successful, TCP/4444 port of target system will be used as the backdoor port. After that, worms will connect to this port and send **tftp** command in order to transmit virus file to the target system and run the file. The infected server will send substantive invalid data packets to the network, thus wasting network bandwidth and even causing failure of network devices and the network. In such a case, the extended ACL can be used to filter data packets destined for these ports.

```
A#configure terminal
A(config)#ip access-list extended Virus_Defence
```

! Deny packets destined for internal and external TCP ports which may have been used by viruses.

```
A(config-ext-nacl)#deny tcp any any eq 135
A(config-ext-nacl)#deny tcp any eq 135 any
A(config-ext-nacl)#deny tcp any any eq 136
A(config-ext-nacl)#deny tcp any eq 136 any
A(config-ext-nacl)#deny tcp any any eq 137
A(config-ext-nacl)#deny tcp any eq 137 any
```

…………! The configuration on other ports is similar.

```
A(config-ext-nacl)#deny tcp any any eq 9996
A(config-ext-nacl)#deny tcp any eq 9996 any
```

! Deny packets destined for internal and external UDP ports which may have been used by viruses.

```
A(config-ext-nacl)#deny udp any any eq 69
A(config-ext-nacl)#deny udp any eq 69 any
A(config-ext-nacl)#deny udp any any eq 135
A(config-ext-nacl)#deny udp any eq 135 any
A(config-ext-nacl)#deny udp any any eq 137
A(config-ext-nacl)#deny udp any eq 137 any
```

! The configuration on other ports is similar.

```
A(config-ext-nacl)#deny udp any any eq 1434
A(config-ext-nacl)#deny udp any eq 1434 any
```

! Deny ICMP packets.

```
A(config-ext-nacl)#deny icmp any any
```

! Permit all other IP packets.

```
A(config-ext-nacl)#permit ip any any
A(config-ext-nacl)#exit
```

Step 2: Apply the ACL *Virus_Defence* to the router-connecting interface of the core device.

```
A(config)#interface gigabitEthernet 2/1
A(config-if)#no switchport
A(config-if)#ip address 192.168.5.1 255.255.255.0
```

! Apply the ACL *Virus_Defence* in the inbound direction of G2/1 to deny virus infected packets from an external network.

```
A(config-if)#ip access-group Virus_Defence in
A(config-if)#exit
```

Step 3: Define the ACL *access_server* that permits only Intranet PCs to access the server.

```
A(config)#ip access-list extended access_server
```

! Permit only specified Intranet PCs to access the server (IP address: 192.168.4.100).

```
A(config-ext-nacl)#permit ip 192.168.2.0 0.0.0.255 host 192.168.4.100
A(config-ext-nacl)#permit ip 192.168.1.0 0.0.0.255 host 192.168.4.100
A(config-ext-nacl)#permit ip 192.168.3.0 0.0.0.255 host 192.168.4.100
A(config-ext-nacl)#deny ip any any
```

Step 4: Apply the ACL *access_server* to the interface connecting with convergence device and server.

```
A(config)#interface gigabitEthernet 2/2
A(config-if)#switch mode trunk
```

! Apply the ACL to the inbound direction of the convergence switch.

```
A(config-if)#ip access-group access_server in
A(config-if)#exit
```

! Create a VLAN.

```
A(config)#vlan 2
A(config-vlan)#exit
A(config)#interface gigabitEthernet 2/48
```

! The server-connecting interface of G2/48 belongs to VLAN 2.

```
A(config-if)#switch access vlan 2
A(config-if)#exit
```

! Apply the ACL to the inbound direction of the server-connecting interface.

```
A(config)#interface vlan 2
A(config-if-VLAN 2)# ip access-group access_server in
A(config-if-VLAN 2)# ip address 192.168.4.2 255.255.255.0
A(config-ext-nacl)#end
```

- Configure the convergence switch: SwitchB

Step 1: Create VLAN 2, VLAN 3, and VLAN 4.

```
B#configure terminal
```

! Create VLAN 2, VLAN 3, and VLAN 4.

```
B(config)#vlan range 2-4
B(config-vlan-range)#exit
```

Step 2: Define ACLs.

! Define the IP extended ACLs vlan_access1 and vlan_access2.

```
B(config)#ip access-list extended vlan_access1
```

! Prohibit PCs of the finance department and market department from accessing PCs of the R&D department.

```
B(config-ext-nacl)#deny ip 192.168.2.0 0.0.0.255 192.168.1.0 0.0.0.255
B(config-ext-nacl)#deny ip 192.168.3.0 0.0.0.255 192.168.1.0 0.0.0.255
B(config-ext-nacl)#permit ip any any
B(config)#ip access-list extended vlan_access2
```

! Prohibit PCs of the R&D department and market department from accessing PCs of the finance department.

```
B(config-ext-nacl)#deny ip 192.168.1.0 0.0.0.255 192.168.2.0 0.0.0.255
B(config-ext-nacl)#deny ip 192.168.3.0 0.0.0.255 192.168.2.0 0.0.0.255
B(config-ext-nacl)#permit ip any any
B(config-ext-nacl)#exit
```

Step 3: Apply ACLs *vlan_access1* and *vlan-access2* to the corresponding interfaces.

! Configure G0/22 as a trunk port and apply *vlan_access1* to this port.

```
B(config)#interface GigabitEthernet 0/22
B(config-if)#switchport mode trunk
B(config-if)#ip access-group vlan_access1 in
```

! Configure G0/23 as a trunk port and apply *vlan_access2* to this port.

```
B(config)# interface GigabitEthernet 0/23
B(config-if)# switchport mode trunk
B(config-if)# ip access-group vlan_access2 in
```

! Configure G0/24 as a trunk port.

```
B(config)#interface GigabitEthernet 0/24
B(config-if)#switchport mode trunk
```

! Configure the IP address of SVI 2.

```
B(config)#interface vlan 2
B(config-if)#ip address 192.168.1.100 255.255.255.0
```

! Configure the IP address of SVI 3.

```
B(config)#interface vlan 3
B(config-if)#ip address 192.168.2.100 255.255.255.0
```

! Configure the IP address of SVI 4.

```
B(config)#interface vlan 4
B(config-if)#ip address 192.168.4.1 255.255.255.0
```

Step 4: Define time range.

! Define the time range that starts from 09:00 to 18:00 in weekdays.

```
B#configure terminal
B(config)#time-range worktime
B(config-time-range)#periodic weekdays 9:00 to 18:00
```

Step 5: Define the traffic rule of R&D department.

```
B#configure terminal
```

! Create the extended ACL *yanfa* in configuration mode.

```
B(config)#ip access-list extended yanfa
```

! Prohibit all IM applications such as QQ and MSN on hosts of R&D department from 09:00 to 18:00 in weekdays.

```
B(config-ext-nacl)#deny tcp 192.168.1.0 0.0.0.255 eq 8000 any time-range worktime
B(config-ext-nacl)#deny tcp 192.168.1.0 0.0.0.255 eq 8001 any time-range worktime
B(config-ext-nacl)#deny tcp 192.168.1.0 0.0.0.255 eq 443 any time-range worktime
B(config-ext-nacl)#deny tcp 192.168.1.0 0.0.0.255 eq 1863 any time-range worktime
B(config-ext-nacl)#deny tcp 192.168.1.0 0.0.0.255 eq 4000 any time-range worktime
B(config-ext-nacl)#deny udp 192.168.1.0 0.0.0.255 eq 8000 any time-range worktime
B(config-ext-nacl)#deny udp 192.168.1.0 0.0.0.255 eq 1429 any time-range worktime
B(config-ext-nacl)#deny udp 192.168.1.0 0.0.0.255 eq 6000 any time-range worktime
B(config-ext-nacl)#deny udp 192.168.1.0 0.0.0.255 eq 6001 any time-range worktime
B(config-ext-nacl)#deny udp 192.168.1.0 0.0.0.255 eq 6002 any time-range worktime
B(config-ext-nacl)#deny udp 192.168.1.0 0.0.0.255 eq 6003 any time-range worktime
B(config-ext-nacl)#deny udp 192.168.1.0 0.0.0.255 eq 6004 any time-range worktime
```

! Permit all other IP traffic.

```
B(config-ext-nacl)#permit ip any any
```

! Apply the ACL to the inbound direction of SVI 2.

```
B(config)#interface vlan 2
B(config-if)#ip access-group yanfa in
```

Verification

Step 1: Verify whether ACEs are correct. The key is that whether the priorities of ACEs are correct and whether ACEs are effective.

```
SwitchA#show access-lists

 120 deny udp 192.168.1.0 0.0.0.255 eq 6004 any time-range worktime (active)
```

Step 2: Verify whether ACL configuration is complete. The key is that whether the correct ACL has been applied to the specified interface.

Device A configuration:

```
A#show run
interface GigabitEthernet 2/1
 no switchport
 no ip proxy-arp
 ip access-group Virus_Defence in
 ip address 192.168.5.1 255.255.255.0
!
interface GigabitEthernet 2/2
 switchport mode trunk
 ip access-group access_server in
!
interface VLAN 2
 no ip proxy-arp
 ip access-group access_server in
 ip address 192.168.4.2 255.255.255.0
```

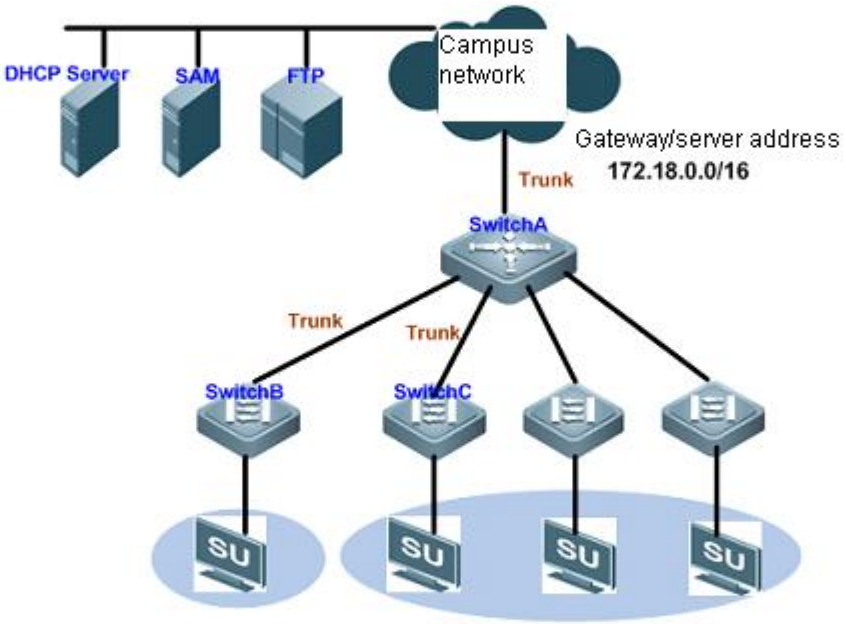
Device B configuration:

```
B#show run
!
interface GigabitEthernet 0/22
 switchport mode trunk
 ip access-group vlan_access1 in
!
interface GigabitEthernet 0/23
 switchport mode trunk
 ip access-group vlan_access2 in
!
interface VLAN 2
 no ip proxy-arp
 ip access-group yanfa in
 ip address 192.168.1.100 255.255.255.0
```

Application of expert ACL & ACL 80

Networking Diagram

Figure 6 Application topology diagram of the expert ACL&ACL 80



The preceding figure shows the simplified topology of a campus network:

Switch A is the convergence device assigning one VLAN for each faculty and is connected to the campus network through 10G optical cable (trunk mode).

Switch B and Switch C are access devices connecting PCs of respective faculties, and are connected to the convergence switch through Gigabit optical cable (trunk mode).

SU client must be installed on each PC so that a PC can access Internet after being authenticated.

Application Requirements

SU software is not embedded in Windows. You must download and install SU client on the PC. However, the PC cannot download software before 802.1x authentication. To solve this problem, the following requirements must be met:

- IP packets and ARP packets accessing the segment address of gateway/server (172.18.0.0/16) are allowed to pass through without authentication, so that the user PC can download software from the specified server or access gateway before authentication.
- DHCP packets (UDP port number being 67/68) are allowed to pass through without authentication, so that the user PC can acquire the IP address in order to proceed with authentication.

Notes

Configure ACL80 or expert ACL on the access device (Switch B/Switch C) and combine the feature of secure tunnel to permit certain packets without authentication.

In this case, ACL 80 is configured on Switch B and expert ACLs are configured on Switch C.

Configuration Steps

- Device B configuration

Note

ACL 80 allows the user to define 16 bytes out of the first 80 bytes of packets to perform per-bit matching and filtering. The user-defined string will be compared with the string extracted from packet (1 means match and 0 means mismatch), so as to determine further action.

Step 1: Configure the customized ACL.

```
B#configure terminal
```

! Create a customized ACL named "tongdao"

```
B(config)#expert access-list advanced tongdao
```

! Permit all ARP packets (protocol number being 0806, offset being 24) with source IP address(the offset in the source IP of ARP packets is 40) falling within the network segment of 172.18.0.0 (hexadecimal value being ac12)

```
B(config-exp-dacl)#permit 0806 ffff 24 ac12 ffff 40
```

! Permit all IP packets (protocol number being 0800, offset being 24) with source IP (the offset in the source IP of IP packets is 38) falling within the network segment of 172.18.0.0 (hexadecimal value being ac12)

```
B(config-exp-dacl)#permit 0800 ffff 24 ac12 ffff 38
```

! Permit DHCP packets with UDP port being 67 (Bootstrap Protocol Server) and 68 (Bootstrap Protocol Client) (offset in protocol number being 35; hexadecimal value of 11 to indicate UDP; offset in port being 46; hexadecimal value of 43/44 corresponding to 67 and 68).

```
B(config-exp-dacl)# permit 11 ff 35 00440043 ffffffff 46
B(config-exp-dacl)#exit
```

Step 2: Globally configure the ACL for secure tunnel application.

! Configure ACL "tongdao" for secure tunnel application

```
B(config)# security global access-group tongdao
```

- Device C configuration:

Step 1: Configure an expert ACL.

```
C#configure terminal
```

! In configuration mode, create an expert ACL named "tongdao1"

```
C(config)#expert access-list extended tongdao1
```

! Permit all IP packets with source IP falling within the network segment of 172.18.0.0

```
C(config-exp-dacl)#permit ip 172.18.0.0 0.0.255.255 any any any
```

! Permit all packets with UDP port number being 67 (Bootstrap Protocol Server) and 68 (Bootstrap Protocol Client)

```
C(config-exp-dacl)# permit udp any any eq bootpc any any eq bootps
```

```
C(config-exp-dacl)#exit
```

Step 2: Globally configure the ACL for secure tunnel application.

! Configure ACL "tongdao1" for secure tunnel application

```
C(config)# security global access-group tongdao1
```

Verifications

Step 1: Verify whether ACEs are correct. The key is that whether the priorities of ACEs are correct and whether ACEs are effective.

```
B# show access-lists
expert access-list advanced tongdao
 10 permit 0806 FFFF 24 AC12 FFFF 40
 20 permit 0800 FFFF 24 AC12 FFFF 38
 30 permit 11 FF 35 00440043 FFFFFFFF 46
C# show access-lists
expert access-list extended tongdao1
 10 permit ip 172.18.0.0 0.0.255.255 any any any
 20 permit udp any any eq bootpc any any eq bootps
```

Run the preceding command to verify whether the corresponding ACEs are correct.

Step 2: Verify whether ACL configuration is complete. The key is that whether the correct ACL has been applied in global configuration mode:

```
B#show run
!
expert access-list advanced tongdao
!
security global access-group tongdao
!
!
C#show run
!
expert access-list advanced tongdao1
!
security global access-group tongdao1
!
```

☑ ACL configuration for different line cards:

The following description applies only to versions later than RGOS10.3.

This principle is also appropriate for hot pluggable line cards, which prompts the users to reset line cards.

If ACL out is implemented on the egress, then IP extended ACL and expert ACL will not support port matching. Besides, expert ACL only supports IP packet matching, not other L2 packets, IPV6 does not support flow_label, DSCP and fragment matching.

If ACL out is processed in the original way, then associating ACL out with SVIs has lots of restrictions:

- Changes the priority of in and out direction; the ACL used in the outbound direction is higher than that used in the inbound direction.
- When you apply an ACL to the outbound direction of an SVI, there is no **deny any any** option by default. But there is **deny any any** option in other ACLs.
- Associating ACL with SVI in Out direction can support IP standard, IP extended, MAC extended, ACL application of expert extended ACLs.
- There are some restrictions for matching destination ip and destination mac in ACL when associating ACL with SVI in the outbound direction. If you want to match destination MAC in MAC extended and expert ACL and apply the ACL in the outbound direction of SVI, the entry will be set and not take effect.
- The set ACL will not take effect if you want to match destination IP address, which is not within the subnet IP range of associated SVI, in IP standard, IP extended and expert ACL. For example, the address of VLAN 1 is 192.168.64.1 255.255.255.0. And now, if you create an IP extended ACL with ACE deny udp any 192.168.65.1 0.0.0.255 eq 255, it will not take effect when applying this ACL to the egress of VLAN 1, for the destination IP address is not within the subnet IP range of VLAN 1; but it will take effect if the ACE is deny udp any 192.168.64.1 0.0.0.255 eq 255, for the destination IP address is up to specification.
- The priority of the ACL associated with an SVI in the outbound direction has the highest priority.
- ACL out does not support user-defined acl type.

Configuring the Firewall

Understanding IP-MAC Binding

Overview

IP-MAC binding refers to that the IP address and MAC address of a host are bound on the router or firewall it directly connects to, so that an IP address can be used only by the host with the matching MAC address. This function is designed to prevent IP address spoofing. To deploy this function, two prerequisites must be met:

1) The MAC address is unique and genuine.
2) IP-MAC binding applies only to hosts that are directly connected to a router or firewall.

Furthermore, a host interface may be configured with multiple IP addresses, thus allowing multiple IP addresses to be bound to the same MAC address.

Configuring IP-MAC Binding

Enabling or Disabling the IP-MAC Binding Function

IP-MAC binding is disabled by default. To use this function, configure binding rules by using the **ipmacbind** command in global configuration mode. IP-MAC binding function will be disabled if all IP/MAC binding rules are deleted.

Configuring IP-MAC Binding

The IP address of a host can be bound to its MAC address by using the **ipmacbind** command to prevent the IP address from being counterfeited by other hosts. Rebind the bound IP address if it already exists. Multiple IP addresses can be bound to the same MAC address. For example:

```
Ruijie(config)# ipmacbind 192.168.52.69 032a.33ac.3f11 log
```

The preceding command binds the IP address 192.168.52.69 to the network card with MAC address 032a.33ac.3.3f11. Here, **log** indicates that the log function regarding IP-MAC binding is enabled. Besides, you can specify the format of any IP address and any MACaddress. For example:

Ruijie(config)# **ipmacbind any any log**

Meanwhile, the IP-MAC binding entries on a LAN can be detected and exported from the ARP table dynamically by using the **ipmacbind auto** command.

```
Ruijie(config)# ipmacbind auto
```

You can configure an IP-MAC binding rule list as well as the rules in the list and apply the list to the interface. Besides, you can specify the default processing of packets not matching the IP-MAC binding rule on the current interface. For example:

```
Ruijie(config)# ipmacbind list number
Ruijie(config-ipmac-bind)#ipmacbind ip mac [log]
Ruijie(config-if-GigabitEthernet 0/0)# ipmacbind list number [ default action {permit | deny
[ log ]} ]
```

Configure the IP MAC binding rule list and the corresponding rules in the list, apply the list to the corresponding interface at the same time, and configure the default rule operation on the current interface.

```
Ruijie(config)# ipmacbind list number
Ruijie(config-ipmac-bind)#ipmacbind ip mac [log]
Ruijie(config-if-GigabitEthernet 0/0)# ipmacbind list number [ default action {permit | deny
[ log ]} ]
```

The **no** form of the **Ipmacbind** command is used to delete IP-MAC binding entries. If an IP address is specified in this command, the IP address is deleted from an IP-MAC binding entry. Besides, you can use the **clear ipmacbind** command to delete the IP-MAC binding entries dynamically exported from the ARP table or all IP-MAC binding entries. For example:

```
Ruijie# clear ipmacbind dynamic
```

The preceding command clears all IP-MAC binding entries dynamically exported from the ARP table by using the **ipmacbind auto** command.

```
Ruijie# clear ipmacbind all
```

The preceding command clears all IP-MAC binding entries including the information of the rule list.

By default, packets without IP MAC address binding rule are permitted to pass. Use the ipmacbind default action command to deny packets without IP MAC address.

```
Ruijie(config)#ipmacbind default action deny
```

Rule description:

The IPMAC binding rule operation only permits or denies two situations. By default, the rule is permit, and the matching rule combinations and the results are as follows:

Deny:

IP Address	MAC Address	Result
False	Correct	Deny
Correct	False	Deny
False	False	Deny
Correct	Correct	Permit

Permit:

IP Address	MAC Address	Result
Correct	False	Deny
Correct	Correct	Permit
False	Correct	Permit
False	False	Permit

Viewing IP-MAC Binding Information

Run the **show ipmacbind** command to view records or statistics on current IP-MAC binding.

```
Ruijie# show ipmacbind table
Totol number of IPMAC-Bind rule: 2
IPMAC-Bind global rule:
No    Type        IP Address     MAC Address     Log
1     <static>    any            00d0.0011.0012   off

IPMAC-Bind list 1 rule:
No     Type        IP Address      MAC Address     Log
1    <static>    192.168.2.2     00d0.0011.0011   off
```

To view all IP-MAC binding entries and the IP-MAC binding rule information:

```
Ruijie# show ipmacbind statistic
IPMAC-Bind global dropped 0 packets
IPMAC-Bind list 1 dropped 0 packets
```

To view the IP MAC function and the number of invalid packets intercepted by the IP MAC binding rule list;

```
Ruijie# show ipmacbind hash
IPMAC-Bind global:
In MAC hash-list 211:
   1: ip-any, mac-00d0.0011.0012
IPMAC-Bind list 1:
In IP hash-list 616:
1: ip-192.168.2.2, mac-00d0.0011.0011
```

To view the IP-MAC binding rule and the hash table corresponding to IP-MAC binding rule list:

Understanding URL Filtering

Overview

URL filtering is an extension of packet filtering, achieving in-depth access control. It is a means of content filtering and restricts intranet users from accessing certain illegal websites.

The process of URL filtering is as follows:

1) The firewall resolves the HTTP request from a client to obtain the requested URL;
2) The firewall uses the predefined URL filtering rules to match the requested URL;
3) If a match is detected, the firewall determines whether to permit or reject the access based on the matching result.
4) If no match is detected, the firewall sends the URL request to a third-party content filtering server (such as Websense or N2H2) and meanwhile suspends the HTTP session until a response is returned from the server. Then the firewall determines whether to permit or reject the HTTP request based on the response. All requests shall be denied and an alarm is reported if the server is unavailable.

Currently, only local URL filtering is supported. The linkage with a third-party content filtering server will be realized in future.

Configuring URL Filtering

URL filtering rules are configured as follows:

5) Specify the URLs to be filtered and add these URLs to a filtering category.
6) Configure filtering rules and add the filtering category to the rules.
7) Apply these rules to interfaces.

It should be noticed that you need to specify an ACL before applying the rules to the interfaces for advertising the URL filtering range.

Registering URLs

To filter a URL, use a URL-related command in global configuration mode to register the URL and the filtering category the URL belongs to. To delete a registered URL, run the **no url** command.

It should be noticed that a URL always begins with a stop (.) in all cases.

For example:

```
Ruijie(config)# ip urlfilter rule test .sina.com.cn
Ruijie(config)# ip urlfilter rule test .*sina.com.cn
Ruijie(config)# ip urlfilter rule test .sina*
Ruijie(config)# ip urlfilter rule test .*sina*
```

In the example, the asterisk (*) is used as the wildcard. The wildcard can be placed only at the end of a URL or after the first stop in a URL.

These URL formats are explained as follows:

- .sina.com.cn represents URLs such as www.sina.com.cn, blog.sina.com.cn, and new.sina.com.cn, instead of Ruijie.blog.sina.com.cn, sports.news.sina.com.cn, and the like.
- .*sina.com.cn represents all URLs ended with "sina.com.cn".
- .sina* represents all URLs in which the first stop is followed by "sina". For example, blog.sina.com.cn matches this rule but Ruijie.blog.sina.com.cn does not.
- *sina* represents all URLs containing "sina" such as Ruijie.blog.sina.com.cn, blog.sina.com.cn, and www.adfsina.com.

Configuring URL Filtering Rules

Filtering rules should be configured after the URL category is configured.

URL filtering rules are configured in global configuration mode.

```
Ruijie(config)# ip urlfilter category 1 test
```

The preceding command is to create a filtering rule numbered 1. Then, the predefined filtering category can be added to this rule. Each rule can accommodate 15 categories. That is, other predefined categories can also be added to this rule. For example:

- Ruijie(config)# ip urlfilter category 1 test1
- Ruijie(config)# ip urlfilter category 1 test2
- Ruijie(config)# ip urlfilter category 1 test3

It should be noticed that Ruijie products allow a category to be added to different rules.

```
Ruijie(config)# ip urlfilter category 1 test
Ruijie(config)# ip urlfilter category 2 test
Ruijie(config)# ip urlfilter category 3 test
```

Applying Rules to Interfaces

After the preceding configuration is complete, you need to apply these rules to interfaces.

Before applying rules to interfaces, remember configuring an ACL rule in configuration mode.

The following example shows how to create a URL that filters all IP addresses and allows access to the URLs defined in rule 1. In this example, logs are recorded when access is denied.

```
Ruijie(config)# access-list 1 permit any
Ruijie(config)# interface gigabitEthernet 0/0
Ruijie(config-if)# ip urlfilter exclusive-domain 1 1 permit in log
```

Now, URL filtering rule configuration is complete.

Viewing Configuration Information and Statistical Information of the URL Filtering Module

Configuration Information

Suppose that some URL filtering rules have been configured. The following describes how to query, configure, and delete these rules,

show ip urlfilter config address

Run the preceding command in configuration mode.

```
Ruijie(config)# show ip urlfilter config address
================[Url without wildcard]===================
cls_name          cls-id           url-address
=========================================================
test1              2                .tianya.cn
----------------------------------------------------------
test2             3                .sohu.com
----------------------------------------------------------
test1             1                .sina.com.cn
----------------------------------------------------------
test1              2                .mop.com
=================[Url no-wildcard end]====================
===================[Url with pre-wildcard]================
cls_name          cls-id           url-address
```

```
==========================================================
test1              2                .*hong.com
-----------------------------------------------------------
test2             3                .*263.net
-----------------------------------------------------------
test1              2                .*163.com
===================[Url pre-wildcard end]===================
===================[Url with post-wildcard]=================
cls_name          cls-id            url-address
===========================================================
test2             3                .taob*
-----------------------------------------------------------
test1              2                .google.com*
-----------------------------------------------------------
test2             3                .ebay*
-----------------------------------------------------------
test1              2                .baid*
===================[Url post-wildcard end]==================
===================[Url with all-wildcard]==================
cls_name          cls-id            url-address
===========================================================
test2             3                .*huawei*
-----------------------------------------------------------
test1              2                .*cisco*
===================[Url all-wildcard end]===================
=================[Relative CLI Command]=====================
ip urlfilter rule test1 .tianya.cn
ip urlfilter rule test2 .sohu.com
ip urlfilter rule test .sina.com.cn
ip urlfilter rule test1 .mop.com
ip urlfilter rule test1 .*hong.com
ip urlfilter rule test2 .*263.net
ip urlfilter rule test1 .*163.com
ip urlfilter rule test2 .taob*
ip urlfilter rule test1 .google.com*
ip urlfilter rule test2 .ebay*
ip urlfilter rule test1 .baid*
ip urlfilter rule test2 .*huawei*
ip urlfilter rule test1 .*cisco*
==========[Relative CLI Command To Del the Rules ]==========
no ip urlfilter rule test1 .tianya.cn
no ip urlfilter rule test2 .sohu.com
no ip urlfilter rule test .sina.com.cn
no ip urlfilter rule test1 .mop.com
no ip urlfilter rule test1 .*hong.com
no ip urlfilter rule test2 .*263.net
no ip urlfilter rule test1 .*163.com
no ip urlfilter rule test2 .taob*
no ip urlfilter rule test1 .google.com*
no ip urlfilter rule test2 .ebay*
no ip urlfilter rule test1 .baid*
no ip urlfilter rule test2 .*huawei*
no ip urlfilter rule test1 .*cisco*
```

Firstly, classify the addresses into four categories: addresses without a wildcard, addresses preceded by a wildcard, addresses followed by a wildcard and addresses with one wildcard at the beginning and one wildcard at the end. And we print out the classified addresses under the same category in a continuous manner.

Secondly, record all the commands you use to configure these addresses. As a result, even a green hand will be able to view the configuration process.

Lastly, provide you a cookie that shows you the commands for deleting configuration, so that you no longer need to run **show run** to query the command for deleting a configuration but copy the desired command and paste it in the CLI.

show ip urlfilter config rule

The **show** command shows the addresses that have been configured in the current system. Now let's learn the configured rules.

```
Ruijie(config)# show ip urlfilter config rule
=================[ Ip UrlFilter Rule configure ]=================
Id     Attribute         Details
-------------------------------------------------------------------------==--------------
--------
1      contain-class:     test
ref-interface:gigabitEthernet 0/0 gigabitEthernet 0/1
---------------------------------------------------------------------------==------------
---------
2      contain-class:     test1
ref-interface:     gigabitEthernet 0/0
gigabitEthernet 0/1
gigabitEthernet 0/2
-----------------------------------------------------------------------------------------
----------
3      contain-class:     test2
ref-interface:     gigabitEthernet 0/2
==============================================================
================[Relative CLI Command]========================
ip urlfilter category 1 test
ip urlfilter category 2 test1
ip urlfilter category 3 test2
=========[Relative CLI Command To Del the Rules ]===============
no ip urlfilter category 1 test
no ip urlfilter category 2 test1
no ip urlfilter category 3 test2
Using this command, you can view the address categories included in a rule and the interface
to which rules apply. Then you can determine the interface from which the desired information
can be obtained.
```

show ip urlfilter config setting

Query information about gigabitEthernet 0/0.

```
Ruijie(config-if)# show ip urlfilter config setting
========[ Url Filter Rules On gigabitEthernet 0/0 ]==============
Rules On Input
==============================================================
Id  Acl   Action  Class-name     Url-address

no ip urlfilter exclusive-domain 2 13 permit in
no ip urlfilter exclusive-domain 3 13 block in
======[ Url Filter Rules On gigabitEthernet 0/0 End]=======
```

In the command output, you can view rule IDs, effective scope of rules (ACL numbers), conform-action, inclusive categories, and URLs in these categories.

Statistical Information

Statistical information is also what administrators care much for.

```
Ruijie(config)# show ip urlfilter statistics
url filter statistics
==============================================
the rule 1
       Total requests allowed: 0
       Total requests blocked: 0
the rule 2
       Total requests allowed: 0
       Total requests blocked: 0
the rule 3
       Total requests allowed: 0
       Total requests blocked: 0
```

Problems Encountered in Use of this Function

By now, you have seen that URL filtering function configuration is very flexible. But flexible things are always hard to command. Next, let's together have a look at some matters that require your attention.

One URL can only belong to one address category at one time.

Just as you have seen, one URL can only belong to one rule at one time according to our rules.

Only one rule applies to one interface.

Perhaps you have noticed that we provide only one action for each rule in regard to the rules for interfaces, i.e., the action we take when the website to access to matches our rules. What about the mismatch? Take opposite action, of course.

Different URLs have different priorities in the matching process.

Rules' priorities are arranged as follows in descending order:

- Rules without a wildcard.
- Rules with a wildcard at the beginning.
- Rules with a wildcard at the end
- Rules with one wildcard at the beginning and the other at the end.

Once matched by a rule with high priority, an address will not be matched by following rules.

```
ip urlfilter rule test .sina.com.cn
ip urlfilter rule test1 .*.*

ip urlfilter category 0 test
ip urlfilter category 1 test1
!
!
ip access-list standard 1
10 permit any

interface gigabitEthernet 0/0
ip urlfilter exclusive-domain 1 1  block in log
ip ref
ip address 130.130.130.1 255.255.255.0
duplex auto
speed auto
!
interface gigabitEthernet 0/1
ip ref
ip address 192.168.52.141 255.255.255.0
duplex auto
speed auto

ip route  0.0.0.0 0.0.0.0  192.168.52.1
```

What is the function of this rule?

He has only configured two rules: one is for filtering .sina.com.cn, and the other is for filtering all websites with the character "." What did he do next? He added the two categories to the two rules, and apply the rule that filters all websites with the character "." to the ingress. It seems that he really wants to disable Internet access.

Well, guess whether the current rule can filter all websites or not? The answer is: of course not.

Take it easy. I will answer your question.

In order to save time and space, I will directly tell you that those websites with .sina.com.cn will not be filtered. Why?.

Let's analyze the process of searching, matching and filtering.

First of all, the website that users visit will match in the rule without wildcard. If they access www.sina.com.cn or news.sina.com.cn, the website will match the rule. Notice that once matched by any rule, the URL a user visits will no longer match following rules. This shall be emphasized. Then, as for our filtering program, the visited website falls into the category of "test" instead of "test 1".

When the category is found out, the filtering begins. Our filtering program on the interface will search in its own rule. When it finds that the category "test" is not included in its own rule, it will adopt the processing mode opposite to what is defined in its own rule to deal with this website. Since the guy defined the rule action is 'block", the action taken for the category "test" that is not in his rule will surely be "permit".

Now, let's have another look from the very beginning before we come to the conclusion why this guy has not filtered all rules. It is because he has not noticed the priority problem of website matching. Though the rule .*.* can match all addresses, .sina.com.cn that has a higher priority will match in a better way.

Therefore, we can say that it is very important to configure rule priority.

Notice should be given to the website with lower level domain name(s) and URL redirection.

When we verified our own products, our filter device was always disabled for some websites. Later, we kept track of the visits to these websites. The result was really surprising. Let's see the example of www.google.com.

Careful users may have found that when they access Google in China, they use www.google.com, but they come to see www.google.cn in the address bar of browser when the webpage is opened. This is called redirection.

However, under a real environment, the access process is more complicated. (Take our environment here for example).

First, we resolve the domain name of Google in DNS. Then, we will access the website of 210.70.14.147. Next, we will visit www.google.cn.

If you want to deal with such websites, you need to add the IP address and google.cn into the rule.

Then, you can use tailored functions as you wish.

Understanding Network Ingress Filtering

Overview

A lot of DoS/DDoS attacks are carried out with forged source IP addresses. NIF (Network Ingress Filtering, RFC 2827) is aimed to defend against such attacks, or limit the scope and lower the risk of being attacked. It will check up whether the source IP address claimed by the data packet entering a network meets the network prefix advertised by route. If not, filter it. Such filtering mechanism implemented on the router at the network ingress will be very effective to prevent IP spoofing attacks. However, it will take no effect on the IP spoofing attacks with legitimate IP address prefix at all.

Configuring NIF

Enabling or Disabling Network Ingress Filtering

NIF is disabled by default. To use this function, run the **ip ingress -filter** command in interface mode. For example:

```
Ruijie(config-if)# ip ingress-filter log
```

The preceding command enables the NIF function on the interface and the log function of NIF at the same time.

The **no** form of **ip ingress-filter** disables the NIF function on the interface. For example:

```
Ruijie(config-if)# no ip ingress-filter log
```

The preceding command disables the NIF function on the interface.

Viewing Network Ingress Filtering Information

Run the **show ip ingress-filter** command to view current IP/MAC binding records or statistical information, e.g.,.

```
Ruijie(config)# show ip ingress-filter
Firewall Network-ingress-filter is enable, blocked 0 flowsInterface FastEthernet 1/0: log is
on, blocked 0 flows
```

Through the preceding command, you can view whether the NIF function is enabled and how much unauthorized information has been blocked.

Understanding TCP SYN Proxy

Overview

SYN proxy is an effective way to guard against SYN Flood attacks. SYN flood attacks occur at the stage of three-way handshakes of TCP. Attackers send a large number of TCP SYN packets to victims, who then open a lot of TCP links and respond attackers by sending TCP SYN ACK. However, attackers do not send TCP ACK packets to complete three-way handshakes. In this case, thus victims' queues are filled with semi-connections and new connections cannot be established until these semi-connections time out. The basic process of TCP SYN proxy is that three-way handshakes between router/firewall proxy service terminal and client terminal are completed first, if the connection is legal, then connection with the service terminal will be established.

Configuring TCP SYN Proxy

Enabling or Disabling TCP SYN Proxy Function

TCP SYN proxy function is disabled by default. Before enabling this function, configure ACL rules to specify the streams to which TCP SYN proxy applies, e.g.,.

```
Ruijie(config)# access-list 100 permit ip 192.168.52.0 0.0.0.255 any
```

Then, run the **ip tcp-intercept list in|out** command in interface configuration mode to apply TCP SYN proxy to the streams that pass through the interface and match the ACL rules, e.g.,.

```
Ruijie(config)# interface gigabitEthernet 0/0
Ruijie(config-if)# ip tcp-intercept list 100 in log
```

The preceding command indicates that TCP SYN proxy is applied to the inbound streams of gigabit0/0 complying with ACL 100 and the log function of TCP SYN proxy is enabled.

Use the **no** form of the **ip tcp-intercept list in|out** command to disable this function, e.g.,.

```
Ruijie(config)# interface gigabitEthernet 0/0
Ruijie(config-if)# no ip tcp-intercept list 100 in log
```

Viewing TCP SYN Proxy Information

Use the **show ip tcp-intercept** command to view current TCP SYN proxy records or statistical information, e.g.,.

```
Ruijie(config-if)# show ip tcp-intercept
Intercepting new connections using access-list 100 at gigabitEthernet 0/0 in
20 incomplete, 1320 established connections (total 1340)
```

Through the preceding command, you can see that TCP SYN proxy has been enabled on gigabit 0/0 interface. In addition, 20 invalid TCP streams unfinished and 1,320 normal TCP streams have been monitored.

Understanding Special Protocol

Overview

Such protocols as FTP, MMS, H.323, etc have separate command control channels and data channels. And the data channels are port numbers, etc randomly specified through the control channels by both channels. If control channel port access is only allowed by configuring ACL and other packet filtering rules on network equipments, and provided that no special means is available for processing, data channels will be completely blocked. Therefore, a special way is needed to establish some temporary pass and access mechanisms for the data channels of these protocols.

Configuring a Special Protocol

Users need to configure rules in configuration mode, where they specify a name that consists of character strings and is easy to remember for a special protocol to access, e.g.,.

You can add FTP to the rule library named "abc", to which the MMS protocol can also be added. These two protocols do not overlay or conflict with each other.

In the same way, a rule library named "123" may be defined.

```
Ruijie(config)# ip inspect name abc ftp
Ruijie(config)# ip inspect name abc mms
Ruijie(config)# ip inspect name 123 mms
Ruijie(config)# ip inspect name 123 h323

Ruijie(config)# show ip inspect all
Inspection Rule Configuration
Inspection name abc
```

```
ftp
mms
Inspection name 123
mms
h323
```

Then, users need to enter the specified interface and add this rule. For example:

```
Ruijie(config)# interface gigabitEthernet 0/0
Ruijie(config-if)# ip inspect abc in
Ruijie(config)# show ip inspect all
Inspection Rule Configuration
Inspection name abc
ftp
mms
Inspection name 123
mms
h323

Interface Configurationn
Interface gigabitEthernet 0/0
Inbound inspection rule is abc
ftp
mms
```

It should be noticed that one interface can only be applied with one special protocol rule library. If added with another, the newly added rule shall replace the original one. For example:

```
Ruijie(config)# interface gigabitEthernet 0/0
Ruijie(config-if)# ip inspect abc in
Ruijie(config)# show ip inspect all
Inspection Rule Configuration
Inspection name abc
ftp
mms
Inspection name 123
mms
h323
Interface Configurationn
Interface gigabitEthernet 0/0
Inbound inspection rule is abc
ftp
mms
Ruijie(config)# interface gigabitEthernet 0/0
Ruijie(config-if)# ip inspect 123 in
Ruijie(config)# show ip inspect all
Inspection Rule Configuration
Inspection name abc
ftp
mms
Inspection name 123
mms
h323
Interface Configurationn
Interface gigabitEthernet 0/0
Inbound inspection rule is 123
mms
h323
```

Understanding TCP Sequence Number Tracking

Overview

The purpose of TCP sequence number check is to guard against intrusion such as TCP session hijacking. It determines whether a data packet is valid by recording and tracking send sequence numbers, acknowledgement sequence numbers, and receive windows of both sides of a TCP connection.

Configuring TCP Sequence Number Tracking

Enabling or Disabling the TCP Sequence Number Tracking Function

The TCP sequence number tracking function is disabled by default. To enable this function, run the **ip inspect** command in interface configuration mode; or you may use **no** form of this command to disable the function.

Configuring TCP Sequence Number Tracking Rules

The TCP sequence number tracking function configuration basically agrees with the special protocol with the difference existing in that TCP protocol is added to **ip inspect name** rule library, e.g.,.

```
Ruijie(config)# ip inspect name abc tcp
```

The preceding command indicates that TCP is added to the detection rule named "abc".

Then, it is still necessary to apply the configured ip inspect name detection rule to the interface, e.g.,.

```
Ruijie(config)# interface gigabitEthernet 0/0
Ruijie(config-if)# ip inspect abc in
```

The preceding command applies the detection rule named "abc" in the inbound direction of gigabit 0/0 interface.

Understanding Session Limit

Overview

This function is mainly designed to prevent flow flood attacks generated at certain IP address or IP network segment by limiting the speed of session establishment and total number of concurrent sessions.

Configuring a Session Limit

Before configuring the session limit function, users need to configure an ACL rule first to define the scope of the session limit function, e.g.,.

If users want to limit all sessions through ports whose sources and destination IP addresses are specified in the limit function, configure the following ACL first.

```
access-list 1 permit any
```

Then configure the rule in interface mode.

For example, now users want to configure a rule under gigabit 0/0 interface, and the rule takes effect in the inbound direction of this interface, the limit scope shall be ACL-defined scope, the speed of session establishment shall be 100 per second and concurrent sessions shall be 100,000 in total. Sessions that meet such requirements shall be allowed while others are blocked and the blocked session will be recorded in a log.

```
Ruijie(config)# in gi 0/0
Ruijie(config-if)# session-limit access-group 1 rate 100 concurrent 100000 in log
```

Use the **no** form of this command to delete configuration.

Viewing Session Limit Information

show session-limit config

```
Ruijie(config-if)# show session-limit config
============[ Show gigabitEthernet 0/0's config]==============
Input
session-limit access-group 1 rate 12 concurrent 123 in log
session-limit access-group 12 rate 20 concurrent 100 in log
session-limit access-group 13 rate 20 concurrent 100 in log
session-limit access-group 14 rate 20 concurrent 100 in log
------------------------------------------------------------------------------------------
-----------------
 Output
session-limit access-group 1 rate 12 concurrent 123 out log
===========[ Show gigabitEthernet 0/0's config end]=============
```

show session-limit del-rule

With this function, you may find the commands used to view and delete configuration.

```
Ruijie(config-if)# show session-limit del-rule
```

```
======[ Show Cmd to del the rule on the gigabitEthernet 0/0 ]=====
Input
no session-limit access-group 1 rate 12 concurrent 123
in log
no session-limit access-group 12 rate 20 concurrent 100
in log
no session-limit access-group 13 rate 20 concurrent 100

Understanding Flow Management

Overview

The purpose of flow management is to prevent some users or applications from occupying excessive resources (e.g., bandwidth). Besides, flow limit is a simple and direct way to guard against ICMP flood and UDP flood attacks when other means of defense are void.

Configuring Flow Management

During flow management configuration, ACLs are used to control bandwidth quota of users, maximum number of concurrent connections, and number of new connections. Bandwidth is classified into uplink bandwidth and downlink bandwidth. If same bandwidth is specified on the uplink and downlink, the system automatically changes the keyword to **both**. The number of concurrent connections and speed of connection establishment are optional and can be left unspecified.

To configure this function, run the **ip rate-control** command in interface configuration mode.

You can use the **no** form of this command to disable this function.

It should be noticed that the command is effective only on the outbound interface.

Understanding Others

Enabling Session Log

At the end of a session, some information of the session, including source IP address, destination IP address, protocol, port, bytes sent and received, session duration, may need to be sent to the log server for future analysis. The session log function is disabled by default. To enable this function, run the **ip session log-on** command.

Sometimes a large number of session logs may be generated. In this case, some session logs may be lost due to limits on network transmission and processing capability of the log server.

Confiuguring Session Timeout

One session that remains inactive in a certain time will be considered completed. This period of time is called the timeout time of a session. Session timeout varies with session statuses. The system has different timeout settings for sessions in different statuses, which does not need to be changed in normal conditions. If you want to change timeout settings, run the **ip session timeout** command.

Configuring Abnormal Session Status Restriction

As for some abnormal session status, it is conducive to security enhancement to control the number of the packets sent from the source terminal. Generally, an appropriate threshold of different abnormal session status has been configured by the system and needs no change. When a change is needed, run the **ip session threshold** command.

Enabling Strict Status Tracking

Strict status tracking applies to TCP connection establishment and ICMP error packets. It interrupts connections in case of abnormal TCP connection (e.g., non-SYN packet) and reception of unreachable ICMP packets. Misreport may occur, therefore, strict status tracking is disabled by default. To enable this function, run the **ip session track-state-strictly** command. It is recommended that you enable this function when there is a high security requirement for better attack defense capability and disable it in internal networks or private networks to protect key services.

Note

When running the **ip session track-state-strictly** command to start the FW module for strict status tracking, the system will interrupt established TCP connections in order to trigger stream creation for effective tracking of the status. As a result, some established TCP services like telnet, ftp, etc will be interrupted when the command is used. Be cautious when using this command.

Enabling ICMP Reverse Flow Check

When ICMP reverse flow check is disabled, only the life time of ICMP reverse flows will be refreshed and flows are deleted and re-established by themselves in case of a ping failure. When the function is enabled, life time of both forward and reverse flows will be refreshed. This function is disabled by default. If there is a routing imbalance, packets are sent only in one direction and packets may be lost in a ping test. In this case, you can enable this function to avoid packet loss.

Configuring Connection Filtering

Invalid IP packets affect the transmission of normal packets. To prevent communication or attacks that hinge on invalid packets, you can enable connection filtering.

Before enabling this function, you need to know characteristics of invalid packets such as the source IP address, destination IP address, protocol, and port and then configure an ACL rule to define the range of forbidden packets. Finally, you can run the **ip session filter** *acl_id* command.

This function takes effect globally. It checks and filters forward and reverse flows, and discards packets that meet the filter rule without creating flow entries on the platform.

The connection filtering function is not disabled or displayed by default.

Network Security Protocol (IPSec)

Overview of IPSec

Purposes of Encryption

Data transmitted on a network without any protection measures is vulnerable to various kinds of attacks. When the data passes a device, any one who accesses this device can read, tamper or forge the data. For example, the protocol analyzer (such as sniffer) can be used to read packets and obtain confidential information. Inside an organization, the malicious users can tamper packets and perform destructive activities by interfering, reducing or blocking network traffic. Hence, it is extremely important to encrypt private, confidential and emergent data when it is transmitted.

Ruijie Networks products support the IPSec and IKE protocols, ensuring that the data is transmitted securely in a network without any protection measures.

- The IPSec protocol is an open standard framework developed by IETF. It works in the network layer to provide encryption and authentication for the traffic between the devices that provide the IPSec protocol services. IPSec can protect all or part of the data above the IP layer. It provides the following optional security services: data confidentiality, data integrity, data origin authentication, and anti-replay. These functions prevent the data from being monitored, tampered and forged when being transmitted over the network.
- IKE is a key management protocol standard that should be used with IPSec. IKE works in the UDP layer to provide secure key exchange and management mechanism. Since IPSec can be used independently, IKE will make IPSec more flexible and easy to configure, strengthening the security.

Supported Standards

Ruijie Networks products implement the following encryption standards:

- IPSec: It specifies a set of security architectures and provides data confidentiality, integrity and data authentication services between IPSec entities. It can protect one or more data streams between hosts, between subnets, and between security gateways.
- AH: It provides the data authentication service and the anti-replay service.
- ESP: It provides the data encryption service, the optional data authentication service, and the anti-replay capability.
- DES: It is an encryption algorithm that uses a 64-bit key to encrypt the packet (there are 56 significant bits).
- 3DES: It is an encryption algorithm that uses a 192-bit key to encrypt packets (there are 168 significant bits).
- AES: It is a sub-key, 128-bit data input algorithm, key length is 128. As the next generation data encryption standard, AES boasts high security, high performance, high efficiency, easy-to-use and flexibility
- NULL: It is the null encryption algorithm that encapsulates, instead of encrypts, packets.
- MD5-HMAC: (Message Digest 5) It is a HASH algorithm used to verify packets and prevent them from being modified.
- SHA-HMAC: (secure HASH algorithm) It is a HASH algorithm used to verify packets and prevent them from being modified.

- IKE: This protocol implements the Oakley and Skeme key exchange protocols within the ISAKMP (Internet Security Association and Key Management Protocol) framework. It performs IPSec end-point authentication, IPSec parameter negotiation and key exchange.
- ISAKMP: It defines the format and parameters of the payload in data exchange, and the key negotiation mode.
- Diffie-Hellman: It is a public key encryption protocol that allows both parties involved in the exchange to establish shared secrecy on an insecure channel.

Terms

Anti-replay: It is a security service that allows recipients to deny outdated packets or packet copies to avoid being attacked. It is a security association that is used for IKE negotiation and provides the authentication service.

Note

The manually created security association does not support the anti-replay function. Only the security associations that pass IKE negotiation support anti-replay.

Data authentication: It includes the following two concepts:

- Data integrity: Check whether the data has been modified.
- Data origin authentication: Check whether the data is really sent by the declared sender.

Data confidentiality: It protects the data from being snooped.

Data stream: It refers to the specific communication data that has a source address/mask, destination address/mask, the next protocol field of IP, and source and destination port IDs. The protocol and port fields can be specified using "any". All the traffic of a certain association that meets the above conditions is called a data stream. A data stream may represent a TCP connection between two hosts, or all the traffic between two subnets.

Peer: It refers to the device involved in IPSec or other devices.

Security Association (SA): It refers to a logical connection that provides the security service for a specific data stream. This security service has such parameters as specific security protocol, security algorithm, key, and data stream description. There are two types of security association: IPSec and IKE. The IPSec SA provides the IPSec protection function for data and allows users to establish a connection either manually or through IKE negotiation. The IKE SA is used to protect the negotiation data of IKE.

Security Parameter Index (SPI): SPI is a 32-bit integer, which is combined with a destination IP address and a security protocol type to form the unique ID of a SA. When a SA is established by using IKE, the SPI value of each SA is a pseudo-random inherited digit. If IKE is not used, specify an SPI value for each SA.

Security association lifetime: It refers to the validity period of a SA. The manually established security association has no lifetime, that is, it can be used permanently until a user deletes it manually. The lifetime of the SA established through IKE negotiated is negotiated with the remote IKE entity. The SA will be deleted once its lifetime expires, and IKE will negotiate about a new SA.

Transform set: The transform set describes the security suite that consists of a security protocol (AH or ESP) and an algorithm. For example, a transform set defines use of the ESP protocol and the DES encryption algorithm.

Crypto map entry: The crypto map entry associates the transform set with the data stream, and describes the peer address, and parameters necessary for communication. It fully describes the contents necessary for IPSec communication with the remote peer. An IPSec SA can be established only by using the crypto map entry.

At present, IPSec can be used to send IP packets in unicast manner only. Because the IPSec workgroup has not released the group key, now IPSec does not support IP packet multicast or broadcast.

If a device uses NAT, the static NAT should be configured, so that IPSec can work normally. NAT must be performed before IPSec encapsulation of the device, that is, IPSec should use the IP address of the public network.

IPSec Configuration

Overview of IPSec Working Process

IPSec provides a secure channel for two IPSec peers, such as two devices. You can define which sensitive data streams should be protected. These data streams will be transmitted along the secure channels. Moreover, you can define parameters to protect these sensitive packets by specifying parameters for these channels. When IPSec detects such a sensitive packet, it will establish a secure channel, through which this packet is sent to the remote peer.

The sensitive data streams can be defined by configuring the access list. Describe the sensitive data streams to be protected on the basis of the source/destination address, protocol and port in the access list. After configuring the access lists, use a crypto map set to apply these access lists to the interface, so that the interface protects the specific incoming and outgoing data streams.

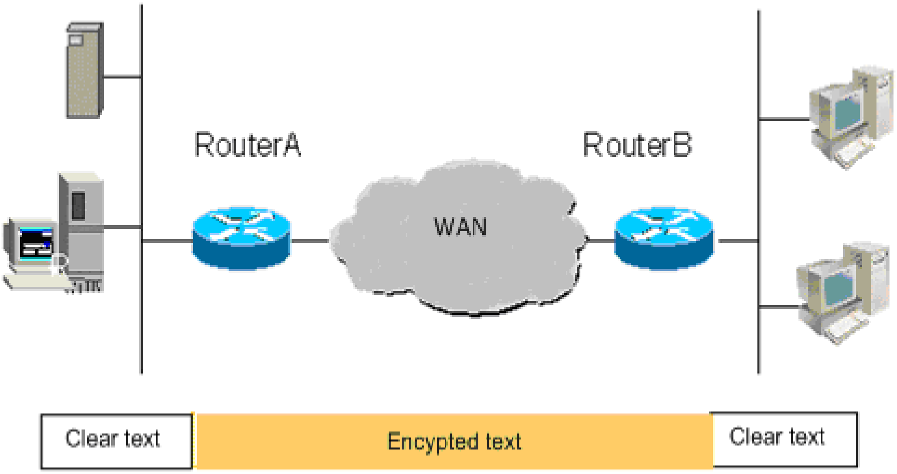
One crypto map set can have multiple entries, each of which corresponds to a different access list. The device finds the entry that matches the current traffic by sequence (the device tries to match the packet with the access list specified by the entry). When a packet matches a permit entry in the specific access list, if the crypto map entry is labeled as ipsec-manual, IPSec is triggered directly to process the data stream securely; if the crypto map entry is labeled as ipsec-isakmp, when an IPSec SA has been established, IPSec protection is provided to the data directly, otherwise IKE negotiation will be triggered automatically to create an IPSec SA. If the user does not configure IPSec or IKE parameters properly, it will be impossible to establish a SA, and the packets will be discarded.

Once a SA is established, the outgoing packet will be encrypted by IPSec and authentication information is filled in before it is sent to the peer. This packet is an incoming packet of the peer, which finds the related SA, and decrypts, authenticates and restores the packet.

The crypto map entry also specifies a transform set that defines the combination of the algorithm and protocol mode used by IPSec. Two IPSec peers must finally use the same transform set in order to communicate effectively.

The following figure shows an example of implementing IPSec protection between subnets:

Figure 7 Implementation of IPSec protection between subnets



IPSec Configuration Tasks

The ultimate purpose of IPSec configuration task is to establish an IPSec SA. An IPSec SA can be established manually or through negotiation by IKE. Manual configuration does not need IKE, but requires more parameters to be specified and has lower level of security. To establish a SA through IKE negotiation, you need to configure the IKE parameters besides configuring the IPSec parameters, so it has a higher level of security.

IPSec configuration tasks include:

- **Configure the default lifetime (optional)**: This is an optional step. You can use this command to modify the default lifetime value of the system. If there is no special description, IKE will use this lifetime value for negotiation, so that the lifetime of IPSec is not longer than the default lifetime.
- **Create an encryption access list**: An encryption access list determines the data streams to be protected. IPSec needs to rely on the encryption access list to filter incoming/outgoing packets. It provides IPSec protection for the matched outgoing data, and checks the validity of the matched incoming packets.
- **Define a transform set**: A transform set describes how to protect data streams. The transform set is a combination of the specific security protocol and algorithm. It specifies an algorithm, a security protocol, and a data encapsulation mode. To specify the degree of and requirements for protection of the data, the user must define an appropriate transform set here in advance.
- **Create a crypto map entry**: To create a crypto map entry, associate the predefined access list with the transform set, and define the key and the peer address to form a complete IPSec scheme description.
- **Configure a multicast policy:** Disable IPSec encapsulation of multicast and broadcast packets.
- **Apply a crypto map entry to an interface**: This action activates IPSec scheme defining. It applies a crypto map entry to an interface to make the crypto map set start working on the interface.
- **Create a Profile crypto map entry:** Define IPSec encryption policies of dynamic multipoint VPN (DMVPN).
- **Apply a Profile crypto map entry to a tunnel interface**: Activate the IPSec functions of DMVPN.
- **Configure extended authentication mode:** This action is used for extended authentication.
- **Configure IPSec packet filter:** Decapsulated packets are no longer filtered.
- **Configure IPSec MIB:** It sends IPSec monitoring information to the SNMP server. This function is disabled by default and needs to be enabled using a command.
-

- **Monitor and maintain IPSec**: Monitor and maintain IPSec, view and adjust the IPSec parameters, and judge whether IPSec works normally.

Note

IKE uses UDP port 500. The IPSec ESP and AH protocols are numbered 50 and 51 respectively. If access list (firewall) filtering data has been configured on the device, then before configuring IPSec, please make sure the traffic for protocols 50 and 51 and UDP port 500 on the interface used by IPSec is not blocked. If possible, add a statement to the access list to explicitly allow the traffic.

Configuring Default Lifetime

To configure the default lifetime, run the following command in global configuration mode or privileged user configuration mode:

Command	**Function**
Ruijie(config)# **crypto ipsec security-association lifetime seconds** *seconds*	Changes the global lifetime limit of IPSec SA. This command will cause the SA timeout after the specified seconds elapse.
Ruijie(config)# **crypto ipsec security-association lifetime kilobytes** *kilobytes*	Changes the global traffic lifetime of IPSec SA. This command will cause the SA timeout after the transmitted traffic (in KBs) protected by IPSec using this SA reaches a specified value.
Ruijie# **clear crypto sa** or Ruijie# **clear crypto sa peer** {*ip-address* | *peer-name*} or Ruijie# **clear crypto sa map** *map-name*	Clears an existing SA. This will immediately interrupt all the existing SAs. The subsequent SAs will use a new lifetime. Otherwise, all the existing SAs will expire on the basis of the original lifetime.

Note

Use the **clear crypto sa** command without parameters to clear the entire SA database. This will also clear the active encryption processes. You can use such keywords as peer and map to clear only one subnet from the SA database. For detailed information, refer to the command reference for **clear crypto sa**.

The default lifetime of the system is 1-hour communication (3600 seconds) or 4,608,000KB traffic (continuous communication for 1 hour at the rate of 10 MBit/s). If the user accepts the default value, skip this step. This default lifetime is used if there is no special description in the crypto map entry. When negotiating the lifetime of IPSec, IKE uses the smaller value of those of the local end and the peer. When the lifetime of the IPSec SA expires, IKE will negotiate again and replace a new set of parameters and key for IPSec to make it start working again.

The SA (and the related key) is timeout on the basis of the lifetime that expires earliest: Use the seconds (specified by the keyword seconds) or the kilobytes of transmitted traffic (specified by the keyword kilobytes). The manually established SA (established by the crypto map entry identified as ipsec-manual) has no lifetime limit.

In order to make sure that a new SA is available when the original SA expires, the new SA must be negotiated before the original SA expires. When there are 30 seconds left before the lifetime expires, or when there are 256 Kbytes left before the traffic that passes this channel reaches the lifetime (determined by the peer that reaches the lifetime first), a new SA is negotiated.

If no traffic takes this channel throughout the lifetime of a SA, this SA will be released but negotiation of a new SA will not be underway when the lifetime elapses. In this case, a new SA will be negotiated only when IPSec finds another packet that should be protected.

Configuring Automatic Disconnection for Idle Tunnels

To configure automatic disconnection for global idle tunnels, run the following command in global configuration mode or privileged EXEC mode:

Command	Function
Ruijie(config)#**crypto ipsec security-association idle-time** *sec*	Specifies the disconnection period for global idle tunnels in seconds. The value range is 60–86400.

DF bit Override Function of IPSec Tunnel

The DF bit override function allows users to specify whether the device is reset, is set to 1, or copies the encapsulated header.

The DF bit on the IP header determines whether the device can fragment the packet. Value 1 indicates that this packet cannot be fragmented, and value 0 indicates that the packet can be fragmented. This function in IPsec tunnel mode allows the device to control whether the DF bit of the packet IP header encapsulated by IPSec is determined by the DF bit value of the original IP header. Only tunnel mode supports this feature.

To configure the DF bit value for all the interfaces, run the following command in global configuration mode:

Command	Function
Ruijie(config)# **crypto ipsec df-bit** [**clear** | **set** | **copy**]	Sets the DF bit of the IP external header for all the interfaces in tunnel mode.

In the following example, the device is configured to clear the DF bit globally, and copy the DF bit on FastEthernet0/0. This way, all the interfaces other than FastEthernet0/0 allow packets larger than the MTU size to be sent (in fragments), while FastEthernet0/0 must determine whether to allow the device to fragment the packet according to the DF bit in the original IP header.

Creating Encryption Access Lists

The encryption access list is used to define which data streams should be encrypted, and which should not be encrypted. For example, you can create an encryption access list to protect all the IP traffic between Subnet A (192.168.202.0/24) and Subnet B (192.168.12.0/24) (access list 120), or the IP traffic between Host A and Host B (access list 101):

```
access-list 120 permit ip 192.168.12.0 0.0.0.255 192.168.202.0 0.0.0.255
access-list 101 permit ip host 2.2.2.2 host 2.2.2.1
```

The encryption access list specified by the IPSec crypto map entry has the following four major functions:

- Filter the outbound traffic that is encrypted by using IPSec (permit = protect).
- When starting to negotiate an IPSec SA, indicate which data streams are protected by the new SA (indicated by a single permit entry).
- Process the inbound traffic, so as to filter and discard those traffic that should have been protected by IPSec.
- When handling the IKE negotiation initiated by the IPSec peer, determine whether to accept the IPSec SA request that represents the requested data stream (only the crypto map entry ipsec-isakmp should be negotiated). You must make sure that the access lists of peers at both ends match. It is recommended that the access lists of peers at both ends are consistent.

To configure the encryption access list, run the following command in global configuration mode:

Command	Function
Ruijie(config)# **access-list** *access-list-number* {**deny** | **permit**} *protocol source source-wildcard destination destination-wildcard* [**log**] Or: Ruijie(config)# **ipv6 access-list** ipv6-acl-name Ruijie(config-ipv6-acl)# **{deny | permit}** *protocol source source-wildcard destination destination-wildcard*	Describes the data stream in terms of its source/destination address and its wildcard, communication protocol and communication port. If the keyword **permit** is used, the policy described in the related crypto map entry will provide encryption protection for all the IP traffics that meet the specified conditions. The keyword **deny** can be used to prevent the traffic from being encrypted by the specific crypto map entry.
Ruijie(config-exp-nacl)# **exit**	Exits ACL configuration mode.

If the keyword **permit** is used, the policy described in the related crypto map entry will provide encryption protection for all the IP traffic that meets the specified conditions. The keyword **deny** can be used to prevent the traffic from being encrypted by the specific crypto map entry.

Note

It is recommended that you define a mirrored encryption access list on the remote peer for each encryption access list defined on the local peer. Otherwise, some data is not protected or the SA cannot be established. Since the ACL has priority, the inclusion relation of ACEs should be noted during the configuration. In case of conflict, the ACE having a higher priority takes effect.

The keyword **any** should be used with great care because it will discard lots of broadcast information and make the device unable to work normally. The encryption access list is not specially designed for and used by IPSec. IPSec uses the extended IP access list, so the value of **access-list-number** ranges from 100 to 199]. If no port is defined, this encryption access list can be used for the data stream in either the inbound direction or the outbound direction.

For example, when you want to protect the IP traffic between Subnet A (192.168.12.0/24) and Subnet B (192.168.10.0/24), the following access list should be defined for the device:

```
access-list 101 permit ip 192.168.12.0 0.0.0.255 192.168.10.0 0.0.0.255
```

For example, if you want to protect the TCP traffic between Subnet A (192.168.12.0/24) and Host C (202.101.11.3), the following access list should be defined for the device:

```
access-list 120 permit tcp 192.168.12.0 0.0.0.255 202.101.11.3 0.0.0.0
```

If port filtering is defined, the destination address in the encryption access list provides the service for this port.

For example, if you need to protect the Telnet traffic between Host D (1.1.1.1) and Host E (2.2.2.2) that provides the Telnet service, define as follows on the device:

```
access-list 133 permit tcp 1.1.1.1 0.0.0.0 2.2.2.2 0.0.0.0 eq telnet
```

Caution

In terms of permit ipv6 any any encryption access list, Ruijie devices are not compatiable with Cisco devices. Because Cisco devices will encrypted “neighbor request packet” and “neighbor advertisement packet” (Similar to ARP packets of IPv4), the IPSec data communication between two non-direct devices failed. To avoid the preceding issue, Ruijie devices will not encrypt “neighbor request packet” and “neighbor advertisement packet”.

Defining Transform Set

Transform set is a combination of the specific security protocol and algorithm. During negotiation of the IPSec SA, the peer must use the same specific transform set to protect the specific data stream.

Because there is no anti-replay negotiation process between peers for the manually established SA, the same transform set must be specified for the two peers. Change to the definition of the transform set will apply to negotiation of the subsequently established SA, instead of the existing SA. If you want these new settings to take effect immediately, use the **clear crypto sa** command to clear all or part of the SA database.

To define a transform set, run the following command in global configuration mode:

Command	**Function**
Ruijie(config)# **crypto ipsec transform-set transform-set-name** *transform1* [*transform2* [*transform3*]]	The transform parameter is an algorithm supported by the system. Algorithms can be combined according to a certain rule.
Ruijie(cfg-crypto-trans)# **mode** {**tunnel** | **transport**} (Optional)	Changes the mode associated with the transform set. Mode setting is useful only for the communication where both the source and the destination addresses and those of the IPSec peer, while not useful for other communications (all other communications are performed in the tunnel mode).
exit	Exits crypto transform configuration mode.
Ruijie# **clear crypto sa** or Ruijie# **clear crypto sa peer** {*ip-address* | *peer-name*} or Ruijie# **clear crypto sa map** *map-name*	Clears the existing SAs, so as to make sure that any change to the transform set applies to the subsequently established SAs (the manually established SAs will be reestablished immediately)

Present below are all the transform sets supported by the system:

transform1 [transform2]	**Description**
ah-md5-hmac	AH protocol and MD5 HMAC algorithm
ah-sha-hmac	AH protocol and SHA HMAC algorithm
ah-sm3-hmac	AH protocol and SM3 HMAC algorithm
esp-des	ESP protocol and DES encryption algorithm
esp-3des	ESP protocol and 3DES encryption algorithm
esp-aes-128	ESP protocol and aes encryption algorithm with key length being 128.
esp-aes-192	ESP protocol and aes encryption algorithm with key length being 192.

transform1 [transform2]	Description
esp-aes-256	ESP protocol and aes encryption algorithm with key length being 256.
esp-sm4	ESP protocol and SM4 encryption algorithm with key length being 128.
ah-md5-hmac esp-des	The AH protocol is located outside, and the MD5 HMAC authentication algorithm is used. The ESP protocol is located inside, and the DES encryption algorithm is used
ah-sha-hmac esp-des	The AH protocol is located outside, and the SHA HMAC authentication algorithm is used. The ESP protocol is located inside, and the DES encryption algorithm is used
ah-md5-hmac esp-des esp-md5-hmac	The AH protocol is located outside, and the MD5 HMAC authentication algorithm is used. The ESP protocol is located inside, and the DES encryption algorithm and the MD5 HMAC authentication algorithm are used
ah-md5-hmac esp-null esp-md5-hmac	The AH protocol is located outside, and the MD5 HMAC authentication algorithm is used. The ESP protocol is located inside, and the null encryption algorithm and the MD5 HMAC authentication algorithm are used
ah-md5-hmac esp-des esp-sha-hmac	The AH protocol is located outside, and the MD5 HMAC authentication algorithm is used. The ESP protocol is located inside, and the DES encryption algorithm and the SHA HMAC authentication algorithm are used
ah-md5-hmac esp-null esp-sha-hmac	The AH protocol is located outside, and the MD5 HMAC authentication algorithm is used. The ESP protocol is located inside, and the null encryption algorithm and the SHA HMAC authentication algorithm are used
ah-sha-hmac esp-des esp-md5-hmac	The AH protocol is located outside, and the SHA HMAC authentication algorithm is used. The ESP protocol is located inside, and the DES encryption algorithm and the MD5 HMAC authentication algorithm are used
ah-sha-hmac esp-null esp-md5-hmac	The AH protocol is located outside, and the SHA HMAC authentication algorithm is used. The ESP protocol is located inside, and the null encryption algorithm and the MD5 HMAC authentication algorithm are used
ah-sha-hmac esp-des esp-sha-hmac	The AH protocol is located outside, and the SHA HMAC authentication algorithm is used. The ESP protocol is located inside, and the DES encryption algorithm and the SHA HMAC authentication algorithm are used
ah-sha-hmac esp-null sp-sha-hmac	The AH protocol is located outside, and the SHA HMAC authentication algorithm is used. The ESP protocol is located inside, and the null encryption algorithm and the SHA HMAC authentication algorithm are used

transform1 [transform2]	Description
esp-des esp-md5-hmac	For the ESP protocol, the DES encryption algorithm and the MD5 HMAC authentication algorithm are used.
esp-null esp-md5-hmac	For the ESP protocol, the null encryption algorithm and the MD5 HMAC authentication algorithm are used.
esp-des esp-sha-hmac	For the ESP protocol, the DES encryption algorithm and the SHA HMAC authentication algorithm are used.
esp-null esp-sha-hmac	For the ESP protocol, the null encryption algorithm and the SHA HMAC authentication algorithm are used.
esp-3des	ESP protocol and 3DES encryption algorithm
esp-3des esp-sha	For the ESP protocol, the 3DES encryption algorithm and the SHA HMAC authentication algorithm are used.
esp-3des esp-md5	For the ESP protocol, the 3DES encryption algorithm and the MD5 HMAC authentication algorithm are used.
ah-md5-hmac esp-des	The AH protocol is located outside, and the MD5 HMAC authentication algorithm is used. The ESP protocol is located inside, and the 3DES encryption algorithm is used
ah-sha-hmac esp-des	The AH protocol is located outside, and the SHA HMAC authentication algorithm is used. The ESP protocol is located inside, and the 3DES encryption algorithm is used
ah-md5-hmac esp-3des esp-sha	The AH protocol is located outside, and the MD5 HMAC authentication algorithm is used. The ESP protocol is located inside, and the 3DES encryption algorithm and the SHA HMAC authentication algorithm are used
ah-sha-hmac esp-3des esp-sha	The AH protocol is located outside, and the SHA HMAC authentication algorithm is used. The ESP protocol is located inside, and the 3DES encryption algorithm and the SHA HMAC authentication algorithm are used
ah-md5-hmac esp-3des esp-md5	The AH protocol is located outside, and the MD5 HMAC authentication algorithm is used. The ESP protocol is located inside, and the 3DES encryption algorithm and the MD5 HMAC authentication algorithm are used
ah-sha-hmac esp-3des esp-md5	The AH protocol is located outside, and the SHA HMAC authentication algorithm is used. The ESP protocol is located inside, and the 3DES encryption algorithm and the MD5 HMAC authentication algorithm are used

Note

Generally, the combination esp-des (without data authentication) will satisfy your requirement. If you want to verify data, you can choose esp-des esp-md5-hmac or esp-des esp-sha-hmac.

Configuring IPSec MIB

IPSec MIB management involves statistics of data streams and encrypted/decrypted data packets and it may affect performance of IPSec data communication in some certain. Therefore, the MIB statistical function is disabled by default. To access the MIB node of IPSec, you need to enable the IPSec MIB function using the CLI command.

Command	**Function**
Ruijie(config)# **crypto mib enable**	Configures IPSec MIB statistics function.

Configuring Multicast Policies

If an ACL covers multicast and broadcast addresses, IPSec encapsulation will be applied to packets related to these addresses. To skip IPSec encapsulation, run the following command:

Command	**Function**
Ruijie(config)#**crypto ipsec multcast disable**	Disables encapsulation of multicast and broadcast packets.

Creating Crypto Map Entry

The crypto map entry can be configured in the following aspects:

- Which traffic should be protected by IPSec: Associate the configured encryption ACL.
- Where the traffic protected by IPSec will be sent to: Which is the remote IPSec peer.
- Local address used for IPSec communication: Apply the crypto map set to the interface. IPSec uses the address of the communication interface as the address of the local peer.
- Which IPSec security policies should be applied to traffic: Choose from the list that consists of one or more transform sets.
- Lifetime of the SA.
- Whether the SA is established manually or through IKE negotiation.

The crypto map entries that have the same crypto map name (but with different map sequence numbers) constitute a crypto map set. Apply the crypto map set to the interface, so that all the IP traffic that passes this interface is judged according to the crypto map set applied to the interface. If a crypto map entry finds an outbound IP channel that should be protected, and the crypto map specifies use of IKE, the SA will be negotiated with the remote peer according to the parameters in this crypto map entry. If the crypto map entry specifies use of the manually established SA, then a SA must have been established during configuration. The data is encrypted for transmission once the SA is established successfully either manually or through IKE negotiation. If negotiation of SA fails, the data is discarded.

The policy described in the crypto map entry will be used during negotiation of SA. To carry out IPSec smoothly between two IPSec peers, the crypto map entries of the two peers must include mutually compatible configuration statements. When two peers try to establish a SA, both of them must have at least one crypto map entry that is compatible with the crypto map entry of the remote peer and at least meets the following conditions:

- The crypto map entry must include a compatible encryption access list (such as mirrored map access list).
- The crypto map entries at both sides must identify the address of the peer (unless the peer is using a dynamic crypto map).
- The crypto map entries must have at least one identical transform set.

Only one crypto map set is applied to a single interface. The crypto map set contains IPSec/IKE or combination of IPSec/manual entry. If you create multiple crypto map entries for a given interface, you have to use the *seq- num* parameter of the map entry to sort these map entries again. The smaller the value of *seq-num*, the higher the priority.

Multiple crypto map entries must be created for a single interface if one of the following situations exists.

- If different data streams on this interface will be processed by different IPSec peers.
- If you want to apply different IPSec securities to different types of traffic (destined for the same or different peers). For example, you want that the traffic among the subnets in a group is authenticated, while the traffic among other subnets is both authenticated and encrypted. In this case, different types of traffic should be defined in two different access lists, and a separate crypto map entry must be created for each encryption access list.

Creating a SA manually

To create a SA manually, run the following commands in global configuration mode at the beginning:

Command	**Function**
Ruijie(config)# **crypto map** *map-name* *seq-num* **ipsec-manual**	Specifies the crypto map entry to be created or modified. When using this command, you will enter crypto map configuration mode.
Ruijie(config-crypto-map)# **match address** *access-list-id* *or* Ruijie(config-crypto-map)# **match ipv6** *ipv6-acl-name*	Specifies an access list for the crypto map list. This access list determines which traffic should be protected by IPSec, and which traffic should not be protected by the IPSec security defined in this crypto map entry.
Ruijie(config-crypto-map)# **match vrf** *vrf-name*	Specifies the crypto map list a VRF that are associated with the access list. Only when the packets under the VRF matching the access list can they be protected by IPSec.
Ruijie(config-crypto-map)# **set peer** {*hostname* | *ip-address*}	Specifies a remote IPSec peer. The traffic protected by IPSec will be sent to this peer. If IKE is not used, only one peer can be configured.
Ruijie(config-crypto-map)# **set transform-set** *transform-set-name*	Specifies which transform set to use. This transform set must be the same as the one specified in the corresponding crypto map entry of the remote peer. (If IKE is not used, only one transform set can be specified.)
Ruijie(config-crypto-map)# **set vrf** *vrf-name*	Specifies the VRF that are associated with tunnel.
Ruijie(config-crypto-map)# **set session-key inbound ah** *spi hex-key-data* or Ruijie(config-crypto-map)# **set session-key outbound ah** *spi hex-key-data*	If the specified transform set includes the AH protocol, you should use this command to set the AH Security Parameter Indexes (SPIs) and passwords for the protected outbound and inbound traffic. Here, the local inbound SPI, protocol and key must be the same as the outbound SPI, protocol and key of the remote peer, and vice versa.

Ruijie(config-crypto-map)# **set session-key inbound esp** *spi* **cipher** *hex-key-data* [**authenticator** *hex-key-data*] or Ruijie(config-crypto-map)# **set session-key outbound esp** *spi* **cipher** *hex-key-data* [**authenticator** *hex-key-data*]	If the specified transform set includes the ESP protocol, you should use this command to set the ESP security parameter indexes and passwords for the protected outbound and inbound traffics. If the transform set includes the ESP encryption algorithm, the encryption key must be provided. If the transform set includes the ESP authentication algorithm, the authentication key must be provided. Here, the local inbound SPI, protocol and key must be the same as the outbound SPI, protocol and key of the remote peer, and vice versa.
Ruijie(config-crypto-map)# **set mtu** *length*	Sets the side of a fragment in tunnel mode.
Ruijie(config-crypto-map)# **exit**	Exits the crypto map configuration mode and return to the global configuration mode.

Repeat the preceding steps to create other necessary crypto map entries.

The following shows a configuration example:

Local peer (router A) configuration:

# Define a transform set named myset

```
crypto ipsec transform-set myset esp-des
```

# Define a manual map set named mymap

```
crypto map mymap 3 ipsec-manual
 set peer 2.2.2.2
 set session-key inbound esp 301 cipher abcdef1234567890
 set session-key outbound esp 300 cipher abcdef1234567890
 set transform-set myset
 match address 101
!
access-list 101 permit ip 192.168.12.0 0.0.0.255 192.168.202.0 0.0.0.255
```

Remote peer (router B) configuration:

# Define a transform set named myset

```
crypto ipsec transform-set myset  esp-des
```

# Define a manual map set named mymap

```
crypto map mymap 3 ipsec-manual
 set peer 2.2.2.1
 set session-key inbound esp 300 cipher abcdef1234567890
 set session-key outbound esp 301 cipher abcdef1234567890
 set transform-set myset
 match address 101
 !
access-list 101 permit ip 192.168.202.0 0.0.0.255 192.168.12.0 0.0.0.255
```

Caution

The keyword **hex-key-data** is a hexadecimal number. The length of **hex-key-data** following the keyword cipher in the configuration command in the sixth step and the length of **hex-key-data** in the configuration command in the fifth step are determined by the encryption algorithm in use (at present, IPSec supports the DES, 3DES and AES encryption algorithms). The length of **hex-key-data** following the keyword authenticator in the configuration command in the sixth step is determined by the data authentication algorithms (including the SHA and MD5 algorithms) in use. In the above example, the encryption algorithm DES is used, and the length of 64 bits is required, so its value is set to abcdef1234567890 (equivalent to 0xabcdef1234567890). Because no data authentication algorithm is used in the above example, the key following authenticator is not configured. You can configure it simply by entering a string that contains digits from 1 to 9 and/or letters from a to f. It is unnecessary to identify it by 0x.

Table:

Name of Algorithm	Length of Key (bits)	Length of Entered Hexadecimal String (bytes)	Configuration Example
Des	64	8	Example: set session-key inbound esp 300 cipher abcdef1234567890
3Des	192	24	set session-key inbound esp 300 cipher abcdef1234567890 abcdef1234567890 abcdef1234567890
aes	128	16	set session-key inbound esp 300 cipher abcdef1234567890abcdef1234567890
Sm4	128	16	set session-key inbound esp 300 cipher abcdef1234567890abcdef1234567890
Md5	128	16	Example: set session-key inbound esp 302 cipher abcdef1234567890 authenticator abcdef1234567890abcdef1234567890
Sha	160	20	Example: set session-key inbound esp 302 cipher abcdef1234567890 authenticator abcdef1234567890abcdef1234567890abcd
Sm3	256	32	Example: set session-key inbound esp 302 cipher abcdef1234567890 authenticator abcdef1234567890abcdef1234567890abcdef1234567890abcdef1234567890

Caution

Generally, a full length of key should be configured. If the key is not complete, the device may append "0" (low security), or may not append "0" (this will cause negotiation of SA failed).

Use of the manual SA is the result prearranged by the local device and IPSec peer administrators. They may want to first use the manual SA for debugging, and then use the IKE-based SA or the remote peer does not support IKE.

Configuring Anti-Replay Window

The anti-replay window is the basic attack protection feature of IPSec. By default, when hash (MD5, SHA, etc) authentication mode is configured, the anti-reply feature will be enabled, yet you can still disable this feature through the following command:

Command	**Function**
Ruijie(config)#**crypto ipsec security-association replay disable**	Disables the anti-replay window.

Caution

Since QoS will divert traffic into different queues, thus leading to the disorder of packet transmission, and if IPSec enables anti-replay window in such a context, IPSec will drop all packets exceeding the window. Therefore, you can disable the anti-replay window to avoid packet loss, but it will also increase the possibility of being attacked.

Configuring Data Security Check

Data security check is the basic attack protection feature of IPSec. The criteria for attack judging is: if the packet which ought to be in encrypted text is received in plain text, such packet is considered unsafe and will be dropped. Under certain circumstances, data security check is not mandatory and can be disabled through the following command.

Command	**Function**
Ruijie(config)#**crypto ipsec optional**	Disables IPSEC data security check.

Caution

Data security check will result in significant resource overhead, and disabling this feature can save CPU resources. In the model of l2tp over ipsec, l2tp can force to enable IPSec, and thus only IPSec-encrypted packets are allowed. This feature can be used according to actual needs.

Configuring to use IKE to create a crypto map entry for the SA

To configure to use IKE to create a crypto map entry for the SA, run the following commands in global configuration mode in the beginning:

Command	**Function**
Ruijie(config)# **crypto map** *map-name seq-num* **ipsec-isakmp**	Specifies the crypto map entry to be created or modified. When using this command, you will enter crypto map configuration mode.

Command	**Function**
Ruijie(config-crypto-map)# **match address** *access-list-id* or Ruijie(config-crypto-map)# **match ipv6** *ipv6-acl-name*	Specifies an access list for the crypto map list. This access list determines which traffic should be protected by IPSec, and which traffic should not be protected by the IPSec security defined in this crypto map entry.
Ruijie(config-crypto-map)# **match vrf** *vrf-name*	Specifies the crypto map list a VRF that are associated with the access list. Only when the packets under the VRF matching the access list can they be protected by IPSec.
Ruijie(config-crypto-map)# **set peer** {*hostname* | *ip-address*}	Specifies a remote IPSec peer. The traffic protected by IPSec will be sent to this peer. You can configure multiple peers.
Ruijie(config-crypto-map)# **set local** *ip-address*	Sets the IP address for local negotiation. If no IP address is specified, the primary address of the interface is used.
Ruijie(config-crypto-map)# **set transform-set** *transform-set-name1* [*transform-set-name2…transform-set-name6*]	Specifies which transform set to use. List the transform set by priority (high priority first).
Ruijie(config-crypto-map)# **set security-association lifetime seconds** *seconds* or Ruijie(config-crypto-map)# **set security-association lifetime kilobytes** *kilobytes*	(Optional) Specifies a SA lifetime for the crypto map entry.
Ruijie(config-crypto-map)# **set security-association idle-time** *seconds*	(Optional) Specify the idle time timeout for the crypto map entry.
Ruijie(config-crypto-map)# **set exchange-mode** *main* | *aggressive*	Sets which mode is used to initiate negotiation using this static entry.
Ruijie(config-crypto-map)# **set pfs** *group1* | *group2*	Specifies the Diffie-Hellman group identification.
Ruijie(config-crypto-map)# **set mtu** *length*	Sets the fragment size in tunnel mode.
Ruijie(config-crypto-map)# **set vrf** *vrf-name*	Specifies the VRF that are associated with tunnel.
Ruijie(config-crypto-map)#**username** *name* **password {0|7}** *pass*	Configures the username and password used for extended authentication.
Ruijie(config-crypto-map)#**reverse-route** [**remote-peer** *ip-address*] [*distance*] [**tag** *tagvalue*] [**track** *trackvalue*] [**bfd**] [**weight** weightvalue]	Configures Ipv4 reverse routing
Ruijie(config-crypto-map)# **reverse-ipv6-route** [**remote-peer** *ip-address*] [*distance*] [**bfd**] [**weight** weightvalue]	Configures Ipv6 reverse routing
Ruijie(config-crypto-map)# **exit**	Exits crypto map configuration mode and returns to global configuration mode.

Repeat the preceding steps to create other necessary crypto map entries.

The following example shows how to configure to establish a SA using IKE:

Local peer (router A) configuration:

# Define a transform set named myset

```
crypto ipsec transform-set myset esp-des
```

# Define a map set named mymap that establishes a SA using IKE

```
crypto map mymap 3 ipsec-isakmp
 set peer 2.2.2.2
 set transform-set myset
 match address 101
!
access-list 101 permit ip 192.168.12.0 0.0.0.255 192.168.202.0 0.0.0.255
```

Remote peer (router B) configuration:

# Define a transform set named myset

```
crypto ipsec transform-set myset  esp-des
```

# Define a map set named mymap that establishes a SA using IKE

```
crypto map mymap 3 ipsec-isakmp
 set peer 2.2.2.1
 set transform-set myset
 match address 101
 !
access-list 101 permit ip 192.168.202.0 0.0.0.255 192.168.12.0 0.0.0.255
```

Note

RGOS supports both the manual SA and the IKE-established SA. The two modes of establishing SAs can also be added to the same crypto map set.

Caution

Use IKE to establish a SA because IKE will negotiate again and use a new key when the lifetime expires, ensuring data security. However, because the content encrypted by using the DES encryption algorithm may be cracked maliciously within a certain time, the key must be modified regularly if the SA is established manually.

Creating a dynamic crypto map

The dynamic crypto map (IKE is needed) requires less configuration. If the IP address of the remote peer is unknown during configuration, the dynamic crypto map function must be used. For example, a mobile subscriber is dynamically assigned an IP address. First, the mobile subscriber uses something other than the IP address, such as the domain name, for the local IKE authentication. Once the authentication is complete, the SA request that meets the dynamic crypto map can be processed, and this dynamic crypto map can accept requests that meet the local policy.

Understanding dynamic crypto map

Only IKE can use the dynamic crypto map. The dynamic crypto map entry acts as a policy template. The missing parameters can be obtained dynamically (IPSec negotiation) to meet requirement of the remote peer. It allows the remote peer and the device to exchange IPSec traffic even if the crypto map of the device does not fully satisfy the requirement of the remote peer.

The dynamic crypto map is used for the remote peer to initiate IPSec negotiation, not for the device to initiate new IPSec negotiation with the remote peer.

The dynamic crypto map set is referred to as a part of the crypto map. Any crypto map entry that refers to the dynamic map is the crypto map entry with the lowest priority in the crypto map set (namely it has the largest sequence number). This way, other crypto map entries will be evaluated first. The dynamic crypto map entry is checked when all the static crypto map entries do not match.

If the device accepts the request from the peer, it will create a new IPSec SA, and install a temporary crypto map entry, which is filled in with the negotiation result. At this point, the device uses a temporary crypto map entry as if it uses a normal crypto map entry. Once the SA expires, the temporary crypto map entry will be deleted.

For the static and dynamic crypto maps, if the incoming traffic not protected meets one permit statement in the access list, the traffic will be discarded because it is not protected by IPSec.

For the static crypto map entry, if the outgoing traffic meets the permit statement in the access list, and the corresponding SA has not been established, the device will initiate SA negotiation with the remote peer. For the dynamic crypto map entry, if a SA does not exist, the traffic is discarded directly (because the dynamic crypto map is not used to initiate a new SA negotiation).

Caution

The **any** keyword should be used carefully in the **permit** entry in the dynamic crypto map. Because **permit** may cover multicast and broadcast, **deny** must be used to exclude the broadcast and multicast traffic, and other traffic that is not protected by IPSec must also be excluded.

The dynamic crypto map entries are grouped into a set like the normal crypto map entries. A set contains crypto map entries that are grouped together using the same crypto map name but have different sequence numbers.

To create a dynamic crypto map entry, use the following commands in global configuration mode:

Command	Function
Ruijie(config)# **crypto dynamic-map** *dynamic-map-name dynamic-seq-num*	Creates a crypto map entry
Ruijie(config-crypto-map)# **set transform-set** *transform-set-name1* [*transform-set-name2...transform-set-name6*]	Specifies which transform set to use. List the transform set by priority (high priority first).

Ruijie(config-crypto-map)# **match address** *access-list-id* or Ruijie(config-crypto-map)# **match ipv6** *ipv6-acl-name*	(Optional) Specifies an access list for the crypto map list. This access list determines which traffic should be protected by IPSec, and which traffic should not be protected by the IPSec security defined in this crypto map entry. Note: Although the access list is optional to the dynamic crypto map, it is strongly recommended to configure it. If it is configured, the data stream ID suggested by the peer must match a permit entry in the crypto map access list. If it is not configured, the device accepts any data stream ID suggested by the peer.
Ruijie(config-crypto-map)# **match vrf** *vrf-name*	Specifies the crypto map list a VRF that are associated with the access list. Only when the packets under the VRF matching the access list can they be protected by IPSec.
Ruijie(config-crypto-map)# **set peer** {*hostname* | *ip-address*}	(Optional) Specifies a remote IPSec peer. You can configure multiple peers. This configuration is rare in the dynamic crypto map entry. The dynamic crypto map is often used when information about the peer is unknown.
Ruijie(config-crypto-map)# **set local** *ip-address*	Sets the IP address of the local peer. If no IP address is specified, the primary address of the interface is used.
Ruijie(config-crypto-map)# **set security-association lifetime seconds** *seconds* or Ruijie(config-crypto-map)# **set security-association lifetime kilobytes** *kilobytes*	(Optional) Specifies a SA lifetime for the crypto map entry.
Ruijie(config-crypto-map)# **set mtu** *length*	Sets the fragment size in tunnel mode.
Ruijie(config-crypto-map)# **set vrf** *vrf-name*	Specifies the VRF that are associated with tunnel.
Ruijie(config-crypto-map)#**username** *name* **password** *pass*	Configures the username and password used for extended authentication.
Ruijie(config-crypto-map)# **exit**	Exits crypto map configuration mode and returns to the global configuration mode.

- **Adding a dynamic crypto map set to the normal (static) crypto map set**

You can add one or more crypto map sets to a static crypto map set through reference of the crypto map entry to the dynamic map set. The crypto map entry that refers to the dynamic crypto map should be set as the entry with the lowest priority in the crypto map set.

To add a dynamic crypto map set to a static crypto map set, run the following command in global configuration mode:

Command	**Function**

Ruijie (config)# **crypto map** *map-name* *seq-num* **ipsec-isakmp dynamic** *dynamic-map-name*	Adds a dynamic crypto map set to a static crypto map set

Applying Crypto Map Entry to an Interface

To apply a crypto map set to an interface, run the following command in interface configuration mode:

Command	Function
Ruijie(config-if)# **crypto map** *map-name*	Applies a crypto map set to an interface.

A crypto map set should be configured for every interface that the IPSec traffic will pass. The device uses this crypto map set to judge all the traffic that passes this interface and apply a specific policy to filter the traffic.

Note

Only one crypto map set can be applied to an interface at one time, while the crypt map set can be applied to multiple interfaces at one time. When the IPSec traffic that passes this interface is processed, the IP address of this interface will be used as the address of the local device.

Creating Profile Crypto Map Entries

To create Profile crypto map entries for using IKE to establish SAs, run the following commands in global configuration mode in the beginning:

Command	Function
Ruijie(config)# **crypto map** *map-name seq-num* **ipsec-isakmp**	Specifies the Profile crypto map entry to be created or modified. When using this command, you will enter crypto map configuration mode.
Ruijie(config-crypto-map)# **match address** *access-list-id*	Specifies an access list for the crypto map list. This access list defines which communications are protected by the IPSec and which are not.
Ruijie(config-crypto-map)# **set peer** {*hostname* |*ip-address*} [*trustpoint1* [*trustpoint2*]]	Specifies remote IPSec peer. Communications protected by the IPSec are forwarding to this peer. Several peers can be configured.
Ruijie(config-crypto-map)# **set local** *ip-address*	Sets the IP address of the negotiation. Use the primary IP address of the interface if it is not otherwise configured.
Ruijie(config-crypto-map)# **set transform-set** *transform-set-name1* [*transform-set-name2…transform-set-name6*]	Specifies the transform set and lists the transform sets according to certain priority (set with higher priorities prevail).
Ruijie(config-crypto-map)# **set security-association lifetime seconds** *seconds*	
Or: Ruijie(config-crypto-map)# **set security-association lifetime kilobytes** *kilobytes*	

Command	Function
Ruijie(config-crypto-map)# **set exchange-mode** *main* | *aggressive*	Sets the mode to initiate negotiations by this static entry.
Ruijie(config-crypto-map)# **set pfs** *group1* | *group2*	Specifies the Diffie-Hellman group mark.
Ruijie(config-crypto-map)# **set mtu** *length*	Sets the length of pre-fragment in tunnel mode.

Repeat the preceding steps to create other necessary crypto map entries.

The following example shows how to configure to establish a SA using IKE:

Local peer (router A) configuration:

# Define a transform set named myset

```
crypto ipsec transform-set myset esp-des
```

# Define a map set named *profile-name* that establishes a SA using IKE.

```
crypto ipsec profile profile-name
set transform-set myset
```

Remote peer (router B) configuration:

# Define a transform set named myset.

```
crypto ipsec transform-set myset  esp-des
```

# Define a map set named *profile-name* that establishes a SA using IKE

```
crypto ipsec profile profile-name
set transform-set myset
```

Note

For the IPV6, IPSEC-IPV4, or IPSEC-IPV6 tunnels, the **match any** command must be configured in the map set *profile-name*. In addition, **Profile map** in this command can apply only to IPIP and IPv6 tunnels.

The dhcp over ipsec configuration takes effect only on the crypto map entry with the smallest value of *seq-num*.

Applying Profile Crypto Map Entries to a Tunnel Interface

To apply a Profile crypto map set to a tunnel interface, run the following command in interface configuration mode:

Command	Function
Ruijie`(config-if-Tunnel 1)#` **tunnel protection ipsec profile** *profile-name*	Applies a crypto map set to a tunnel interface.

A crypto map set must be configured for every interface IPSec traffic passes through. Then the device can use the crypto map set to decrypt all packets through these interfaces.

Note

Profile crypto map entries can apply only to a tunnel interface. An attempt to apply a Profile crypto map entry to a non-tunnel interface may fail. In addition, only GRE, IPIP, and IPv6 tunnels are supported. If the **match any** command is configured in an entry, the entry applies only to IPIP and IPv6 tunnels.

Configuring Extended Authentication

Extended authentication uses AAA authentication items to verify the identities of users. To configure this function, run the following command in configuration mode:

Command	Function
Ruijie `(config)#` **crypto map** *map-name* **client authentication list** *aaa-name*	Uses AAA authentication to verify identities of users.

Configuring Accounting Mode of Extensible Authentication

When the extensible authentication is implemented by using Authentication, Authorization and Accounting (AAA)/Remote Authentication Dial In User Service (RADIUS), some RADIUS servers require accounting packets for the keepalive purpose. In this case, the accounting mode of the extensible authentication needs to be configured. To do so, run the following command in configuration mode:

Command	Function
Ruijie `(config)#` **crypto map** *map-name* **client accounting list** *aaa-name*	Applies the AAA accounting list.

Note

After this command is configured, accounting packets are used only for the keepalive purpose, and accounting data such as traffic will not be updated.

Configuring IPSec Packet Filtering

This function determines whether decrypted original IPSec packets need to be filtered. To configure this function, run the following command in configuration mode:

Command	Function
Ruijie `(config)#` **crypto ipsec no-filter**	Decrypted packets are not filtered.

Monitoring and Maintaining IPSec

Some changes to the configuration only take effect when subsequent SAs are negotiated. If you want the new settings to take effect immediately, you must delete existing SAs, so that they will be established again using the new settings. The manually established SAs must be deleted and established again. Otherwise, changes will never take effect. If the device is processing the IPSec traffic, you may just want to clear the content that may be affected by the configuration change from the SA database (that is, only delete the SAs established by a given crypto map set). All the contents are only cleared from the SA database when the configuration is changed significantly, or the amount of the IPSec traffic that the device is processing is very small.

To delete and initiate the IPSec SA again, run the following commands in global configuration mode:

Command	**Function**
Ruijie# **clear crypto sa**	Clears the entire SA database. This will also delete all the active security threads.
Ruijie# **clear crypto sa peer** {*ip-address* | *peer-name*}	Clears the SAs with specific peer addresses.
Ruijie# **clear crypto sa map** *map-name*	Clears the SAs of a specific crypto map set.
Ruijie# **clear crypto sa spi** *destionation-address* {ah | esp} *spi*	Clears the SAs with the specified destination address, protocol, or SPI.

To view configuration information of IPSec, run the following command in normal user mode:

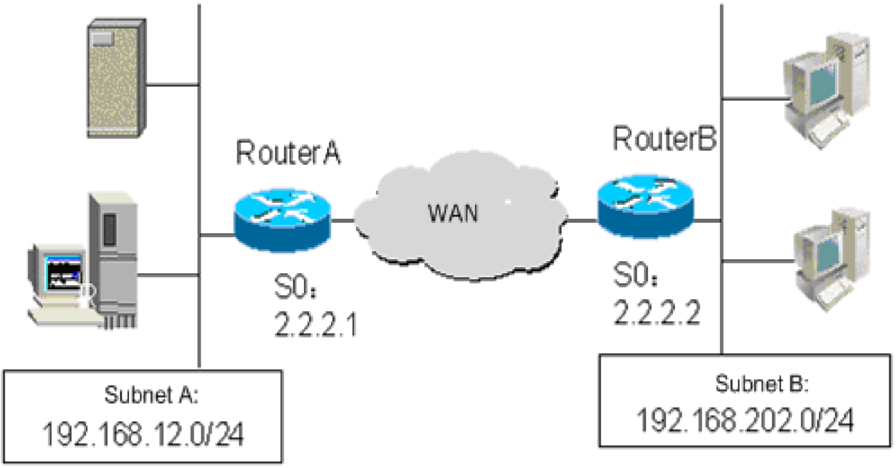
Command	**Function**
Ruijie# **show crypto ipsec transform-set**	Views configuration of a transform set.
Ruijie# **show crypto map** [*map-name*]	Views configuration of all or the specified crypto maps.
Ruijie# **show crypto ipsec sa**	Views information about the IPSec SA.
Ruijie# **show crypto dynamic-map** [*tag map-name*]	Views information about the dynamic crypto map.
Ruijie# **debug crypto ipsec**	Displays debug messages about the IPSec event.

IPSec Configuration Example

Configuration requirements

As shown in Figure 8, in order to protect the IP traffic from Subnet A (192.168.12.0/24) to Subnet B (192.168.202.0/24), use the Ethernet interface (192.168.12.1) of Router A and the Ethernet interface (192.168.202.1) of Router B as the security gateways at both ends, using the channel mode and the protection mode ESP-DES-SHA (the encryption and authentication services are available).

Figure 8 IPSec configuration example



Router configuration

In order to protect the IP traffic between hosts in two subnets, you can use the manually established SA or the IKE-established SA. Because Router A and Router B have similar configurations, the following only shows the configuration of the manually established SA for Router A. For the configuration of the IKE-established SA, refer to the typical case in the "IKE Configuration Guide" chapter .

Configuration of Router A:

# Use an access list to define the traffic to be protected

```
access-list 101 permit ip 192.168.12.0 0.0.0.255 192.168.202.0 0.0.0.255
```

# Define a transform set:

```
crypto ipsec transform-set myset esp-des esp-sha-hmac
```

# The crypto map associates the IPSec access list with the transform set, and specifies the destination of the protected traffic

```
crypto map mymap 10 ipsec-manual
    match address 101
    set transform-set myset
    set session-key inbound esp 301 cipher 0123456789abcdef authenticator
0000111122223333444455556666777788889999
set session-key outbound esp 300 cipher 0123456789abcdef authenticator
5555666677778888999900001111222233334444
    set peer 2.2.2.2
!
interface Fastethernet 0
  ip address 192.168.12.1 255.255.255.0
```

# Apply the crypto map to the interface

```
interface Serial 0
ip address 2.2.2.1
crypto map mymap
!
```

```
    ip route 0.0.0.0 0.0.0.0 2.2.2.2
```

IKE Configuration

IKE Working Process

IKE is a key management protocol standard that is used with the IPSec standard. IPSec is an IP security function that provides robust authentication and IP packet encryption. IPSec can be configured without using IKE. However, IKE enhances the IPSec function by providing additional functions and flexibility and making it easier to configure the IPSec standard. IKE is a hybrid protocol that implements the Oakley key exchange and the Skeme key exchange (ISAKMP, Oakley and Skeme are security protocols implemented by IKE) within the Internet Security Association and Key Management Protocol (ISAKMP) framework.

IPSec must be configured (depending on IPSec of IKE) and applied to the interface before IKE can work. When an outgoing packet that meets requirements is detected on the interface, IPSec will trigger IKE to negotiate with the peer IKE. They establish a secure channel between the peers to transmit various supported IPSec parameters. Finally, a consistent SA is established at both ends to enable IPSec at both ends to work. If there are data that meets requirements to be transmitted when the lifetime of the IPSec SA expires over time, IKEs at both ends will start to negotiate IPSec again, and so on.

IKE can be used to eliminate the need to manually specify all the IPSec parameters and keys in the crypto map tables for the two parties in communication. It allows you to specify the lifetime of the IPSec SA. IKE makes IPSec change the key regularly and thus strengthen the security. IKE enables IPSec to provide the anti-replay service.

IKE Configuration Task

IKE configuration tasks including:

Enabling or Disabling IKE: make sure IKE is working.

Ensuring Compatibility between Access List and IKE: if an access list (firewall) is configured on the device, you must make sure that the UDP packets of IKE are not prohibited.

Creating IKE Policies: specify parameters in each IKE policy.

Selecting Working Mode: There are two working modes-main mode (default) and aggressive mode. (note: aggressive mode is also called violent mode).

Configuring Local Identity: specifiy local indeidentity for IKE negotiation.

Setting Automatic Mode Recognition: specify whether the IKE negotiation responder automatically accept the negotiation in aggressive mode.

Configuring Digital Certificate: a digital certificate for IKE authentication.

Configuring Pre-shared Key: the pre-shared key is shared by the two peers participating in IKE negotiation.

Configuring DPD Detection: two mechanisms are used to implement DPD-- on-demand and periodic.

Configuring NAT Traversal Timeout: the UDC header is added to solve the NAT traversal problem. Use the keepalive packets to maintain the UDP linkage and to avoid the NAT connection timeout.

Exlude Ruijie vendor information: Ruijie vendor information is often delivered during IKE negotiation. If incompatibility is found in vendor informationIKE Session limit, exlude Ruijie vendor information

IKE SESSION LIMIT: set a limit on the number of IKE sessions. .

Ruijie Networks' IKE session mode: except for Digital signature authentication, switch all IKE negotiation within the network to Ruijie Networks' IKE session mode.

Extended Authentication Timeout: configure extended authentication timeout,

Configure domain authentication: confgure extended domain authentication to associate IPSEC tunnel with VRF.

Configure cisco's compatible extended authentication: configure this command on devices that negotiate with cisco's devices.

Exclude designated IP addresses from extended Digital signature authentication.

TRACK Correlation: in a scenario where there the primary and backup linkage exist at the same time, the IPSec is used to monitor the status of primary linkage. When the primary link is UP, the IPSec channel in the backup link will be removed automatically. Currently, we can use TRACK and DLDP to monitor the primary linkage.

Backup Link Detection: when the backup linkage detection does not work, the negotiation process will be intervened.

IKE Maintenance (optional): maintain IKE, make sure IKE is working, chech parameters.

Enabling or Disabling IKE

IKE is enabled by default. If you do not want to use IKE with IPSec together, you can disable it with a command. However, only the manual IPSec SA can work.

To disable or enable IKE, run the following command in global configuration mode:

Command	Function
Ruijie(config)# **no crypto isakmp enable**	Disables the IKE function.
Ruijie(config)# **crypto isakmp enable**	Enables the IKE function.

If IKE is disabled, subsequent configuration will not take effect.

Caution

Disabling IKE will result in:

- During IPSec communication, the encryption key never changes, and you need to modify your key regularly.
- The anti-replay service is unavailable.
- You must establish all the SAs manually.

Ensuring Compatibility between Access List and IKE

IKE is an application running on the basis of UDP that transmits packets in the UDP format through port 500. If an access list (firewall) is configured on the device, and UDP packets are prohibited, IKE negotiation will fail. Therefore, you must make sure that the UDP packets of IKE are not prohibited.

Creating IKE Policies

Both parties participating in IKE negotiation must have at least one set of consistent IKE policies. This is mandatory for successful IKE negotiation. You must create multiple policies with priorities on each peer, so as to make sure at least one policy matches the policy of the remote peer.

Define the following five parameters in each IKE policy:

Parameter	Keyword	Value Range	Default Value
Encryption algorithm	Des	56-bit DES-CBC	56-bit DES-CBC
	3des	168-bit DES-CBC	
	aes	128-bit AES-CBC	
HASH algorithm	Sha	SHA-1 (HMAC variant)	SHA-1 (HMAC variant)
	md5	MD5 (HMAC variant)	
Authentication method	pre-share	Pre-shared key	Digital signature authentication
	rsa-sig	Digital signature authentication	
	digital-email	Digital envelope authentication	
Diffie-Hellman group ID	1	768-bit Diffie-Hellman group	768-bit Diffie-Hellman group
	2	1024-bit Diffie-Hellman group	
	5	3072-bit Diffie-Hellman group	
	14	2048-bit Diffie-Hellman group	
	15	3072-bit Diffie-Hellman group	
	16	4096-bit Diffie-Hellman group	
	17	6144-bit Diffie-Hellman group	
	18	8192-bit Diffie-Hellman group	
Lifetime of IKE SA	Void	1 minute to 1 day (in seconds)	1 day (86400 seconds)

When IKE negotiation starts, IKE tries to find a consistent policy on the two peers. The initiator of negotiation sends all the policies to the remote responder. The responder searches, by priority, the policies that match with the local policies in the policies received from the remote peer.

If both peers participating in negotiation have the same encryption, HASH, authentication and Diffie-Hellman parameters, and the lifetime specified by the policy of the remote peer is smaller than or equal to the lifetime specified by the compared policy, then they match (if no lifetime is specified, the shorter lifetime specified by the policy of the remote peer is used). If no acceptable matching policy is found, IKE refuses to negotiate and IPSec is not established. If a matching policy is found, IKE negotiates and establishes the IPSec SA.

You can select a value of each parameter by making a tradeoff between security and performance:

- Encryption algorithms: At present, 56-bit DES-CBC, 168-bit 3DES-CBC, and 128-bit AES-CBC are supported.
- Hash algorithms: SHA-1 and MD5. MD5 has less digest and is often considered a little faster than SHA-1. Attacks on MD5 are proved to be successful in one way, but extremely difficult. However, the HMAC variant (MD5) used by IKE can block this attack.
- Authentication method: Currently RGOS supports pre-shared key method and digital certificate authentication. To authenticate with the pre-shared key method, you need to configure a correct pre-shared key. To authenticate using a digital certificate, you need to configure a correct certificate for both parties (refer to the section regarding certificate configuration).
- There are two options for the Diffie-Hellman group ID: 768-bit or 1024-bit Diffie-Hellman. 1024-bit Diffie-Hellman is more difficult to crack, but occupies more CPU resources.
- The lifetime of the IKE SA, different from that of the IPSec SA, refers to the validity period of IKE negotiation. It can be set to any value. The following is a general rule: The shorter the lifetime (to a critical point), the securer the IKE negotiation is. If a longer lifetime is used, however, negotiation of IPSec SA will be faster.

You can create multiple IKE policies, each of which corresponds to a different combination of parameters. A unique priority (1-10000, where 1 represents the highest priority) should be assigned to each created policy.

You can configure multiple policies on each peer. However, you must make sure that one of these policies has exactly the same encryption, HASH, authentication and Diffie-Hellman parameters as the remote peer (they can have different lifetimes). If no policy is configured, the device uses the default policy, which is set to have the lowest priority and includes the default value of each parameter.

To configure a policy, run the following commands in global configuration mode in the beginning:

Command	**Function**
Ruijie(config)# **crypto isakmp policy priority**	Identifies the policy to be created. Each policy is uniquely identified by the priority.
Ruijie(config-isakmp)# **encryption des | 3des | aes-128 | aes-192 | aes-256**	Specifies an encryption algorithm.
Ruijie(config-isakmp)# **hash {sha | md5}**	Specifies a HASH algorithm.
Ruijie(config-isakmp)# **authentication {pre-share | rsa-sig }**	Specifies an authentication method.
Ruijie(config-isakmp)# **group {1 | 2| 5}**	Specifies a Diffie-Hellman group ID.
Ruijie(config-isakmp)# **lifetime** *seconds*	Specifies the lifetime of IKE SA.
Ruijie(config-isakmp)# **exit**	Returns to global configuration mode.

If no value is specified for parameters, the default values are used.

To view the configured IKE policy, run the following command in privileged user mode:

Command	**Function**
Ruijie# **show crypto isakmp policy**	Shows all the existing IKE policies.

Note The configuration does not include the default policy and the default values of configured policies. To view these settings, use the **show crypto isakmp policy** command.

Selecting Working Mode

There are two working modes: main mode (default) and aggressive mode.

A working mode should be configured for the initiator. To do so, run the following commands at the crypto map entry where IKE is configured to establish a SA:

Command	**Function**
Ruijie(config)# **crypto map** *map-name seq-num* **ipsec-isakmp**	Specifies the crypto map entry to be created or modified. When using this command, you will enter crypto map configuration mode.
Ruijie(config-crypto-map)# **set exchange-mode {main | aggressive}**	Selects a working mode of IKE negotiation. The main mode is used by default.

By default, the responder negotiates in main mode. To use the aggressive mode, run the following command in global configuration mode.

Command	**Function**
Ruijie(config)**# crypto ipsec-isakmp mode-detect**	Negotiates in the mode used by the initiator.

To view the working mode of IKE, run the following command in privileged user mode:

Command	**Function**
Ruijie**# show crypto isakmp sa**	Browses all the current IKE SAs.

Configuring Local Identity

When selecting a working mode, you set the mode (main or aggressive mode) in which the initiator initiates the first negotiation message. If the main mode is selected, this configuration will not affect negotiation. If the aggressive mode is selected, this configuration specifies the identity type in the first negotiation message of the initiator, which directly affects negotiation in aggressive mode. Currently, you can set three forms: 1. Local address; 2. Domain name; 3. User name@domain name. You can set as necessary.

Command	**Function**

Ruijie(config)# **self-identity address** | **fqdn** | **user-fqdn** *identity* | dn	Specifies the form of the negotiation identity in aggressive mode. Address: The primary IP address of the local interface through which negotiation is initiated. Fqdn: Specifies the domain name form for the local identity. User-fqdn: Specifies the user name@domain name form for the local identity. Dn: DN value of the certificate

Setting Automatic Mode Recognition

The device, as the center, needs to accept dial-in in multiple modes (main mode and aggressive mode). The device needs to respond to the two different types of initiation and negotiate. Therefore, this command is mainly used in this working environment. Configuration of this command for the initiator has no influence.

Command	**Function**
Ruijie(config)**# crypto isakmp mode-detect**	Specifies that the responder negotiates by using automatic recognition.

Configuring Digital Certificate

By default, IKE authenticates by using a digital certificate. A digital certificate must be configured if this method is used. Refer to the "Digital Certificate Configuration" chapter.

Configuring Digital Envelope

The digital envelope authentication meets the need of IKE *IPSEC VPN Technology Specification.* The method is nearly the same with digital certificate. The different is when using digital envelope authentication, user should configure peer certificate first.

Here are key configurations, when configuring digital envelope:

Command	**Function**
Router(config)# **crypto pki certificate peer** *address*	Import peer certificate.
Ruijie(config)# **crypto isakmp policy** *Priority*	Identifies the policy to be created. Each policy is uniquely identified by the priority.
Ruijie(config-isakmp)# **authentication digital-email**	Specifies an authentication method.

Here are key configurations, when configuring new state code digital envelope authentication:

Command	**Function**
Router(config)# **crypto pki certificate peer** *address*	Import peer certificate.
Ruijie(config)# **crypto isakmp policy** *Priority*	Identifies the policy to be created. Each policy is uniquely identified by the priority.
Ruijie(config-isakmp)# **authentication digital-email asymmetric sm2**	Specifies new state code authentication mode.

Configuring Pre-shared Key

The pre-shared key is shared by the two peers participating in IKE negotiation. Therefore, each pre-shared key corresponds to a pair of IKE peers. On a given peer, you should specify a key that is the same as those of multiple pre-shared remote peers. For the purpose of security, you should configure different keys for different peer pairs.

To configure a pre-shared key, run the following commands in global configuration mode:

Command	Function
Router(config)# **ip host** *hostname address*	If hostname is used to identify the remote peer, specify the IP address corresponding to this hostname.
Ruijie(config)# **crypto isakmp key 0|7** *keystring* { **hostname** *peer-hostname* | **address** *peer-address* } [**no-xauth**]	Specifies a pre-shared key that is used with the remote IKE peer. Number 0 indicates the plain text is used. Number 7 indicates the cipher text is used.
Router(config)# **crypto isakmp key 0|7** *keystring* **address** *peer-address* [*mask*] [**no-xauth**]	Specifies a pre-shared key used for the IKE peer of a certain network segment. Both *peer-address* and *mask* are 0.0.0.0. 0.0.0.0 is the default pre-shared key.

You must configure the same pre-shared key on each pair of peers.

Note

1. Like Cisco devices, versions later than RGOS 8.31 use the digital signature authentication in the IKE policy by default. If the pre-shared key is needed, IKE policy configuration must be added. See the following example:

```
crypto isakmp policy 1
 authentication pre-share
!
```

Earlier versions of RGOS only support authentication using the pre-shared key.

2. If the hostname of a remote IKE negotiation peer has been registered on DNS, the second step mentioned above can be omitted.

3. On Cisco devices, if the peer uses the hostname to identify the pre-shared key, the initiator will initiate negotiation in aggressive mode.

4. After the extended authentication command **crypto map** *map-name* **client authentication list** *aaa-name* is configured, use the command **no-xauth** to disable the extended authentication for devices with designated address.

Configuring DPD Detection

Currently, two mechanisms are used to implement DPD: 1. on-demand. This mechanism sends packets when a tunnel is idle in a time longer than what is configured. This will trigger sending of a DPD message. 2. periodic. This mechanism actively sends a DPD message when the idle time of the tunnel exceeds the configured time. The maximum number of retransmission times is 5. (For DPD configuration in earlier versions, refer to the version 8.2 configuration guide)

To configure DPD detection, run the the following commands:

Command	Function
Router(config)# **crypto isakmp keepalive** *seconds*	seconds - Idle time of the tunnel The default retransmission interval is 5 seconds, and the on-demand mechanism is used
Router(config)# **crypto isakmp keepalive** *seconds retries*	seconds - Idle time of the tunnel retries – Retransmission interval The on-demand mechanism is used by default.
Router(config)# **crypto isakmp keepalive** *seconds retries* **on-demand**	seconds - Idle time of the tunnel retries - Retransmission interval on-demand - The on-demand mechanism
Router(config)# **crypto isakmp keepalive** *seconds* **periodic**	seconds - Idle time of the tunnel periodic - periodic mechanism The default Retransmission interval is 5 seconds.
Router(config)# **crypto isakmp keepalive** *seconds retries* **periodic**	seconds - Idle time of the tunnel retries - Retransmission interval periodic - periodic mechanism

Configuring NAT Traversal Timeout

As the RFC3947 and IPSEC NAT-t are supported, the UDC header is added to solve the NAT traversal problem. To avoid the NAT connection timeout, the keepalive mode shall be used to send packets. The default time is 5 minutes.

Command	Function
Router(config)# **crypto isakmp nat keepalive** *seconds*	Seconds: the interval of sending the packets in keepalive mode. The default interval is 5 minutes.

Excluding Ruijie Vendor Information

Ruijie vendor information is often delivered during IKE negotiation. If incompatibility is found in vendor information, run the following command:

Command	Function
Router(config)# **crypto isakmp vendorid disable**	Excludes the vendor id information.

Configuring IKE Session Limit

To set a limit on the number of IKE sessions, run the following command:

Command	Function
Router(config)# **crypto isakmp session limit number**	Sets a limit on the number of IKE sessions.

Configuring Ruijie IKE Negotiation Mode

To switch all IKE negotiation (except for Digital signature authentication) within the network to Ruijie Networks' IKE session mode, run the following command:

Command	Function
Router(config)# **crypto isakmp rg-sm1**	Switches all IKE negotiation (except for Digital signature authentication) within the network to Ruijie Networks' IKE session mode

Configuring Extended Authentication Timeout

To configure extended authentication timeout, run the following command:

Command	Function
Router(config)# **crypto isakmp xauth timeout** *seconds*	Configures the timeout time of extended authentication, with the value ranging from 5 to 90 seconds.

Configuring AAA Server Response Timeout

To configure AAA server response timeout, run the following command:

Command	Function
Router(config)# **crypto isakmp xauth timeout** *seconds*	Configures the timeout time of waiting AAA server response, with the value ranging from 5 to 10000 seconds.

Configuring Client Policy Delivery

When both Key ID authentication and extended authentication are used on a client, run the following commands in configuration mode to configure client policy delivery:

Command	Function
Ruijie(config)# **crypto isakmp client configuration group** name	Creates or modifies a client configuration delivery entry. When using this command, you will enter client policy delivery configuration mode.
Router(config-isakmp-group)# **key 0|7** *keystring*	Configures the shared key used for Key ID authentication. This configuration takes effect only in aggressive mode.
Router(config-isakmp-group)# **dns** pri-dns sec-dns	Configures the DNS from which a policy is delivered to a client.
Router(config-isakmp-group)# **netmask** mask	Configures the subnet mask from which a policy is delivered to a client.
Router(config-isakmp-group)# **pool** pool-name	Configures the address pool from which an IP address is selected for delivering a policy to a client.

Router(config-isakmp-group)# **network center** *net-addr/prefix*	(optional) open for the networks under the client's server. Only tht packeks forwarding to these networks can pass over the IPSec tunnel. Currently, the maximum unmber of these nuetworks is 5.

Configuring domain authentication

To enable domain authentication:

Command	**Function**
Router(config)# **crypto isakmp authorize** [**split**]	enables domain authentication:

To configure domain-delimiter:

Command	**Function**
Router(config)# **crypto isakmp domain-delimiter** *keyword* [**prefix| suffix**]	Specifies domain-delimiter；by default, the **suffix** is domain.

To specify domain-name ,

Command	**Function**
Router(config-isakmp-group)# **domain** *domain-name* [**vrf**] *vrf-name*	Specifies the domain-name and associates domain-name with vrf-name

Configuring cisco's compatible extended authentication:

To adopt cisco's compatible extended authentication for IKE negotiation. Run the following commands in configuration mode:

Command	**Function**
Router(config)# **crypto isakmp xauth cisco_comp**	Adopts Cisco's compatible extended authentication.

Note

After configured the command **crypto map** *map-name* **client authentication list** *aaa-name* on a crypto map, all clients need to be authenticated. However, some client with designated IP address do not need extended authentication. To exclude these designated IP addresses from extended Digital Signature Authentication, run the commend mentioned in the above table.

Configuring IP address pool

Use the following commands to issue an IP address for a XAUTH client:

Command	**Function**
Router(config)# **crypto isakmp ippool** *pool-name*	Creates an address pool
Ruijie(config-isakmp-ippool)#**address** *low-ip high-ip*	Configures the range of the IP address pool.

TRACK Correlation

In a scenario where there is a backup linkage or multiple linkage, the IPSec is used to monitor the status of primary linkage. When the primary linkage is up, the IPSec channel in the backup linkage will be removed so as to clear the reverse routing. And then the normal data forwarding is guranteed.Currently, TRACK and DLDP are used to monitor primary linkage. Refer to the corresponding files for the configuration of TRACK and DLDP.

Command	Function
Ruijie(config)#**crypto isakmp link-redundency backup** *backup_interface* **track** *track_id*	Monitors *track id* via the TRACK protocol. The IPSEC channel on *backup_interface* will be removed after *track id* is up.
Ruijie(config)#**crypto isakmp link-redundency backup** *backup_interface* **dldp** *master_interface*	Monitors *master_interface* via the DLDP protocol. The IPSEC channel on *backup_interface* will be removed after the *master_interface* is up.
Ruijie(config)#**crypto isakmp link-redundency backup** *backup_interface* **intf-down** *master_interface*	Monitors the DOWN event in *master_interface*. The IPSEC channel on *backup_interface* will be removed after it occurs.

Backup Linkage Detection

When the default backup linkage detection does not work, the negotiation process will be intervened

Command	Function
Ruijie(config)#**crypto isakmp link-redundency detect ike**	Only negotiate the first stage of IKE and ensure its basic function to be normal.

⚠ Caution

the command will only be configured when the default detection does not work. The default detection will detect the backup linkage in a better way.

IKE Maintenance

Clear an IKE connection

To clear an IKE connection, run the following commands in privileged user mode:

Command	Function
Ruijie# **show crypto isakmp sa**	Shows the existing IKE connections, and note down the connection ID of the connection you want to clear.
Ruijie# **clear crypto isakmp** [*connection-id*]	Clears an IKE connection. When connection-id is not used, all IKE connections are cleared.
Directly execute: Ruijie# **clear crypto isakmp**	Clears all the local IKE connections.

IKE diagnosis

To obtain the IKE diagnostics information, run the following commands in privileged user mode:

Command	Function
Ruijie# **show crypto isakmp policy**	Shows all the IKE policy parameters.
Ruijie# **show crypto isakmp sa**	Shows all the current IKE SAs.
	Shows IKE address pool
Ruijie# **debug crypto isakmp**	Shows debug messages about the IKE event.
	Shows debug message about the IKE address pool event.

IKE Configuration Example

The following shows an IKE configuration example:

```
crypto isakmp enable
crypto isakmp policy 4
    group 1
    encryption 3des
crypto isakmp policy 5
  authen pre-share
  group 2
  lifetime 1000
crypto isakmp policy 6
  authen rsa-sig
  group 1
  lifetime 1000
For details, run the following command in privileged user mode:
Ruijie # show crypto isakmp policy
Protection suite of priority 4
encryption algorithm:  3DES - Data Encryption Standard (56 bit keys).
  hash algorithm:        Secure Hash Standard
  authentication method: Rsa-Sig
  Diffie-Hellman group:  #1 (1024 bit)
  lifetime:             1000 seconds
Protection suite of priority 5
  encryption algorithm:  DES - Data Encryption Standard (56 bit keys).
  hash algorithm:        Secure Hash Standard
  authentication method: Pre-shared key
  Diffie-Hellman group:  #2 (1024 bit)
  lifetime:             1000 seconds
Protection suite of priority 6
  encryption algorithm:  DES - Data Encryption Standard (56 bit keys).
  hash algorithm:        Secure Hash Standard
  authentication method: Rsa-Sig
  Diffie-Hellman group:  #1 (768 bit)
  lifetime:             1000 seconds
Default protection suite
```

```
  encryption algorithm:  DES - Data Encryption Standard (56 bit keys).
  hash algorithm:        Secure Hash Standard
  authentication method: Rsa-Sig
  Diffie-Hellman group:  #1 (768 bit)
  lifetime:              86400 seconds
```

Typical Application Cases

Statically Configuring Tunnels

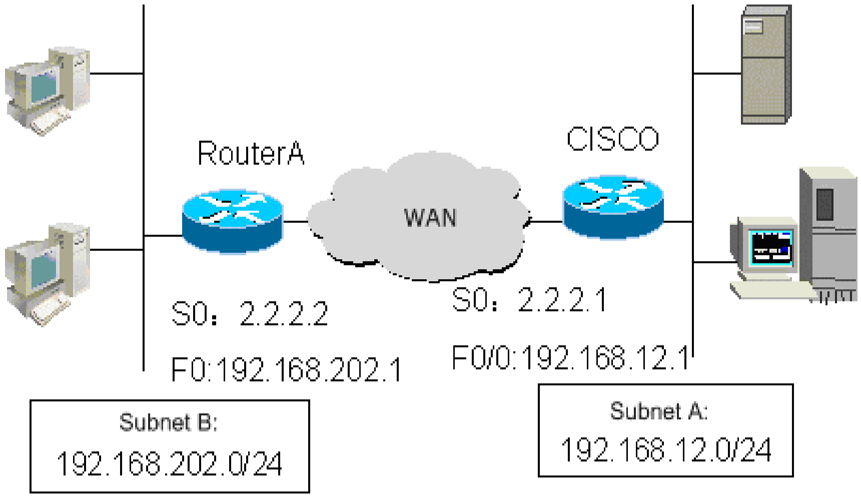
Analysis

In this case, the IP traffic between two subnets is protected by using a Cisco device connected to Subnet A as the gateway at one side, and using a Ruijie device connected to Subnet B as the gateway at the other side. The following requirements should be met:

- The 3DES algorithm is used in phase 1.
- The tunnel mode is used.
- The protection method is ESP-DES-MD5 (the encryption and authentication services are available).

In the following application, a Cisco device is used as the center, and Ruijie devices are used as remote branches. See Figure 9 :

Figure 9 Typical IPSec application



Router configuration

This section describes how to manually establish a SA and establish a SA using IKE for Ruijie router, namely Router A. Meanwhile, it also provides configurations of Cisco devices for your reference in actual work.

8) Configuration for establishing a SA using IKE

Configuration of Router A:

```
!
hostname "RouterA"
```

# Enable IKE

```
crypto isakmp enable
crypto isakmp policy 1
authentication pre-share
encryption 3des
!
```

# Configure a pre-shared key and a transform set

```
crypto isakmp key 0 preword address 2.2.2.1
crypto ipsec transform-set myset  esp-des esp-md5-hmac
```

# Define a crypto map set

```
crypto map mymap 5 ipsec-isakmp
 set peer 2.2.2.1
 set transform-set myset
 match address 101
!
interface FastEthernet0
 ip address 192.168.202.1 255.255.255.0
```

# Apply the crypto map to the interface

```
interface Serial0
 ip address 2.2.2.2 255.255.255.0
 encapsulation ppp
 crypto map mymap
!
ip route 0.0.0.0 0.0.0.0 Serial0
```

# Define an encryption access list to protect the IP traffic between the subnet 192.168.202.0/24 and the subnet 192.168.12.0/24

```

```

Monitoring and debugging

9) Monitoring and debugging the IKE-based SA

On any host in Subnet B, send a packet to Subnet A. IKE negotiation is triggered and finally an IPSec SA is established successfully.

# Turn on the debugging switches of IKE and IPSec:

```
RouterA# debug  crypto ipsec
IPSEC debugging is on
RouterA# debug  crypto isakmp
ISAKMP debugging is on
```

# You can see the following debugging information during negotiation:

```
Get acquire: 192.168.202.0/0.0.0.255 -> 192.168.12.0/0.0.0.255 , prot 0, port 0/0
Acqurire negotiate with 2.2.2.1
(36) Beginning Quick Mode exchange, M-ID of 4445127
(36) sending packet to 2.2.2.1 (I) QM_SI1_WR1
ipsec_output:423, get item acclist 101
ipsec_output:429, match  3
(36) received packet from 2.2.2.1 (I) QM_SI1_WR1
payload format: <Hdr>,<hash> <sa> <nonce> <id>
(36) processing SA payload. message ID = 4445127
(36) Creating IPSec SAs.
    inbound SA has spi 4445127
    protocol esp, DES_CBC
    auth MD5
    outbound SA has spi 275385850
    protocol esp, DES_CBC
    auth MD5
    lifetime of 3600 seconds, soft 3570 seconds
    lifetime of 4608000 kilobytes, soft 256 kilobytes
ipsec_output:423, get item acclist 101
ipsec_output:429, match  3
(36) sending packet to 2.2.2.1 (I) QM_IDLE
(36) Phase_2 negotiate complete!
```

# In order to view and confirm whether the SAs of IKE and IPSec have been established, use the following command:

```
RouterA# show crypto isakmp sa
destination    source         state                 conn-id
lifetime(second)
 2.2.2.1       2.2.2.2         QM_IDLE               36
5013
```

# The preceding information shows that an IKE SA has been established successfully

```
RouterA# show crypto ipsec sa
Interface: Serial0
Crypto map tag:mymap, local addr  2.2.2.2  //The current crypto map set is named mymap that
uses the local address 2.2.2.2
    media mtu 1500
    local  ident (addr/mask/prot/port): (192.168.202.0/0.0.0.255/0/0))
    remote  ident (addr/mask/prot/port): (192.168.12.0/0.0.0.255/0/0))
PERMIT                 //Protect the traffic between 192.168.202.0/24 and 192.168.12.0/24
current_peer: 2.2.2.1      //The address of the remote peer is 2.2.2.1
    #pkts encaps: 3, #pkts encrypt: 3, #pkts digest 3
    #pkts decaps: 3, #pkts decrypt: 3, #pkts verify 3
    #send errors 0, #recv errors 0
//Statistical data in turn: number of encapsulation packets, number of encryption packets,
number of digest packets, number of de-capsulation packets, number of decryption packets, number
of verification packets, send errors, and receive errors.
    inbound esp sas:                  //Security association for the inbound packet
processing, with the protocol ESP
            spi:0x43D3C7 (4445127)          //The SPI value is 4445127
        transform: esp-des esp-md5-hmac    //The transform set is esp-des-md5
             in use settings={Tunnel,}      //Tunnel mode
sa timing: remaining key lifetime (k/sec): (4607999/3578)
//There are 4607999 kbytes/3578 seconds left before expiry of the SA
             IV size: 8 bytes               //The IV vector length is 8
             Replay detection support:Y     //Anti-replay processing

    outbound esp sas:                      //Security association for the outbound packet
processing, with the protocol ESP
            spi:0x106A0DFA (275385850)      //The SPI value is 275385850
        transform: esp-des esp-md5-hmac    //The transform set is esp-des-md5
             in use settings={Tunnel,}      //Tunnel mode
sa timing: remaining key lifetime (k/sec): (4607999/3577)
//There are 4607999 kbytes/3577 seconds left before expiry of the SA
             IV size: 8 bytes               //The IV vector length is 8
             Replay detection support:Y     //Anti-replay processing
```

The preceding statistical data shows that IPSec has been established and some packets are protected.

Monitoring and debugging the manually established SA

Because the manually established SA exists from the beginning, you needn't negotiate it and cannot view its debugging information. You can only view some statistical data:

```
RouterA# show crypto ipsec sa
Interface: Serial0
Crypto map tag:mymap, local addr  2.2.2.2  //The current crypto map set is named mymap that uses the local address 2.2.2.2
    media mtu 1500
    local  ident (addr/mask/prot/port): (192.168.202.0/0.0.0.255/0/0))
    remote  ident (addr/mask/prot/port): (192.168.12.0/0.0.0.255/0/0))
PERMIT                               //Protect the traffic between 192.168.202.0/24 and 192.168.12.0/24
current_peer: 2.2.2.1                    //The address of the remote peer is 2.2.2.1
    #pkts encaps: 8, #pkts encrypt: 8, #pkts digest 8
    #pkts decaps: 8, #pkts decrypt: 8, #pkts verify 8
    #send errors 0, #recv errors 0
//Statistical data in turn: number of encapsulation packets, number of encrypted packets, number of digest packets, number of decapsulated packets, number of decryption packets, number of verification packets, send errors, and receive errors.
inbound esp sas:                     //Security association for the inbound packet processing, with the protocol ESP
spi: 0x12C (300)               //The SPI value is 300
transform: esp-des esp-md5-hmac    //The transform set is esp-des-md5
in use settings={Tunnel,}      //Tunnel mode
no sa timing                             //Expired
IV size: 8 bytes               //The IV vector length is 8
Replay detection support:N     //No anti-replay processing

outbound esp sas:                //Security association for the outbound packet processing, with the protocol ESP
spi: 0x12D (301)               //The SPI value is 301
transform: esp-des esp-md5-hmac    //The transform set is esp-des-md5
in use settings={Tunnel,}      //Tunnel mode
no sa timing                             //Expired
IV size: 8 bytes           //The IV vector length is 8
Replay detection support:N      //No anti-replay processing
```

The preceding statistical data shows that IPSec has been established and some packets are protected.

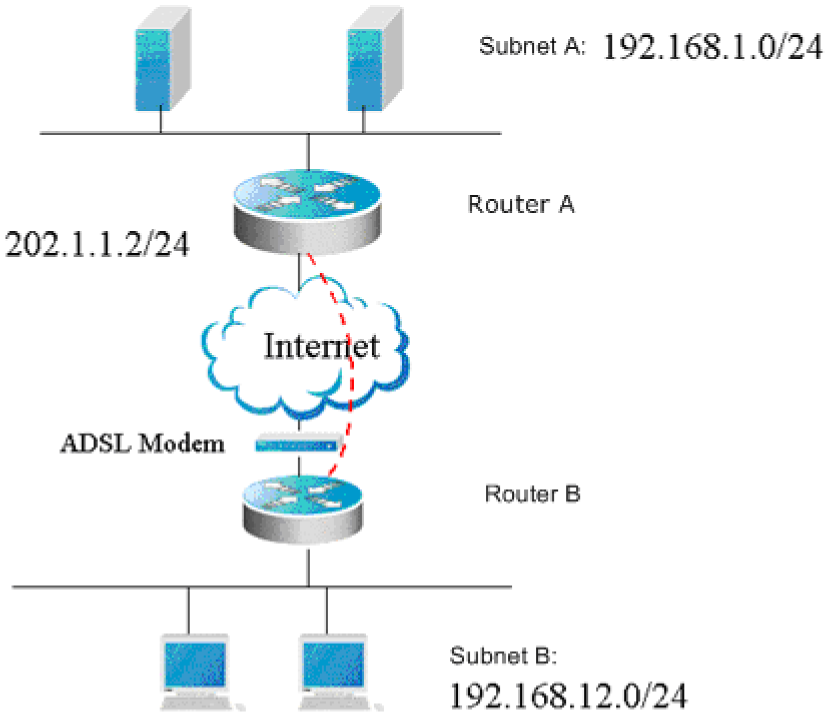
Dynamically Configuring Tunnels

Case analysis

In this case, the IP traffic between two subnets is protected by using Ruijie Router A connected to Subnet A as the gateway at one side, and using Ruijie Router B connected to Subnet B as the branch gateway at the other side, as shown in Figure-4. The following requirements should be met:

- The tunnel mode is used.
- The protection method is ESP-DES-MD5 (the encryption and authentication services are available).
- The IP address of the WAN interface of Router A is fixed: 202.1.1.2/24. The router is connected to the Internet through a dedicated line.
- Router B is connected to the Internet through ADSL using the PPPOE protocol. Its IP address is allocated by the ISP dynamically.
- Use IKE to establish the SA.
- Use the pre-shared key.

Figure 10 IPSec typical case



Router configuration

This section provides configuration for establishing a SA between Ruijie routers, namely Router B and Router A.

Configuration of Router B:

```
!
hostname "RouterB"
```

# Enable IKE

```
crypto isakmp enable
```

# Configure a pre-shared key and a transform set

```
crypto isakmp policy 1
 authentication pre-share
crypto isakmp key 0 preword address 202.1.1.2
crypto ipsec transform-set myset  esp-des esp-md5-hmac
```

# Define a crypto map set

```
crypto map mymap 5 ipsec-isakmp
 set peer 202.1.1.2
 set transform-set myset
 match address 101
!
interface FastEthernet0
 ip address 192.168.12.1 255.255.255.0
interface FastEthernet1
 no ip addrsss
 pppoe enable
 pppoe-client 1 dial-pool-number 1 dial-on-demand
```

# Apply the crypto map to the interface

```
interface Dialer0
  mtu 1488
ip address negotiate
  encapsulation ppp
  ppp pap sent-username xxx password xxx
  crypto map mymap
dialer idle-timeout 2400
  dialer pool 1
  dialer-group 1
!
dialer-list protocol ip permit
ip route 0.0.0.0 0.0.0.0 Dialer0 permanent
```

# Define an encryption access list to protect the IP traffic between the subnet 192.168.12.0/24 and the subnet 192.168.1.0/24

```
access-list 101 permit ip 192.168.12.0 0.0.0.255 192.168.1.0 0.0.0.255
!
end
```

Configuration of Router A:

```
!
hostname “RouterA”
```

# Define an IKE policy, using the pre-shared key for authentication, and using the default values for other parameters

```
crypto isakmp policy 1
 authentication pre-share
```

# Configure the default pre-shared key. Because the IP address of the remote end is dynamic, you couldn't know in advance it is necessary to configure the default pre-shared key

```
crypto isakmp key 0 preword address 0.0.0.0 0.0.0.0
```

# Define a transform set

```
crypto ipsec transform-set myset esp-des esp-md5-hmac
```

# Define a dynamic crypto map

```
crypto dynamic-map dymymap 5
 set transform-set myset
 match address 101
!
```

# Add a dynamic crypto map set to a static crypto map set

```
crypto map mymap 10 ipsec-isakmp dynamic  dymymap
!
interface FastEthernet0/0
 ip address 192.168.1.1 255.255.255.0
```

# Apply the crypto map to the interface

```
interface Serial0
 ip address 202.1.1.2 255.255.255.0
 encapsulation ppp
 crypto map mymap
!
ip route 0.0.0.0 0.0.0.0  Serial0
```

# Define an encryption access list to protect the IP traffic between the subnet 192.168.1.0/24 and the subnet 192.168.12.0/24

```
access-list 101 permit ip 192.168.1.0 0.0.0.255 192.168.12.0 0.0.0.255
!
end
```

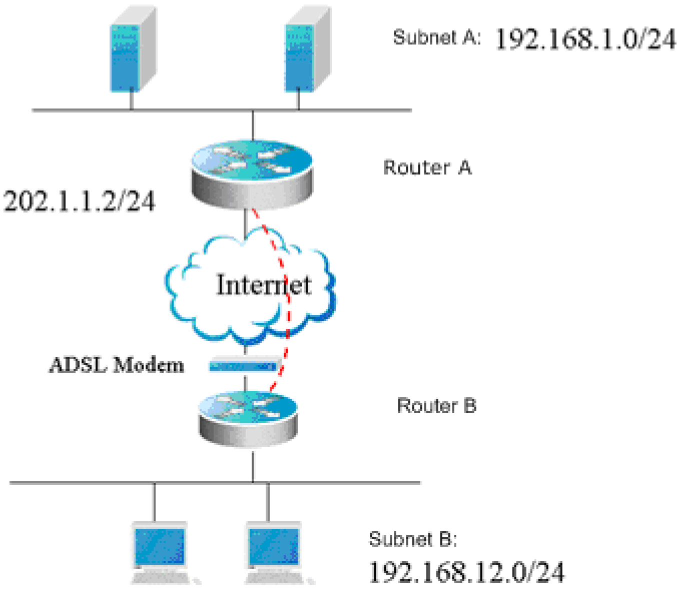
Initiating Negotiation with the Domain Name

Case analysis

In this case, the IP traffic between two subnets is protected by using Ruijie Router A connected to Subnet A as the gateway at one side, and using Ruijie Router B connected to Subnet B as the branch gateway at the other side. The following requirements should be met:

- The tunnel mode is used.
- The protection method is ESP-DES-MD5 (the encryption and authentication services are available).
- The IP address of the WAN interface of Router A is always 202.1.1.2/24. The router is connected to the Internet through a dedicated line.
- Router B is connected to the Internet through ADSL using the PPPOE protocol. Its IP address is allocated by ISP dynamically.
- Use the pre-shared key, and specify the pre-shared key for the central router using the host name.
- Use IKE to establish the SA.

Figure 11



Router configuration

This section describes how to establish a SA between Ruijie routers, namely Router B and Router A.

Configuration of Router B:

```
!
hostname "RouterB"
```

# Enable IKE

```
crypto isakmp enable
```

# Configure the local identity

```
self-identity fqdn www.google.com
```

# Configure a pre-shared key and a transform set

```
crypto isakmp key 0 preword address 202.1.1.2
crypto ipsec transform-set myset  esp-des esp-md5-hmac
```

# Define a crypto map set

```
crypto map mymap 5 ipsec-isakmp
 set peer 202.1.1.2
 set exchange-mode aggressive
 set transform-set myset
 match address 101
!
interface FastEthernet0
 ip address 192.168.12.1 255.255.255.0
interface FastEthernet1
 no ip addrsss
 pppoe enable
 pppoe-client 1 dial-pool-number 1 dial-on-demand
```

# Apply the crypto map to the interface

```
interface Dialer0
  mtu 1488
ip address negotiate
  encapsulation ppp
  ppp pap sent-username xxx password xxx
  crypto map mymap
dialer idle-timeout 2400
  dialer pool 1
  dialer-group 1
!
dialer-list protocol ip permit
ip route 0.0.0.0 0.0.0.0 Dialer0 permanent
```

# Define an encryption access list to protect the IP traffic between the subnet 192.168.12.0/24 and the subnet 192.168.1.0/24

```
access-list 101 permit ip 192.168.12.0 0.0.0.255 192.168.1.0 0.0.0.255
!
end
```

Configuration of Router A:

```
!
hostname “RouterA”
```

# Define an IKE policy, using the pre-shared key for authentication, and using the default values for other parameters

```
crypto isakmp policy 1
 authentication pre-share
```

# Configure a default pre-shared key. Because the IP address of the remote end is dynamic, the pre-shared key is found by specifying the hostname

```
crypto isakmp key 0 preword hostname www.google.com
```

# Configure automatic recognition for the center

```
crypto isakmp mode-detect
```

# Define a transform set

```
crypto ipsec transform-set myset esp-des esp-md5-hmac
```

# Define a dynamic crypto map

```
crypto dynamic-map dymymap 5
 set transform-set myset
 match address 101
!
```

# Add a dynamic crypto map set to a static crypto map set

```
crypto map mymap 10 ipsec-isakmp dynamic  dymymap
!
interface FastEthernet0/0
 ip address 192.168.1.1 255.255.255.0
```

# Apply the crypto map to the interface

```
interface Serial0
 ip address 202.1.1.2 255.255.255.0
 encapsulation ppp
 crypto map mymap
!
ip route 0.0.0.0 0.0.0.0  Serial0
```

# Define an encryption access list to protect the IP traffic between the subnet 192.168.1.0/24 and the subnet 192.168.12.0/24

```
access-list 101 permit ip 192.168.1.0 0.0.0.255 192.168.12.0 0.0.0.255
!
End
```

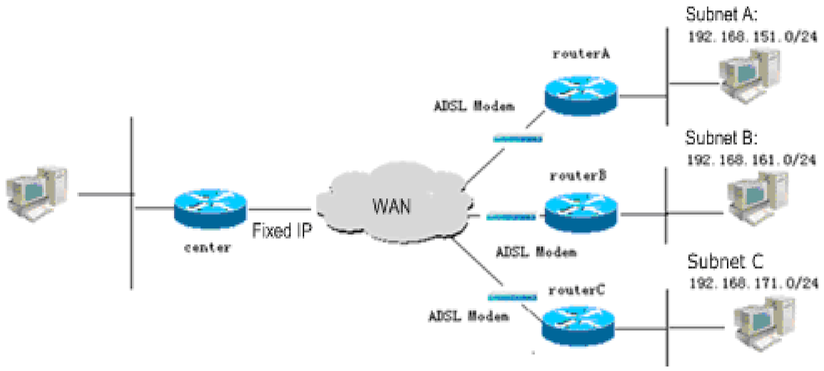
Dynamically Configuring to Use Certificate Negotiation

Case analysis

Configure a dynamic crypto map set for the center. The IKE negotiation policy uses the digital signature for authentication. The branch is connected to the center through L2TP. L2TP will trigger IKE negotiation. The IPSec tunnel must be established successfully before the L2TP tunnel can be established. L2TP is used to run OSPF, so that both the center and the branch can learn their own subnet routes. The following requirements should be met:

- The tunnel mode is used.
- The protection method is ESP-DES (the encryption service is available).
- The IP address of the WAN interface of the center is always 63.23.12.212/29. The center is connected to the Internet through a dedicated line.
- The branch router is connected to the Internet through ADSL using the PPPOE protocol. Its IP address is allocated by the ISP dynamically.
- The central router is configured with IKE negotiation policies and uses the certificate for authentication.

Figure 12



Configuration of Center:

```
hostname center
!
!
route-map static-ospf permit 10
 match ip address 1
!
access-list 1 permit 0.0.0.0 255.255.255.0

For configurations of Router B and Router C, refer to the configuration of Router A.

Caution

Because the private key of a device is confidential information that does not exist in the system configuration file, when you copy and paste the preceding configuration information to the device console or use the **copy tft flash** command to copy this configuration file to the device configuration file **config.txt**, the preceding certificate-related configurations cannot be performed. To configure a certificate, you must run the **crypto pki import pem terminal** command to import a certificate. This example only shows the configurations that are visible to you.

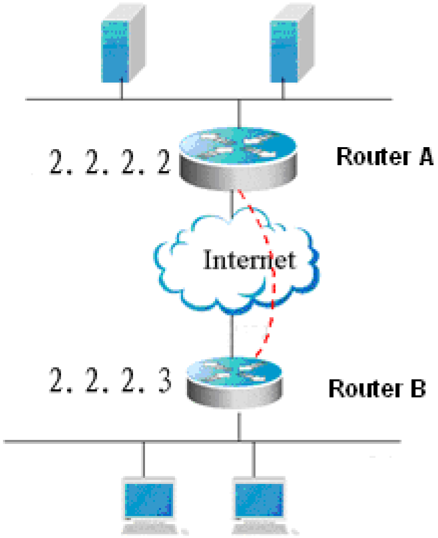
Reverse Route Injection

Analysis

In this case, the IP traffic between two subnets is protected by using the Router A as the central gateway at one side, and using Router B as the branch gateway at the other side, as shown in Figure 5. The following requirements should be met:

- The 3DES algorithm is used in phase 1.
- The tunnel mode is used.
- The protection method is ESP-3des (the encryption and authentication services are available).

Figure 13



Router configuration

```

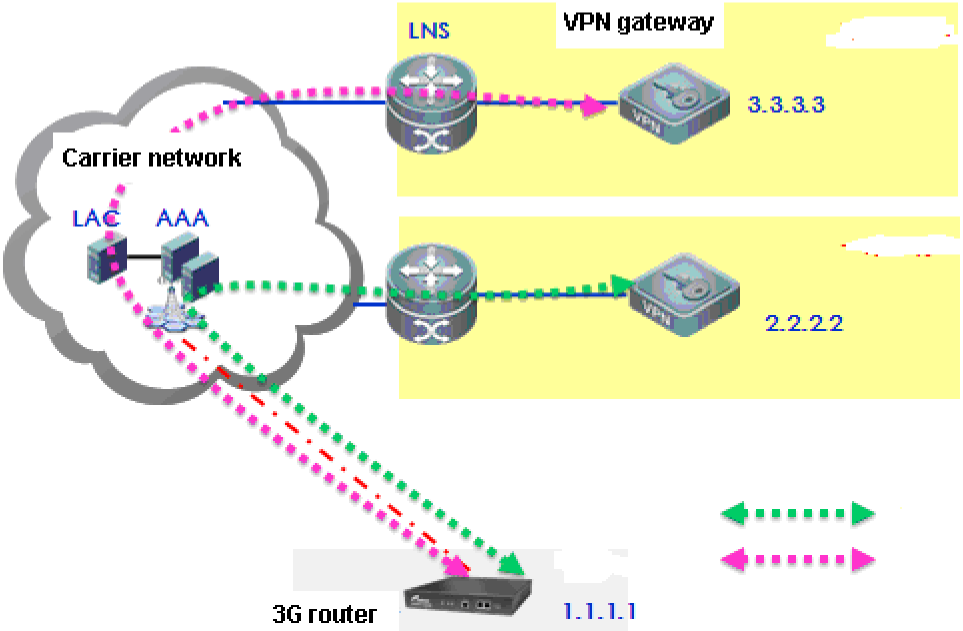
Mutual Backup of Multiple Peers

Analysis

In this case, there are multiple servers and each server uses a different certificate chain. The access device is configured with multiple peers and certificate chains. While the convergence device has the same configuration as that in the other case. As shown in the figure below, the following requirements should be met:

- Multiple VPN gateways are located in different places to provide access services.
- Every convergence router uses a different certificate chain.
- The access router changes according to the peer configuration.

Figure 14



Router configuration

12) Convergence router A

//Use the default policy.

```

end
```

Applying Profile crypto map entries in different tunnels

- Analysis

In this case, the IP traffic between two subnets is protected by using a Cisco device connected to Subnet A as the gateway at one side, and using a Ruijie device connected to Subnet B as the gateway at the other side. The following requirements should be met:

- The 3DES algorithm is used in phase 1
- The transmission mode is used.
- The protection method is ESP-DES-MD5 (the encryption and authentication services are available).

In the following application, a Cisco device is used as the center, and Ruijie devices are used as remote branches. See Figure 15.

IPSEC OVER MPLS

Analysis

MPLS on E-government extranet connects networks of official organs. To enhance MPLS networking security, encryption protection is adopted for network communication data. The following requirements should be met:

The data transferring on MPLS networks must be encrypted by IPSec.

To make sure the IPSEC encryption do not interfere with data transferring on MPLS networks, adopt IPSEC OVER MPLS.

Configuring the Digital Certificate

Overview

To ensure the security, authenticity, reliability, integrity and non-repudiation of the information transmitted between clients over network, the identity of clients must be verified, while the digital certificate is one of the methods to realize this function. PKI digital certificate technology associates the identity of individual or entity with a public key, and centrally issues the certificate through Certificate Authority (CA) to guarantee the validity and security of certificates. The digital certificates are electronic files issued by CA and binding the identity, public key and CA signature of the entity, with public key and private key forming a key pair in the public key cryptography system. Both sides of communication verify the validity of the certificate through CA signature in digital certificate, and use the public key contained in the certificate to verify the digital signature created by the peer device using the private key, thus completing authentication. There are two types of digital certificates: X.509 certificates and PGP certificates. X.509 certificates are supported by Ruijie products.

Digital certificates can be used in the IKE negotiation and SSL of IPSec. Certificate authentication can be used in the IKE configuration of IPSec and boasts the following merits:

- Higher security than PSK
- No need to separately configure PSK between every two peers of communication (easy to use)
- Security problems caused by key compromise can be addressed through certificate revocation.
- Use of overdue keys can be avoided by controlling the duration of key pairs through certificate validity

The X.509 certificate on the router can be acquired manually and through SCEP protocol. The merits of using the SCEP protocol to acquire the digital certificate of the router are shown below:

- The private key remains in the cryptographic equipment, ensuring higher security.
- The SCEP protocol adopts PKCS7 digital envelop during communication, ensuring the security of communication process.
- Supported by CA, SCEP is capable of updating digital certificates automatically.

Terminology

Public-Key Infrastructure (PKI) is a set of hardware, software, people, policies, and procedures needed to create, manage, distribute, use, store, and revoke digital certificates.

X.509: X.509 is an international standard recommended by ITU-T, and defines a widely accepted PKI, including data format and the process of public key distribution through the digital certificate issued by CA.

CA: As an authoritative, trustworthy and impartial third-party organization, CA is responsible for issuing and managing the digital certificates of all entities participating in online transaction. It effectively manages the key and issues digital certificates to prove the validity of such key, and associates the public key with one entity.

Root CA: CA at the top of the hierarchy.

Certificate or digital certificate: In this chapter, it refers to X.509 certificate (data structure defined by X.509), and is used to associate an entity with a public key to indicate the identity of the entity. A certificate contains a public key, name and digital signature of CA. Generally, the certificate also contains the validity period of the key, name of CA, serial number and etc, with format complying with ITUT X.509 standard.

CA root certificate: the self-signed certificate issued by root CA for itself; it is used to sign the other certificates issued by root CA.

Privacy-enhanced Mail (PEM): base64 encoded text format defined in RFC 1421-RFC 1424; generally used for e-mail and certificate import/export.

PKCS: A group of public-key cryptography standards devised and published by RSA Security, and is a widely-applied industry standard in information transfer. PKCS#1 defines a RSA encryption and signature algorithm; PKCS#7 defines a syntactic representation of enciphered message; PKCS#12 defines a method to create the security archive (PKCS12 can contain certificate, private key and other security achieves, and is a commonly used format for issuing certificates). The files exported in PKCS format are DER encoded binary files, and sometimes need to be converted into PEM encoded text files.

Certificate Revocation List (CRL): a list with time stamp to specify the certificates revoked by a CA. It can be freely obtained from the public directory, and is one of the two methods specified by Internet Public-Key Infrastructure (X.509) working group (PKIX) to check certificate state. Each certificate in the CRL is identified using its serial number. Therefore, by querying the serial number of certificate in the recently released CRL, the user's certificate system can check whether a certificate has been revoked; if the certificate is contained in CRL, then the certificate should be rejected. X.509 version 2 CRL contains version number, issuer DN (globally unique), validity period, serial number of the revoked certificate, time of revocation, reason of revocation, the algorithm for CA to issue this CRL and the signature thereof.

Simple Certificate Enrollment Protocol (SCEP): A draft protocol defined by Cisco to securely apply for a certificate for the router from CA. It is currently deployed on various network devices.

Configuring CA Server and Applying for & Exporting a Certificate

Installing the Certificate Services on a Windows 2003 Server

Step 1: Select Add/Remove Programs in Control Panel and click Add/Remove Windows Components.

Step 2: Select **Certificate Services** in the pop-up window.

Step 3: Click **Next** and select **Stand-alone root CA** in the pop-up window.

Step 4: Click **Next** and fill in CA related information.

Step 5: Click **Next** and set a database directory (or use the default path).

Step 6: Click **Next** to install the certificate services.

Setting Up CA Server on IIS

Step 1: Select Add/Remove Programs and click Add/Remove Windows Components.

Step 2: Select **Application Server** and then click **Details**.

Step 3: Select **Internet information services (IIS)** and then click **Details**.

Step 4: Select **World Wide Web Service** and then click **Details**.

Step 5: In the following dialog box, select **Active Server Pages** and **World Wide Web Service** and click **OK** for three times. If **World Wide Web Publishing Service** is selected, **Common Files** and **Internet Service Manager** will be selected as well by default.

Step 6: Return to the main window and click **Next** to proceed with installation.

Step 7: Enter Control Panel and select Administrative Tools; select Internet Services Manager.

Step 8: Right-click the default website.

Step 9: Select **Virtual Directory**, as shown below.

Step 10: Click **Next** and enter the alias of the virtual directory.

Step 11: Click **Next** and configure a content directory.

Step 12: Click the **Browse** button and select the directory for installing certificate services.

Note

On a Windows 2003 server, the installation directory of certificate services is shown below:

Step 13: Click **Next** and complete virtual directory configuration using default settings.

Step 14: Start the Internet explorer on the CA server and type in "127.0.0.1/Cert_Server".

Applying for and Exporting a Certificate

Currently, certificates to be installed on Ruijie routers are acquired on the PC. Suppose the IP address of a CA server is 192.168.64.130. Perform the following steps to apply for a certificate.

Step 1: Start the Internet explorer on a client (usually a PC) and type in "192.168.64.130/Cert_Server".

Step 2: Click **Next** and select **Advanced Application** as the application type.

Step 3: Click **Next** and select a method of submitting an application (using a form).

Step 4: Click **Next** and fill in detailed information.

Note

Mark keys as exportable must be checked, as RSA key pairs applicable to Ruijie routers are generated by a CA server, and certificates and key pairs must be exported eventually.

Step 5: Click **Submit** to complete certificate application.

Step 6: Return to homepage and select **Check on a pending certificate**.

Step 7: Click **Next**. If the CA center has issued a certificate, the certificate is displayed.

Step 8: Click **Next** and prepare to install this certificate, as shown below:

Step 9: Click **Install this certificate**. The system will prompt that this certificate is successfully installed.

Step 10: After installation of a certificate, the certificate needs to be exported.

Step 11: Select **Internet Options** and click the **Content** tab.

Step 12: Click the **Certificate** button.

Step 13: Select the certificate to be exported and click **Export**:

Step 14: Click **Next**.

Step 15: Click **Next**.

Note

Include all certificates in the certification path if possible must be checked. This export certificate file contains the issued certificate, private key and CA root certificate.

Step 16: Click **Next** and enter a file protection password.

Step 17: Click **Next** and enter the name of the file saving this certificate.

Step 18: Click **Next** and confirm the information, and then Click **Finish** to export the certificate.

Step 19: The certificate is exported as a pfx file. Then you need to convert the pfx file into a pem file by using "pfx2pem" tool available in the CD-ROM.

Step 20: Click **Convert**,

By this time, you will find the converted pem file in the corresponding directory. Use the Wordpad program to open this pem file; you will find the private key, certificate and the corresponding root certificate.

Caution

The password of source file is the password entered while exporting the certificate on IE; the password of the target file is the password you need to set currently. This password must be entered when you import the certificate to a device. See the "Exporting a certificate" section.

Configuring the URL of CRL

After the certificate services are installed, the default URLs of CRL are:

http://%SERVER_DNS_NAME%/CertEnroll/%CA_NAME%%CRL_SUFFIX%.crl

file://\\%SERVER_DNS_NAME%\CertEnroll\%CA_NAME%%CRL_SUFFIX%.crl

Where, the default value of *%SERVER_DNS_NAME%* is the hostname of this system rather than the domain name or IP address; if the domain name or stationary IP address must be used, CA server configurations must be changed. To change CA server configurations, perform the following steps:

Step 1: Select **Control Panel** and double-click **Administrative Tools**, and select **Certification Authority**.

Step 2: Right-click **CA Server**.

Step 3: Select **Properties** and click the **Policy Module** tab in the pop-up window.

Step 4: Click **Configure** and click the **X.509 Extensions** tab in the **Properties** window.

Step 5: Click **Add CDP**.

Step 6: Click **OK** to add a new CRL address

Example:

To specify an IP address:

Type in: http://192.168.64.130/CertEnroll/%CA_NAME%%CRL_SUFFIX%.crl

Type in: file:\\192.168.64.130\CertEnroll\%CA_NAME%%CRL_SUFFIX%.crl

To specify a domain name:

Type in: http://www.ruijie.com.cn/CertEnroll/%CA_NAME%%CRL_SUFFIX%.crl

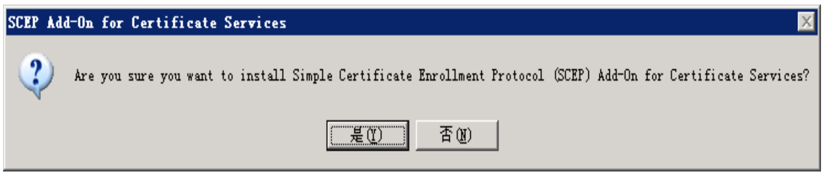
Type in: file://\\www.ruijie.com.cn\CertEnroll\%CA_NAME%%CRL_SUFFIX%.crl

Note

Currently, only the first CRL address is considered valid on Ruijie routers. Therefore, the desired CRL address should be placed on the top.

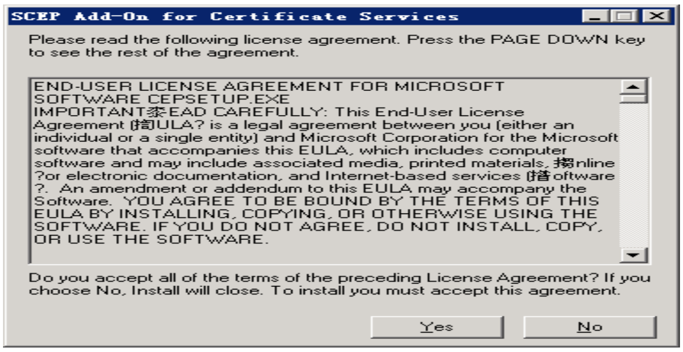
Installing SCEP Add-on

Step 1: Download the SCEP add-on for Windows Server 2003 from the following website: http://go.microsoft.com/fwlink/?LinkId=32060, and then double-click it to install.



Are you sure you want to install Simple Certificate Enrollment Protocol (SCEP) Add-On for Certificate Services?

Step 2: Click **Yes** to accept the license agreement.



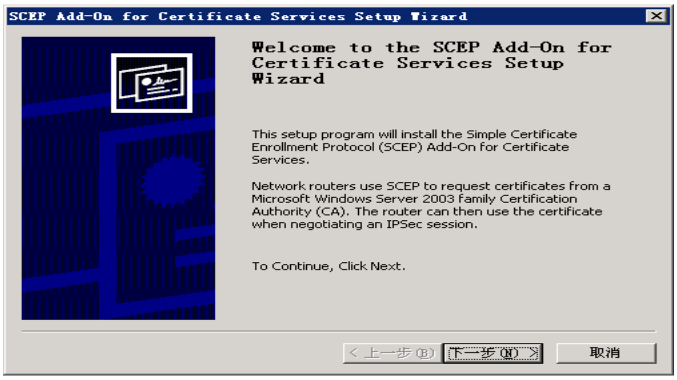
SCEP Add-On for Certificate Services

Please read the following license agreement. Press the PAGE DOWN key to see the rest of the agreement.

END-USER LICENSE AGREEMENT FOR MICROSOFT SOFTWARE CEPSETUP.EXE
IMPORTANT菍EAD CAREFULLY: This End-User License Agreement (挘ULA? is a legal agreement between you (either an individual or a single entity) and Microsoft Corporation for the Microsoft software that accompanies this EULA, which includes computer software and may include associated media, printed materials, 揂nline ?or electronic documentation, and Internet-based services (揝oftware ?. An amendment or addendum to this EULA may accompany the Software. YOU AGREE TO BE BOUND BY THE TERMS OF THIS EULA BY INSTALLING, COPYING, OR OTHERWISE USING THE SOFTWARE. IF YOU DO NOT AGREE, DO NOT INSTALL, COPY, OR USE THE SOFTWARE.

Do you accept all of the terms of the preceding License Agreement? If you choose No, Install will close. To install you must accept this agreement.

Step 3: Click **Next** to proceed with installation.



SCEP Add-On for Certificate Services Setup Wizard

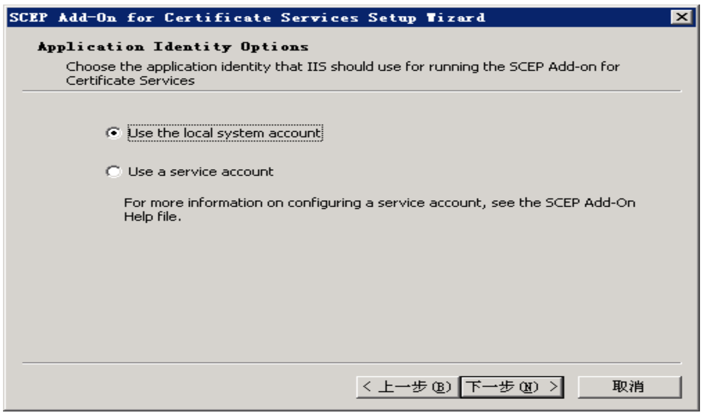
Welcome to the SCEP Add-On for Certificate Services Setup Wizard

This setup program will install the Simple Certificate Enrollment Protocol (SCEP) Add-On for Certificate Services.

Network routers use SCEP to request certificates from a Microsoft Windows Server 2003 family Certification Authority (CA). The router can then use the certificate when negotiating an IPSec session.

To Continue, Click Next.

Step 4: Select **Use the local system account** and then click **Next**.



SCEP Add-On for Certificate Services Setup Wizard

Application Identity Options

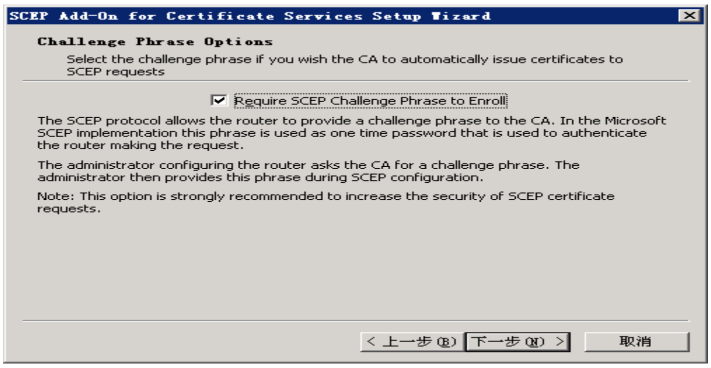
Choose the application identity that IIS should use for running the SCEP Add-on for Certificate Services

● Use the local system account

○ Use a service account

For more information on configuring a service account, see the SCEP Add-On Help file.

Step 5: It is suggested that you check **Require SCEP Challenge Phrase to Enroll**. After the device is ready to use CA to enroll, visit http://ca/certsrv/mscep/msdep.dll (from any client). The user will be required to provide the "passphrase" needed for enrollment. The "passphrase" is effective within 60 minutes. Click **Next**.



SCEP Add-On for Certificate Services Setup Wizard

Challenge Phrase Options

Select the challenge phrase if you wish the CA to automatically issue certificates to SCEP requests

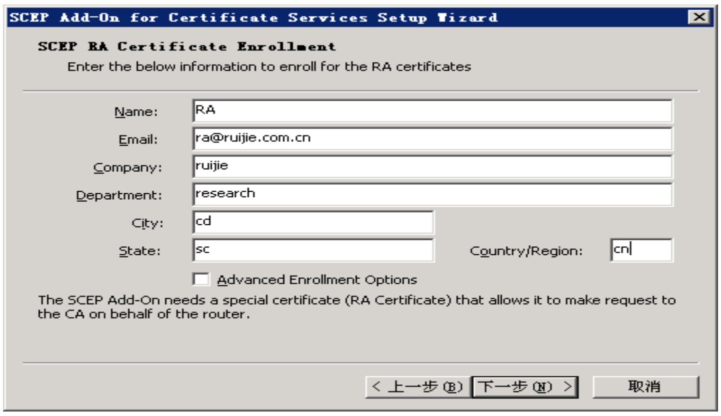
☑ Require SCEP Challenge Phrase to Enroll

The SCEP protocol allows the router to provide a challenge phrase to the CA. In the Microsoft SCEP implementation this phrase is used as one time password that is used to authenticate the router making the request.

The administrator configuring the router asks the CA for a challenge phrase. The administrator then provides this phrase during SCEP configuration.

Note: This option is strongly recommended to increase the security of SCEP certificate requests.

Step 6: Click **Next**.



SCEP Add-On for Certificate Services Setup Wizard

SCEP RA Certificate Enrollment

Enter the below information to enroll for the RA certificates

Name: RA

Email: ra@ruijie.com.cn

Company: ruijie

Department: research

City: cd

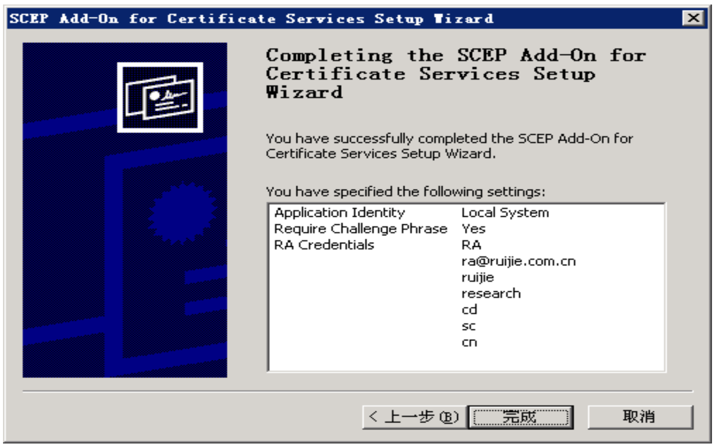
State: sc

Country/Region: cn

□ Advanced Enrollment Options

The SCEP Add-On needs a special certificate (RA Certificate) that allows it to make request to the CA on behalf of the router.

Step 7: Check the settings and click **Finish**.



SCEP Add-On for Certificate Services Setup Wizard

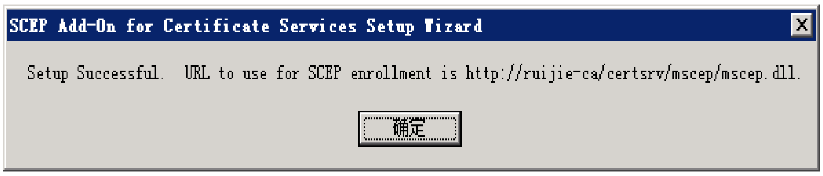
Completing the SCEP Add-On for Certificate Services Setup Wizard

You have successfully completed the SCEP Add-On for Certificate Services Setup Wizard.

You have specified the following settings:

```
Application Identity       Local System
Require Challenge Phrase   Yes
RA Credentials             RA
                           ra@ruijie.com.cn
                           ruijie
                           research
                           cd
                           sc
                           cn
```

Step 8: The URL used for SCEP enrollment is shown below:



SCEP Add-On for Certificate Services Setup Wizard

Setup Successful. URL to use for SCEP enrollment is http://ruijie-ca/certsrv/mscep/mscep.dll.

Digital Certificate Configuration

Digital Certificate Configuration Tasks

The purpose of digital certificate configuration is to enable the device to have its own certificate and verify the certificate of the communication peer.

Digital certificate configuration involves the following tasks:

- **Acquire certificate:** Acquire CA root certificate and the router certificate and private key issued directly by this CA. RGOS currently supports offline certificate application. The detailed steps are shown in the "Applying for and Exporting a Certificate" section. It also supports online SCEP certificate application and application for a certificate application file.

- **Import certificate:** Import the CA root certificate and router certificate and private key issued directly by this CA into the device.
- **Acquire router certificate through SCEP:** Acquire router certificate from the specified CA through SCEP.
- **Certificate configuration command (optional):** Configure a certificate chain and configure a certificate by importing binary certificate file (DER formatted file) in hexadecimal format.
- **Configure certificate revocation checking policy (optional):** Configure whether to check CRL during certificate check in order to verify whether the certificate has been revoked.
- **Download CRL (optional):** Configure the URL for downloading a CRL and start CRL download immediately through the command.

Importing a Certificate

Through the aforementioned steps, you may have acquired PEM-formatted CA root certificate, router certificate and private key. Run the following commands in global configuration mode to import these contents into the device:

Command	Function
Ruijie(config)# **crypto pki import pem terminal** *password* [**id** *string*]	Starts the interactive process to import CA root certificate, router certificate and private key. Password refers to the protective password of PEM-formatted private key. For details, see the "Applying for and Exporting a Certificate" section.

Caution The system will check certificate validity during the import process, and expired or inactive certificates will not be imported. Therefore, before importing a certificate, you must check whether the system time is the current Beijing time. To change system time, you can use the **clock** or **calendar** command. Refer to the "Basic System Management" chapter of *Basic Configuration Guide* for details. If the certificate is sm2, you need to set the ID. You can use the **crypto pki sm2-identity** command in global configuration mode to configure the ID.

Certificate import interface and process are shown below:

Assuming that PEM-formatted certificate data you acquired have been archived in one file, use a text editor (Windows Wordpad is recommended) to open the file and you will see the following contents:

-----END CERTIFICATE-----
```

Caution

Caution Where, contents between “-----BEGIN CERTIFICATE-----” and “-----END CERTIFICATE-----” are certificate texts; contents between “-----BEGIN RSA PRIVATE KEY-----” and “-----END RSA PRIVATE KEY-----” are private key texts; other contents are descriptions about the PKCS12#format.

Note

the difference between CA root certificate and router certificate: The subject and issuer of CA root certificate are the same, while those of router certificate are different. Taking the above-given process as the example, the relevant information about CA root certificate is shown below:

```
subject=/Email=dingjs@star-net.cn/C=CN/ST=FuJian/L=FuZhou/O=Regiant Network Co.
Ltd/OU=Research Apartment 5/CN=CA test server
issuer=/Email=dingjs@star-net.cn/C=CN/ST=FuJian/L=FuZhou/O=Regiant Network Co.
Ltd/OU=Research Apartment 5/CN=CA test server
The subject and issuer of router certificate are shown below:
subject=/Email=dingjs@star-net.cn/C=CN/ST=FuJian/L=FuZhou/O=Regiant Network Co.
Ltd/OU=Research Apartment 5/CN=dingjs
issuer=/Email=dingjs@star-net.cn/C=CN/ST=FuJian/L=FuZhou/O=Regiant Network Co.
Ltd/OU=Research Apartment 5/CN=CA test server
```

Run the command for importing a certificate on the control console (operation instructions are given in brackets)

```
Ruijie (config)# crypto pki import pem terminal 12345678
```

```
% Enter PEM-formatted CA certificate.(prompting you to enter PEM-formatted CA root certificate
texts)
% End with a blank line or "quit" on a line by itself.(prompting you to enter blank line or
enter "quit" to exit)
(Copy the texts of CA root certificate shown in Step 1 and paste here, as shown below)

-----END CERTIFICATE-----
quit
% Certificate successfully imported
Ruijie (config)#
```

Caution

Caution Currently, Ruijie products can only support one CA root certificate and one router certificate. If another certificate is imported, the previous one is overwritten.

The import is only considered successful when CA root certificate, private key and router certificate are all successfully imported, and device configurations will be updated then, or else all import operations will be cancelled without causing any impact on the configurations. For example, when the import of router certificate fails, the import of CA root certificate and private key will all be cancelled

While copying and pasting certificate texts, do not omit any character, especially the "begin" and "end" lines. After successful import, execute the "write" operation to store the certificate and private key into FLASH, or else the import contents will be lost after shutdown.

The fingerprint of CA root certificate is used to avoid the artificial falsification of CA root certificate during the process of transmission. The CA will issue fingerprint information (including fingerprint and the hmac algorithm for fingerprint calculation) together with the CA root certificate. The user of CA root certificate must use the same fingerprint algorithm used by CA to calculate fingerprint, and check with the fingerprint issued by the CA. RGOS supports the fingerprint algorithm of SHA-1.

Verify the result of certificate import. After a successful import, the certificate will be stored in DER-encoded hexadecimal format in the system configuration file. Run the **show running** command to query the serial number and DER encoded contents of the certificate (refer to the "Configuration Example" section), or you can also run the **show crypto pki cert** command (see the "Monitoring and Maintenance" section). Note that the private key will not be displayed.

Acquiring Router Certificate Through SCEP

To configure a trustpoint, run the following commands:

Command	Function
Ruijie (config)#**crypto pki trustpoint** *CA_name*	Enters trustpoint configuration mode. *CA_name* is the common name of the CA corresponding to this trustpoint, namely the character string entered in the **Common name for this CA** field in Step 9 of the "Installing the Certificate Services on a Windows 2003 Server" section.
Ruijie (ca-trustpoint)# **asymmetric** sm2	Specifies a certificate algorithm and uses RSA (optional) in a default condition.
Ruijie (ca-trustpoint)#**enrollment url** *http://192.168.50.203/certsrv/mscep/mscep.dll*	Configures the certificate enrollment URL of this trustpoint, namely the URL shown in step 8 of the "Installing SCEP add-on" section (domain name); if there is no DNS server, an IP address can also be used; manually replace the domain name with the corresponding IP address.
Ruijie (ca-trustpoint)#**enrollment retry period** *number*	Configures the polling period when this trustpoint enters the polling state during certificate enrollment. Number is a numeric value (unit: minute); the default value is one minute.
Ruijie (ca-trustpoint)#**enrollment retry count** *number*	Configures the polling count when this trustpoint enters the polling state during certificate enrollment. Number is a numeric value (unit: time); the default value is 60 times.
Ruijie (ca-trustpoint)# **enrollment auto-enroll** *percentage*	Specifies the update period of the certificate corresponding to the trustpoint; percentage ranges from 1 through 100 to specify when the certificate will be updated.
Ruijie (ca-trustpoint)# **enrollment renewable**	Enables the CA server corresponding to the trustpoint to support certificate update

Command	Function
Ruijie (ca-trustpoint)#**exit**	Exits trustpoint configuration mode.

To acquire a CA root certificate, run the following command:

Command	Function
Ruijie (config)# **crypto pki authenticate** *CA_name*	Acquires the CA root certificate.

To register a certificate, run the following command:

Command	Function
Ruijie (config)# **crypto pki enroll** *CA_name*	Enrolls trustpoint and acquires the router certificate corresponding to this trustpoint.

The process of acquiring a router certificate through SCEP is as follows:

Ensure the time matches with standard time on each device. Use the **show clock** command on the router to ensure that the time is correct.

Configure an IP address to ensure that the router can access the CA server.

Configure the hostname of the router

```
ruijie(config)#hostname router
router(config)#
Generate a key
router(config)#crypto pki key generate rsa
gernerate-key
Choose the size of the key modulus in the range of 360 to 2048 for your General Purpose Keys.
Choosing a key modulus greater than 512 may take a few minutes.
How many bits in the modulus:1024  //Modulus size of the key
Configure the trustpoint corresponding to the CA
router(config)#crypto pki trustpoint CA
router(ca-trustpoint)#enrollment url http://192.168.50.203/certsrv/mscep/mscep.dll //URL
for enrollment
router(ca-trustpoint)#exit
```

Acquire and verify the CA root certificate.

```
router(config)#crypto pki authenticate CA
Certificate has the following attributes:
MD5 fingerprint: B4DE1DD7 E9902423 5E6330D7 D750A432
SHA1 fingerprint: AD070162 672A7C57 BD5EE522 A95AAFA1 351524D0
% Do you accept this certificate?[yes/no]:yes   //Enter yes to accept the CA certificate
Trustpoint CA certificate accepted.
```

To acquire the fingerprint and passphrase of the certificate, visit: http://ca-ip-address/certsrv/mscep/mscep.dll.

The following webpage will be displayed, prompting you to proceed with authentication. Make sure that the administrator can visit this website using the fingerprint and passphrase.

Simple Certificate Enrollment Protocol (SCEP) Add-On for Certificate Services

Welcome

The CA certificate's thumbprint is B4DE1DD7 E9902423 5E6330D7 D750A432.

Your enrollment challenge password is 8873AF8B02FC0F3E and will expire within 60 minutes. This password can only be used once.

Each enrollment requires a new challenge password. You can refresh this web page to obtain a new challenge password.

For more information please see the online documentation mscephlp.htm.

Now the fingerprint and passphrase are acquired. You need to enter the following contents on the router (replies from CA are also provided for your reference)

router(config)#crypto pki enroll CA

```
%
%Start certificate enrollment ..
%Create a challenge password. You will need to verbally provide this
   password to the CA Administrator in order to revoke your certificate.
   For security reasons your password will not be saved in the configuration.
   Please make a note of it.

Password:F4EEE4FEB3766007    //Enter the password acquired from CA
Re-enter password:F4EEE4FEB3766007
%The subject name in the certificate will include: router
```

Display the state of the trustpoint

router(config)#show crypto pki trustpoints CA status

```
Trustpoint CA Status:
  Issuing CA certificate configured:
    Subject Name:
      /CN=CA
    Fingerprint MD5: B4DE1DD7 E9902423 5E6330D7 D750A432
    Fingerprint SHA1: AD070162 672A7C57 BD5EE522 A95AAFA1 351524D0
  Router General Purpose certificate pending:    Requested Subject Name:
      /unstructuredName=router
    Request Fingerprint MD5: E8F50E2A 1FB46B00 52C6A9DB CC20AA42
Request Fingerprint SHA1: B1031204 E7A2D547 CC48F0A6 2BAE8420 829637D8
    Enrollment polling: 2 times (58 left)
  Last enrollment status: Pending    //In pending state
  State:
    Keys generated ............. Generated
    Issuing CA authenticated ....... Yes
Certificate request(s) ..... Pending
```

When "Certificate requests pending" shows up (as shown above), check "Pending Requests" on the CA server and issue this certificate. Generally, the request will take 10 to 15 seconds.

Right-click the certificate and choose **All Tasks** > **Issue**.

The certificate will then be moved to the "Issued Certificate" node. Return to the router console and query trustpoint status.

router(config)#show crypto pki trustpoints CA status

```
Trustpoint CA Status:
  Issuing CA certificate configured:
    Subject Name:
      /CN=CA
    Fingerprint MD5: B4DE1DD7E 99024235 E6330D7D 750A432
    Fingerprint SHA1: AD070162 672A7C57 BD5EE522 A95AAFA1 351524D0
  Router General Purpose certificate configured:
    Subject Name:
      /unstructuredName=router
    Fingerprint MD5: 7FFF7F4C 225850A3 D0D39EA3 EFAD8D5A
    Fingerprint SHA1: 84E3678C F2DE94DD 63397145 87CDC9C6 1010A82F
  Last enrollment status: Granted    //Certificate application is successful
  State:
    Keys generated ............. Generated
    Issuing CA authenticated ....... Yes
    Certificate request(s) ..... Yes
```

Configuring SNC certificate

Configure trustpoint:

Command	Function
Ruijie (config)#**crypto pki trustpoint** *CA_name*	Enters trustpoint configuration mode. *CA-name* is the common name of the corresponding CA, namely, the string entered in the **CA common name (C)** field in step 9 in the “Installing Certificate Services on a Windows 2003 Server” section.
Ruijie (ca-trustpoint)#**enrollment url** *http://192.168.50.203/certsrv/mscep/mscep.dll* **auto-up**	Configures the certificate enrollment URL of this trustpoint, namely the URL shown in step 8 of the "Installing SCEP add-on" section; if there is no DNS server, an IP address can also be used; manually replace the domain name with the corresponding IP address. adds **auto-up** in this command to get automatically generated certificate.
Ruijie (ca-trustpoint)#**exit**	Exits trustpoint configuration mode.

The configuration of getting SNC certificate and SECP certificate are similar. The only difference lies in **auto-up** at the end of SNC certificate enrollment URL configuration., as shown below:

```
router(config)#crypto pki trustpoint CA
router(ca-trustpoint)#enrollment url http://192.168.50.203/certsrv/mscep/mscep.dll auto-up
//enrollment url
router(ca-trustpoint)#exit
```

Configuring an Offline Certificate

Configure trustpoint:

Command	Function
Ruijie (config)#**crypto pki trustpoint** *CA_name*	Enters trustpoint configuration mode. *CA-name* is the common name of the corresponding CA, namely, the string entered in the **CA common name (C)** field in step 9 in the "Installing Certificate Services on a Windows 2003 Server" section.
Ruijie (ca-trustpoint)# **asymmetric** sm2	Specifies a certificate algorithm and uses RSA (optional) in a default condition.
Ruijie (ca-trustpoint)# **enrollment offline subject**	Configures the unique name of the router.
Ruijie (ca-trustpoint)#**exit**	Exits trustpoint configuration mode.

To register a certificate, run the following command:

Command	Function
Ruijie (config)# **crypto pki enroll** *CA_name*	Registers trustpoint and obtains the router certificate corresponding to the trustpoint.

The process for configuring an offline certificate is as follows:

- Step 1 Generate an RSA public/private key pair (mandatory).
- Step 2 Define a CA (mandatory).
- Step 3 Register an offline certificate (mandatory).
- Step 4 The CA issues a certificate (mandatory).
- Step 5 Import the certificate (mandatory).

Generate an RSA key pair:

```
Ruijie (config)#crypto pki key generate rsa //Generate a key.
Ruijie (config)#crypto pki trustpoint CA_name //Define a CA. CA-name: FQDN of the CA, which will be provided by the CA administrator
ruijie(ca-trustpoint)#enrollment offline subject //Set DN information of the offline certificate
```

You are about to be asked to enter you Distinguished Name(DN) information that will be incorporated into your certificate request. There are quite a few fields but you can leave some blank.

Common Name (eg, YOUR name) []: //Your first name and last name

Organizational Unit Name (eg, section) []: //Your organizational unit name

Organization Name (eg, company) []: //Your organization name

Locality Name (eg, city) []: //Your city or region

State or Province Name (full name) []: //Your state or province

Country Name (2 letter code) [CN]: //2-letter country code of your organization

```
The subject name is: cn=fhsjflsdgingsd,ou=research,o=ruijie,l=CD,st=SC,c=CN
Is it correct[yes/no]:yes
ruijie(config)#crypto pki enroll CA_name          //Register an offline certificate
%The subject name in the certificate will include:
cn=fhsjflsdgingsd,ou=research,o=ruijie,l=CD,st=SC,c=CN

% End with a blank line or "quit" on a line by itself.
```

//Paste the CA root certificate in PEM format.

Certificate has the following attributes:

```
MD5 fingerprint: D869FAEE D797E625 B248217D 2050BF48
SHA1 fingerprint: D0B10C45 751402F0 646B4DBF E5B26AE2 74207498
%% Do you accept this certificate?[yes/no]:yes
% CA Certificate successfully imported
% Enter PEM-formatted certificate.
% End with a blank line or "quit" on a line by itself.
```

//Paste the router certificate in PEM format issued by the CA.

```
% Router Certificate successfully imported
```

Certificate Configuration Commands (Optional)

Certificate configuration commands include certificate chain configuration commands and certificate configuration commands.

To create a certificate chain, run the following command in global configuration mode. Use the **no** form of this command to delete a certificate chain:

Command	Function

Ruijie(config)# **crypto pki certificate chain**	Creates a router certificate chain and enters certificate chain configuration mode (config_cert_chain).

To add a certificate to the certificate chain, run the following command in certificate chain configuration mode. Use the **no** form of this command to delete the certificate:

Command	**Function**
Ruijie(config_cert_chain)# **certificate** [**CA**] *serial_num*	Enters certificate configuration mode (config-pubkey) in order to enter certificate data with the specified serial number; *serial_num* is the serial number of the certificate; The *CA* parameter indicates the CA root certificate.

To enter certificate data, run the following command line by line in certificate configuration mode (config-pubkey).

Command	**Function**
Ruijie(config-pubkey)# *308202E6 30820290 A0030201 0202107F FFBB3997 39B4814B E16B4FF9 067A4B30*	Enters certificate data.

To exit certificate configuration mode, type in "quit" and the system will immediately analyze and verify the certificate data. If the certificate data is illegal, the contents entered will be cancelled. Note that "exit" and "Ctrl+Z" do not take effect in certificate configuration mode.

Command	**Function**
Ruijie(config-pubkey)# **quit**	Ends certificate data input and exits certificate configuration mode.

Caution

The commands configured in this section are only used to store, display and delete certificates. It is not recommended that you configure the certificate by entering certificate data line by line manually, as it is quite troublesome. Refer to relevant instructions for certificate import. After a successful import, run the **show running** command and you will see that the system has automatically created the certificate chain and converted CA certificate and router certificate into the format shown herein as system configurations. Actually, as Ruijie products do not provide the command for separately configuring private keys, you can only import the certificate as per relevant instructions.

If you want to manually configure the certificate by using the **certificate** command, configure the CA root certificate first and then configure the router certificate, as the former one will be needed for verification while configuring the later one.

When using the **no** form of the command to delete a CA root certificate or certificate chain, the CA root certificate, router certificate and private key in system configuration all will be deleted.

To check certificate configurations, run the **show running** command or the **show crypto pki cert** command. For details, refer to the "Monitoring and Maintenance" section.

Example of manually configuring a CA root certificate:

```
Ruijie(config)# crypto pki certificate chain
Ruijie(config-cert-chain)# certificate ca

Configuring Certificate Revocation Check Policy (Optional)

When checking whether the certificate of the communication peer is valid, Ruijie products provide strict and loose verification. In strict verification mode, the certificate must be verified for revocation. If the correct CRL is not found, the peer certificate will not be accepted; in loose verification mode, the certificate will not be verified for revocation. By default, the strict mode will be used. Run the following command in global configuration mode, you can change the check policy to loose mode, and use the **no** form of this command to restore to strict mode.

Command	Function
Ruijie(config)# **crypto pki revocation-check none**	When this command is used, there is no need to check whether the certificate has been revoked according to CRL while checking the certificate of communication peer.

Note

The check policy shall be determined according to the fact that whether the device may receive the revoked peer certificate. For example, when the certificate is used in IKE center-branch network model, as the central device needs to accept the negotiation requests initiated by many dialers, and some certificates may have been revoked, the strict mode must be configured then to avoid unauthorized access. The branch devices only initiate the negotiation attempt with the central device, and are not possible to receive a revoked certificate. Therefore, the loose mode will be sufficient and network resources needed for CRL update can also be saved.

Downloading a CRL (Optional)

By default, strict certificate revocation is used. At this time, you must download a CRL. The maximum size of a CRL file allowed by the RGOS is 1 MB; otherwise, CRL download will be rejected. On Ruijie products, a CRL file can be downloaded through HTTP from a URL obtained in the following methods (priority arranged in descending order):

15) Specified by using the **crypto pki crl url** *http://www.myca.cn/certsrv/certcrl.crl* command
16) Extension of CRL distribution point of CA root certificate configured on the device;
17) Extension of CRL distribution point of router certificate configured on the device;

CRL can be downloaded by the following means:

- Manually download CRL by using the **crypto pki crl request** command;
- When CA root certificate and router certificate are configured and strict mode is adopted for certificate check, the CRL will be detected every one minute for presence and expiration, and will be downloaded automatically;
- When strict mode is adopted for certificate check, the system will verify whether the local CRL has expired or not and download immediately during certificate check if the local CRL has expired.

Note

Note When a digital certificate is no longer needed by the device, delete relevant configurations or configure a loose certificate revocation check policy for the following considerations:

1. CRL expiration check executed once every minute can be saved;
2. If the CRL file is large, automatic update will consume certain network resources and occupy FLASH space and memory space.

To manually specify the URL for downloading CRL, run the following command in global configuration mode; use the **no** form of this command to delete this configuration:

Command	Function
Ruijie(config)# **crypto pki crl url** *url_string*	Manually specifies the URL for downloading a CRL file.

Caution

url_string must begin with http://; port 80 is used as the downloading port by default, or else you must specify a port after the domain name, for example, http://www.myca.cn:1020/; the directory name is **certsrv** by default, or you can specify a directory by running the **http://www.myca.cn***/CertDir/* command; the CRL file is **certcrl.crl** by default, or you can specify it by running the **http://www.myca.cn/certsrv/***mycertcrl.crl*; the value of *url_string* must contain no space; if your URL must contain spaces, you can type in "%20" instead, for example, http://www.myca.cn/certsrv/CA%20Server%20Crl.crl.

The domain of url_string can use an IP address directly, such as http://202.101.211.123, or an internal host name, such as http://myserver. No matter the URL is obtained through manual configuration or certificate, the device will automatically proceed with domain name resolution or host name resolution while starting to download CRL file. Make sure the relevant configurations are correct. If domain name resolution is needed, the correct DNS server address must be configured; if internal host name resolution is needed, use the **ip host** command to configure the IP address of the host.

The extension of CRL distribution point may contain multiple URLs. RGOS can only use one URL. Pay attention to this issue during CA server configuration.

To manually download a CRL, run the following command in global configuration mode:

Command	Function
Ruijie(config)# **crypto pki crl request**	Manually starts CRL download; start CRL download according to the currently configured certificate and URL (this command cannot be stored).

During CRL download, run the **crypto pki crl request** command and the system will prompt that the download process has started. Upon successful download, the message “%Crl download and decode successfully!” will be displayed on the console; use the **dir** command to check the file in FLASH and its creation time, or you can check the result of CRL download, as shown below:

```
Ruijie# dir
Directory of flash:/
```

```
5    an      68 0xdbc28957 Jan  1 2005 00:00:00 tftp_config.bin
8    an  4301816 0x3e415b47 Jun 28 2005 15:03:46 rgos.bin
20    an     5311 0xeaa56cb0 Jul  4 2005 10:04:37 config.text
26    an      427 0x5bd43f32 Jun 29 2005 10:00:07 certcrl.crl
Ruijie# show clock
clock: 2005-6-29 10:0:19
```

The name of the CRL file is **certcrl.crl**; the download time is 2005-6-29 10:00:07; the current time is 10:00:19. We can see that this CRL was downloaded just now.

In addition, Ruijie products also allow you to use the **show crypto pki crl** command to query information about the present CRL file (see the "Monitoring and Maintenance" section).

Configuration Example

This section shows the outputs of the **show running** command after completing certificate configuration. It shall be noted that the private key will not be displayed in the system configuration file as it is considered private information. Therefore, certificate configuration cannot be completed by copying and pasting the following configurations to the console or running the **copy tft flash** command to copy the configuration file to **config.txt**. To configure a certificate, you must run the **crypto pki import pem terminal** Command to import the certificate. This example only shows the visible configuration results.

Caution

For how the certificate application module uses the digital certificate, refer to instructions on relevant application modules.

Configuration example is shown below:

```
Ruijie# sh run

Monitoring and Maintenance

Ruijie products allow you to query certificate information by using the following command in privileged user mode:

Command	Function
Ruijie# **show crypto pki certificate**	Displays CA root certificate and router certificate configured in the system. When no certificate is configured, there will be no output.

The following shows an example of the **show crypto pki certificate** command output:

```
Ruijie# show crypto pki certificate
%CA certificate info:                            //CA certificate information
Certificate:
Data:
Version: 3 (0x2)                                //X.509v3

```

Caution When the **crypto pki revocation-check none** command is used during startup, the existing URL file will not be resolved automatically after startup, and the **show crypto pki crl** command has no output.

Ruijie products allow you to query system debugging information displayed in certificate operations by using the follow0069ng commands in privileged user mode:

Command	Function
Ruijie# **debug crypto pki event**	Displays event tracking information about relevant certificate operations
Ruijie# **debug crypto pki error**	Displays error tracking information about relevant certificate operations

The preceding debugging information will help you diagnose the problems arising during digital certificate configuration and application.

Configuring VPDN

Overview of VPDN

RGOS supports two types of VPDN tunnels: L2TP and PPTP.

Layer Two Tunneling Protocol (L2TP);

Point-to-Point Tunneling Protocol (PPTP).

These two types of VPDN tunneling protocols have their own history. For their configuration and usage, see the following sections. PPTP is commonly used in the Microsoft Windows series products, while L2TP is commonly used in the network devices from such vendors as Cisco. As an industry standard, L2TP is supported by Windows 2000/XP.

Caution

In this chapter, a router refers to the generic route and security gateway unless specially specified.

Configuring PPTP

Overview of PPTP

Point-to-Point-Tunneling Protocol (PPTP) is a network technology that supports multi-protocol VPN. With the PPTP protocol, remote users can dial in the local ISP through Microsoft Windows NT® Workstation, Windows® 95, Windows® 98, Windows® 2000 and other systems with the PPP function enabled, so as to connect and access the corporate network over the Internet securely. Its standard description document is RFC 2637, which is proposed jointly by Microsoft and several industry leading communication device developers. Now it has been recommended to Internet Engineering Task Force(IETF).

The PPTP protocol transmits PPP packets through the tunnel in the IP network. Although it does not modify the PPP protocol in any way, it defines a new PPP packet carrier. By defining the client-server architecture, PPTP divides the functions of the network access server (NAS) and has them implemented by PPTP network server (PNS) and PPTP access concentrator (PAC). The PNS is designed to run on general operating systems. Based on the TCP/IP network, it only requires IP interfaces. The PAC typically has one or more PSTNs, ISDNs or other PPP-enabled physical interfaces.

RGOS now can be used as the PNS, that is, it accepts the PPTP tunnel initiated by the remote client. In this case, the router accepts connection requests from the remote PPTP client and negotiates with the client to establish tunnels.

Note

Now the PNS is only supported on the R26, R36, SecVPN, and RSR series routers but not on the NBR1000.

Configuring the PPTP Server

Configuration Tasks

Configuring a Local Address Pool (Optional)

In order to accept the PPTP connection initiated by the remote client, the PNS must allocate an IP address to the remote client if no IP address is set for it to use internal VPN. Generally, an idle IP address in a specified address pool is allocated to the client. RGOS provides the following commands to configure the local address pool.

Command	Function
Ruijie(config)# **ip local pool** *poolname first-ip* [*last-ip*]	Creates a local address pool.
Ruijie(config)# **no ip local pool** *poolname*	Deletes a specified address pool.

poolname is the name of the local address pool to be created, *first-ip* and *last-ip* are the first and last address in the address range set for the local address pool, respectively.

Configuring User Information (Optional)

To authenticate the remote client that tries to access the local PNS, run the following command.

Command	Function
Ruijie(config)# **username** *user-name* **password** *password*	Configures the user information.
Ruijie(config)# **no username** *user-name*	Deletes the specified user.

user-name is the name of the user who is allowed to dial in, and *password* is the password of the user. The router maintains a local database that contains the user names and passwords.

Configuring VPDN Globally

Enabling/Disabling the VPDN Function

If the user requires the router to accept the PPTP access by the remote client and establish a PPTP tunnel, the VPDN function must be enabled on the router. To enable or disable the VPDN function, run the following command:

Command	Function
Ruijie(config)# **vpdn enable**	Enables the VPDN function.
Ruijie(config)# **no vpdn enable**	Disables the VPDN function.

Note

that if the VPDN function is disabled, all the existing PPTP tunnels and sessions are retained, but new PPTP tunnels and sessions cannot be created.

Setting Source Address of VPDN

RGOS offers the following commands for users to set the (local) source address of the VPDN function. After the source address of VPDN is set, the destination address of the tunnel set for the remote client must match it before a PPTP tunnel can be established properly.

Command	Function
Ruijie(config)# **vpdn source-ip** *ip-address*	Sets the source address of VPDN.
Ruijie(config)# **no vpdn source-ip** *ip-address*	Cancels the set source address of VPDN.

By default, the system does not check whether the destination address in the received tunnel establishment request is a specific value.

Setting Maximum Number of VPDN Sessions

To set the maximum number of sessions allowed by the VPDN server, run the following command. Once specified, the access requests that exceed the maximum value will be denied.

Command	Function
Ruijie(config)# **vpdn session-limit sessions**	Sets the maximum number of VPDN sessions.

Ruijie(config)# **no vpdn session-limit**	Restores the maximum number of VPDN sessions to the default value.

By default, the maximum number of sessions is one configured with this command.

Setting Domain Resolution

RGOS offers the following commands for users to set the domain resolution in VPDN domain authentication. With this command configured, the domain type can be identified.

Command	**Function**
Ruijie(config)# **vpdn domain-delimiter** @/%#-\	Sets the domain delimiter: prefix and suffix.
Ruijie(config)# **no vpdn domain-delimiter**	Cancels the VPDN domain authentication option.

By default, the system does not resolve the domain field.

Enabling Domain Authentication

RGOS offers the following commands for users to set the VPDN domain authentication function.

Command	**Function**
Ruijie(config)# **vpdn authorize domain split**	Enables the domain authentication, and enables the domain split.
Ruijie(config)# **no vpdn authorize domain**	Disables the domain authentication.

By default, the system does not enable the domain authentication.

Setting VPDN Rate Limiting

RGOS offers the following commands for users to limit the rate of creating VPDN sessions, namely, to limit the number of VPDN tunnels allowed to be created at one time.

Command	**Function**
Ruijie(config)# **vpdn limit_rate** *rate_num*	Enables rate limiting. The *rate_num* parameter indicates the number of tunnels allowed to be created, ranging from 5 to 100.
Ruijie(config)# **no vpdn limit_rate**	Disables rate limiting.

By default, the system does not enable rate limiting.

Configuring a Virtual-Template Interface

Setting a Virtual-Template Interface

To set the virtual-template interface, run the following commands.

Command	**Function**
Ruijie(config)# **interface virtual-template** *number*	Creates a specified virtual -template interface.
Ruijie(config)# **no interface virtual-template** *number*	Deletes the specified virtual- template interface.

number is the sequence number of the specified virtual-template interface. The created virtual-template will act as the configuration profile of the virtual-access interface that binds and carries PPTP sessions.

Configuring VPDN Group

Setting VPDN Group

To set a VPDN group, run the followng commands:

Command	Function
Ruijie(config)# **vpdn-group** *name*	Configures a VPDN group.
Ruijie(config)# **no vpdn-group** *name*	Deletes a VPDN group.

name is the name of the VPDN group. Users can access the VPDN group to establish a tunnel.

Setting Tunneling Mode

To set the tunneling mode, run the following commands:

Command	Function
Ruijie (config-vpdn)# **accept-dialin**	Permits the remote client’s access.
Ruijie (config-vpdn)# **no accept-dialin**	Denies the remote client’s access.

If a user wants the local router to perform the PNS function, the user must allow the remote client to dial in.

Setting Tunneling Protocol

To set the tunneling protocol, run the following commands.

Command	Function
Ruijie(config-vpdn-acc-in)# **protocol** {**any** | **l2tp** | **pptp**}	Sets the tunneling protocol.
Ruijie(config-vpdn-acc-in)# **no protocol**	Cancels the set tunneling protocol.

The tunneling mode must be set before the tunneling protocol is set. To make the local router perform the PNS function, the user must run the **protocol pptp** or **protocol any** command.

Setting Virtual Template to Be Used

To set a virtual template used by a VPDN group, run the following commands.

Command	Function
Ruijie(config-vpdn-acc-in)# **virtual-template** *number*	Sets a virtual template to be used.
Ruijie(config-vpdn-acc-in)# **no virtual-template**	Cancels the virtual template in use.

The tunneling mode must be set first before a virtual template used by a VPDN group is set.

Setting the Name of the Remote Peer

If the name of the remote client has been set, this VPDN group is effective only for the remote client that matches the host name. If not, this VPDN group will become the default VPDN group of the system, and can provide the VPDN service for any remote client. If the name of remote client is not configured for any VPDN group, the system will use the first found VPDN group that matches conditions to accept access from a remote dial-in user.

Command	**Function**
Ruijie(config-vpdn)# **terminate-from hostname** *name*	Sets the name of the remote host.
Ruijie(config-vpdn)# **no terminate-from**	Cancels the set name of the remote host.

name indicates the name of the remote host.

Setting Local Name

To set the local name, run the following commands. This name will be sent to the remote peer as a record property.

Command	**Function**
Ruijie(config-vpdn)# **local name** *name*	Sets the local name.
Ruijie(config-vpdn)# **no local** *name*	Cancels the set local name.

name indicates the local name. By default, RGOS uses the name of the router as the local name and sends it to the remote host of the tunnel.

Setting Source Address of VPDN group

To set the source address of a VPDN group, run the following commands. Only when the destination address in the tunnel establishment request sent by the remote client matches it, will the corresponding VPDN group apply.

Command	**Function**
Ruijie(config-vpdn)# **source-ip** *src-ip*	Sets the source address of a VPDN group.
Ruijie(config-vpdn)# **no source-ip**	Cancels the set source address of a VPDN group.

Setting PPTP Flow Control Parameters

To set the PPTP flow control parameters, run the following commands. In general application, the default value of this parameter can be used.

Command	**Function**
Ruijie(config-vpdn)# **pptp flow-control receive-window winsize**	Sets the size of the receive window of the PPTP session. The value range is 1 to 64
Ruijie(config-vpdn)# **no pptp flow-control receive-window**	Cancels the set size of the receive window of the PPTP session and restores to the default value. PAC is 16, and PNS is 64
Ruijie(config-vpdn)# **pptp flow-control** *static-rtt interval*	Sets the static reference time of waiting for ACK on receiving/sending PPTP session packets. The value range is 100 to 5000 (in milliseconds).

Command	Function
Ruijie(config-vpdn)# **no pptp flow-control**	Cancels the set static reference time of waiting for ACK on receiving/sending PPTP session packets, and restore to the default value 1500 milliseconds.

winsize is the size of the receive window of the PPTP session, and *interval* is the static reference time of waiting for an ACK message.

Setting PPTP Tunnel Parameters

To set the PPTP tunnel parameters, run the following commands. In general application, the default value of this parameter can be used.

Command	Function
Ruijie(config-vpdn)# **pptp tunnel echo** *interval*	Sets the time interval at which the PPTP tunnel actively sends echo messages. The value range is 0 to 1000 (in seconds).
Ruijie(config-vpdn)# **no pptp tunnel echo**	Cancels the set interval of sending PPTP echo messages, and restore to the default value 60 seconds.

interval is the time interval at which the PPTP tunnel actively sends ECHO messages. Value **0** indicates that the tunnel does not actively send ECHO messages. The values other than **0** indicates that the tunnel actively sends ECHO messages to detect the tunnel status after it does not receive any valid packet from the remote end of the tunnel within this time interval.

Setting the Supported Domain Name

To set the domain name, run the following commands. After the domain authentication is enabled, this command will take effect. Only the domain matching the content of this command can be identified. If the domain does not match the content of this command, another VPDN group will be used for matching. If no matched group is found, the authentication will fail.

Command	Function
Ruijie(config-vpdn)# **domain** *domain-name* **vrf** *vrf-name*	Sets the authentication domain name and the corresponding VRF instance.
Ruijie(config-vpdn)# **no pool**	Removes the domain setting.

domain-name is the name of a domain, and *vrf-name* is the name of a VRF instance.

Binding a Domain Name to an Address Pool

To bind a domain name to an address pool, run the following command in vpdn-domain configuration mode. The domain name is verified during the process of VPDN tunnel negotiation to obtain the address pool binding information configured with this command. After the PPP negotiation is successful, the specified address pool will be used to assign an address to the peer end of the tunnel. By default, the address is assigned by the address pool configured in the virtual-template interface.

Command	Function
Ruijie(config-vpdn)# **domain** *domain-name* **vrf** *vrf-name* Ruijie(config-vpdn-domain)# **pool** *pool-name*	Sets the address pool bound to the authentication domain name.

Ruijie(config-vpdn)# **no domain** *domain-name*	Removes address pool binding.

domain-name is the name of a domain, *vrf-name* is the name of a VRF instannce and *pool-name* is the name of an address pool.

Setting the DNS Negotiation Address for Binding PPP to the Domain Name

To set the DNS negotiation address of PPP through domain name matching, run the following command in vpdn-domain configuration mode. By default, the DNS address of PPP configured in the virtual-template interface is used for negotiation.

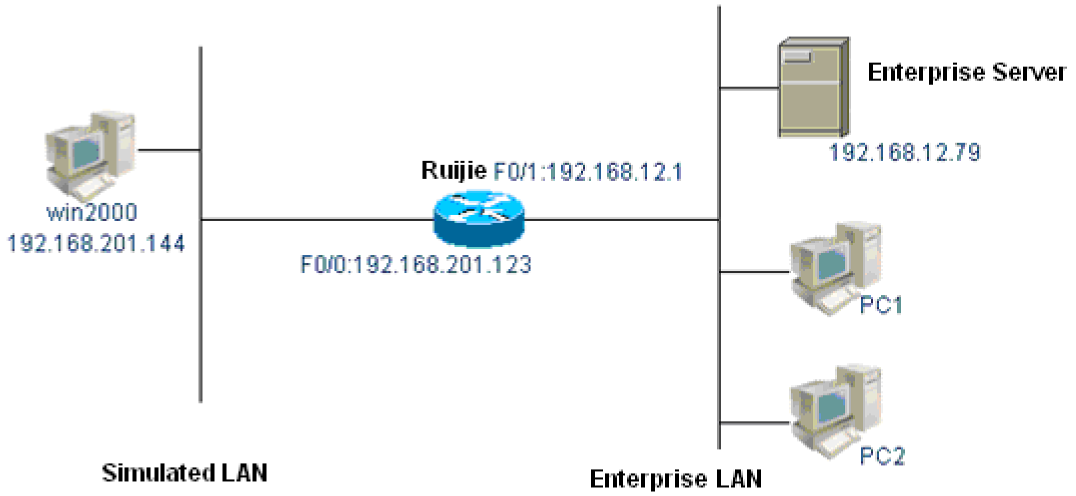
Command	Function
Ruijie(config-vpdn)# **domain** *domain-name* **vrf** *vrf-name* Ruijie(config-vpdn-domain)#**dns** *A.B.C.D A.B.C.D*	Sets the DNS negotiation address of PPP bound to the authentication domain name.
Ruijie(config-vpdn)# **no dns**	Removes DNS binding.

domain-name is the name of a domain, *vrf-name* is the name of a VRF instance and *A.B.C.D* is the address of the DNS.

Configuration Examples

The network topology in this example is shown in the following figure. The Ruijie router is used as the gateway of the corporate LAN, and the PPTP protocol is used to provide the VPDN dial-in service. Use a Windows 2000 PC as the VPDN remote client to create a PPTP tunnel to the router and access the server in the corporate LAN. To reduce testing complexity, use Ethernet to simulate the IP WAN between the remote client and R3660. The IP addresses are configured as shown in the following diagram.

Figure 19 Using a router as the PNS



The configurations of R3660 and Windows 2000 PC are respectively described as follows:

18) Configuration of R3660:

```
Ruijie# show running-config

```

Double-click **Network and Dial-up Connections** on the Windows 2000 PC to create a network connection. Select **Connect to a private network through the Internet** for **Network connection type**, select **Do not dial initial**

connection for **Public network**, and fill in the destination address 192.168.201.123. Name this connection as Vpdnconnect. On the page for setting the properties of Vpdnconnect, use PPTP as the VPDN server type, and define the PAP authentication and optional encryption in the security settings. After you click **Dial**, enter the user name **PC** and password **1111** configured in the router.

Upon completion of configuration, the Windows 2000 PC can access the server, for exmaple, the server with the IP address as 192.168.12.79, in the corporate intranet after dialing in the router, as shown below:

```
F:\>ipconfig /all

```

The routing information on the router is shown below:

```
Ruijie#sh ip route
Codes: C - connected, S - static, R - RIP
  O - OSPF, IA - OSPF inter area
  E1 - OSPF external type 1, E2 - OSPF external type 2
Gateway of last resort is 0.0.0.0 to network 0.0.0.0
  1.0.0.0/8 is variably subnetted, 2 subnets, 2 masks
C  1.1.1.0/24 is directly connected, Virtual-Access1
```

```
C  1.1.1.4/32 is directly connected, Virtual-Access1
C 192.168.12.0/24 is directly connected, FastEthernet0/1
C 192.168.201.0/24 is directly connected, FastEthernet0/0
S* 0.0.0.0/0 is directly connected, FastEthernet0/0
Ruijie#
```

Note

that in order to enable remote VPDN users to access the intranet servers, routes to these users must be configured on the servers. Generally, you can simply set the default gateway of these servers to the internal gateway address of the router, which is 192.168.12.1 in this example.

Monitoring and Maintaining PPTP

Monitoring PPTP

To query the information about currently created tunnels and remote dial-in users, run the **show vpdn** command.

Command	Function
Ruijie# **show vpdn tunnel**	Displays information about all the existing VPDN tunnels.
Ruijie# **show vpdn session**	Displays information about all the existing VPDN sessions.
Ruijie# **show vpdn**	Displays information about all the existing VPDN tunnels and sessions.

In the configuration example, the following information can be viewed:

```
Ruijie# sh vpdn
%No active L2TP tunnels
PPTP Tunnel and Session Information Total tunnels 1 sessions 1
LocID Remote Name  State  Remote Address Port Sessions
1      estbed  192.168.201.144 1436 1
LocID RemID TunID Intf Username  State  Last Chg
1  49152 1  Vi1  pc   connected 00:31:33
Ruijie#
```

Information about the L2TP and PPTP tunnels and sessions are displayed by category. The tunnel type and statistical values are displayed first, and all the tunnel and session information is displayed later . Statistical values of the tunnels and sessions: Total tunnels 1 sessions 1. The tunnel information includes tunnel ID (LocID), remote host name (Remote Name), tunnel state (State), IP address of the remote host (Remote Address), TCP port number of the PPTP tunnel (Port), number of sessions in this tunnel (Sessions). The session information about the local call ID (LocID), remote call ID (RemID), the ID of the tunnel to which this session belongs (TunID), name of the Virtual-Access interface used by this session (Intf), user name (Username), session state (State), and the time of last state change (Last Chg).

To view detailed tunnel information, run the **show vpdn tunnel pptp** *locid* command. In this example, the following information can be viewed:

```
R3660# show vpdn tunnel pptp 1
PPTP tunnel id 1 is up, remote id is 0, 1 active session
Tunnel state is estbed
Remote tunnel name is
Internet Address 192.168.201.144, port 1436
Local tunnel name is
Internet Address 192.168.201.123
```

The command output contains the tunnel status, name of the peer user, peer IP address, local host name, and local IP address.

Maintaining PPTP

RGOS provides the **clear vpdn** command to clear the specified tunnel and all its sessions.

Command	Function
Ruijie# **clear vpdn tunnel** [[**l2tp** | **pptp**] [*remote name*]]	Clears all the tunnels or the tunnel of the specified type and with the specified remote host name, and all their or its sessions.

remote name is the remote host name for which the tunnel should be cleared. In the configuration example, if **clear vpdn tunnel pptp** or **clear vpdn tunnel** is used after a tunnel is created, the session and the tunnel will be cleared. The command output is as follows:

```
Ruijie# show vpdn
%No active L2TP tunnels
%No active PPTP tunnels
```

During network debugging, you can run the **debug vpdn** command to track the establishment process of PPTP tunnels and sessions. In addition, the debugging information obtained by using the **debug ppp** command is extremely important for tracking call failures. For details, refer to description of the PPP protocol.

Command	Function
Ruijie# **debug vpdn** { **error** | **event** | **packet** }	Displays the debugging information during creation and use of the VPDN tunnel and session on the configuration terminal. **Error** indicates error information, **Event** indicates a general event, and **Packet** indicates the content in the control packet.

Note The debugging information may vary slightly with the RGOS software version.

During creation of PPTP tunnels and sessions, the **debug vpdn event** command outputs the following information:

```
VPDN: Pptp recv start-control-connection-request from host 192.168.200.114
PPTP: New tunnel socket id =9
VPDN: Pptp get tunnel info for 192.168.200.114 ok!
VPDN: Pptp send start-control-connection-reply, ok
VPDN: Pptp tunnel id 0 state change: idle --> estbed
PPTP: Add send-echo-request timer, interval = 60
```

```
VDPN: Pptp tunnel id 0 recv outgoing-call-request!
Pptp: Tunnel to 192.168.200.114 get config para. from vpdn-group pptp!
VPDN: Must process using ACCEPT_DIALIN parameters
Pptp: Session va0 get config para. from vpdn-group pptp!
VPDN: Pptp session va0 state change: idle --> connected
PPTP: Receive outcall request,process ok!assign local call id = 1
VPDN: Pptp tunnel id 0 send out-call reply
%LINK CHANGED: Interface virtual-access 0, changed state to up
VPDN: Pptp tunnel to 192.168.200.114 peer callid 1 recv set-linkinfo
VPDN: Pptp tunnel to 192.168.200.114 peer callid 1 recv set-linkinfo
%LINE PROTOCOL CHANGE: Interface virtual-access 0, changed state to UP
```

During creation of PPTP tunnels and tunnels, the **debug vpdn packet** command outputs the following information:

```
PPTP: I Start-Control-Connection-Request len 156 Magic Cookie 0x1A2B3C4D

FAQs

The following gives an FAQ about VPDN access over PPTP.

Suppose a PPTP dial-up connection is created on a Windows 2000 PC.

When setting the properties of the new dial-up connection, set **Security measure options** to **Advanced (user-defined setting) (D)**, set **Data encryption** to **Optional encryption (connect even if no encryption available)** on the **Setting** tab page, and allow PAP, CHAP and MS-CHAP authentication according to the authentication type configured in virtual-template that RGOS uses for PPTP dial-in. Additionally, **VPN server type** on the **Network** tab page is set to **Automatic**. After this setting, the Windows 2000 PC will try to create an L2TP tunnel before it creates a PPTP tunnel. This takes a long time. Therefore, you can set **VPN server type** to **Point-to-Point Tunneling Protocol (PPTP)**. As a result, a PPTP tunnel is directly created without an attempt to creating an L2TP tunnel.

When the RGOS router is located behind other firewalls, the TCP port 1723 of the firewall must be enabled.

Configuring L2TP

Overview

The Layer 2 Tunnel Protocol (L2TP), as specified in RFC 2661, is a standard tunneling protocol that Internet Engineering Task Force (IETF) proposes by combining two existing tunneling protocols, namely, Cisco Layer 2 Forwarding (L2F) protocol and Microsoft Point-to-Point Tunneling Protocol (PPTP).

L2TP, an extension of the Point-to-Point Protocol (PPP), implements user authentication and data transmission using PPP. Different from PPTP, L2TP uses UDP as the transmission protocol for control and data messages.

L2TP is also an important and effective way to implement VPN. VPN allows network users to access the enterprise intranet more conveniently and securely, no matter whether the users access the network in dial-up mode or in other modes.

RGOS supports L2TP tunnels in two modes.

- L2TP tunnel initiated by the local client: In this mode, the router acts as the L2TP client and actively initiates negotiation with the L2TP server to establish a tunnel.
- L2TP tunnel initiated by the remote client: In this mode, the router accepts a connection request from the remote L2TP client and negotiates with it to establish a tunnel.

Note Both modes are supported on the R26, R36, and SecVPN platforms, but the NBR platform supports only L2TP tunnel initiated by the local client.

Initiation by the Local Client

Configuration Task List

- Creating and configuring an L2TP-class interface (optional)
- Creating and configuring a pseudowire-class interface (optional)
- Creating and configuring a virtual-ppp interface (mandatory)

Creating and Configuring an L2TP-class Interface

This is an optional step for establishing an L2TP tunnel initiated by the local client. In this step, you can set the parameters for the L2TP control connection. The operations of configuring an L2TP-class interface include:

- Setting an L2TP-class unit
- Setting time for the L2TP control connection
- Setting authentication for the L2TP control connection
- Setting maintenance and update for the L2TP control connection

Setting an L2TP-class Unit

Use the following commands to set an L2TP-class unit for setting parameters for the L2TP control connection.

Command	Function
Ruijie(config)# **l2tp-class** *l2tp-class-name*	Configures or creates an L2TP-class interface of the specified name.
Ruijie(config)# **no l2tp-class** *l2tp-class-name*	Deletes an L2TP-class interface of the specified name.

l2TP-class-name is the name of the created or set L2TP-class unit. The L2TP-class interface created here can be referenced by the pseudowire-class interface by name.

Setting Time for the L2TP Control Connection

Use the following commands to set time for the L2TP control connection.

Command	Function
Ruijie(config-l2tp-class)# **receive-window** *size*	Sets the size of the receiving window of the control connection.
Ruijie(config-l2tp-class)# **no receive-window**	Restores the default size of the receiving window of the control connection.
Ruijie(config-l2tp-class)# **retransmit** {**initial** {**retries** *initial-retries* | **timeout** {**max** | **min**} *initial-timeout*} | **retries** *retries* | **timeout** {**max** | **min**} *timeout*}	Sets retransmission of the control connection.
Ruijie(config-l2tp-class)# **no retransmit** { **initial** {**retries** | **timeout** {**max** | **min**} }| **retries** | **timeout** {**max** | **min**} }	Restores default retransmission setting of the control connection.
Ruijie(config-l2tp-class)# **timeout setup** *seconds*	Sets the timeout period for establishing a control connection.
Ruijie(config-l2tp-class)# **no timeout setup**	Restores the default timeout period for establishing a control connection.

size is the size of the receiving window, and the default value is 8.

initial-retries is the number of SCCRQ retransmission times, and the default value is 2.

initial-timeout is the interval of SCCRQ retransmission. The default minimum interval is 1 second, and the default maximum interval is 8 seconds.

retries is the number of retransmission times of control messages, and the default value is 5.

timeout is the interval of control message retransmission. The default minimum interval is 1 second, and the default maximum interval is 8 seconds.

seconds is the upper limit of time for establishing a control connection (tunnel), and the default value is 120 seconds.

Setting Authentication for the L2TP Control Connection

Use the following commands to set authentication for the L2TP control connection (tunnel).

Command	Function
Ruijie(config-l2tp-class)# **authentication**	Enables authentication.
Ruijie(config-l2tp-class)# **no authentication**	Disables authentication.
Ruijie(config-l2tp-class)# **no hostname**	Uses the default local host name.
Ruijie(config-l2tp-class)# **hostname** *host-name*	Sets the local host name corresponding to this control connection.
Ruijie(config-l2tp-class)# **password** *pass-words*	Sets the tunnel password.
Ruijie(config-l2tp-class)# **no password**	Cancels the tunnel password.

RGOS does not require tunnel authentication by default, but uses the name of the router as the local host name. If tunnel authentication is required, both ends must use the same tunnel password. *host-name* is the local host name set by users, and *pass-words* is the password used for tunnel authentication.

Setting Maintenance and Update for the L2TP Control Connection

Use the following commands to set maintenance and update for the control connection (tunnel).

Command	Function
Ruijie(config-l2tp-class)# **hello** *interval*	Sets the interval of sending Hello messages.
Ruijie(config-l2tp-class)# **no hello**	Restores the default interval of sending Hello messages.

Here, *interval* is the interval of sending Hello messages. Its default value is 60 seconds.

Creating and Configuring a Pseudowire-class Interface

This is an optional step for establishing an L2TP tunnel initiated by the local client. In this step, you can set L2TP data transmission parameters. The operations of setting a pseudowire-class interface include:

- Setting a pseudowire-class unit
- Setting the encapsulation mode for L2TP data transmission
- Setting IP parameters for L2TP data transmission
- Setting the L2TP control connection

Setting a Pseudowire-class Unit

Use the following commands to set a pseudowire-class unit for seting L2TP data transmission parameters.

Command	Function
Ruijie(config)# **pseudowire-class** *pseudowire-class-name*	Creates or configures a pseudowire-class interface of the specified name.
Ruijie(config)# **no pseudowire-class** *pseudowire-class-name*	Deletes the pseudowire-class interface of the specified name.

pseudowire-class-name is the name of the created or set pseudowire-class unit. Here, the created pseudowire-class interface can be referenced by the peudowire rule of the virtual-ppp interface by name.

Setting the Encapsulation Mode for L2TP Data Transmission

Use the following command to set the encapsulation mode for L2TP data transmission.

Command	Function
Ruijie (config-pw-class)# **encapsulation l2tpv2**	Sets the encapsulation mode for L2TP data transmission.

Note that once the encapsulation mode is set for data transmission in L2TP channels, it cannot be changed. If a user needs to set L2TP data transmission parameters on the peudowire-class interface, the user must first set the encapsulation mode for L2TP data transmission.

Setting IP Parameters for L2TP Data Transmission

Use the following commands to set IP parameters for L2TP data transmission.

Command	Function
Ruijie (config-pw-class)# **ip dfbit set**	Disables channel data fragmentation.
Ruijie (config-pw-class)# **no ip dfbit set**	Enables channel data fragmentation.
Ruijie (config-pw-class)# **ip ttl** *ttl-value*	Sets TTL for the IP header of the channel.
Ruijie (config-pw-class)# **no ip ttl**	Restores the default TTL.
Ruijie (config-pw-class)# **ip local interface** *interface-name*	Specifies the local interface (address) of the channel.
Ruijie(config-pw-class)# **no ip local interface** *interface-name*	Cancels the specified local interface (address) of the channel.

Setting IP parameters for L2TP data transmission actually means setting the IP header of the UDP data that carries L2TP. The system allows channel data fragmentation by default. The default TTL is 255, and the system will set the nearest local address (interface) in the route for it based on the specified peer address.

Setting the L2TP Control Connection

Use the following commands to set the L2TP control connection.

Command	Function
Ruijie(config-pw-class)# **protocol l2tpv2** [*l2tp-class-name*]	Sets the L2TP control connection parameter.
Ruijie(config-pw-class)# **no protocol**	Use the default control connection parameter.

Here, **l2tpv2** creates a control connection in compliance with the L2TP protocol specified in the RFC 2661. *l2TP-class-name* is set to an existing L2TP-class interface to limit the control connection parameter. If no L2TP-class interface is available, the default L2TP control connection parameter is used.

Creating and Configuring a Virtual-ppp Interface

This is a mandatory step for establishing an L2TP tunnel initiated by the local client. A specified L2TP session will be created in this step. The operations of setting a virtual-ppp interface include:

- Setting a virtual-ppp interface

- Setting the IP address
- Setting authentication
- Setting the pseudowire rule

For information about setting the IP address and authentication parameter, see related sections in the interface configuration guide.

Setting a Virtual-ppp Interface

Use the following commands to set a virtual-ppp interface for establishing an L2TP session.

Command	**Function**
Ruijie(config)# **interface virtual-ppp** *number*	Creates or configures a specified virtual-ppp interface.
Ruijie(config)# **no interface virtual-ppp** *number*	Deletes the specified virtual-ppp interface.

number is the name of the specified virtual-ppp interface. The created virtual-ppp interface will be used to create and bind an L2TP session.

Setting the Pseudowire Rule

Use the following commands to set the pseudowire rule on the virtual-ppp interface for establishing an L2TP session.

Command	**Function**
Ruijie (config-if)# **pseudowire** *peer-ip-address vcid* {**encapsulation l2tpv2** [**pw-class** *pw-class-name*] | **pw-class** *pw-class-name* }	Sets the pseudowire rule.
Ruijie (config-if)# **no pseudowire**	Deletes the pseudowire rule.

Once the pseudowire rule is set on a virtual-ppp interface, the virtual-ppp interface will automatically attempt to establish an L2TP session with the specified LNS. If a failure occurs, the virtual-ppp interface will attempt to establish an L2TP session 10 seconds later again. Here, *peer-ip-address* is the address of the remote LNS, *vcid* is the global ID, and *pw-class-name* is the name of the referenced pseudowire-class interface.

You can set an L2TP session with the specified LNS name when the DNS service is enabled. Our products support only the DNS client service, and the name of specified LNS must be registered on the DNS server.

Command	**Function**
Ruijie (config-if)# **pseudowire** *peer-ip-address vcid* {**encapsulation l2tpv2** [**pw-class** *pw-class-name*] | **pw-class** *pw-class-name* }	Sets the pseudowire rule.
Ruijie (config-if)# **no pseudowire**	Deletes the pseudowire rule.

Once the pseudowire rule is set on a virtual-ppp interface, the virtual-ppp interface will automatically attempt to establish an L2TP session with the specified LNS. If a failure occurs, the virtual-ppp interface will attempt to establish an L2TP session 10 seconds later again. Here, *peer-hostname* is the hostname of the remote LNS. Ruijie DNS will convert this hostname to a specific IP address (note that the hostname must be registered on the DNS server). *vcid* is the global ID, and *pw-class-name* is the name of the referenced pseudowire-class interface.

Setting the VRF Attribute

Use the following commands to set the VRF attribute on the virtual-ppp interface for establishing an L2TP session.

Command	Function
Ruijie(config-Virtual-ppp 1)# **vpdn vrf** *vrf-name*	Sets the name of the VRF to which L2TP tunnel packets belong.
Ruijie(config-Virtual-ppp 1)#**no vpdn vrf**	Deletes the VRF attribute configuration.

The command for setting the VRF attribute is generally used together with the **ip vrf forward** command of an interface. Once the VRF attribute is configured on the virtual-ppp interface, the encapsulated packets will be sent to the specified VRF. If the VRF of the interface is different from that of the tunnel, the VRF attribute of packets changes before and after encapsulation, implementing VRF spanning.

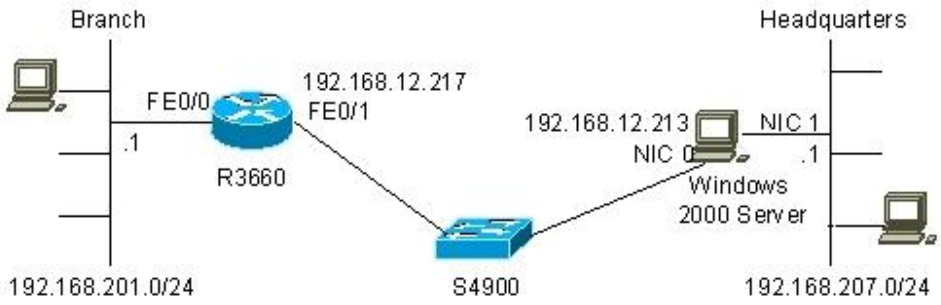
Configuration Examples

Two configuration examples are given below. In one configuration example, The Windows 2000 server is used as the remote L2TP server, and the tunnel authentication is not performed due to limitations of the Windows 2000 server. In the other configuration example, Cisco 2620 is used as the L2TP server, and tunnel authentication is performed.

Establishing a Tunnel with the Windows 2000 Server

Figure shows the networking topology of the L2TP tunnel established by using Ruijie router and the Windows 2000 server.

Figure 20 Networking topology of the L2TP tunnel established by using the Windows 2000 server (LNS)



The configurations of the R3660 and Windows 2000 server are respectively described as follows:

20) R3660 configuration:

```
R3660# show running-config
Building configuration...
Current configuration : 868 bytes
!
hostname R3660
access-list 101 permit ip any 192.168.207.0 0.0.0.255

line vty 0 4
!
!
end
```

In this configuration, the intranet of the branch shares (using the NAT function) the L2TP tunnel that the interface virtual-ppp 1 establishes with the headquarters, to access the intranet of the headquarters. The intranet of the branch shares (using the NAT function) the WAN interface FastEthernet 0/1 to access the Internet. Distribution of such data streams is controlled by using the access control list (ACL).

21) Configuration of the Windows 2000 server:

```
Microsoft Windows 2000 [Version 5.00.2195]

======================================================================
Persistent Routes:
  None
C:\>
```

Note that the routing and remote access function must be enabled on the Windows 2000 server to accept the remote VPDN access. Set the access control policies (including the ACL, authentication type, IP address allocation policies, and encryption method). Default values are used here. Then, in **Network and Dial-up Connections**, click **New connection** and **Accept incoming connections** to accept the access from the remote L2TP, and set which users' L2TP access requests are accepted.

Note

On Windows 2000/XP, L2TP is bound with IPSec/IKE, which undoubtedly increases the workload of network administrators, because most L2TP clients (such as network devices from Cisco and Quidway) do not bind L2TP to IPSec/IKE. Establishing an L2TP tunnel by using a Windows 2000/XP PC is also difficult due to such binding. Fortunately, network administrators can cancel the binding by modifying the registry on Windows 2000/XP. To do so, choose **Start** > **Run**, and then enter **regedit** to open the registry editor. Find the directory **HKEY_LOCAL_MACHINE/ SYSTEM / CurrentControlSet / Services / RasMan /Parameters**. Create a double-byte value named **ProhibitIpSec** and set it to **1**. Press **F5** to refresh the registry, and finally, restart the Windows 2000. Then, network administrators do not need to consider the complicated IPSec/IKE setting when using L2TP.

L2TP tunnels of Windows 2000/XP mentioned in this document are not bound with IPSec/IKE unless otherwise specified.

The following shows how the host "DENGL-NECBOOK" of the branch accesses the Internet and the intranet of the headquarters.

```

```

The preceding shows that the host "DENGL-NECBOOK" of the branch successfully accesses the Internet and the intranet of the headquarters. This host does not need VPDN configuration. Network administrators need to only allocate an intranet address (192.168.201.78 here) to it and set its gateway address to 192.168.201.1, which can be seen in the following information in the NAT recording node of the R3660.

```
Ruijie# show ip nat translations
Pro Inside global      Inside local        Outside local       Outside global
icmp 192.168.103.6:512  192.168.201.78:512 192.168.207.2:512  192.168.207.2:512
icmp 192.168.12.217:512 192.168.201.78:512 192.168.12.1:512   192.168.12.1:512
Ruijie# show ip route
Codes: C - connected, S - static,  R - RIP

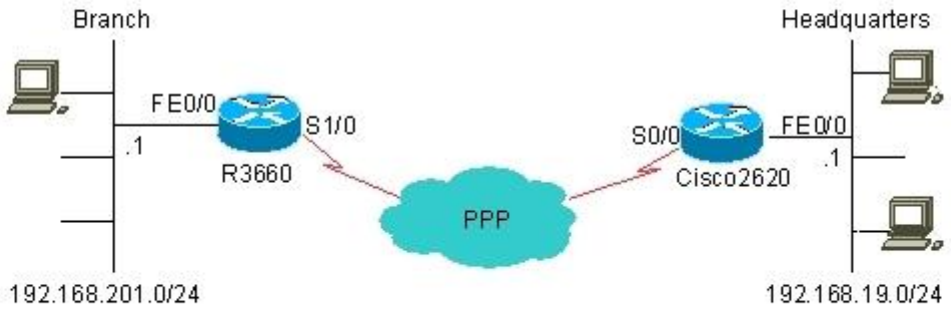
Establishing a Tunnel with Cisco 2620

Figure 21 shows the networking topology of the L2TP tunnel established by using Ruijie router and Cisco 2620. Cisco 2620 acts as the L2TP network server (LNS).

Figure 21 Networking topology of the L2TP tunnel established by using Cisco 2620 (LNS)



The configurations of R3660 and Cisco 2620 are respectively described as follows:

22) R3660 configuration

```

In this configuration, the intranet of the branch shares (through route setting) the L2TP tunnel that the interface virtual-ppp 1 establishes with the headquarters, to access the intranet of the headquarters. The intranet of the branch shares (using the NAT function) the WAN interface Serial 0 to access the Internet. Distribution of such data streams is controlled by means of route setting. Users can also use the interface FastEthernet 0 as the WAN interface as required (for example, using the ADSL line as the WAN line), share this interface through NAT, and use the line connected to the interface Serial 0 for connecting to the headquarters. This configuration can be seen in the routing table and the ARP table.

Different from the Windows 2000 server, L2TP on Cisco 2620 is not bound with IPSec/IKE. Nevertheless, Cisco L2TP requires tunnel authentication by default, while L2TP on the Windows 2000 server does not support tunnel authentication. Cisco 2620 learns routes reachable to the network 192.168.201.0/24 over OSPF, a dynamic routing protocol, which can be seen in the routing table.

```
Cisco2620# show ip route

R3660#
```

Establishing a Tunnel with the Windows 2000 PC by Using hostname

Connect Ruijie router to a Windows 2000 PC. For information about the networking topology and PC configuration, see "Establishing a Tunnel with the Windows 2000 Server."

The hostname of the Windows 2000 PC must have been registered on the DNS server. The DNS client function must be enabled on Ruijie router and route configuration must be correct so that Ruijie router can ping the DNS server successfully.

Ruijie LAC router configuration:

```
l2tp-class 1
!
pseudowire-class 1
 encapsulation l2tpv2
!
no service password-encryption
!
ip name-server 192.168.5.119
ip name-server 61.154.22.41
!
no ip ref load-sharing original
!
interface FastEthernet 0/0
 ip ref
 ip address 192.168.52.90 255.255.255.0
 duplex auto
 speed auto
!
interface FastEthernet 0/1
 duplex auto
 speed auto
!
interface Virtual-ppp 1
 pseudowire hostname mm.hxs.meibu.com 1 encapsulation l2tpv2
 ppp pap sent-username user1 password  11
 ip address negotiate
!
ip route 0.0.0.0 0.0.0.0 192.168.52.1
!
```

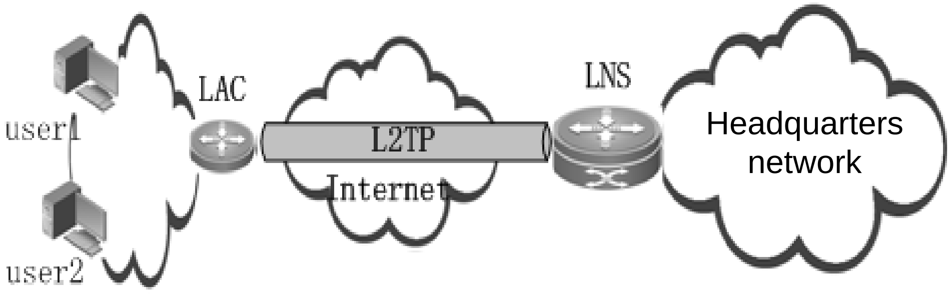
```
ref parameter 75 400
line con 0
line aux 0
line vty 0 4
 login
```

The tunnel is automatically triggered for connection.

IPv6 over L2TP Configuration Example

In the following figure, Ruijie RG-RSR20 (LAC) and RG-RSR30 (LNS) are used to establish a network connection of the L2TP tunnel. To establish an IPv6 over L2TP tunnel, the LNS assigns an IPv6 prefix to the client connected to the virtual PPP interface of the LAC over Dynamic Host Configuration Protocol version 6 Prefix Delegation (DHCPv6-PD), and delivers the domain name and DNS address over DHCPv6.

Figure 22 Establishing the IPv6 over L2TP Tunnel by RG-RSR20 (LAC) and RG-RSR30 (LNS)



The configuration of RG-RSR20 is as follows:

```
RSR20# show running-config

Initiation by the Remote Client

Configuration Task List

- Configuring a local address pool (optional)
- Configuring user information (optional)
- Setting VPDN global parameters (mandatory)
- Configuring a virtual-template interface (mandatory)
- Configuring VPDN-group (mandatory)

Configuring a Local Address Pool

This is an optional step for establishing an L2TP tunnel initiated by the remote client. In order to accept the L2TP connection initiated by the remote client, the LNS must allocate an IP address to the remote client if an IP address used inside the VPN is not set for the remote client. Generally, an idle IP address in a specified address pool is allocated to the client.

Use the following commands to configure a local address pool.

Command	Function
Ruijie(config)# **ip local pool** *poolname first-ip* [*last-ip*]	Creates or sets a local address pool.
Ruijie(config)# **no ip local pool** *poolname*	Deletes an address pool of the specified name.

poolname is the name of the local address pool to be created or set, *first-ip* is the first address in the address range set for the local address pool, and *last-ip* is the last address in the address range set for the local address pool.

Configuring User Information

This is an optional step for establishing an L2TP tunnel initiated by the remote client. The purpose of configuring user information is to authenticate remote L2TP clients that attempt to access the local client.

Use the following commands to configure user information.

Command	Function
Ruijie(config)# **username** *user-name* **password {0|7}** *password*	Configures user information.
Ruijie(config)# **no username** *user-name*	Deletes the specified user.

user-name is the name of the dial-in user who is allowed to access, and *password* is the password of the user. The router locally maintains a database that records names of dial-in users permitted to access and their passwords.

Setting VPDN Global Parameters

This is a mandatory step for establishing an L2TP tunnel initiated by the remote client. VPDN global parameters are set in this step. The operations of setting VPDN global parameters include:

- Enabling or disabling the VPDN function
- Setting the VPDN source address

- Setting the maximum number of VPDN sessions
- Setting the domain resolution option
- Enabling or disabling domain authentication
- Ignoring the source-address check of VPDN
- Setting VPDN rate limit
- Enabling or disabling the VPDN function is mandatory and setting the VPDN source address is optional.

Enabling or Disabling the VPDN Function

If a user requires the router to accept the L2TP access from the remote client and establish an L2TP tunnel and session, the VPDN function must be enabled on the router.

Use the following commands to enable or disable the VPDN function.

Command	Function
Ruijie(config)# **vpdn enable**	Enables the VPDN function.
Ruijie(config)# **no vpdn enable**	Disables the VPDN function.

The VPDN enabling and disabling support instant configuration and use (that is, they are available immediately when they are configured). If the VPDN function is disabled, all the existing L2TP tunnels and sessions will be disconnected.

Setting the VPDN Source Address

After the VPDN source address is set, the destination address of the tunnel set for the remote client must be consistent with the VPDN source address before an L2TP tunnel is established successfully.

Use the following commands to set the VPDN (local) source address.

Command	Function
Ruijie(config)# **vpdn source-ip** *ip-address*	Sets the VPDN source address.
Ruijie(config)# **no vpdn source-ip** *ip-address*	Cancels the set VPDN source address.

The system does not check whether the destination address in the received tunnel establishment request is a specific value by default.

Setting the Maximum Number of VPDN Sessions

After the maximum number of VPDN sessions is set, access requests beyond the maximum value will be denied.

Use the following commands to set the maximum number of sessions supported by the VPDN server.

Command	Function
Ruijie(config)# **vpdn session-limit** *sessions*	Sets the maximum number of VPDN sessions.
Ruijie(config)# **no vpdn session-limit**	Restores the default maximum number of VPDN sessions.

The maximum number of sessions is the one configured by using this command by default.

Setting the Domain Resolution Option

Use the following commands to set the domain resolution option in VPDN domain authentication. Domains of different types can be identified based on configuration.

Command	**Function**
Ruijie(config)**# vpdn domain-delimiter @/%#-\**	Sets the domain delimiter, prefix or suffix.
Ruijie(config)**# no vpdn domain-delimiter**	Cancels the VPDN domain authentication option.

The system does not resolve the domain field by default.

Enabling or Disabling Domain Authentication

Use the following commands to enable or disable the VPDN domain authentication, that is, determine whether to strip the domain field.

Command	**Function**
Ruijie(config)**# vpdn authorize domain split**	Enables domain authentication, that is, enables domain splitting.
Ruijie(config)**# no vpdn authorize domain**	Disables domain authentication.

Domain authentication is disabled by default.

Ignoring the Source Address Check of VPDN

Use the following commands to ingore errors on received L2TP control packets that do not comply with the RFC specifications so as to ensure the normal negotiation.

Command	**Function**
Ruijie(config-vpdn)# **vpdn ignore_source**	Ignores the source address check of packets sent from the peer end.
Ruijie(config-vpdn)# **no vpdn ignore_source**	Strictly checks the source address of packets sent from the peer end.

The system strictly checks the source address by default.

Setting VPDN Rate Limit

Use the following commands to limit the rate of establishing VPDN tunnels, namely, to limit the number of VPDN tunnels that can be established at one time.

Command	**Function**
Ruijie(config)# **vpdn limit_rate** *rate_num*	Enables rate limit. *rate_num* is the number of tunnels that can be established at a time. The value range is 5 to 100.
Ruijie(config)# **no vpdn limit_rate**	Disables rate limit.

Rate limit is disabled by default.

Configuring Rate Limit Function for VPDN Transmission

Ruijie products enable users to limit the L2TP session creation rate on the LAC, so as to limit the number of ICQ packets that can be sent at a time. To configure the rate limit function, run the following commands:

Command	Function
Ruijie(config)# **vpdn send limit_rate** *rate_num*	Enables the rate limit function. *rate_num*: Indicates the number of ICRQ packets that can be sent at a time. The value range is from **4** to **100**.
Ruijie(config)# **no send vpdn limit_rate**	Disables the rate limit function.

The rate limit function is disabled by default.

Configuring a Virtual-Template Interface

This is a mandatory step for establishing an L2TP tunnel initiated by the remote client. This interface will become the template of the virtual-access interface that binds and carries L2TP sessions. The operations of configuring a virtual-template interface include:

For information about setting the local IP address, setting the authentication mode, and setting the peer IP address, see sections regarding the interface configuration guide.

Setting a Virtual-Template Interface

Use the following commands to set a virtual-template interface.

Command	Function
Ruijie(config)**# interface virtual-template** *number*	Creates or configures a specified virtual-template interface.
Ruijie(config)**# no interface virtual-template** *number*	Deletes the specified virtual-template interface.

number is the sequence number of the specified virtual-template interface. The created virtual-template interface will be used as the configuration template of the virtual-access interface that binds and carries L2TP sessions.

Configuring VPDN-group

This is a mandatory step for establishing an L2TP tunnel initiated by the remote client. VPDN-group parameters are set in this step. The operations of configuring VPDN-group include:

- Setting a VPDN-group interface (mandatory)
- Setting the tunneling mode (mandatory)
- Setting the tunneling protocol (mandatory)
- Setting a virtual template to be used (mandatory)
- Setting the peer name (optional)
- Setting the local name (optional)
- Setting the VPDN-group source address (optional)
- Setting the L2TP control connection parameters (optional)
- Setting L2TP data transmission parameters (optional)

- Setting the vrf option (optional)
- Setting the supported domain name (optional)
- Re-performing PPP negotiation (optional)
- Ignoring errors on control packets (optional)

Setting a VPDN-group Interface

Use the following commands to set a VPDN-group interface.

Command	Function
Ruijie(config)# **vpdn-group** *name*	Creates or configures the specified VPDN-group interface.
Ruijie(config)# **no vpdn-group** *name*	Deletes the specified VPDN-group interface.

name is the name of the specified VPDN-group interface. The created VPDN-group interface allows related clients to access and establish tunnels.

Setting the Tunneling Mode

Use the following commands to set the tunneling mode.

Command	Function
Ruijie (config-vpdn)# **accept-dialin**	Allows access from the dial-in remote client.
Ruijie (config-vpdn)# **no accept-dialin**	Denies the access from the dial-in remote client.

If a user needs the local router to provide the LNS function, access from the dial-in remote client must be allowed.

Setting the Tunneling Protocol

Use the following commands to set the tunneling protocol.

Command	Function
Ruijie(config-vpdn-acc-in)# **protocol** {**any** | **l2tp** | **pptp**}	Sets the tunneling protocol.
Ruijie(config-vpdn-acc-in)# **no protocol**	Cancels the set tunneling protocol.

The tunneling mode must be set before a tunneling protocol is set.

Setting a Virtual Template to Be Used

Use the following commands to set a virtual template used by the VPDN-group.

Command	Function
Ruijie(config-vpdn-acc-in)# **virtual-template** *number*	Sets a virtual template to be used.
Ruijie(config-vpdn-acc-in)# **no virtual-template**	Cancels the virtual template.

The tunneling mode must be set before a virtual template is set for the VPDN-group.

Setting the Peer Name

If the peer name is set, this VPDN-group is effective only to the remote client that matches the host name. If no peer name is set, this VPDN-group is the default VPDN-group and can provide the VPDN service for any remote client.

Use the following commands to set the peer name.

Command	Function
Ruijie(config-vpdn)# **terminate-from hostname** *name*	Sets the name of the peer host.
Ruijie(config-vpdn)# **no terminate-from**	Cancels the set peer name.

name is the name of the peer host.

Setting the Local Name

The local name is sent to the peer end as a record property.

Use the following commands to set the local name.

Command	Function
Ruijie(config-vpdn)# **local name** *name*	Sets the local name.
Ruijie(config-vpdn)# **no local name**	Cancels the set local name.

name is the local name. The router name is used as the local name and sent to the peer host of the tunnel by default.

Setting the VPDN-group Source Address

The destination address in the tunnel establishment request sent from the remote client must match the VPDN-group source adress. In this way, the VPDN-group can be applied.

Use the following commands to set the VPDN-group source address.

Command	Function
Ruijie(config-vpdn)# **source-ip** *src-ip*	Sets the VPDN-group source address.
Ruijie(config-vpdn)# **no source-ip**	Cancels the set VPDN-group source address.

src-ip is the VPDN-group source address.

Setting the L2TP Control Connection

Use the following commands to set the L2TP control connection.

Command	Function
Ruijie(config-vpdn)# **l2tp tunnel authentication**	Enables tunnel authentication.
Ruijie(config-vpdn)# **no l2tp tunnel authentication**	Disables tunnel authentication.
Ruijie(config-vpdn)# **l2tp tunnel hello** *interval*	Sets the interval of sending Hello messages.
Ruijie(config-vpdn)# **no l2tp tunnel hello**	Deletes the set interval of sending Hello messages.

Command	Function
Ruijie(config-vpdn)# **l2tp tunnel password** *pass-word*	Sets the tunnel password.
Ruijie(config-vpdn)# **no l2tp tunnel password**	Deletes the set tunnel password.
Ruijie(config-vpdn)# **l2tp tunnel receive-window** *size*	Sets the size of the receiving window of the tunnel control connection.
Ruijie(config-vpdn)# **no l2tp tunnel receive- window**	Restores the default size of the receiving window of the tunnel control connection.
Ruijie(config-vpdn)# **l2tp tunnel retransmit** {**retries** *number* | **timeout** {**min** | **max**} *seconds*}	Sets retransmission of tunnel control messages.
Ruijie(config-vpdn)# **no l2tp tunnel retransmit** {**retries** | **timeout** {**min**|**max**}}	Restores the default retransmission setting of tunnel control messages.
Ruijie(config-vpdn)# **l2tp tunnel timeout** {**no-session**| **setup**} *seconds*	Sets the maximum interval of establishing a no-session/control connection of the tunnel.
Ruijie(config-vpdn)# **no l2tp tunnel timeout** {**no-session** | **setup**}	Restores the default maximum interval of establishing a no-session/control connection of the tunnel.
Ruijie(config-vpdn)# **l2tp tunnel force_ipsec**	Enables forced encryption. It is used when external encryption is required. After this command is executed, packets can be sent to VPDN tunnels only after encryption.
Ruijie(config-vpdn)# **no l2tp tunnel force_ipsec**	Disables forced encryption.
Ruijie(config-vpdn)# **l2tp tunnel avp-hidden-compatible**	Supports the RFC2661 standard AVP Hidden parsing algorithm compatibly.
Ruijie(config-vpdn)# **no l2tp tunnel avp-hidden-compatible**	Restores the default Cisco standard AVP Hidden parsing algorithm.

Tunnel authentication is not needed for establishing L2TP tunnels by default (but required on Cisco devices by default). The default interval of sending Hello control messages is 60 seconds. The default receiving window size of control messages is 4. The default number of retransmission times of control messages is 5. The default minimum and maximum intervals of retransmitting control messages are 1 second and 8 seconds respectively. The default maximum interval of no session in a tunnel is 600 seconds. The default maximum time supported by tunnels in establishing a control connection is 300 seconds. If L2TP tunnel authentication is required, the same tunnel password must be configured at both ends of the L2TP tunnel. Nevertheless, the system does not configure tunnel passwords for any L2TP tunnels by default and does not require tunnel authentication. The *interval* parameter is the interval of sending Hello messages, in seconds. The unit of the *seconds* parameter is also seconds. The forced IPSec encryption and authentication are disabled by default. The default AVP Hidden parsing algorithm uses the Cisco standard. After the RFC2661 standard AVP Hidden parsing algorithm is supported compatibly, the RFC2661 standard is used to parse and hide AVP.

Setting L2TP Data Transmission Parameters

Use the following commands to set IP/UDP parameters for transmitting L2TP messages.

Command	Function
Ruijie(config-vpdn)# **l2tp ip udp checksum**	Sets the UDP checksum.

Ruijie(config-vpdn)# **no l2tp ip udp Checksum**	Cancels the UDP checksum setting.
Ruijie(config-vpdn)# **ip tos** *tos-value*	Sets the IP TOS field.
Ruijie(config-vpdn)# **no ip tos**	Cancels the IP TOS setting.
Ruijie(config-vpdn)# **ip precedence** *value*	Sets the IP Precedence field.
Ruijie(config-vpdn)# **no ip precedence**	Cancels the IP Precedence setting.

tos-value is the value of the TOS field of the IP header that carries L2TP messages, and *value* is the value of the Precedence field of this IP header. For L2TP messages to be carried in L2TP tunnels of RGOS, the checksum field of UDP that carries L2TP messages must be blank, the TOS of the IP header that carries L2TP messages and the Precedence field of this IP header must be 0 by default.

Note that the TOS and Precedence fields are supported only in L2TP. Though they can be configured in PPTP, the configuration does not take effect.

Setting the VRF Option

Use the following commands to set the VRF to which specified L2TP tunnel packets belong. The configuration maps to the **ip vrf forward** command of the VT interface, implementing VRF spanning.

Command	Function
Ruijie(config-vpdn)#**vpn vrf** *vrf-name*	Sets the VRF attribute for the tunnel.
Ruijie(config-vpdn)# **no vpn vrf**	Deletes the VRF attribute setting of the tunnel.

vrf-name is the name of the VRF.

Setting the Supported Domain Name

The command for setting the supported domain name takes effect after the domain authentication is enabled. Only the domain matching the content of this command can be identified. If a domain does not match the content of this command, another VPDN group is used for matching. If no matched VPDN group is found, the authentication fails.

Use the following commands to set the domain name.

Command	Function
Ruijie(config-vpdn)# **domain** *domain-name* **vrf** *vrf-name*	Sets the authentication domain name and the related VRF.
Ruijie(config-vpdn)# **no domain** *domain-name*	Cancels the domain setting.

domain-name is the name of domain, and *vrf-name* is the name of the VRF.

Setting the Domain Name-Bound Address Pool

The command for setting the domain name-based address pool is configured in **vpdn-domain** command mode. Domain names are authenticated and information about the bound address pool configured using this command is obtained during VPDN tunnel negotiation. After the PPP negotiation is successful, the specified bound address pool is used to assign peer addresses of tunnels. The address pool configured in the virtual-template interface is used for address assignment by default.

Use the following commands to set the domain name-bound address pool.

Command	**Function**
Ruijie(config-vpdn)# **domain** *domain-name* **vrf** *vrf-name* Ruijie(config-vpdn-domain)# **pool** *pool-name*	Sets the address pool bound to the authentication domain name.
Ruijie(config-vpdn)# **no domain** *domain-name*	Cancels the address pool binding.

domain-name is the name of the domain, *vrf-name* is the name of the VRF, and *pool-name* is the name of the address pool.

Setting the DNS Negotiation Address of PPP Bound to a Domain Name

The command for setting the DNS negotiation address of PPP bound to a domain name is configured in **vpdn-domain** command mode. The domain name is authenticated and information about the bound DNS negotiation address of PPP configured using this command is obtained during VPDN tunnel negotiation. This address is used for DNS negotiation during PPP negotiation. The DNS address of PPP configured in the virtual-template interface is used for negotiation by default.

Use the following commands to set addresses used by DNS during PPP negotation by matching domain names.

Command	**Function**
Ruijie(config-vpdn)# **domain** *domain-name* **vrf** *vrf-name* Ruijie(config-vpdn-domain)#**dns** *A.B.C.D A.B.C.D*	Sets the DNS negotiation address of PPP bound to the authentication domain name.
Ruijie(config-vpdn)# **no dns**	Cancels the DNS binding.

domain-name is the name of the domain, *vrf-name* is the name of VRF, and *A.B.C.D* is the DNS address.

Re-Performing PPP Authentication

When the client triggers the LAC to start dialing, the LAC acts as the LNS to authenticate the client. This command is used to perform CHAP authentication on the client again after an L2TP tunnel is established. This commad is valid only on the LNS.

Use the following commands to forcibly perform complete PPP authentication again.

Command	**Function**
Ruijie(config-vpdn)# **force-local-chap**	Forces the LNS to perform CHAP authentication on the client again.
Ruijie(config-vpdn)# **no force-local-chap**	Cancels CHAP re-authentication.

Re-Performing PPP Negotiation

When the client triggers the LAC to start dialing, the LAC acts as the LNS to negotiate with the client. This command is used to perform LCP negotiation with the client again after an L2TP tunnel is established. This commad is valid only on the LNS.

Use the following commands to forcibly perform PPP negotiation again.

Command	**Function**

Ruijie(config-vpdn)# **force-local-lcp**	Forces the LNS to perform LCP negotiation with the client again.
Ruijie(config-vpdn)# **no force-local-lcp**	Cancels LCP re-negotiation.

Ignoring Errors on Control Packets

Use the following commands to ignore errors on received L2TP control packets that do not comply with the RFC specifications to ensure normal negotiation.

Command	Function
Ruijie(config-vpdn)# **lcp renegotiation always**	Ignores errors on packets from the peer end.
Ruijie(config-vpdn)# **no lcp renegotiation always**	Checks whether control packets comply with RFC specifications.

Configuring the Function of Not Carrying Tunnel Authentication Response AVP in SCCRP Packets

This command enables the L2TP LNS to return SCCRP packets without Challenge Response AVP 13 when receiving SCCRQ packets without Challenge AVP 11 after tunnel authentication is configured. You can run the no form of this command to disable this function. This command is mainly used to ensure compatibility with the SCCRQ link detection function of devices provided by some manufacturer. It avoids returning SCCRP packets with all-zero authentication information when the other party sends SCCRQ packets without authentication information.

Command	Function
Ruijie(config-vpdn)#**l2tp tunnel zxkeepalive-compatible**	Returns SCCRP packets without the challenge response AVP upon receiving SCCRQ packets without the challenge AVP.
Ruijie(config-vpdn)#**no l2tp tunnel zxkeepalive-compatible**	Returns SCCRP packets with the all-zero challenge response AVP upon receiving SCCRQ packets without the challenge AVP.

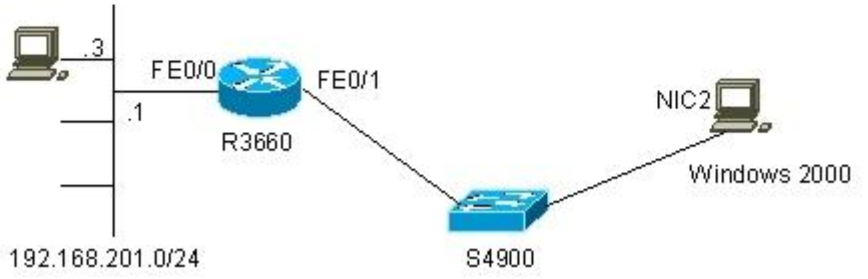
Configuration Examples

Three configuration examples are given below. In one configuration example, the Windows 2000 server is used as the remote L2TP client for access, and tunnel authentication is not performed due to limitations of the Windows 2000 server. In another example, Cisco 3640 is used as the remote L2TP client, and tunnel authentication is required. In the other example, Cisco 2620 is used as the L2TP client, and tunnel authentication is required.

Establishing a Tunnel with the Windows 2000 Server

Figure shows the networking topology of the L2TP tunnel established by using Ruijie router R3660 and the Windows 2000 server.

Figure 23 Networking topology of the L2TP tunnel established by using the Windows 2000 server (LAC)



The configurations of the R3660 and Windows 2000 server are respectively described as follows:

24) R3660 configuration:

```
R3660# show running-config

In **Network and Dial-up Connections**, click **New connection** and select **Connect to a private network through the Internet** to establish a virtual private connection to the specified LNS, namely, R3660. Set the destination address to **192.168.12.217**. In the properties, set **Security measure** to **Advanced (user-defined setting)**. In **Advanced security settings**, set **Data encryption** to **Optional encryption (connect even if no encryption available)**, click **Password not encrypted (PAP)** to use PAP as the authentication protocol, and click **OK** to save these property settings. Then, you can use the user **RGNOS** set the R3660 and its password to establish a virtual connection.

The following shows the routing and communication information after a virtual connection is established successfully.

26) R3660:

```
R3660# show ip route
Codes: C - connected, S - static,  R - RIP
O - OSPF, IA - OSPF inter area
E1 - OSPF external type 1, E2 - OSPF external type 2
Gateway of last resort is not set
192.168.101.0/24 is variably subnetted, 2 subnets, 2 masks
C      192.168.101.8/32 is directly connected, Virtual-Access1

The following shows the routing and communication information on the R3660 and Cisco 3640 after an L2TP tunnel is established.

30) R3660:

```
R3660# show ip route
Codes: C - connected, S - static,  R - RIP
O - OSPF, IA - OSPF inter area
E1 - OSPF external type 1, E2 - OSPF external type 2
Gateway of last resort is not set
192.168.101.0/24 is variably subnetted, 2 subnets, 2 masks
C      192.168.101.9/32 is directly connected, Virtual-Access1
C      192.168.101.0/24 is directly connected, Loopback1
C   192.168.12.0/24 is directly connected, FastEthernet0/1
C   192.168.201.0/24 is directly connected, FastEthernet0/0
R3660# show vpdn
L2TP Tunnel and Session Information Total tunnels 1 sessions 1
LocID RemID Remote Name   State  Remote Address  Port  Sessions L2TP Class/
                                                     VPDN Group
9    21511 C3640        est    192.168.12.242  1701  1       1
LocID     RemID     TunID     Username, Intf/     State  Last Chg
                           Vcid, Circuit
1      14        9         ,Vi1           est    00:18:06
%No active PPTP tunnels
```

```
R3660#ping 192.168.101.9
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echoes to 192.168.101.9, timeout is 2 seconds:
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/4 ms
R3660#
```

The preceding information shows that an L2TP tunnel has been established successfully and communication can be made successfully.

31) Cisco 3640:

```
C3640# show ip route
Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
      D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area

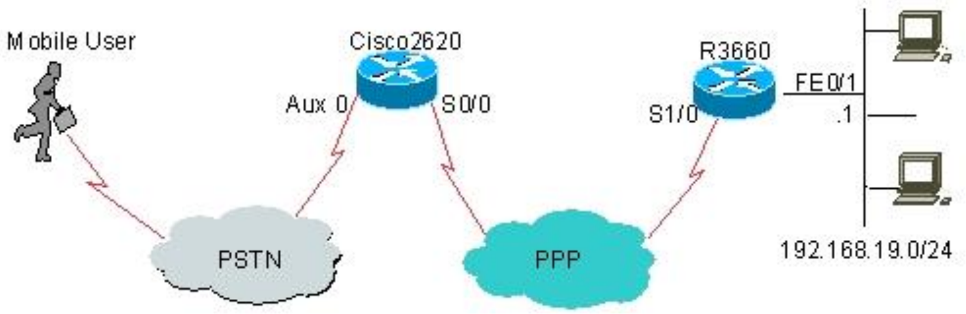
Sending 5, 100-byte ICMP Echoes to 192.168.101.2, timeout is 2 seconds:
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/4 ms
C3640#
```

The preceding information shows that an L2TP tunnel has been established successfully on Cisco 3640 and communication can be made successfully.

Establishing a Tunnel with Cisco 2620

Figure shows the networking topology of the L2TP tunnel established by using the Ruijie router R3660 and Cisco 2620. Here, Cisco 2620 actually works as both the access server (AS) and LAC. The AS and LAC functions are generally provided by ISPs, and devices with the same functions but with more powerful performance, such as Cisco AS5300 or Cisco AS5800, are often used to provide the functions. Cisco 2620 is used to establish an L2TP tunnel here. The L2TP tunnel is established between Cisco 2620 and the R3660, but PPP negotiation is performed between mobile or dial-up users (mobile user in Figure) and the R3660. The mobile user needs to only configure a dial-up connection and connect to the server in dial-up mode by using the allocated user name and password, which are not closely related to L2TP here. This is also an advantage of this tunneling mode. L2TP tunnel settings are transparent to users. The mobile user configuration and usage are not described here. For information about dial-up setting, see instructions of the related operating system.

Figure 25 Networking topology of the L2TP tunnel established with Cisco 2620 (LAC)



The configurations of R3660 and Cisco 2620 are respectively described as follows:

32) R3660 configuration:

line vty 0 4
!
!
End
```

Note

When you need to connect to the same LNS in dial-up mode on the same device, VP ports must belong to different VRFs if different domains are used. Otherwise, the same destination address will be assigned to two VP ports, the routes of the two VP ports are dupliated, and only one route is available. On the LNS side, two VA ports belong to different VRFs, and packets forwarded by different tunnels will be sent to different VRFs. Packets sent from the LNS to one VP port may be returned by the other VP port, resulting in route dissymmetry. In this case, data forwarding is not affected, but pinging the peer address from the LNS may fail.

IPv6 over L2TP

In the following figure, Ruijie RG-RSR30 (LNS) and a client establish the IPv6 over L2TP tunnel. The LNS assigns the IPv6 address to the client via ND, and delivers the domain name and DNS address over DHCPv6.

Figure 27 Establishing IPv6 over L2TP Tunnel by RG-RSR30 (LNS) and Client

Monitoring and Maintaining L2TP Tunnels

RGOS provides L2TP monitoring and maintenance functions.

Monitoring L2TP Tunnels

Use the following commands to monitor L2TP tunnels.

Command	Function
Ruijie# **show vpdn** [**session | tunnel** [**l2tp** *locid*]] Or Ruijie> **show vpdn** [**session | tunnel** [**l2tp** *locid*]]	Displays information about the current VPDN tunnel and session. Displays information about the tunnel of the specified ID.
Ruijie# **debug vpdn error**	Enables the VPDN error debugging function.
Ruijie# **no debug vpdn error**	Disables the VPDN error debugging function.
Ruijie# **debug vpdn event**	Enables the VPDN event debugging function.
Ruijie# **no debug vpdn event**	Disables the VPDN event debugging function.
Ruijie# **debug vpdn packet**	Enables the VPDN packet debugging function.
Ruijie# **no debug vpdn packet**	Disables the VPDN packet debugging function.
Ruijie# **debug vpdn l2x-data**	Enables the VPDN l2x-data debugging function.
Ruijie# **no debug vpdn l2x-data**	Disables the VPDN l2x-data debugging function.
Ruijie# **debug vpdn l2x-errors**	Enables the VPDN l2x-errors debugging function.
Ruijie# **no debug vpdn l2x-errors**	Disables the VPDN l2x-errors debugging function.
Ruijie# **debug vpdn l2x-events**	Enables the VPDN l2x-events debugging function.
Ruijie# **no debug vpdn l2x-events**	Disables the VPDNl2x-events debugging function.
Ruijie# **debug vpdn l2x-packets**	Enables the VPDN l2x-packets debugging function.
Ruijie# **no debug vpdn l2x-packets**	Disables the VPDN l2x-packets debugging function.

Displaying Information About the Current L2TP Tunnel

You can use the **show vpdn** command in real time as required to view information about the current L2TP tunnel (including channel information and session information).

Note

The length of usernames is unlimited. The **show vpdn** command displays only the first 12 charaters of a username for the sake of format alignment. You can use the **show vpdn tunnel l2tp** *locid* command to view the full username.

```
Ruijie# show vpdn tunnel

```

Performing Overall VPDN Debugging

RGOS provides VPDN debugging functions, which are useful to both L2TP and PPTP. The following is an overall VPDN debugging example, in which the LNS accepts the dial-in request from the peer end and finally establishes a tunnel (including channels and sessions).

```
Ruijie# debug vpdn error
vpdn protocol errors debugging is on
Ruijie# debug vpdn event
vpdn events debugging is on
Ruijie# debug vpdn packet
vpdn packet debugging is on
Ruijie# show debug
VPDN:
vpdn events debugging is on
vpdn protocol errors debugging is on
vpdn packet debugging is on

Performing L2TP Data Debugging

If a user needs to check whether L2TP can send control messages successfully, enable the L2TP data debugging function. The following is an L2TP data debugging example, in which the LNS accepts the dial-in request from the peer end and finally establishes a tunnel (including channels and sessions) after the l2x-data debugging function is enabled.

```
Ruijie# no debug all
All possible debugging has been turned off
Ruijie# debug vpdn l2x-data
L2X data packets debugging is on
Ruijie#
L2X: Punting to L2TP control message queue
L2X: Punting to L2TP control message queue
L2X: Punting to L2TP control message queue
L2X: Punting to L2TP control message queue
L2X: Punting to L2TP control message queue
L2X: Punting to L2TP control message queue
%UPDOWN: Interface Virtual-Access1, changed state to up
%UPDOWN: Line protocol on Interface Virtual-Access1, changed state to up
Ruijie#
```

Performing L2TP Error Debugging

Users can enable the l2x-erorrs debugging function to check whether a tunnel estabishment failure results from configuration inconsistency at both ends (for example, different tunnel authentication passwords at both ends). The following is an example of errors reported due to a tunnel authentcation failure.

```
Ruijie# no debug all
All possible debugging has been turned off
Ruijie# debug vpdn l2x-errors
L2X protocol errors debugging is on
Ruijie# config terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# interface virtual-ppp 1
Ruijie(config-if)# no shutdown
Ruijie(config-if)# end
Ruijie#

Ruijie# no debug all
All possible debugging has been turned off
Ruijie#
```

Performing L2TP Event Debugging

Users can enable the l2x-events debugging function to check the entire process of L2TP tunnel negotiation and establishment. The following is an L2TP event debugging example, in which the LNS accepts the dial-in request from the peer end and finally establishes a tunnel (including channels and sessions) after the l2x-events debugging function is enabled. The tunnel authentication function is enabled here.

```
Ruijie# show vpdn tunnel
%No active L2TP tunnels
%No active PPTP tunnels
Ruijie# no debug all
All possible debugging has been turned off
Ruijie# debug vpdn l2x-events
L2X protocol events debugging is on

Maintaining L2TP Tunnels

Use the following command to clear a specified L2TP tunnel.

Command	Function
Ruijie# **clear vpdn tunnel** [{ **pptp** | **l2tp**} [*remote-host-name*]]	Clears a specified tunnel.

remote-host-name is the name of the peer host of a tunnel. In addition, all L2TP-related configuration commands in RGOS support instant configuration and use. Users can set or change L2TP parameters as required. The following is an example of clearing all tunnels.

```
Ruijie# show vpdn
L2TP Tunnel and Session Information Total tunnels 1 sessions 1

FAQs

Common questions about L2TP tunnel establishment on the RGOS and their answers are presented as follows:

- Establishing an L2TP tunnel by interconnecting with a Windows PC: Note that L2TP is supported only in Microsoft Windows 2000 and later versions. Only the PPTP tunneling protocol is supported in earlier versions. Windows 2000 and Windows XP support L2TP by binding L2TP to IPSec/IKE. If you need to use a Windows 2000/XP PC to establish L2TP tunnels with other non-Microsoft network products, you must modify its registry to cancel this binding.
- Establishing an L2TP tunnel by interconnecting with a Windows PC: When you click **New connection** in **Network and Dial-up Connections** to create a virtual private connection (namely, **Connect to a private network through the Internet (V)**), the **Require data encryption (disconnect if none)** checkbox is selected by default and **Password requiring security measure** instead of PAP is used for authentication. However, the commoner method

is to use PAP or CHAP for authentication and not to encrypt data for transmission. Therefore, you need to modify the properties of this connection manually.

- Establishing an L2TP tunnel by interconnecting with a Windows PC: When you click **New connection** and **Accept incoming connections (A)** in **Network and Dial-up Connections** to create a connection, the MS-CHAPv2 method is used for user authentication by default and CHAP is forbidden for authentication. If you need to use CHAP for authentication, you must modify the configuration file of **Remote access policy** in the settings of the started **Routing and remote access** service, that is, add CHAP as an optional authentication method.
- Establishing an L2TP tunnel by interconnecting with a Windows PC: L2TP on Windows does not support the tunnel authentication function. The tunnel authentication function must be disabled in the L2TP settings of Ruijie router connected to the Windows PC. Tunnel authentication is disabled on Ruijie router by default.
- Establishing an L2TP tunnel by interconnecting with a Cisco device: Cisco IOS requires tunnel authentication by default, whereas tunnel authentication is diabled on Ruijie router by default.
- Establishing an L2TP tunnel by interconnecting with a Cisco device: If Ruijie router acts as the LNS and the Cisco device acts as the LAC to provide the L2TP tunnel service for remote dial-up users, **ip domain-lookup** instead of **ip cef** must be set on the Cisco device, just as on Cisco 2620 (LAC) in the preceding configuration example. Otherwise, the Cisco device will not forward PPP negotiation packets and other data to dial-up users.
- Establishing an L2TP tunnel by means of negotiation: The tunnel authentication settings at both ends of a tunnel must be consistent, that is, tunnel authentication is enabled or disabled at the same time at both ends. If it is enabled at both ends, the same tunnel authentication password must be set.
- Do not attempt to use Cisco routers (IOS versions 12.2 and 12.3) to establish an L2TP tunnel with a Windows 2000 PC, because it will be a waste of time.
- In consideration of being compatible with L2TP on different Windows versions and Cisco IOS of earlier versions, as well as the forwarding efficiency, RGOS does not support the AVP Hidden function and data message sequencing function. When an L2TP tunnel is etablished by interconnecting with Cisco IOS of later versions, ensure that the AVP Hidden function and data message sequencing function are disabled and default settings of the system are used.
- RGOS provides the LAC function, but does not support the LAC access server function.
- When RGOS is used to implement the LNS function, it is recommended that the address of the virtual-template interface be set in IP unnumbered mode, just as the settings on Cisco devices in consideration of fast route forwarding. Generally, IP unnumbered is bound to a loopback interface, as shown in the examples.
- In terms of instant configuration and use property of L2TP, effective changes (namely, non-repetitive operations) of control connection properties will cause the active disconnection of the related L2TP tunnel and all sessions on the tunnel. Effective changes of data transmission properties affects data transmission immediately.
- When the RGOS router is located behind a firewall, UDP port 1701 of the firewall must be enabled.
- When designing an L2TP tunnel, ensure that the route between the client and the server is available. When a router acts as the client, routes generated after an L2TP tunnel is established are different from those generated when a Windows PC acts as the client. If an L2TP tunnel is successfully established on a router (either a Cisco or a Ruijie product), two routes are generated, just as routes generated after other PPP link interfaces become UP. One is reachable to the server network segment, and the other is a direct route. However, when a Windows PC is used as the client, after an L2TP tunnel is established, a new route that traverses the L2TP tunnel and is reachable to the network 0.0.0.0/0 is added, in addition to the original route and the preceding two new routes.

Configuring VPDN 2.0

VPDN 2.0 Overview

VPDN 2.0, used to meet the need of VPDN with large capacity, has changed the configuration mode in VPDN server side.

The new virtual-vpdn interface configuration mode, which has replaced the original virtual-template one in VPDN server side, can meet the need of more tunnels' convergence.

Note

10.43b21 version support the function of VPDN 2.0, but only its L2TP tunnel mode. For the configuration in server side, only the configuration command related to interface has been changed. The original VPDN global parameter, and the configuration unrelated to interface have not. Users can continue to use them.

Configuring L2TP

Configuring Large Capacity L2TP

Configuration Task List

Configuring VPDN Address Pool (Optional)

This is an optional step for establishing an L2TP tunnel initiated by the remote client. In order to accept the L2TP connection initiated by the remote client, the LNS must allocate an IP address to the remote client if an IP address used inside the VPN is not set for the remote client. Generally, an idle IP address in a specified address pool is allocated to the client. Use the following commands to configure a VPDN address pool. VPDN module will manage the allocation by itself.

Command	Function
Ruijie(config)# **vpdn pool** *pool_name first-ip last-ip*	Creats or sets local address pool.
Ruijie(config)# **no vpdn pool** *pool_name*	Deletes the specified address pool.

poolname is the name of the local address pool to be created or set, *first-ip* is the first address in the address range set for the local address pool, and *last-ip* is the last address. When allocating address by using AAA, user can choose not to configure it. When we delete the address pool with "no" command, the corresponding binding command vpdn intf_pool on interface will also be deleted.

Configuring User Information

This is an optional step for establishing an L2TP tunnel initiated by the remote client. The purpose of configuring user information is to authenticate remote L2TP clients that attempt to access the local client.

Use the following commands to configure user information.

Command	Function
Ruijie(config)# **username** *user-name* **password {0|7}** *password*	Configures user information.
Ruijie(config)# **no username** *user-name*	Deletes the specified user.

user-name is the name of the dial-in user who is allowed to access, and *password* is the password of the user. The router locally maintains a database that records names of dial-in users permitted to access and their passwords.

Setting VPDN Global Parameters

This is a mandatory step for establishing an L2TP tunnel initiated by the remote client. VPDN global parameters are set in this step. The operations of setting VPDN global parameters include:

Enabling or Disabling the VPDN Function

If a user requires the router to accept the L2TP access from the remote client and establish an L2TP tunnel and session, the VPDN function must be enabled on the router.

Use the following commands to enable or disable the VPDN function.

Command	Function
Ruijie(config)# **vpdn enable**	Enables the VPDN function.
Ruijie(config)# **no vpdn enable**	Disables the VPDN function.

The VPDN enabling and disabling support instant configuration and use (that is, they are available immediately when they are configured). If the VPDN function is disabled, all the existing L2TP tunnels and sessions will be disconnected.

Setting the VPDN Source Address

After the VPDN source address is set, the destination address of the tunnel set for the remote client must be consistent with the VPDN source address before an L2TP tunnel is established successfully.

Use the following commands to set the VPDN (local) source address.

Command	Function
Ruijie(config)# **vpdn source-ip** *ip-address*	Sets the VPDN source address.
Ruijie(config)# **no vpdn source-ip** *ip-address*	Cancels the set VPDN source address.

The system does not check whether the destination address in the received tunnel establishment request is a specific value by default.

Setting the Maximum Number of VPDN Sessions

After the maximum number of VPDN sessions is set, access requests beyond the maximum value will be denied.

Use the following commands to set the maximum number of sessions supported by the VPDN server.

Command	Function
Ruijie(config)# **vpdn session-limit** *sessions*	Sets the maximum number of VPDN sessions.
Ruijie(config)# **no vpdn session-limit**	Restores the default maximum number of VPDN sessions.

The maximum number of sessions is the one configured by using this command by default.

Setting the Domain Resolution Option

Use the following commands to set the domain resolution option in VPDN domain authentication. Domains of different types can be identified based on configuration.

Command	Function
Ruijie(config)# **vpdn domain-delimiter @/%#-**	Sets the domain delimiter, prefix or suffix.
Ruijie(config)# **no vpdn domain-delimiter**	Cancels the VPDN domain authentication option.

The system does not resolve the domain field by default.

Enabling or Disabling Domain Authentication

Use the following commands to enable or disable the VPDN domain authentication, that is, determine whether to strip the domain field.

Command	Function
Ruijie(config)# **vpdn authorize domain split**	Enables domain authentication, that is, enables domain splitting.
Ruijie(config)# **no vpdn authorize domain**	Disables domain authentication.

Domain authentication is disabled by default.

Ignoring the Source Address Check of VPDN

Use the following commands to ingore errors on received L2TP control packets that do not comply with the RFC specifications so as to ensure the normal negotiation.

Command	Function
Ruijie(config-vpdn)# **vpdn ignore_source**	Ignores the source address check of packets sent from the peer end.
Ruijie(config-vpdn)# **no vpdn ignore_source**	Strictly checks the source address of packets sent from the peer end.

The system strictly checks the source address by default.

Setting VPDN Rate Limit

Use the following commands to limit the rate of establishing VPDN tunnels, namely, to limit the number of VPDN tunnels that can be established at one time.

Command	Function
Ruijie(config)# **vpdn limit_rate** *rate_num*	Enables rate limit. *rate_num* is the number of tunnels that can be established at a time. The value range is 5 to 100.
Ruijie(config)# **no vpdn limit_rate**	Disables rate limit.

Rate limit is disabled by default. When negotiating tunnel with large capacity, please enable the function so that to reduce shaking. When using virtual-template interface, please configure the number as 40. When using virtual-vpdn interface, please configure the number as 100.

Resolving Device Serial Number of VPDN

Use the following commands to set VPDN to resolve device serial number. According to the options, users can choose the division method. If the system has enabled LNS(L2TP) function, VPDN will resolve the device serial number transmitted from the peer side.

Command	**Function**
Ruijie(config)# **vpdn accept serial-number prefix**	Enables the function of resolving device serial number with prefix.
Ruijie(config)# **vpdn accept serial-number suffix**	Enables the function of resolving device serial number with suffix.
Ruijie(config)# **no vpdn accept serial-number**	Disables the function of resolving device serial number.

By default, the resolving device serial number function is disabled.

Transmitting Device Serial Number of VPDN

Use the following commands for to set VPDN to transmmit device serial number. If the system has enabled LNS(L2TP) function, VPDN will transmmit the device serial number to the peer side.

Command	**Function**
Ruijie(config)# **vpdn lac-send-devid**	Enables the function of transmmiting device serial number.
Ruijie(config)# **no vpdn lac-send-devid**	Disables the function of transmmiting device serial number.

By default, the transmmiting device serial number function is disabled.

Configuring a Virtual-Template Interface

This is a mandatory step for establishing an L2TP tunnel initiated by the remote client. This interface will become the logical interface that binds and carries L2TP sessions, and can only be used in LNS side. The operations of configuring a virtual-vpdn interface include:

> For information about setting the local IP address and setting the authentication mode see sections regarding the interface configuration guide. The virtual-vpdn interface can not configure ip unnumbered command, but can configure IP address and Mask directly.

Setting a Virtual-vpdn Interface

Use the following commands to set a virtual-vpdn interface. An interface can be binded with many sessions.

Command	Function
Ruijie(config)# **interface virtual-vpdn** *number*	Creates or configures a specified virtual-vpdn interface.
Ruijie(config)# **no interface virtual-vpdn** *number*	Deletes the specified virtual-vpdn interface.

number is the sequence number of the specified virtual-vpdn interface, and the range is <1-1024> . The created virtual-vpdn interface will be used as the logical interface that binds and carries L2TP sessions. When negotiating tunnels by using virtual-vpdn interface, the L2TP tunnel does not support IPV6 negotiation. All the PPP authentication of virtual-vpdn interface in vpdn-group's domain configuration need to be configured on the default virtual-vpdn interface of vpdn-group.

Setting VPDN Address Pool

Use the following commands to set the binding address pool on virtual-vpdn interface.

Command	Function
Ruijie(config)# **interface virtual-vpdn** *number*	Creates or configures a specified virtual-vpdn interface.
Ruijie(config-Virtual-vpdn *number*)# **vpdn intf_pool** *pool_name*	Binds the address pool on the interface.
Ruijie(config-Virtual-vpdn *number*)# **no vpdn intf_pool**	Deletes the binding address pool on the interface.

number is the sequence number of the specified virtual-vpdn interface, and the range is <1-1024>. *pool_name* is the name of the binding address pool. The VPDN binding address pool can only be used on the virtual-vpdn interface of L27P module.

Configuring VPDN-group

This is a mandatory step for establishing an L2TP tunnel initiated by the remote client. VPDN-group parameters are set in this step. The operations of configuring VPDN-group include:

Setting a VPDN-group Interface

Use the following commands to set a VPDN-group interface.

Command	Function
Ruijie(config)# **vpdn-group** *name*	Creates or configures the specified VPDN-group interface.
Ruijie(config)# **no vpdn-group** *name*	Deletes the specified VPDN-group interface.

name is the name of the specified VPDN-group interface. The created VPDN-group interface allows related clients to access and establish tunnels.

Setting the VPDN-group Source Address

The destination address in the tunnel establishment request sent from the remote client must match the VPDN-group source adress. In this way, the VPDN-group can be applied.

Use the following commands to set the VPDN-group source address.

Command	Function
Ruijie(config-vpdn)# **source-ip** *src-ip*	Sets the VPDN-group source address.
Ruijie(config-vpdn)# **no source-ip**	Cancels the set VPDN-group source address.

src-ip is the VPDN-group source address. When configuring with VPDN 2.0, the command is mandatory.

Setting the Tunneling Mode

Use the following commands to set the tunneling mode.

Command	Function
Ruijie (config-vpdn)# **accept-dialin**	Allows access from the dial-in remote client.
Ruijie (config-vpdn)# **no accept-dialin**	Denies the access from the dial-in remote client.

If a user needs the local router to provide the LNS function, access from the dial-in remote client must be allowed.

Setting the Tunneling Protocol

Use the following commands to set the tunneling protocol.

Command	Function
Ruijie(config-vpdn-acc-in)# **protocol** {**any** | **l2tp** | **pptp**}	Sets the tunneling protocol.
Ruijie(config-vpdn-acc-in)# **no protocol**	Cancels the set tunneling protocol.

The tunneling mode must be set before a tunneling protocol is set.

Setting a Logical Interface to Be Used

Use the following commands to set a logical interface to be used by VPDN-group,.

Command	Function
Ruijie(config-vpdn-acc-in)# **virtual-vpdn** *number*	Sets the using logical interface.
Ruijie(config-vpdn-acc-in)# **no virtual-vpdn** *number*	Cancels the set logical interface.

Before setting a logical interface used by VPDN-group, users should set the tunnel mode as L2TP and configure source-ip command in distributed system first. The logical interface can only be used in L2TP mode, and can not be used together with virtual virtual-template interface. All the PPP authentication of virtual-vpdn interface in vpdn-group's domain configuration need to be configured on the default virtual-vpdn interface of vpdn-group.

Setting the Peer Name

If the peer name is set, this VPDN-group is effective only to the remote client that matches the host name. If no peer name is set, this VPDN-group is the default VPDN-group and can provide the VPDN service for any remote client.

Use the following commands to set the peer name.

Command	Function
Ruijie(config-vpdn)# **terminate-from hostname** *name*	Sets the name of the peer host.
Ruijie(config-vpdn)# **no terminate-from**	Cancels the set peer name.

name is the name of the peer host.

Setting the Local Name

The local name is sent to the peer end as a record property.

Use the following commands to set the local name.

Command	Function
Ruijie(config-vpdn)# **local name** *name*	Sets the local name.
Ruijie(config-vpdn)# **no local name**	Cancels the set local name.

name is the local name. The router name is used as the local name and sent to the peer host of the tunnel by default.

Setting the L2TP Control Connection

Use the following commands to set the L2TP control connection.

Command	Function
Ruijie(config-vpdn)# **l2tp tunnel authentication**	Enables tunnel authentication.
Ruijie(config-vpdn)# **no l2tp tunnel authentication**	Disables tunnel authentication.
Ruijie(config-vpdn)# **l2tp tunnel hello** *interval*	Sets the interval of sending Hello messages.
Ruijie(config-vpdn)# **no l2tp tunnel hello**	Deletes the set interval of sending Hello messages.
Ruijie(config-vpdn)# **l2tp tunnel password** *pass-word*	Sets the tunnel password.
Ruijie(config-vpdn)# **no l2tp tunnel password**	Deletes the set tunnel password.
Ruijie(config-vpdn)# **l2tp tunnel receive-window** *size*	Sets the size of the receiving window of the tunnel control connection.
Ruijie(config-vpdn)# **no l2tp tunnel receive-window**	Restores the default size of the receiving window of the tunnel control connection.

Command	Function
Ruijie(config-vpdn)# **l2tp tunnel retransmit** {**retries** *number* | **timeout** {**min** | **max**} *seconds*}	Sets retransmission of tunnel control messages.
Ruijie(config-vpdn)# **no l2tp tunnel retransmit** {**retries** | **timeout** {**min**|**max**}}	Restores the default retransmission setting of tunnel control messages.
Ruijie(config-vpdn)# **l2tp tunnel timeout** {**no-session**| **setup**} *seconds*	Sets the maximum interval of establishing a no-session/control connection of the tunnel.
Ruijie(config-vpdn)# **no l2tp tunnel timeout** {**no-session** | **setup**}	Restores the default maximum interval of establishing a no-session/control connection of the tunnel.
Ruijie(config-vpdn)# **l2tp tunnel force_ipsec**	Enables forced encryption. It is used when external encryption is required. After this command is executed, packets can be sent to VPDN tunnels only after encryption.
Ruijie(config-vpdn)# **no l2tp tunnel force_ipsec**	Disables forced encryption.
Ruijie(config-vpdn)# **l2tp tunnel avp-hidden-compatible**	Supports the RFC2661 standard AVP Hidden parsing algorithm compatibly.
Ruijie(config-vpdn)# **no l2tp tunnel avp-hidden-compatible**	Restores the default Cisco standard AVP Hidden parsing algorithm.
Ruijie(config-vpdn)# **l2tp tunnel clear timeout** *seconds*	Sets the unix of vpdn-group's delete on time of session.
Ruijie(config-vpdn)# **no l2tp tunnel clear timeout**	Closes vpdn-group's delete on time function.

Tunnel authentication is not needed for establishing L2TP tunnels by default (but required on Cisco devices by default). The default interval of sending Hello control messages is 60 seconds. The default receiving window size of control messages is 4. The default number of retransmission times of control messages is 5. The default minimum and maximum intervals of retransmitting control messages are 1 second and 8 seconds respectively. The default maximum interval of no session in a tunnel is 600 seconds. The default maximum time supported by tunnels in establishing a control connection is 300 seconds. If L2TP tunnel authentication is required, the same tunnel password must be configured at both ends of the L2TP tunnel. Nevertheless, the system does not configure tunnel passwords for any L2TP tunnels by default and does not require tunnel authentication. The *interval* parameter is the interval of sending Hello messages, in seconds. The unit of the *seconds* parameter is also seconds. The forced IPSec encryption and authentication are disabled by default. The default AVP Hidden parsing algorithm uses the Cisco standard. After the RFC2661 standard AVP Hidden parsing algorithm is supported compatibly, the RFC2661 standard is used to parse and hide AVP. The interval of delete on time is 1 to 65535 minutes.

Setting L2TP Data Transmission Parameters

Use the following commands to set IP/UDP parameters for transmitting L2TP messages.

Command	Function
Ruijie(config-vpdn)# **l2tp ip udp checksum**	Sets the UDP checksum.

Ruijie(config-vpdn)# **no l2tp ip udp Checksum**	Cancels the UDP checksum setting.
Ruijie(config-vpdn)# **ip tos** *tos-value*	Sets the IP TOS field.
Ruijie(config-vpdn)# **no ip tos**	Cancels the IP TOS setting.
Ruijie(config-vpdn)# **ip precedence** *value*	Sets the IP Precedence field.
Ruijie(config-vpdn)# **no ip precedence**	Cancels the IP Precedence setting.

tos-value is the value of the TOS field of the IP header that carries L2TP messages, and *value* is the value of the Precedence field of this IP header. For L2TP messages to be carried in L2TP tunnels of RGOS, the checksum field of UDP that carries L2TP messages must be blank, the TOS of the IP header that carries L2TP messages and the Precedence field of this IP header must be 0 by default.

Note that the TOS and Precedence fields are supported only in L2TP. Though they can be configured in PPTP, the configuration does not take effect.

Setting the VRF Option

Use the following commands to set the VRF to which specified L2TP tunnel packets belong. The configuration maps to the **ip vrf forward** command of the VT interface, implementing VRF spanning.

Command	Function
Ruijie(config-vpdn)#**vpn vrf** *vrf-name*	Sets the VRF attribute for the tunnel.
Ruijie(config-vpdn)# **no vpn vrf**	Deletes the VRF attribute setting of the tunnel.

vrf-name is the name of the VRF.

Setting the Supported Domain Name

Use the following commands to set the domain name. The command for setting the supported domain name takes effect after the domain authentication is enabled. When the domain matching the content of this command is identified, put the configuration info of the domain into the L2TP session. If no matched domain info is found, deal with it by default.

Command	Function
Ruijie(config-vpdn)# **domain** *domain-name* **virtual-vpdn** *number*	Sets the authentication domain name and the related logical interface (when a virtual-vpdn logical interface is used).
Ruijie(config-vpdn)# **no domain** *domain-name*	Cancels the domain setting.

domain-name is the name of domain. *number* is the number of the logical interface, and the range is <1-1024>.

Re-Performing PPP Authentication

When the client triggers the LAC to start dialing, the LAC acts as the LNS to authenticate the client. This command is used to perform CHAP authentication on the client again after an L2TP tunnel is established. This commad is valid only on the LNS.

Use the following commands to forcibly perform complete PPP authentication again.

Command	Function
Ruijie(config-vpdn)# **force-local-chap**	Forces the LNS to perform CHAP authentication on the client again.
Ruijie(config-vpdn)# **no force-local-chap**	Cancels CHAP re-authentication.

Re-Performing PPP Negotiation

When the client triggers the LAC to start dialing, the LAC acts as the LNS to negotiate with the client. This command is used to perform LCP negotiation with the client again after an L2TP tunnel is established. This commad is valid only on the LNS.

Use the following commands to forcibly perform PPP negotiation again.

Command	Function
Ruijie(config-vpdn)# **force-local-lcp**	Forces the LNS to perform LCP negotiation with the client again.
Ruijie(config-vpdn)# **no force-local-lcp**	Cancels LCP re-negotiation.

Ignoring Errors on Control Packets

Use the following commands to ignore errors on received L2TP control packets that do not comply with the RFC specifications to ensure normal negotiation.

Command	Function
Ruijie(config-vpdn)# **lcp renegotiation always**	Ignores errors on packets from the peer end.
Ruijie(config-vpdn)# **no lcp renegotiation always**	Checks whether control packets comply with RFC specifications.

Setting the Domain Name’s Delete on Time of Session

Use the following commands to set the domain name’s delete on time of session. The command will be configured in vpdn-domain’s command mode.

Command	Function
Ruijie(config-vpdn)# **domain** *domain-name* **vrf** *vrf-name* Ruijie(config-vpdn-doamin)# **clear timeout** *seconds*	Sets the unix of domain name’s delete on time of session.
Ruijie(config-vpdn)# **no lcp renegotiation always**	Cancles the delete on time function.

domain-name is the name of domain, and *vrf-name* is the name of the VRF. Seconds is the interval of delete on time, and the range is 1 to 65535 minutes.

Setting No Sending of STOP Packet

The command is used to configure the behavior unmatched the RFC standard. It can only support one behavior, that is, do not send stop packet, when receiving SCCRQ repeatedly.

Command	Function
Ruijie(config-vpdn)# **l2tp tunnel none-rfc-compatible send-stop-pkt**	Does not send STOP packet, when receiving SCCRQ repeatedly
Ruijie(config-vpdn)# **no l2tp tunnel none-rfc-compatible send-stop-pkt**	Does send STOP packet, when receiving SCCRQ repeatedly

Setting SCCRP Packet's No Carrying of Tunnel Authentication ResponseAVP

After configuring tunnel authentication of LNS side in L2TP, if the accepted SCCRQ packet does not carry challenge AVP 11, the replied SCCRQ packet will not carry challenge response AVP13. The no command will close the function. The command can be compatible with SCCRQ's link detection function developed by other vendor, so that to avoid that after the configuring of tunnel authentication, the accepted SCCRQ packet with no carrying of authentication information will get back with all the information being 0.

Command	Function
Ruijie(config-vpdn)#**l2tp tunnel zxkeepalive-compatible**	If the accepted SCCRQ does not carry challenge AVP, the replied SCCRQ packet will not resend challenge resend AVP.
Ruijie(config-vpdn)#**no l2tp tunnel zxkeepalive-compatible**	If the accepted SCCRQ does not carry challenge AVP, the replied SCCRQ packet will resend challenge resend AVP with all the information being 0.

Setting Supported Flow-limit QOS by VPDN

Use the following commands to set VPDN's supporting of flow-limit QOS rule. It can be configured in vpdn-group to show that all the sessions in the group will obey the rule. It can also be configured in domain to show that all the sessions in the domain will obey the rule. The function can only use together with virtual-vpdn interface.

Command	Function
Ruijie(config-vpdn)# **flow-label** *flow-id*	Configures QOS rule in vpdn-group.
Ruijie(config-vpdn)#**no flow-label**	Deletes QOS rule.
Ruijie (config-vpdn-domain)# **flow-label** *flow-id*	Configures QOS rule in domain.
Ruijie (config-vpdn-domain)# **no flow-label**	Deletes QOS rule.

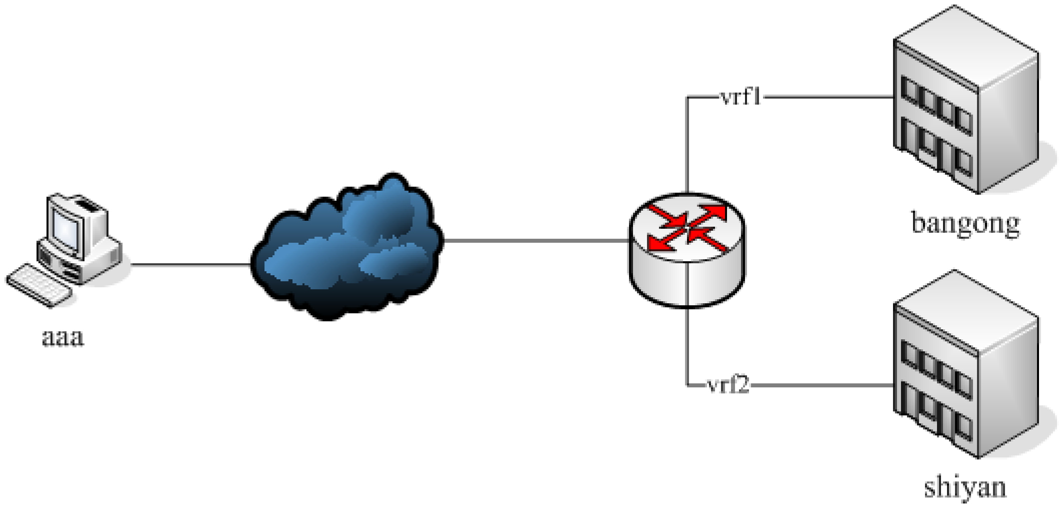
flow-id is the corresponding QOS rule's number, and its range is <1-1023>.

Configuration Examples

Configuration Example of L2TP Large Capacity and Domain Authentication

The following topology shows, according to domain information, a user dials in two networks by using one public network address.

Figure 28



```
ip vrf vrf1
ip vrf vrf2
!
vpdn enable
vpdn domain-delimiter @/%#-\ suffix
vpdn authorize domain split
vpdn pool vpdnusers 192.168.101.3 192.168.101.50
vpdn pool bangong 192.168.101.51 192.168.101.150
vpdn pool shiyan 192.168.101.151 192.168.101.253
!
!
username user@bangong password 7 025144391715

username user@ruijie password 7 164290823468
!
!
interface GigabitEthernet 1/1/1
ip address 192.168.19.1 255.255.255.0
duplex auto
speed auto
!
interface Virtual-vpdn 1
ppp authentication pap
ip address 192.168.101.2 255.255.255.0
```

```
vpdn intf_pool vpdnusers
!
interface Virtual-vpdn 2
ip vrf forward vrf1
ip address 192.168.101.2 255.255.255.0
ppp authentication pap
vpdn intf_pool bangong
!
interface Virtual-vpdn 3
ip vrf forward vrf2
ip address 192.168.101.2 255.255.255.0
ppp authentication pap
vpdn intf_pool shiyan
!
vpdn-group 1
! Default L2TP VPDN group
source-ip 192.168.19.1
accept-dialin
  protocol l2tp
  virtual-vpdn 1           /* bind logical interface */
domain bangong virtual-vpdn 2   /*specified domain*/
domain shiyan virtual-vpdn 3    /* specified domain */
!
!
line con 0
line aux 0
line vty 0 4
```

Sessions of dialing user who has no domain name will be binded with virtual-vpdn 1 interface. Sessions of dialing user whose domain name is bangong will be binded with virtual-vpdn 2 interface, and belongs to vrf1. Sessions of dialing user whose domain name is shiyan will be binded with virtual-vpdn 3 interface, and belongs to vrf2.

Configuration Example of Virtual-vpdn and OSPF

Different from virtual-access and virtual-ppp interface, virtual-vpdn interface can be binded with multichannel sessions. In this way, the configuration of its corresponding router protocol is also different.

LNS side：

```
username user1 password pass
!
vpdn enable
vpdn pool 10 76.1.11.1 76.1.11.100
vpdn pool 1 100.11.1.11 100.11.100.250
!
```

```
vpdn authorize domain split

```

Monitoring and Maintaining VPDN 2.0

The methods of monitoring and maintaining VPDN 2.0 is just the same as the old one. Refer to the chapter of monitoring and maintaining L2TP.

Configuring the Tunnel Interface

Understanding the Tunnel interface

Overview

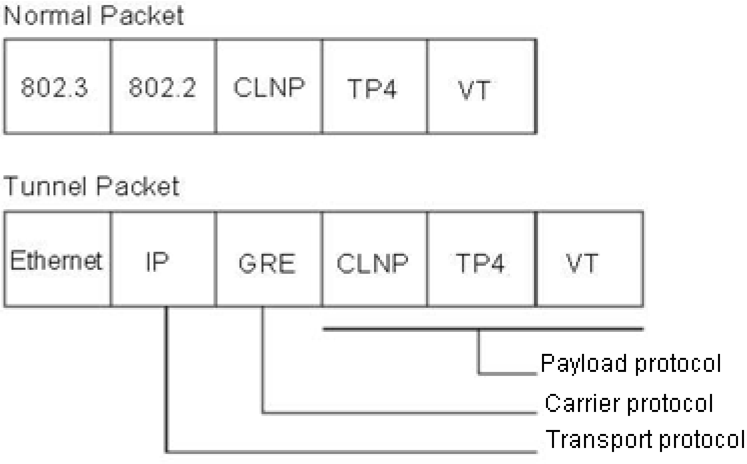
The tunnel interface is used to realize tunnel functions. Without specifically binding a certain transport protocol or payload protocol, the tunnel interface provides a standard point-to-point transmission link, and hence one tunnel interface must be configured for each separate link.

Tunnel function involves the following three key components:

34) Payload protocol: The protocol for encapsulating the payload (network data) transmitted through a tunnel. Currently, software of Ruijie products only support the use of the IP protocol as the payload protocol on the tunnel interface;
35) Carrier protocol: The protocol for secondary encapsulation and identification of the payload to be transmitted. Ruijie products support the following encapsulation modes on the tunnel interface: GRE and IPIP;
36) Transport protocol: The network protocol for transmitting the payload packets further encapsulated by the carrier protocol. Ruijie products use the most widely applied IP protocol as the transport protocol.

Figure shows the formation of a data packet encapsulated for transmission over an IP tunnel before and after the transmission.

Figure 29 The formation of data packet transmitted over the tunnel network before and after the transmission



IP tunnel transmission function is accomplished through GRE Ethernet encapsulation. In practice, if two private networks using the same protocol need to communicate with each other through the public network using a different protocol, they can use the tunnel function.

Tunnel transmission is applicable to the following circumstances:

37) Allowing the communication between non-IP local networks over a single-protocol network (IP network), as a tunnel supports different payload protocols; allowing the scope enlargement of a network running a hop-limited protocol;
38) Allowing the connection of discontinuous subnets over a single-protocol network (IP network);
39) Allowing the provision of VPN (virtual private network) over wide area network.

Since a tunnel will encapsulate the payload before transmission, such complexity in processing requires you to pay attention to the following issues under certain circumstances.

40) Since a tunnel is a point-to-point link which seems to have only one hop during routing, the actual routing overhead may involve multiple hops. Note that routing on a tunnel link may be different from the actual condition.
41) Since a tunnel will encapsulate the payload into a transport protocol, you need to give the corresponding consideration when configuring the firewall, especially the ACL. It shall also be noted that the transmission bandwidth (such as MTU) of a payload protocol is smaller than the theoretical value.

The followings will only introduce the attributes specific to the tunnel interface. The configuration of other attributes (including IP address and other relevant parameters, firewall and parameters of backup center) will be introduced in relevant sections.

Configuring the Tunnel Interface

Tunnel interface configuration tasks

Entering designated Tunnel interface configuration mode

To create a tunnel interface and enter interface configuration mode, run the following commands in global configuration mode:

Command	Function
Ruijie(config)# **interface tunnel** *tunnel-number*	Enters designated tunnel interface configuration mode.

Ruijie(config)# **no interface tunnel** *tunnel-number*	Deletes the existing tunnel interface.

Same as other logic interfaces, a tunnel interface is created once you enter the designated tunnel interface for the first time.

Configuring the source address of a Tunnel interface

A tunnel interface needs to identify the source address and destination address of the tunnel configured. In order to ensure the stability of a tunnel interface, the Loopback address is generally used as the source address and destination address of tunnel. Before normal operations of tunnel interface, check the connectivity between source address and destination address.

To configure the source address of a tunnel interface, run the following commands in tunnel interface configuration mode:

Command	Function
Ruijie(config-if)# **tunnel source** {*ip-address* | **interface-name** *interface-number*}	Configures the source address of the tunnel interface.
Ruijie(config-if)# **no tunnel source**	Removes the source address configuration of the tunnel interface.

The **tunnel source** command configures the actual source address for communication over a tunnel interface, namely the local endpoint of the tunnel.

Configuring the destination address of a Tunnel interface

To configure the destination address of a tunnel interface, run the following commands in tunnel interface configuration mode:

Command	Function
Ruijie(config-if)# **tunnel destination** { *ip-address* }	Configures the destination address of the tunnel interface.
Ruijie(config-if)# **no tunnel destination**	Removes destination address configuration of the tunnel interface.

The **tunnel destination** command configures the actual destination address for communication over a tunnel interface, namely the remote endpoint of the tunnel.

Caution

On the same router, tunnel interfaces that use the same encapsulation protocol cannot have the same source address or destination address.

Configuring Tunnel mode

The tunnel mode is referred to as the carrier protocol of a tunnel. The default tunnel mode is GRE. Of course, the user can also select a tunnel mode according to actual application.

Command	Function

Ruijie(config-if)# **tunnel mode** { **gre** {ip | ipv6}| **ipip** | ipv6ip}	Configures tunnel mode.
Ruijie(config-if)# **no tunnel mode**	Removes tunnel mode configuration and restores the default setting.

Caution The use of the **tunnel mode** command is related to device models.

Configuring Tunnel checksum

Under certain circumstances, tunnel checksum needs to be used to guarantee data integrity.

Command	**Function**
Ruijie(config-if)# **tunnel checksum**	Configures tunnel checksum.
Ruijie(config-if)# **no tunnel checksum**	Disables tunnel checksum.

By default, the checksum function of a tunnel interface is disabled.

Caution This command is only supported by the router.

Configuring the key of a tunnel interface

The key of a tunnel interface can ensure the security on both ends of a tunnel to a certain extent and prevent sniffing and attack from outside.

Command	**Function**
Ruijie(config-if)# **tunnel key** *key-value*	Configures the key of the tunnel interface.
Ruijie(config-if)# **no tunnel key**	Removes the key of the tunnel interface.

The key of a tunnel interface works only when the tunnel mode is GRE, as each GRE data packet will contain the tunnel key configured.

Caution (1) Both ends of a tunnel must use the same key configuration to allow normal communication;

(2) Although each GRE data packet will contain the key configured when the encapsulation mode is GRE, it is still unwise to guarantee security by relying on this key.

(3) This command is only supported by the router.

Configuring tunnel reception rules

If the payload protocol is inadequate to maintain the order of data packets, Ruijie products allow the configuration of tunnel reception rules to drop the disordered data packets. If the payload protocol is inadequate to maintain the order of data packets, this function can help realize the sequential transmission of data packets.

Command	Function
Ruijie(config-if)# **tunnel sequence-datagrams**	Configures sequential reception of packets on the tunnel.
Ruijie(config-if)# **no tunnel sequence-datagrams**	Removes sequential reception configuration of the tunnel.

This configuration is effective only when the tunnel mode is GRE.

Caution This command is only supported by the router.

Configuring TTL of a tunnel

Since a tunnel is a point-to-point link which seems to have only one hop during routing, the actual routing overhead may involve multiple hops. Ruijie products allow you to configure the TTL of a tunnel, namely to set the TTL in the transport protocol header of the packet transmitted over a tunnel. Being the intermediate node of tunnel, the router will reduce the TTL value in the transport protocol header and drop packets with TTL value being 0.

Command	Function
Ruijie(config-if)# **tunnel ttl** *hop-count*	Configures the TTL of the tunnel.
Ruijie(config-if)# **no tunnel ttl**	Removes TTL configuration of the tunnel and restores to the default value of 255.

By default, the TTL value of a tunnel transport protocol is 255.

Configuring TOS of a tunnel

In tunnel interface mode, configure the ToS byte of outer-layer transport protocol IPv4, or the 8 bits of traffic class of IPv6.

Command	Function
Ruijie(config-if)# **tunnel tos** *num*	Configures the TOS of the tunnel.
Ruijie(config-if)#**no tunnel tos**	Removes TOS configuration of the tunnel.

By default, if both the inner-layer carrier protocol and outer-layer encapsulation protocol of tunnel are IPv4, then the ToS byte of inner-layer IPv4 header will be copied to the outer-layer IPv4 header. If both the inner-layer carrier protocol and outer-layer encapsulation protocol of tunnel are IPv6, then the traffic class 8 bits of inner-layer IPv6 header will be copied to the outer-layer IPv6 header. In other cases, the outer-layer IPv4 ToS and IPv6 traffic class are 0.

Configuring PMTUD of a tunnel

Even if the payload IP message header is configured with DF (Don't Fragment) bit, the size of the payload protocol message may exceed the MTU of the destination outlet of tunnel after encapsulation, resulting in message fragmentation. On the way to the peer terminal of tunnel, the PMTU may become smaller and the intermediate forwarding device will fragment the encapsulated messages. Ruijie products provide the **tunnel path-mtu-discovery** command in interface configuration mode, allowing automatic discovery of PMTU in order to adjust the MTU size of tunnel interface and avoid message fragmentation.

Command	**Function**
Ruijie(config-if)# **tunnel path-mtu-discovery [age-timer** {*aging-mins* | **infinite} | min-mtu** *mtu-bytes]*	Enables the PMTUD function of the tunnel interface; Age-timer (optional): configures the aging timer of MTU on the tunnel interface; upon expiration of this timer, the MTU on the tunnel interface will reset to the initial MTU less the header length of carrier protocol messages; aging-mins: aging time ranging from 10 to 30 minutes, with default value being 10 minutes; infinite: disable MTU age-timer. Min-mtu (optional): configures MTU lower limit that can be adjusted by PMTUD; mtu-bytes: lower limit of MTU, ranging from 92 to 65535 bytes, with default value being 95 bytes.
Ruijie(config-if)# **no tunnel path-mtu-discovery [age-timer | min-mtu]**	Disables the PMTUD function of the tunnel interface

PMTUD can work only in GRE or IPIP tunnel mode, and is not enabled by default.

Caution

The PMTUD function requires the tunnel interfaces on both ends of the tunnel to be able to receive and process ICMP messages, especially when there is a firewall. This command is only supported by RGOS 10.4(2) or later versions.

After you run the **show interface tunnel** command, states of PMTUD are as follows:

Path MTU Discovery state:init

Path MTU Discovery state:keep

Path MTU Discovery state:learning

PMTUD learning has three state machines:

Initially, PMTUD is in init state.

When the timer expires and probe packets are being sent, PMTUD changes to the learning state and then learning packets are sent.

If an MTU change is not detected after five consecutive probe packets are sent, PMTUD changes to the keep state and begins sending keep packets.

Command	**Function**
Ruijie(config-if)# **tunnel path-mtu-discovery** *aging-mins mtu-bytes*	Enables the PMTUD function of the tunnel interface. Age-timer: configures the aging timer of MTU on the tunnel interface; upon expiration of this timer, the tunnel will send probe messages to discover Path MTU; aging-mins: aging time ranging from 1 to 65535 seconds. Min-mtu: configures MTU lower limit that can be adjusted by PMTUD; mtu-bytes: lower limit of MTU, ranging from 92 to 1500 bytes.

Ruijie(config-if)# **no tunnel path-mtu-discovery**	Disables the PMTUD function of the tunnel interface.

PMTUD can work only in GRE or IPIP tunnel mode, and is not enabled by default.

Caution The PMTUD function requires the tunnel interfaces on both ends of the tunnel to be able to receive and process ICMP messages, especially when there is a firewall. This command is only supported by RGOS 10.4(1) or later versions.

Configuring the keepalive function of a tunnel

When the physical interface sending tunnel messages is UP but the line failure prevents the tunnel messages from reaching the opposite terminal, the tunnel keepalive function can be used to detect the reachability of the tunnel interface.

Command	Function
Ruijie(config-if)# **keepalive** [*seconds* [*retries*]]	Configures the keepalive function of the tunnel.
Ruijie(config-if)# **no keepalive**	Disables the keepalive function of the tunnel

Caution This command is only supported by RGOS 10.4(2) or later versions.

This command cannot be used together with the **tunnel vrf** or **ip vrf forward** command.

This command applies only to GRE IP-capable 4 over 4 tunnels and IPIP tunnels.

Command	Function
Ruijie(config-if)# **tunnel keepalive** *period retries*	Configures the keepalive function of the tunnel.
Ruijie(config-if)# **no tunnel keepalive**	Disables the keepalive function of the tunnel

Caution This command is only supported by RGOS 10.4(1).

This command cannot be used together with the **tunnel vrf** or **ip vrf forward** command.

This command applies only to GRE IP-capable 4 over 4 tunnels and IPIP tunnels.

Configuring Tunnel nested encapsulation limit

Tunnel nested encapsulation refers to the circumstance that messages have undergone multi-level nested tunnel encapsulation on the local device before being sent out. The route change on the local device may result in infinite nested encapsulation. Excessive nesting will result in the continual fragmentation and recombination operations of the router and severely compromise routing performance. In order to avoid the occurrence of aforementioned phenomena, RGOS software can automatically avoid infinite nested encapsulation. Only 4-level nesting is allowed by default. Use the **tunnel nested-limit** command to modify the default value. This command is used on the tunnel interface of the innermost layer.

Command	Function
Ruijie(config-if)#**tunnel nested-limit** *num*	Configures the tunnel nested encapsulation limit. Default value: 4-level; value range: 0-10.
Ruijie(config-if)#**no tunnel nested-limit**	Restores the nested encapsulation limit to the default value.

Configuring Tunnel VRF

Identify which VRF would be used by the outer-layer transport protocol IPv4 for route selection and forwarding. Run the following commands:

Command	Function
Ruijie(config-if)# **tunnel vrf** *vrf-name*	Configures Tunnel VRF.
Ruijie(config-if)# **no tunnel vrf**	Removes Tunnel VRF configuration.

By default, the outer-layer IPv4 uses a global VRF table for route selection and forwarding. The source IP address and destination IP address of outer-layer encapsulation must be in the same VRF table. If in the designated VRF, there is no available route to the destination IP address, then this tunnel interface will be in down state.

Caution

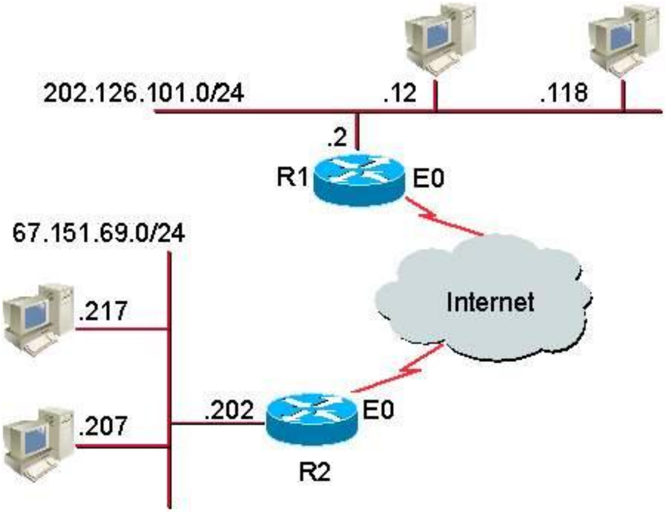
Currently, the tunnel VRF function can only support IPv4 over IPv4 GRE tunnel.

This command is only supported by RGOS 10.4(2) or later versions.

Example of Tunnel Interface Configuration

The network connections of this configuration example are shown in Figure .

Figure 30 Network connections of Tunnel interface configuration example



In the configuration example, a tunnel is created between R1 and R2. The subnet 202.126.101.0/24 behind R1 communicates with the subnet 67.151.69.0/24 behind R2 via the tunnel between R1 and R2. Such communication is carried out through the tunnel. The external network between R1 and R2 is transparent and invisible: a virtual private network (VPN). Tunnel configurations of R1 and R2 are shown below.

Configuration of R1:

```
interface Tunnel0
ip address 21.21.21.3 255.255.255.0
tunnel source 179.208.12.221
tunnel destination 179.208.12.55
!
interface FastEthernet0/0
ip address 179.208.12.221 255.255.255.0
!
interface FastEthernet0/1
ip address 202.106.101.2 255.255.255.0
!
```

Configuration of R2:

```
interface Tunnel0
ip address 21.21.21.5 255.255.255.0
tunnel source 179.208.12.55
tunnel destination 179.208.12.221
!
interface FastEthernet0/0
ip address 179.208.12.55 255.255.255.0
!
interface FastEthernet0/1
ip address 67.151.69.202 255.255.255.0
!
```

From the preceding configuration, you can learn that both R1 and R2 use Ethernet interface f0/0 to create a tunnel and use Ethernet interface f0/1 to connect to Intranet and serve as the gateway of Intranet.

Monitoring and Maintaining Tunnel interfaces

Ruijie products enable you to monitor and maintain tunnel interfaces by using the **show interfaces tunnel** and **debug [gre/ip | ipip]** commands.

Command	Function
Ruijie# **show interfaces tunnel** *tunnel-number*	Queries the status of a tunnel interface
Ruijie# **show tunnel gre**	Queries the general configurations of a GRE tunnel
Ruijie# **debug [gre/ip | ipip]**	Turns on tunnel debug switch.
Ruijie# **no debug [gre/ip | ipip]**	Turns off tunnel debug switch.

The examples show how to use **show interfaces tunnel** command and **debug** command.

42) Usage of the show interfaces tunnel command

```
Ruijie# show interfaces tunnel 1
Tunnel 1 is UP  , line protocol is UP
Hardware is  Tunnel
```

```
Interface address is: 1.1.1.1/24
MTU 1500 bytes, BW 9 Kbit
Encapsulation protocol is Tunnel, loopback not set
Keepalive interval is 0 sec , no set
Carrier delay is 0 sec
RXload is 1 ,Txload is 1
Tunnel source 192.168.200.200 (FastEthernet 0/0), destination 192.168.200.100
Tunnel protocol/transport GRE/IP, key 0xea
Order sequence numbers 0/0 (tx/rx)
Checksumming of packets enabled  Queueing strategy: WFQ
5 minutes input rate 0 bits/sec, 0 packets/sec
5 minutes output rate 0 bits/sec, 0 packets/sec
0 packets input, 0 bytes, 0 no buffer
Received 0 broadcasts, 0 runts, 0 giants
0 input errors, 0 CRC, 0 frame, 0 overrun, 0 abort
0 packets output, 0 bytes, 0 underruns
0 output errors, 0 collisions, 0 interface resets
```

You can learn about the parameter settings and working status of the tunnel interface from the above information, such as the status of interface and link, IP address configuration, MTU configuration, bandwidth configuration and etc.

43) Usage of the **debug** command

```
Ruijie# debug gre/ip
Ruijie#
GRE: to decaps 192.168.200.100->192.168.200.200(len=132
ttl=255) 112
```

The above information indicates that a GRE/IP data packet is received from destination terminal (192.168.200.100) and de-encapsulated to obtain the IP payload packet.

Troubleshooting Faults on the Tunnel Interface

If both ends of a tunnel cannot communicate normally, carry out troubleshooting from the following aspects:

44) Make sure there is a reachable physical path between two ends of the tunnel, that is, the two ends are reachable for each other even if this tunnel is unavailable. Normal communication can be carried out between the source address (local terminal) of the tunnel and the destination address (peer terminal) of the tunnel.

45) Make sure the source address corresponds with the destination address, i.e., the source address must be identical with the destination address.

46) Make sure the tunnel uses the correct encapsulation mode (GRE by default), and both ends of the tunnel must use the same encapsulation mode.

47) After using GRE as the tunnel encapsulation protocol, make sure the checksum, Key and reception rule configurations are identical on both ends.

Configuring the AAA Function

Access control specifies the users who are allowed to access a server and lists the services that are accessible on the network. Authentication, authorization and accounting (AAA) is a key security mechanism for access control.

Overview

AAA presents a unified framework for configuring the authentication, authorization and accounting functions, which is supported by Ruijie products.

AAA provides the following services in a modular manner:

- Authentication: It verifies whether a user can get the right to access. User authentication is performed using RADIUS, TACACS+, or Local before a user accesses the network or a service on the network.
- Authorization: It determines the services which are accessible to a user by defining a series of attribute-value pairs (AVPs). These AVPs describe the operations the user is authorized to do. These AVPs can be stored on a network device or a remote RADIUS security server.
- Accounting: It records network resource usage of users. The network device starts sending resource usage of users to the Radius security server in the form of statistics when the accounting function is enabled. Every accounting record is stored in the security server as AVPs. These records can be read by special software to implement the accounting, statistics and tracing of network resource usage.

Note

Some products only provide the authentication function. For all problems with product specifications, contact the marketing or technical support personnel.

Although AAA is the primary access control method boasting superior security protection, Ruijie products also provide simpler control access methods, such as the local username authentication and line password authentication.

AAA has the following advantages:

- Excellent flexibility and controllability
- Expandability
- Standardized authentication
- Multiple backup systems

Basic AAA Principles

AAA types can be dynamically configured on a per-user (line) or per-server basis by creating method lists and applying them to specific services or interfaces.

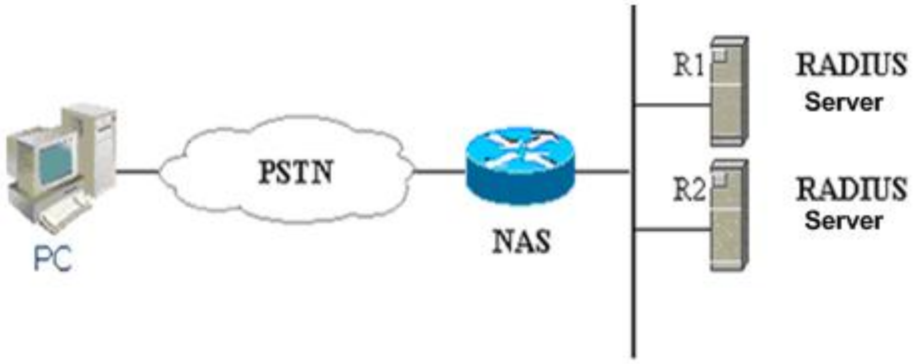
Method List

Since a variety of methods are available for user AAA, a method list should be used to define the sequence in which these methods are performed. The method list can define one or more security protocols for authentication, so that a backup system takes effect when the first method fails. In Ruijie products, a next method is selected if no response is received from the previous method till there is successful communication with a method or all methods in the list are attempted. If all methods listed are attempted but communication is not set up, AAA fails.

Caution

Only when there is no response from a method, Ruijie products will attempt the next method. During the authentication, if the user access is refused by a method, the authentication process ends and no other methods will be attempted.

Figure 31 Typical AAA network configuration



The preceding figure illustrates typical AAA network configuration, including two RADIUS security servers R1 and R2 and a network access server (NAS) that can function as a RADIUS server.

Supposed the system administrator has defined a method list, where user identity information is first obtained from R1, R2, and then the local username database on the NAS. If a remote PC user attempts to access the network via dialup, the NAS first queries the authentication information from R1. If the user is authenticated by R1, R1 sends a ACCEPT reply to the NAS, allowing the user to access the network. If R1 returns a REJECT reply, the user access is refused and connection from the user is rejected. If R1 does not reply, the NAS regards that timeout occurs and queries authentication information from R2. This process continues unless the user is authenticated, user access is rejected, or the session is terminated. If TIMEOUT is returned for all methods, the authentication fails and the user is disconnected.

Caution

The REJECT response is different from the TIMEOUT response. The server returns a REJECT message if a user fails to comply with the standard in the available authentication database. The server returns a TIMEOUT message if there is no response from the security server to the authentication. When an TIMEOUT message is detected, the next authentication method in the method list is selected to continue the authentication process.

Note

This document uses RADIUS for an example to describe the AAA function of security servers. For security access implementation based on TACACS+, see *Configuring TACACS+*.

AAA Configuration Steps

First you shall choose a security solution, evaluate the potential security risks in the specific network and select the proper measures to prevent unauthorized access. It is recommended that AAA be used to ensure network security.

AAA Configuration Description

AAA configuration may become simple when you understand the basic operation process of AAA. To configure AAA on network devices of Ruijie, perform the following steps:

48) Enable AAA by using the **aaa new-model** command in global configuration mode.
49) Configure parameters of the security protocol, RADIUS for example if you decide to use the security server.
50) Define the authentication method list by using the **aaa authentication** command.
51) Apply the method list to specific interface or line, if necessary.

Caution

When the specific method list is used, if no named method list is specified, the default authentication method list will apply.

As a result, if you do not want to use the default authentication method list, you shall define a specific method list.

For complete descriptions of the commands mentioned in this chapter, see related chapters in the *Security Configuration Command Reference*.

Enabling AAA

Before activating AAA security features, be sure to enable AAA.

To enable AAA, use the following command in global configuration mode:

Command	Function
Ruijie(config)# **aaa new-model**	Enables AAA.

Disabling AAA

To disable AAA, use the following command in global configuration mode:

Command	Function
Ruijie(config)# **no aaa new-model**	Disables AAA.

Follow-up Configuration

The following tables lists the possible configuration tasks that need to be completed after AAA enabling and chapters they are described in.

AAA access control security solution

Configuration task	Chapter
Configuring RADIUS Security Parameters	Configuring RADIUS
Configuring Local Login Authentication	Configuring Authentication
Defining AAA Authentication Method List	Configuring Authentication
Applying Method List to Specific Interface or Line	Configuring Authentication
Configuring RADIUS Authorization	Configuring Authorization
Enabling RADIUS Accounting	Configuring Accounting

If you are using AAA for authentication, see the *"Configuring Authentication" section*.

Configuring Authentication

Users need to be authenticated before they access network resources. In most cases, AAA is recommended for authentication.

Defining AAA Authentication Method List

To configure the AAA authentication, the first step is to define a named list of authentication methods, and then the applications use the defined method list for authentication. The method list defines the authentication types and sequence in which they are performed. The defined authentication methods, except the default method list, are specific to applications. Before a named method list is defined, all applications use the default method list.

A method list is simply a named list describing the authorization methods to be queried in sequence. Method lists enable you to designate one or more security protocols to be used for authorization, thus ensuring a backup system in case the initial method fails. Ruijie products use the first method listed to authorize users for specific network services; if that method fails to respond, Ruijie products select the next method listed in the method list. This process continues till there is successful communication with a listed authorization method, or all methods defined are exhausted.

⚠ Caution

Only when there is no response from a method, Ruijie products will attempt the next method. During the authentication, if the user access is refused by a method, the authentication process ends and no other methods will be attempted.

Configuration Examples

A typical AAA network has two RADIUS servers: R1 and R2. Suppose the network administrator has chosen a security solution, and the NAS authentication uses an authentication method to authenticate the Telnet connection. User authentication is initially attempted on R1, then on R2 if there is no response from, R1, and finally in the local database of the NAS if there is no response from R2 either. To design such an authentication process, you must configure an authentication method list accordingly by using the following commands:

Command	Function
configure terminal	Enters global configuration mode.
aaa authentication login default group radius local	Configures a default authentication method list named *default*. The protocols included in this method list are arranged behind the name according to the order in which they will be queried. The default method list applies to all applications by default.

To apply a method list to a specific Login connection, the system administrator must create a named method list and then apply it to the specific connection. The following example shows how to apply the authentication method list to line 2 only.

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.
aaa authentication login test group radius local	Defines a method list named test in global configuration mode.
line vty *2*	Enters VTY line 2 configuration mode.
login authentication *test*	Applies the test method list to VTY line 2 in line configuration mode

If a remote PC user attempts to Telnet the NAS, the NAS first queries the authentication information from R1. If the user is authenticated by R1, R1 sends a ACCEPT reply to the NAS, allowing the user to access the network. If R1 returns a REJECT reply, the user access is refused and connection from the user is rejected. If R1 does not reply, the NAS regards that timeout occurs and queries authentication information from R2. This process continues unless the user is authenticated, user access is rejected, or the session is terminated. If both servers (R1 and R2) return TIMEOUT, the authentication will be performed by the local database of the NAS.

Caution

The REJECT response is different from the TIMEOUT response. The server returns a REJECT message if a user fails to comply with the standard in the available authentication database. The server returns a TIMEOUT message if there is no response from the security server to the authentication. When an TIMEOUT message is detected, the next authentication method in the method list is selected to continue the authentication process.

Authentication Type

Ruijie products support the following authentication types:

- Login authentication -- applies when a user tries to log in to the NAS through the command line interface (CLI).
- Enable authentication -- applies when an online user requests more rights on the CLI.
- PPP authentication -- applies to PPP dial-up users.
- DOT1X(IEEE802.1x) authentication -- applies to users who try to access through IEEE802.1x.

Configuring AAA Authentication

The following tasks are common for the configuration of AAA authentication.

- Enable AAA by using the **aaa new-model** command in global configuration mode.
- Configure the security protocol parameters if you decide to use the security server, such as RADIUS and TACACS+. See the "Configuring Radius" and "Configuring TACACS+" sections for details.
- Define the authentication method list by using the **aaa authentication** command.
- Applying the method list to a specific interface or line, if possible.

Caution TACACS+ is not supported by the DOT1X authentication on Ruijie products.

Configuring the AAA Login Authentication

This section describes how to configure the AAA Login authentication methods supported by Ruijie products:

Caution AAA security features can be made available only after AAA is enabled by using the **aaa new-model** command in global configuration mode. For the details, see the "AAA Overview" chapter.

In many cases, the user needs to Telnet the NAS for configuring the NAS remotely. To prevent unauthorized access to the NAS, user authentication is required.

The AAA security services make it easy for the network devices to perform line-based Login authentication. No matter which Login authentication method you use, you just need to use the **aaa authentication login** command to define one or more authentication method lists and apply them to the specific line that needs the Login authentication.

To configure the AAA Login authentication, run the following commands in global configuration mode:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.
aaa authentication login {default |*list-name} method1 [method2...]*	Defines an accounting method list. To define multiple method lists, repeat this command.
line vty *line-num*	Enters the line to which the AAA authentication applies.
login authentication {default|*list-name*}	Applies the method list to the line.

The keyword **list-name** is a character string used to name the created authentication method list, while **method** means the actual authentication algorithm. Only when the current method returns an ERROR message (no reply), the next authentication method will be attempted. If the current method returns a FAIL message, no authentication method will be used any more. To make sure that users can be authenticated even if no response is received from any method, use the **none** keyword.

In the following example, users can still be authenticated even if the RADIUS server returns TIMEOUT. Use the **aaa authentication login default group radius none** command.

Caution Since the keyword **none** enables every dial-up user to be authenticated even if the security server does not reply, it is used only as a backup authentication method. Normally, the **none** keyword is not recommended. You can use it as the last authentication method preceded by the local authentication method in the scenario where possible dial-up users are all trustful and their work are susceptible to any delay caused by system faults.

Keyword	Description
local	Uses the local username database for authentication.
none	User authentication is not performed.
group radius	Uses RADIUS to get authentication information.
group tacacs+	Uses TACACS+ to get authentication information.

The preceding table lists the AAA login authentication methods supported by Ruijie products.

Using the Local Database for Login Authentication

To use the local database for Login authentication, configure the local database first. Ruijie product supports authentication based on the local database. To enable the username authentication, run the following commands in global configuration mode:

Command	Function
configure terminal	Enters global configuration mode.
username *name* [**password** *password*]	Creates a local user and sets a password.
end	Returns to privileged mode.
show running-config	Verifies the configuration.

To define and apply the local login authentication method list, use the following commands:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.
aaa authentication login {default | *list-name*} **local**	Defines the local authentication method list.
end	Returns to privileged mode.
show aaa method-list	Verifies the configured method list.
configure terminal	Enters global configuration mode.
line vty *line-num*	Enters line configuration mode
login authentication {**default** | *list-name*}	Applies the method list.
end	Returns to privileged mode.
show running-config	Verifies the configuration.

Using Radius for Login Authentication

To use RADIUS for Login authentication, configure the RADIUS server. Ruijie products support the authentication based on the RADIUS server. To configure the RADIUS server, use the following commands in global configuration mode:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.

Command	Function
radius-server host *ip-address* [**auth-port** *port*] [**acct-port** *port*]	Configures the RADIUS server
end	Returns to privileged mode.
show radius server	Shows the RADIUS server.

After the RADIUS server is configured, make sure there is successful communication with the RADIUS server before configuring RADIUS for authentication. For details about the RADIUS server configuration, see the "Configuring RADIUS" section.

Then you can configure the RADIUS server based method list. Use the following commands:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.
aaa authentication login {**default** | *list-name*} **group radius**	Defines the local authentication method list.
end	Returns to privileged mode.
show aaa method-list	Verifies the configured method list.
configure terminal	Enters global configuration mode.
line vty *line-num*	Enters line configuration mode
login authentication {default | *list-name*}	Applies the method list.
end	Returns to privileged mode.
show running-config	Verifies the configuration.

Configuring the AAA Enable Authentication

This section describes how to configure the AAA Enable authentication methods supported by our product:

In many cases, the user needs to Telnet the NAS. After being authenticated, the user can access the CLI and is assigned 0–15 privilege levels initially, each having different commands. You can use the **show privilege** command to query the current level. For the details, see the "Using the CLI" section.

After logging in to the CLI, you can use the **enable** command to obtain higher privilege level if you fail to execute some commands. To prevent unauthorized access to the network, authentication needs to be performed when a user applies for a higher privilege level. This authentication type is called Enable authentication.

To configure the AAA Enable authentication, use the following commands in global configuration mode:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.
aaa authentication enable default *method1 [method2...]*	Defines an Enable authentication method list, for example RADIUS.

Only one Enable authentication method list can be defined globally, so there is no need to name the method list. The keyword **method** means the actual authentication algorithm. Only when the current method returns an ERROR message (no reply), the next authentication method will be attempted. If the current method returns a FAIL message, no authentication method will be used any more. To make sure that users can be authenticated even if no response is received from any method, use the **none** keyword.

Once configured, the Enable authentication method takes effect. When using **enable** command in privileged mode, the system prompts a message indicating authentication is required if you want to obtain a higher privilege level. There is no need to authenticate if the privilege level to be set is lower than or equal to the current one.

Caution

The current username will be recorded if the Login authentication(except for **none** method) is done when accessing the CLI. At this time, if the Enable authencation processes, a message indicating that the username must be entered will not be prompted and you can use the same username of Login authentication. Note that the password input must be consistent.

The username information will not be recorded if there is no Login authentication when you access the CLI, or the **none** method is used. At this time, if the Enable authentication is required, you shall enter the username again. This username will not be recorded, so you shall enter in each Enable authentication.

Some authentication methods can bind the security level. Then in the process of authentication, except for the returned response according to the security protocol, it is necessary to verify the bound security level. If the service protocol can bind the security level, the level shall be verified while authenticating. If the binded level is more than or equal to the level to be configured, the enable authentication and level switchover succeed. But if the bound level is less than the level to be configured, the Enable authentication fails, prompting an error message and keeping the current level. If the service protocol fails to be bound to the security level, you can configure the level without verification of the bound level.

Now only RADIUS and Local authentication can be bound to security levels. To this end, security levels need to be checked only for these two methods.

Using the Local Username Database for Enable Authentication

When configuring the local Enable authentication, you can configure the privilege level of local users. By default, the privilege level is 1. To configure the local Enable authentication, configure the local database and privilege levels. To enable the username authentication, use the following commands in global configuration mode:

Command	Function
configure terminal	Enters global configuration mode.
username *name* [**password** *password*]	Creates the local user and sets a password.
username *name* [**privilege** *level*]	Sets the user privilege level. (Optional)
end	Returns to privileged mode.
show running-config	Verifies the configuration.

To define the local Enable authentication method list, run the following commands:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.
aaa authentication enable default local	Defines the local authentication method list.
end	Returns to privileged mode.
show aaa method-list	Verifies the configured method list.

Command	Function
show running-config	Verifies the configuration.

Using RADIUS for Enable Authentication

The standard RADIUS server can pass the privilege level bound to the Service-Type attribute (the standard attribute number is 6), can specify the privilege with 1 or 15 level. The extened RADIUS server (for example, SAM) can configure the privilege level of the administrator (the private attribute number is 42), can specify 0-15 privilege level. For the details of the RADIUS server, see the "Specifying the RADIUS Private Attribute Type" section in "Configuring RADIUS".

To configure the RADIUS Enable authentication, configure the RADIUS server and then the RADIUS Enable authentication method list. Use the following commands in global configuration mode:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.
aaa authentication enable default group radius	Defines the RADIUS authentication method.
end	Returns to privileged mode.
show aaa method-list	Verifies the configured method list.
show running-config	Verifies the configuration.

Configuring the AAA Authentication for PPP Users

PPP is a link-layer protocol of carrying the network-layer datagram in the point-to-point link. In many circumstances, the user accesses the NAS by means of asynchronous or ISDN dail-up. Once the connection has been set up, the PPP negotiation will be enabled. To prevent the unauthorized access to the network, authentication is required for the dail-up user in the process of PPP negotiation.

This section describes how to configure the AAA Enable authentication methods supported by Ruijie products. To configure the AAA Enable authentication, use the following command in global configuration mode:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.
aaa authentication ppp {**default** | *list-name*} *method1 [method2...]*	Defines a PPP authentication method list. RADIUS, TACACS+ remote authentication and using the local database are the supported authentication methods.
interface *interface-type interface-number*	Enters the asynchronous or ISDN interface to which AAA authentication applies.
ppp authentication {chap | pap} {default | ***list-name***}	Applies the method list to the asynchronous or ISDN interface.

For details about PPP configuration, see the related chapter in *Configuring PPP and MP*.

Configuring the AAA Authentication for 802.1x Users

IEEE802.1x is a standard of Port-Based Network Access Control, providing the point-to-point secure access for the LAN, and a means of the authentication of the user connecting to the LAN device.

This section describes how to configure the 802.1x authentication methods supported by Ruijie products. To configure the AAA Enable authentication, use the following command in global configuration mode:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.
aaa authentication dot1x {**default** | *list-name*} *method1* *[method2...]*	Defines an IEEE802.1x authentication method list. RADIUS remote authentication and using the local database are the supported authentication methods.
dot1x authentication *list-name*	Applies the method list to 802.1x users.

For details about IEEE802.1x configuration, see the related chapter in *Configuring 802.1x*.

Example of Authentication Configuration

The following example illustrates how to apply both RADIUS authentication and local authentication to a network device.

```
Ruijie(config)# aaa new-model
Ruijie(config)# username Ruijie password starnet
Ruijie(config)# radius-server host 192.168.217.64
Ruijie(config)# aaa authentication login test group radius local
Ruijie(config)# line vty 0
Ruijie(config-line)# login authentication test
Ruijie(config-line)# end
Ruijie# show running-config
!
aaa new-model
!
!
aaa authentication login test group radius local
username Ruijie password 0 starnet
!
radius-server host 192.168.217.64
!
line con 0
line vty 0
login authentication test
line vty 1 4
!
!
```

In the preceding example, the access server uses the RADIUS server (IP address: 192.168.217.64) to perform Login authentication for users. If the RADIUS server does not reply, the local database will be used for authentication.

Example of Terminal Service Application Configuration

In the environment of the terminal service application, the terminal first connects to the asynchronous console, then offers the service accessing the network network server. However, if AAA is enabled, the Login authentication is necessary in all lines. To access the server, the terminal must pass the Login authentication and it influences the terminal service. You can separate two lines by configuration that makes the line using the terminal service directly connecting the server without the Login authentication, and ensures the device security by the Login authentication of the line connecting the device. That is to say, you can configure a login authentication list specific for the terminal service but the authentication method as **none**. Then apply the configured list to the line with terminal service enabled, while other lines connecting the local device is unchanged. In this way, the terminal can skip the local login authentication.

The following example illustrates the configuration steps:

```
Ruijie(config)# aaa new-model
Ruijie(config)# username Ruijie password starnet
Ruijie(config)# radius-server host 192.168.217.64
Ruijie(config)# radius-server key test
Ruijie(config)# aaa authentication login test group radius local
Ruijie(config)# aaa authentication login terms none
Ruijie(config)# line tty 1 4
Ruijie(config-line)# login authentication terms
Ruijie(config-line)# exit
Ruijie(config)# line tty 5 16
Ruijie(config-line)# login authentication test
Ruijie(config-line)# exit
Ruijie(config)# line vty 0 4
Ruijie(config-line)# login authentication test
Ruijie(config-line)# end
Ruijie(config)# show running-config
!
aaa new-model
!
!
aaa authentication login test group radius local
aaa authentication login terms none
username Ruijie password 0 starnet
!
radius-server host 192.168.217.64
radius-server key 7 093b100133
!
line con 0
line aux 0
line tty 1 4
login authentication terms
line tty 5 16
login authentication test
line vty 0 4
login authentication test
!
!
```

In the preceding example, the NAS uses the RADIUS server (IP address: 192.168.217.64) to perform login authentication for users. If the RADIUS server does not reply, the local database will be used for authentication. Login authentication is unnecessary for TTY 1-4 is the used line of the terminal service, while using other TTY and VTY lines needs the login authentication.

Configuring Authorization

The AAA authorization enables the administrator to control the use of services or rights. After the AAA authorization service is enabled, the network device configures the user sessions by using the user configuration file stored locally or in the server. After the authorization is completed, the user can only use the services allowed in the profile or has the assigned rights.

Authorization Types

Ruijie products support the following AAA authorization methods:

- Exec authorization: The user terminal loggs in to the CLI of the NAS and is granted the privilege level (0-15).
- Command authorization: After a user logs in to the CLI of the NAS, the user is specific commands are authorized.
- Network authorization: Grants the available service to the user session in the network.

Note

Only TACACS+ supports the command authorization method. For the detailed information, see the "Configuring TACACS+" section.

Preparations for Authorization

The following tasks must be completed before the AAA authorization is configured:

- Enable the AAA server. For details, see the AAA Overview chapter.
- (Optional) Configure the AAA authentication. The authorization is performed after the user is authenticated. But independent authorization can also be performed without authentication. For details of the AAA authentication, see the "Configuring Authentication section.
- (Optional) Configure security protocol parameters. If the security protocol is required for authorization, configure the security protocol parameters. The network authorization only supports RADIUS; the Exec authorization supports RADIUS and TACACS+. For details of the RADIUS, see the "Configuring RADIUS" section. For details of the TACACS+, see the "Configuring TACACS+ section.
- (Optional) If the local authorization is required, use the **username** command to define the user rights.

Configuring Authorization List

To enable AAA authorization, use the following commands in global configuration mode:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.
aaa authorization exec network{default | *list-name} method1 [method2*|*…*]	Defines the AAA Exec authorization method.

Command	Function
aaa authorization network network{**default** | *list-name} method1 [method2*|*…*]	Defines the AAA Network authorization method.

Configuring AAA Exec Authorization

The Exec authorization grants the privilege level of command execution for the user terminal logging in to the NAS. You can use the **show privilege** command to display the specific level after the user logs in to the NAS CLI successfully (by telnet, for example).

No matter which Exec authorization method you use, you just need to use the **aaa authorization exec** command to define one or more authorization method lists and apply them to the line that needs the Exec authorization.

To configure the AAA Exec authorization, use the following commands in global configuration mode:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.
aaa authorization exec network{**default** | *list-name} method1 [method2*|*…*]	Defines the AAA Exec authorization method. If you need to define multiple methods, execute this command repeatedly.
line vty *line-num*	Enters the line to which the AAA Exec authorization method is applied.
authorization exec {**default** | *list-name*}	Applies the method to the line.

The keyword **list-name** is a character string used to name the created authorization method list, while the keyword **method** means the actual authorization algorithm. Only when the current method returns an ERROR message (no reply), the next authorization method will be attempted. If the current method returns a FAIL message, no authorization method will be used any more. To make sure that users can be authorized successfully even if no response is received from any method, use the **none** keyword.

In the following example, the Exec authorication is still successful even if the RADIUS server returns TIMEOUT:

aaa authorization exec default group radius none

Keyword	Description
local	Uses the local username database for Exec authorization.
none	Exec authorization is not performed.
group radius	Uses RADIUS for Exec authorization.
group tacacs+	Uses TACACS+ for Exec authorization.

The preceding table lists the AAA Exec authorization methods supported by Ruijie products.

Caution

The exec authorization is always used together with the login authentication, and they can be applied to the same line at the same time. But note that it is possible to have different results of the authentication and the authorization towards the same user because they can use different methods and servers. If the Exec authorization fails, a user cannot access the CLI even though the login authentication of the user is successful.

Using the Local Username Database for Exec Authorization

To configure the local Exec authorization, configure the local database first. You can configure the privilege level of local users. By default, the privilege level is 1. Use the following commands in global configuration mode:

Command	Function
configure terminal	Enters global configuration mode.
username *name* [**password** *password*]	Creates a local user and sets a password.
username *name* [**privilege** *level*]	Sets the user privilege level. (Optional)
end	Returns to privileged mode.
show running-config	Verifies the configuration.

To define the local Exec authorization method list, use the following commands:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.
aaa authorization exec {**default** | *list-name*} **local**	Defines the local authorization method list.
end	Returns to privileged mode.
show aaa method-list	Verifies the configured method list.
configure terminal	Enters global configuration mode.
line vty *line-num*	Enters line configuration mode.
authorization exec {**default** | *list-name*}	Applies the method list.
end	Returns to privileged mode.
show running-config	Verifies the configuration.

Using RADIUS for Exec Authorization

To configure the RADIUS Exec authorization, onfigure the RADIUS server. For details about the RADIUS server configuration, see the "Configuring RADIUS" section.

After configuring the RADIUS server, the RADIUS authorization method list can be configured. Use the following commands in global configuration mode:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.
aaa authentication enable {default | *list-name*} **group radius**	Defines RADIUS authentication method.
end	Returns to privileged mode.
show aaa method-list	Verifies the configured method list.
configure terminal	Enters global configuration mode.
line vty *line-num*	Enters line configuration mode.
authorization exec {**default** | *list-name*}	Applies the method list.

Command	Function
end	Returns to privileged mode.
show running-config	Verifies the configuration.

Example of Configuring Exec Authorization

The following example illustrates how to configure Exec authorization. The local login authentication and the "Radius+local" Exec authorization are used when the user logs in through VTY lines 0-4. The NAS uses the RADIUS server with IP address set to 192.168.217.64 and shared keyword **test***.* The local username and password are *Ruijie,* and the privilege level is *6*.

```
Ruijie# configure terminal
Ruijie(config)# aaa new-model
Ruijie(config)# radius-server host 192.168.217.64
Ruijie(config)# radius-server key test
Ruijie(config)# username Ruijie password Ruijie
Ruijie(config)# username Ruijie privilege 6
Ruijie(config)# aaa authentication login mlist1 local
Ruijie(config)# aaa authentication exec mlist2 group radius local
Ruijie(config)# line vty 0 4
Ruijie(config-line)# login authentication mlist1
Ruijie(config-line)# authorization exec mlist2
Ruijie(config-line)# end
Ruijie(config)# show running-config
!
aaa new-model
!
aaa authorization lexec mlist2 group radius local
aaa authentication login mlist1 local
!
username Ruijie password Ruijie
username Ruijie privilege 6
!
Radius-server host 192.168.217.64
radius-server key 7 093b100133
!
line con 0
line vty 0 4
authorization exec mliat2
login authentication mlist1
!
end
```

Configuring AAA Network Authorization

Ruijie product support PPP and SLIP network authorization. The network authorization makes service configuration regarding traffic, bandwidth, and timeout available on the network connection. The network authorization only supports

RADIUS and TACACS+. The authorization information assigned by the server are encapsulated in the RADIUS attribute or TACACS+ attribute. Authorization information may vary with netowrk connections.

Caution Now AAA network configuration does not support 802.1X. For details about the 802.1X authorization, see the "Configuring 802.1X" section.

To configure the AAA network authorization, use the following commands in global configuration mode:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.
aaa authorization network{**default** | *list-name} method1 [method2*|*…*]	Defines an AAA network authorization method. If you need to define multiple methods, use this command repeatedly.

The keyword **list-name** is a character string used to name the created authorization method list, while **method** means the actual authorization algorithm. Only when the current method returns an ERROR message (no reply), the next authorization method will be attempted. If the current method returns a FAIL message, no authorization method will be used any more. To make sure that users can be authenticated even if no response is received from any method, use the **none** keyword.

Using RADIUS for Network Authorization

To configure RADIUS Network authorization, configure the RADIUS server. For details about the RADIUS server configuration, see the "Configuring RADIUS" section.

After configuring the RADIUS server, the RADIUS Network authorization method list can be configured. Use the following commands in global configuration mode:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.
aaa authentication network {**default** | *list-name*} **group radius**	Defines a RADIUS Network authorization method.

Example of Configuring Network Authorization

The following example illustrates how to configure Network authorization.

```
Ruijie# configure terminal
Ruijie(config)# aaa new-model
Ruijie(config)# radius-server host 192.168.217.64
Ruijie(config)# radius-server key test
Ruijie(config)# aaa authorization network test group radius local
Ruijie(config-line)# end
Ruijie(config)# show running-config
!
```

```
aaa new-model
!
aaa authorization network test group radius none
!
radius-server host 192.168.217.64
radius-server key 7 093b100133
!
```

Configuring Accounting

The AAA accounting function enables you to trace the services and network resources used by the user. After the accounting function is enabled, the NAS or router sends network access records of users to the RADIUS security server by means of AVP. You may use some analysis software to analyze these data to implement the billing, audit and tracing function for the user's activities.

Accounting Types

Ruijie products currently support the following accounting types:

- Exec accounting -- records the accounting information when users access or exit the CLI of the NAS.
- Command accounting – records the specific commands executed after the user logs in to the CLI of the NAS.
- Network accounting – records the related information on the user session in the network.

Note

The command accounting function supports only TACACS+. For details, see the "Configuring TACACS+" section.

Preparations for Accounting

The following tasks must be completed before the AAA accouting is configured:

- Enable the AAA server. For details, see the "AAA Overview" chapter.
- Define the security protocol parameters. It is required to configure the security protocol parameters for accouting. The network accounting only supports RADIUS; the Exec accounting supports RADIUS and TACACS+; the Command accounting supports TACACS+ only. For details of RADIUS, see the "Configuring RADIUS" section. For details of TACACS+, see the "Configuring TACACS+" section.
- (Optional) Configure the AAA authentication. Certain types of accounting (for example, Exec accounting) are performed after the user is authenticated. In some circumstances, the accouting can also be performed without authentication. For details about AAA authentication, see the "Configuring Authentication" section.

Configuring AAA Exec Accounting

The Exec accounting records the information when users access or exit the CLI of the NAS. When a user logs in and accesses the NAS CLI, it sends the accounting start information to the security server. When the user exits the CLI, it sends the accounting stop information to the server.

Caution

Exec accounting starts only after login authentication of the user is successful. If no login authentication or **none** authentication method has been configured, Exec accounting is not performed. If a user does not send no accounting start information to the security server when logging in, no accounting stop information will be sent when the user logs out.

To configure the AAA Exec accounting, use the following commands in global configuration mode:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.
aaa accounting exec {**default** | *list-name}* **start**-**stop** *method1 [method2*|*…*]	Defines the AAA Exec accounting method list. If you need to define multiple method lists, use this command repeatedly.
line vty *line-num*	Enters the line to which the AAA Exec accounting applies.
accounting exec {**default** | *list-name*}	Applies the method list to the line.

The keyword **list-name** is a character string used to name the created accounting method list, while the keyword **method** means the actual accounting algorithm. Only when the current method returns an ERROR message (no reply), the next accounting method will be attempted. If the current method returns a FAIL message, no accounting method will be used any more. To make sure that users can be authorized successfully even if no response is received from any method, use the **none** keyword.

Note

The keyword **start-stop** is used for the NAS to send the accounting information at the start and end of the network service to the security server.

Using the RADIUS for Exec Accounting

To configure RADIUS Exec acounting, configure the RADIUS server. For details about the RADIUS server configuration, see the "Configuring RADIUS" section.

After configuring the RADIUS server, the RADIUS accounting method list can be configured. Use the following commands in global configuration mode:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.
aaa accounting exec {**default** | *list-name*} **start**-**stop** **group radius**	Defines a RADIUS accounting method.
end	Returns to privileged mode.
show aaa method-list	Verifies the configured method list.
configure terminal	Enters global configuration mode.
line vty *line-num*	Enters the line configuration mode.
accounting exec {**default** | *list-name*}	Applies the method list.

Command	Function
end	Returns to privileged mode.
show running-config	Verifies the configuration.

Example of Configuring Exec Accounting

The following example illustrates how to configure Exec accounting. The local login authentication and the RADIUS Exec authorization are used when the user logs in through VTY lines 0-4. The IP address and shared key of the RADIUS server are 192.168.217.64 and *test* respectively. The local username and password both are *Ruijie*

```
Ruijie# configure terminal
Ruijie(config)# aaa new-model
Ruijie(config)# radius-server host 192.168.217.64
Ruijie(config)# radius-server key test
Ruijie(config)# username Ruijie password Ruijie
Ruijie(config)# aaa authentication login auth local
Ruijie(config)# aaa accouting exec acct start-stop group radius
Ruijie(config)# line vty 0 4
Ruijie(config-line)# login authentication auth
Ruijie(config-line)# accounting exec acct
Ruijie(config-line)# end
Ruijie(config)# show running-config
!
aaa new-model
!
aaa accounting exec acct start-stop group radius
aaa authentication login auth local
!
username Ruijie password Ruijie
!
radius-server host 192.168.217.64
radius-server key 7 093b100133
!
line con 0
line vty 0 4
accounting exec acct
login authentication auth
!
end
```

Configuring AAA Network Accounting

Network accounting records the accounting information about user sessions, including the numbers of packets and bytes, IP address and username. Now network accounting only supports RADIUS.

Note The format of RADIUS accounting information varies with the RADIUS security server. The contents of the accounting records may also vary with Ruijie product versions.

To configure the AAA network accounting, use the following commands in global configuration mode:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.
aaa accounting network{default | *list-name}* start-stop *method1 [method2*|…]	Defines the AAA network accounting method list. If you need to define multiple method lists, use this command repeatedly.

The keyword **list-name** is a character string used to name the created accounting method list, while the keyword **method** means the actual accounting algorithm. Only when the current method returns an ERROR message (no reply), the next accounting method will be attempted. If the current method returns a FAIL message, no accounting method will be used any more. To make sure that users can be authorized successfully even if no response is received from any method, use the **none** keyword.

Using RADIUS for Network Accounting

To configure RADIUS network acounting, configure the RADIUS server. For details about the RADIUS server configuration, see the "Configuring RADIUS" section.

After configuring the RADIUS server, the RADIUS accounting method list can be configured. Use the following commands in global configuration mode:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.
aaa accounting network {**default** | *list-name*} **start-stop group radius**	Defines a RADIUS accounting method.

Example of Configuring Network Accounting

The following example illustrates how to configure network authorization using RADIUS.

```
Ruijie# configure terminal
Ruijie(config)# aaa new-model
Ruijie(config)# radius-server host 192.168.217.64
Ruijie(config)# radius-server key test
Ruijie(config)# aaa accounting network acct start-stop group radius
Ruijie(config-line)# end
Ruijie(config)# show running-config
!
aaa new-model
!
```

```
aaa accounting network acct start-stop group radius
!
radius-server host 192.168.217.64
radius-server key 7 093b100133
!
```

Monitoring AAA users

To view the information of the current login users, use the following commands in privileged user mode:

Command	Function
show aaa user { *id* | all }	View the information of the current AAA user.

Configuring VRF-supported AAA Group

Virtual Private Networks (VPNs) provide a secure method for bandwidth share on the backbone networks of ISPs. One VPN is the collection of the shared routes. Users connect to the ISP network through one or multiple interfaces. The VPN routing table is also called VPN routing//forwarding(VRF) table. AAA can specify the VRF for each self-defined server group.

In global configuration mode, use the following commands to configure VRF for the AAA group:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.
aaa group server radius *gs_name*	Configures the RADIUS server group and enters server group configuration mode.
ip vrf forwarding *vrf_name*	Specifies the VRF for the group.
end	Returns to privilege mode.

Note VRF must be supported by Ruijie products.

Configuring Login Lockout for Failed Authentication

To prevent users from cracking passwords, use a command to specify the number of attempts. If the number of login attempts exceeds the limit, the user is locked and cannot log in again in a period.

In global configuration mode, use the following commands to configure login parameters:

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.

Command	Function
aaa local authentication attempts *<1-2147483647>*	Configures the number of login attempt.
aaa local authentication lockout-time*<1-2147483647>*	Configures the time (in hours) in which a user is locked when the number of login attempts of the user exceeds the limit.
show aaa user lockout {all | user-name *<word>*}	Displays the list of locked users.
clear aaa local user lockout {all | user-name *<word>*}	Clears the lockout user list.
End	Returns to privilege mode.

Note

By default, the number of login attempts is 3 and the lockout time is 15 hours.

Configuring Domain Name-based AAA Service

This section is organized as follows::

- Overview
- Domain name-based AAA service configuration tasks
- Domain name-based AAA service configuration notes

Caution

The domain name-based AAA service is applied to the IEEE802.1x authentication service. For the detailed IEEE802.1x protocol configurations, see the "Configuring 802.1x" section.

Overview

In the multi-domain environment, one NAS can provide the AAA service for users in different domains. Due to the different user attributes (such as the username, password, service type, privilege, ect) in each domain, users need to be distinguished by setting domains and each domain is configured with a unique attribute set including the AAA service method list (RADIUS for example).

Note

Ruijie products support the following username formats:

1. userid@domain-name
2. domain-name\userid
3. userid.domain-name
4. userid

Users named in the format of "userid" belong to the default domain.

Basic principles for configuring the domain name-based AAA service are as follows:

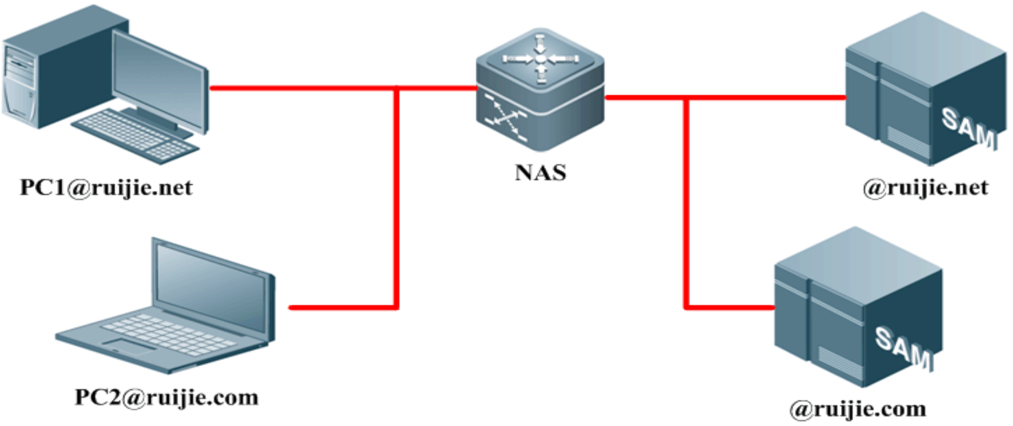
- Parsing the domain name of users
- Searching for the user domain according to the domain name

- Searching for the AAA service method list name according to the domain configurations
- Searching the corresponding method list according to the method list name in the system
- Providing the AAA service by using the method list

Note If one of the abovementioned steps fails, the AAA service cannot be used.

The following is the typical topology of a multi-domain environment:

Figure 32 Typical topology for a multi-domain network



Domain name-based AAA Service Configuration Tasks

Note The system supports up to 32 domains.

Enabling AAA

Command	Function
configure terminal	Enters global configuration mode.
aaa new-model	Enables AAA.

For detailed command descriptions, see the "Enabling AAA" section.

Defining the AAA Service Method List

Command	Function
configure terminal	Enters global configuration mode.
aaa authentication dot1x {**default** | *list-name*} *method1* [*method2*...]	Defines the IEEE802.1x authentication method list.
aaa accounting network {**default** | *list-name*} **start-stop** *method1* [*method2*...]	Defines the Network accounting method list.
aaa authorization network {**default** | *list-name*} *method1* [*method2*...]	Defines the Network authorization method list.

For detailed command descriptions, see the "Configuring authentication", "Configuring Accounting" and "Configuring authorization" sections..

Enabling the Domain Name-based AAA Service

Command	Function
configure terminal	Enters global configuration mode.
aaa domain enable	Enables the domain name-based AAA service.

Creating a Domain

You shall follow the following rules when searching for a domain by username:

52) A single character such as “.”, “\”, “@” can be used to distinguish between usernames and domain names.

53) The single “@” character is followed by the character string “domain-name”. With multiple “@” characters in the username, use the character string following the last “@” characeter as the domain-name. For example, if the username is a@b@c@d, use the a@b@c as the username and use the d as the domain-name.

54) The single “\” character follows the character string “domain-name”. With multiple “\” characters in the username, use the character string followed by the first “\” characeter as the domain-name. For example, if the username is a\b\c\d, use the b\c\d as the username and use the a as the domain-name.

55) The single “.” character is followed by the character string “domain-name”. With multiple “.” characters in the username, according to the pre-settings, use the character string following the last “.” characeter as the domain-name. For example, if the username is a.b.c.d, use the a.b.c as the username and use the d as the domain-name.

56) If all characters of “.”, “\” and “@” exist in the username, when matching the domain-name, use the rules in sequence of the “@”, “\” and “.” characters.

Command	Function
configure terminal	Enters global configuration mode.
aaa domain *domain-name*	Creates a domain and enters domain configuration mode.

Note

The AAA service supports domain names that have a maximum of 64 characters. Domain names are case insensitive.

Configuring the Domain Attribute Set

Use the following commands to select the AAA service method list in domain configuration mode:

Command	Function
authentication dot1x {**default |** *list-name*}	In domain configuration mode, select the authentication method list.
accounting network {**default |** *list-name*}	In domain configuration mode, select the accounting method list.
authorization network {**default |** *list-name*}	In domain configuration mode, select the authorization method list.

Use this command to configure the domain state:

Command	Function
state {block | active}	In domain configuration mode, set the domain state.

Use this command to check whether the username carries the domain name:

Command	Function
username-format {without-domain | with-domain}	In domain configuration mode, check whether the username carries the domain name information when the NAS is interacting with the server.

Use this command to set the maximum number of users supported in the domain:

Command	Function
access-**limit** *num*	In domain configuration mode, set the upper limit of users allowed in the domain. This function applies only to 802.1x users. By default, no upper limit is configured.

Note

1. Only AAA service method lists that have been configured can be selected in domain configuration mode. Otherwise, the system prompts that the AAA service method list you select does not exist.
2. With the domain name-based AAA service enabled, if there is no domain information carried by the username, use the default domain; if there is no configurations for the user domain in the system, the user is determined to be illegitimate and provides no AAA service.
3. In domain configuration mode, the default method list is selected if no other list is available.

Querying the Domain configuration

Use the following command to query the domain name-based AAA service information.

Command	Function
show aaa domain [*domain-name*]	Queries the current domain name-based AAA service information

Domain Name-based AAA Service Configuration Notes

When configuring the domain name-based AAA service, note the following points:

57) If the domain name-based AAA service is enabled, use the method list in the domain. If the service is not enabled, use the method list selected according to the access protocol (such as 802.1x, ect) for the AAA service. For example, if the service is not enabled, use the **dot1x authentication** *authen-list-name,* **dot1x accounting** *acct-list-name authen-list-name* and **dot1x accounting** *acct-list-name acct-list-name* command to provide the AAA service for the authentication and accouting method list name.
58) If the domain name-based AAA service is enabled, the default domain needs to be configured manually by default. The default domain is named "default" and is used to provide AAA services if the username does not contain domain

name. Without the default domain configured, the user whose name does not carry the domain information fails to use the AAA services.

59) If the domain information is carried by the auth-user but the domain is not configured on the device, it fails to provide the AAA service for the user.

60) The AAA service method list selected by the domain must be consistent with the one defined by the AAA service. Or it fails to provide the AAA service for the users in the domain.

61) The domain name carried by the user shall accurately match the one configured on the device. For example, the domain.com and the domain.com.cn have been configured on the device, and the request message carried by the user is aaa@domain.com, the device determines that the user belongs to the domain.com but not the domain.com.cn.

Domain Name-based AAA Service Configuration Example

The following is an example of configuring the domain name-based AAA service:

```
Ruijie(config)# aaa new-model
Ruijie(config)# radius-server host 192.168.197.154
Ruijie(config)# radius-server key test
Ruijie(config)# aaa authentication dot1x default group radius
Ruijie(config)# aaa domain domain.com
Ruijie(config-aaa-domain)# authentication dot1x default
Ruijie(config-aaa-domain)# username-format without-domain
```

After the configuration, with the user a1 in the radius server, use the 802.1x client to login the server for authentication by entering the username a1@domain.com and the correct password. The following shows the related domain name information:

```
Ruijie#show aaa domain domain.com

=============Domain domain.com=============
State: Active
Username format: Without-domain
Access limit: No limit
802.1X Access statistic: 0

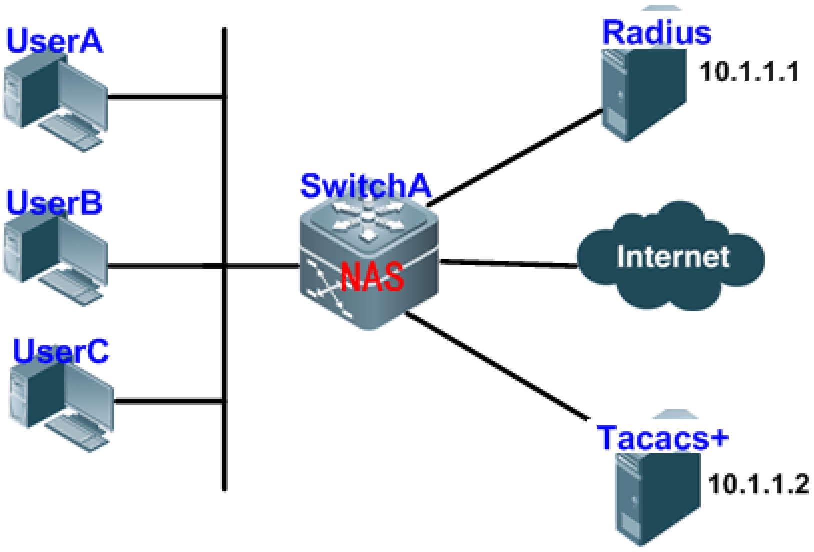
Selected method list:
 authentication dot1x default
```

Typical AAA Configuration Example

Typical AAA Aplication

Network Topology

Figure 33 Typical AAA Application Topology



Network Requirements

According to Figure 3, the following requirements must be met for better NAS security management:

62) The administrators shall have their own usernames and passwords, facilitating account management and preventing account leakage.

63) The user authentication methods are divided into local authentication and collection authentication. The method of combining the collection-authentication with the local-authentication shall be adopted, with the collection-authentication mainly-used and the local-authentication as backup. In the process of the collection-authentication, the Radius server authentication shall be passed first, if there is no reply, it will switch to the local authentication.

64) Different users can be configured to access the specified network device during the authentication.

65) Role-based management: Network management users are divided into the superusers and common users. Superusers have rights to query and configure the NAS, while common users only have limited query rights.

66) The user authentication information, the authorization information and the network information are recorded in the server for subsequent query and audit. (This example uses TACACS+ for accounting.)

Configuration Key-points

From the analysis of the part of "*Network Requirements*", deploying the AAA function can address the preceding requirements, which is to dynamically configure the ID authentication, authorization and accounting type for the user (line) or the server. Define the ID authentication, authorization and accounting type by creating the method list, and apply the method list to the specified service or interface. For details, see the "Configuration Steps" section.

Configuration Steps

#Enable AAA:

! Enable the AAA function on the device

```
Ruijie#configure terminal
Ruijie(config)#aaa new-model
```

# Configure the security server:

The security server provides the AAA services. Software of the server can record, calculate and analyze the various information in the form of logs.

! Configure the RADIUS server information (the shared key for the communication between the device and the RADIUS server is **ruijie**)

```
Ruijie(config)#radius-server host 10.1.1.1
Ruijie(config)#radius-server key ruijie
```

! Configure TACACS+ server information (the shared key for the communication between the device and the Tacacs+ server is **redgiant**)

```
Ruijie(config)#tacacs-server host 10.1.1.2
Ruijie(config)#tacacs-server key redgiant
```

# Configure the local user:

! Configure password encryption (the key information for the local password and the security server are saved and displayed in the simply-encrypted format).

```
Ruijie(config)#service password-encryption
```

! Configure the local user database (Configure the username and the password, and set the user privilege level).

```
Ruijie(config)#username bank privilege 10 password yinhang
Ruijie(config)#username super privilege 15 password star
Ruijie(config)#username normal privilege 2 password normal
Ruijie(config)#username test privilege 1 password test
```

! Configure the local enable password for the local Enable authentication.

```
Ruijie(config)#enable secret w
```

! Configure the line login password (It does not work when the AAA function is enabled. So the line login password configuration is to prevent the login failure with the AAA function disabled).

```
Ruijie(config)#line vty 0 15
Ruijie(config-line)#password w
```

! Configure the line user privilege level (with the Exec authorization disabled, or no Exec authorization method list is applied in the line and no default Exec authorization method list, the configure line user privilege level should be used).

```
Ruijie(config)#line vty 0 15
Ruijie(config-line)#privilege level 10
```

# Configure the authentication

1. Login authentication

The Login authentication is used to control the user access. There are two methods to define the authentication method list: 1) Radius; 2) Local.

! Configure login authentication method list and apply it to the corresponding line

```
Ruijie(config)# aaa authentication login hello group radius local
Ruijie(config)# line vty 0 15
Ruijie(config-line)# login authentication hello
```

To prevent the user from using the exhaust algorithm to crack the password during the Login authentication, AAA is used to limit the user Login attempts. When the the number of authentication attempts reaches the configured limit, the user is locked from login in a period (by default, three login authentication attempts are allowed and the lockout time is 15 hours.).

! Configure the number of allowed authentication attempts to 2 and the authentication lockout time to 10 hours

```
Ruijie(config)#aaa local authentication attempts 2
Ruijie(config)#aaa local authentication lockout-time 10
```

2. Enable authentication

The Enable authentication is used to switch the user privilege level. An authentication process is needed before the user switches the privilege level to the superuser using the **enable** command. There are two methods to define the authentication method list: 1) Radius; 2) Local. The Enable authentication can only set the default method list, which will be automatically applied after the configuration.

! Configure the enable authentication method list (RADIUS, TACACS+, and Local in descending order)

```
Ruijie(config)#aaa authentication enable default group radius local
```

# Configure the authorization

1. Exec authorization

The Exec authorization is used to control the user command privilege level. For example, level 15 is assigned to the superuser, level 14 is assigned to the configuration user, level 2 is assigned to the common user. The remote Exec authorization takes precedence over the local one.

! Configure the Exec authorization method list (TACACS+ has higher priority over Local) and apply it to the line

```
Ruijie(config)#aaa authorization exec shouquan group tacacs+ local
Ruijie(config)#line vty 0 15
Ruijie(config-line)#authorization exec shouquan
```

! Configure the exec authorization for the console (by default, the Exec authorization is not for the console)

```
Ruijie(config)#aaa authorization console
```

2. Command authorization

The Command authorization is used to offer the execution privilege of the key commands only to the administrators. The Command authorization authorizes the level of the command but not that of the current user. The RADIUS protocol is not supported.

! Configure the Command authorization method list (TACACS+ has higher priority over Local) and apply it to the line.

```
Ruijie(config)#aaa authorization commands 2 abc group tacacs+ local
Ruijie(config)#line vty 0 15
Ruijie(config-line)#authorization commands 2 abc
```

# Configure the accounting

1. Exec accounting

The Exec accouting is used to send the information about a user when the user accesses and exits the server for subsequent query, statistics, and audit.

! Configure the Exec accouting method list (TACACS+ accounting) and apply it to the line.

```
Ruijie(config)#aaa accounting exec default start-stop group tacacs+
```

2. Command accounting

The Command accouting is used to send the commands of a specific level executed by the user to the server for subsequent query, statistics and the audit.

! Configure the command accounting method list (TACACS+ only) and apply it to all lines.

```
Ruijie(config)#aaa accounting commands 2 default start-stop group tacacs+
```

Configuration verification

Step 1: Use the **show running-config** command to query the current configurations:

```
Ruijie(config)#show run

Building configuration...
Current configuration : 2337 bytes

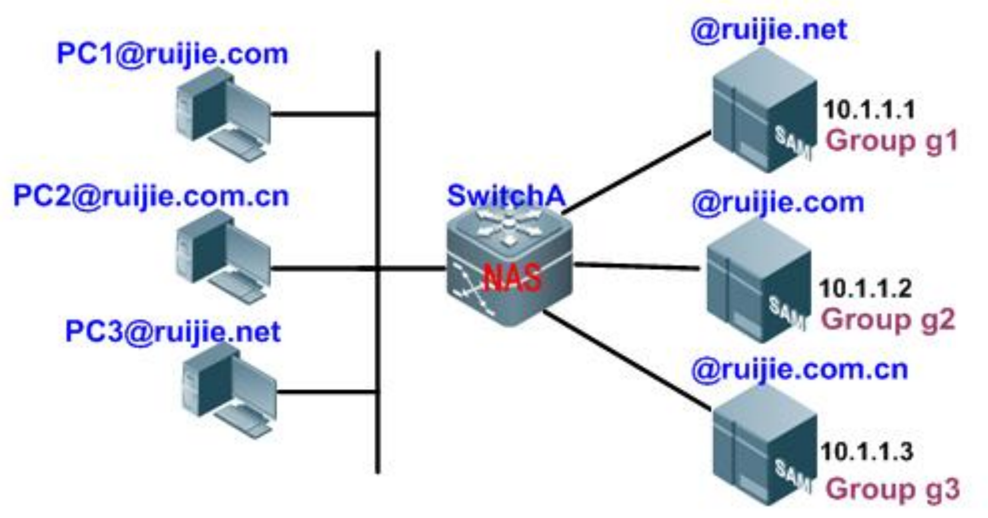
!
!
aaa new-model
aaa local authentication attempts 2
aaa local authentication lockout-time 10
!
!
!
aaa authorization exec shouquan group tacacs+ local
aaa authorization commands 2 abc group tacacs+
aaa accounting exec default start-stop group tacacs+
aaa accounting commands 2 default start-stop group tacacs+
aaa authentication login hello group radius local
aaa authentication enable default group radius local
!
!
vlan 1
!
!
username bank password 7 09361c1c2f041c4d
username bank privilege 10
username super password 7 093c011335
username super privilege 15
username normal password 7 09211a002a041e
username normal privilege 2
username test password 7 093b100133
service password-encryption
!
!
!
!
tacacs-server key 7 072c062b121b260b06
tacacs-server host 10.1.1.2
radius-server host 10.1.1.1
radius-server key 7 072c16261f1b22
enable secret 5 $1$2MjW$xr1t0s1Euvt76xs2
!
!
!
!
!
line con 0
line vty 0 4
 authorization exec shouquan
 authorization commands 2 abc
 privilege level 10
 login authentication hello
 password 7 0938
line vty 5 15
 authorization exec shouquan
 authorization commands 2 abc
 privilege level 10
 login authentication hello
 password 7 005d
!
!
end
```

Step 2: In the actual application, use the **show aaa user {** *id* **| all }** command to query the current AAA user information.

AAA Multi-domain Authentication Application

Network Topology

Figure 34 AAA multi-domain authentication topology



Network Requirements

Configure the NAS device to enable the domain name-based AAA services:

- Use the 802.1x client for the login authentication with the username PC1@ruijie.com or PC2@ruijie.com.cn or PC3@ruijie,.net and the password.
- User network management: classify the users into superusers and common users, wherein the superusers are able to read and write while the common users are able to read only.
- The user authentication, authorization and network behavior are saved in the authentication server for subsequent query and audit.

Configuration Key Points

Configure the domain name-based AAA services to address the preceding network requirements.

The following example describes how to configure AAA multi-domain authentication on a 802.1x client.

Configuration Steps

#Enable AAA:

! Enable the AAA functions on the device

```
Ruijie#configure terminal
Ruijie(config)#aaa new-model
```

# Configure the security server:

The security server provides the AAA services. The user information is stored in the server and the software of the server can record, calculate and analyze the various information in the form of logs.

! Configure the RADIUS server information (the shared key for the communication between the device and the Radius server is **ruijie**)

```
Ruijie(config)#aaa group server radius g1
Ruijie(config-gs-radius)#server 10.1.1.1
Ruijie(config-gs-radius)#exit
Ruijie(config)#aaa group server radius g2
Ruijie(config-gs-radius)#server 10.1.1.2
Ruijie(config-gs-radius)#exit
Ruijie(config)#aaa group server radius g3
Ruijie(config-gs-radius)#server 10.1.1.3
Ruijie(config-gs-radius)#exit
Ruijie(config)#radius-server key ruijie
```

# Configure the local user:

! Configure the password encryption (the key information for the local password and the security server is saved and displayed in the simply-encrypted format).

```
Ruijie(config)#service password-encryption
```

! Configure the local user database (Configure the username and the password, and set the user privilege level).

```
Ruijie(config)#username bank privilege 10 password yinhang
Ruijie(config)#username super privilege 15 password star
Ruijie(config)#username normal privilege 2 password normal
Ruijie(config)#username test privilege 1 password test
```

! Configure the local Enable password for the local Enable authentication.

```
Ruijie(config)#enable secret w
```

# Define the AAA service method list

! Configure dot1x authentication.

```
Ruijie(config)#aaa authentication dot1x renzheng group radius local
```

! Configure network authorization.

```
Ruijie(config)#aaa authorization network shouquan group radius
```

! Configure network accounting.

```
Ruijie(config)#aaa accounting network jizhang start-stop group radius
```

# Enable the domain name-based AAA services

```
Ruijie(config)#aaa domain enable
```

# Create a domain and configure the domain attribute set

! Create a domain.

```
Ruijie(config)#aaa domain ruijie.com
```

! Associate the AAA service method list

```
Ruijie(config-aaa-domain)#authentication dot1x renzheng
Ruijie(config-aaa-domain)#authorization network shouquan
Ruijie(config-aaa-domain)#accounting network jizhang
```

! Configure the domain state.

```
Ruijie(config-aaa-domain)#state active
```

! Exclude the domain name from the username.

```
Ruijie(config-aaa-domain)#username-format without-domain
!
Ruijie(config)#aaa authentication dot1x renzheng group g2
Ruijie(config)#aaa authorization network shouquan group g2

Ruijie(config)#aaa accounting network jizhang start-stop group g2
```

The configurations of the ruijie.com.cn and the ruijie.net are similar.

Configuration Verification

Step 1: Use the **show running-config** command to query the current configurations (take the domain name **ruijie.com** for example):

```
Ruijie#show run

Building configuration...
Current configuration : 2013 bytes

!
aaa new-model
aaa domain enable
!
aaa domain ruijie.com
 authentication dot1x renzheng
 accounting network jizhang
 authorization network shouquan
 username-format without-domain
!
!
aaa group server radius g1
 server 10.1.1.1
!
aaa group server radius g2
 server 10.1.1.2
!
```

```
aaa group server radius g3
 server 10.1.1.3
!
!
aaa accounting network jizhang start-stop group g2
aaa authorization network shouquan group g2
aaa authentication dot1x renzheng group g2
!
!vlan 1
!
!
no service password-encryption
!
!
radius-server key ruijie
!
!
!

Step 2: Query the domain name-based AAA service domain information:
Ruijie#show aaa domain

=============Domain ruijie.com=============
State: Active
Username format: Without-domain
Access limit: No limit
802.1X Access statistic: 0

Selected method list:
 authentication dot1x renzheng
 authorization network shouquan

               accounting network jizhang
```

Configuring RADIUS

Overview of RADIUS

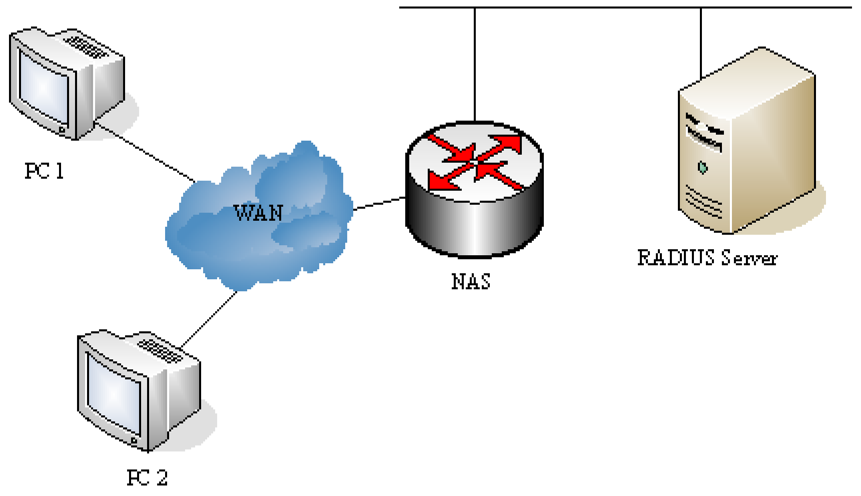
The Remote Authentication Dial-In User Service (Radius) is a distributed client/server system that works with the AAA to perform authentication for the users who are attempting to make connection and prevent unauthorized access. In the RGOS implementation, the RADIUS client runs on the router or the network access server (NAS) to send the authentication requests to the central RADIUS server. The central server stores all information of user authentication and network services.

Since RADIUS is a completely open protocol, it has become a component and been installed in such systems as Unix and Windows 2000, so it is the most popular security protocol for the time being.

The running process of RADIUS is as follows:

- Prompt the user to enter username and password.
- The username and the encrypted password are sent to the RADIUS server via the network.
- The RADIUS returns one of the following responses:
- ACCEPT: indicating that the user is authenticated.
- REJECT: indicating that the user authentication fails and the username and password must be entered again.
- CHALLENGE: indicating that the RADIUS server requests more authentication information from the user.
- The user authorization information is included in the ACCEPT response.

Figure 35 Typical RADIUS network



In addition to the authentication service, the RADIUS server also provides authorization and accounting services.

The RADIUS security protocol, also called the RADIUS method, is configured in the unit of a RADIUS server group. Every RADIUS method corresponds to a RADIUS server group which may consist of one or more RADIUS servers. For details about the RADIUS method, refer to *AAA-SCG.* If a RADIUS server group has multiple RADIUS servers, these RADIUS servers are used in polling mode till there is successful communication or all servers become unreachable.

RADIUS Configuration Tasks

To configure RADIUS on the network device, perform the following tasks first:

- Enable AAA. For the details, see *AAA-SCG*.
- Define a RADIUS authentication method list by using the **aaa authentication** command. For details about usage of the **aaa authentication** command, see the “Configuring Authentication” section.
- Apply the defined authentication method list to the specific line; otherwise the default authentication method list will be used for authentication. For more details, see the “Configuring Authentication” section.

Configuring RADIUS Protocol Parameters

Before configuring RADIUS on the network device, ensure that the RADIUS server is reachable. To configure RADIUS protocol parameters, run the following commands:

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **radius-server host** *ip-address* [**auth-port** *port*] [**acct-port** *port*]	Configures the IP address or hostname of the remote Radius security server and specifies the authentication port and accounting port.
Ruijie(config)# **radius-server key** *string*	Configures the shared key used for the communication between the device and the Radius server.
Ruijie(config)# **radius-server retransmit** *retries*	Specifies the times of sending a request before a RADIUS server is considered unreachable (3 by default).
Ruijie(config)# **radius-server timeout** *seconds*	Specifies the waiting time before the network device resends a request (5 seconds by default).

Caution

When configuring RADIUS, you must configure a RADIUS Key. Ensure that the network device and the RADIUS server use the same shared key.

Specifying Radius Authentication

This means defining the authentication method list for the Radius after the After specifying a RADIUS server and a RADIUS shared key, you must define a RADIUS authentication method list. RADIUS authentication is performed via AAA, so you need to run the **aaa authentication** command to define an authentication method list and specify the RADIUS authentication method. For more details, see *AAA-SCG*.

Specifying the Standard Radius Attribute Type

This section describes how to configure types of standard attributes. Now the RADIUS Calling-Station-ID attribute (the attribute value is 31) is supported.

Configuring Calling-Station-ID Format

The RADIUS Calling-Station-ID attribute is used to identify the NAS when the NAS is sending a request to the RADIUS server. The value of the RADIUS Calling-Station-ID is character strings, which can be in multiple formats. The MAC address for the NAS is usually used as the value of the Calling-Station-ID to solely identify the NAS. The table below describes the formats of the MAC address:

Format	Description
ietf	The standard format specified by IETF (in RFC3580). A hyphen (-) is used as the seperator, for example: 00-D0-F8-33-22-AC.
normal	Normal format of the MAC address (dotted hexadecimal format). A dot (.)is used as the seperator. For example: 00d0.f833.22ac.
unformatted	No format or seperator. By default, unformatted is used. For example: 00d0f83322ac.

To configure the format of the RADIUS Calling-Station-ID MAC-based attribute, run the following commands:

Command	Function
configure terminal	Enters global configuration mode.
radius-server attribute 31 mac format {ietf | normal | unformatted}	Configures the format of the RADIUS Calling-Station-ID MAC-based attribute. The default format is **unformatted**.

Specifying Private Radius Attribute Type

This section describes how to configure private attributes of RADIUS. By default, private RADIUS attributes are classified into Ruijie attributes and extended vendor types:

ID	Function	TYPE	Extended TYPE
1	max-down-rate	1	76
2	port-priority	2	77
3	user-ip	3	3
4	vlan-id	4	4
5	last-supplicant-version	5	5
6	net-ip	6	6
7	user-name	7	7
8	password	8	8
9	file-directory	9	9
10	file-count	10	10
11	file-name-0	11	11
12	file-name-1	12	12
13	file-name-2	13	13
14	file-name-3	14	14
15	file-name-4	15	15
16	max-up-rate	16	16
17	current-supplicant-version	17	17
18	flux-max-high32	18	18

ID	Function	TYPE	Extended TYPE
19	flux-max-low32	19	19
20	proxy-avoid	20	20
21	dailup-avoid	21	21
22	ip-privilege	22	22
23	login-privilege	42	42
26	ipv6-multicast-address	79	79
27	ipv4-multicast-address	87	87
62	sdg-type	62	62
85	sdg-zone-name	85	85
103	sdg-group-name	103	103

Note

Some private attributes are supported only by specific products. You can run the **show radius vendor-specific** command to view private attribute lists supported by products.

Two attributes cannot be configured with the same type number.

The following is an example about private attributes of network devices:

```
Ruijie# show radius vendor-specific
id   vendor-specific    type-value
----- -------------------- ----------
1   max-down-rate     76
2   port-priority     77
3   user-ip       3
4   vlan-id       4
......
Ruijie# configure
Ruijie(config)# radius attribute 4 vendor-type 67
Ruijie(config)# show radius vendor-specific
id   vendor-specific    type-value
----- -------------------- ----------
1   max-down-rate     76
2   port-priority     77
3   user-ip       3
4   vlan-id       67
......

Ruijie(config)#
```

Configuring RADIUS Server Reachability Detection

The device maintains the reachability state of each RADIUS server configured: reachable or unreachable. The device does not send authentication, authorization and accounting requests of users to an unreachable RADIUS server, unless all RADIUS servers in the RADIUS server group are unreachable.

The device can carry out proactive detection of the specified RADIUS server, and this feature is disabled by default. If you enable proactive detection of the specified RADIUS server, the device will periodically send detection requests (authentication requests or accounting requests) to the RADIUS server at an interval of:

- 60 minutes (the default value) for reachable RADIUS servers
- 1 minute (a constant value) for unreachable RADIUS servers

Note

To enable proactive detection of the specified RADIUS server, the following conditions must be met:

1. The test user name for this RADIUS server has been configured on the device.
2. At least one tested port of this RADIUS server (authentication port or accounting port) has been configured on the device.

For a reachable RADIUS server, the device will consider this RADIUS server unreachable if the following two conditions are met:

1. The time configured by using the **radius-server dead-criteria time** *seconds* command has elapsed since the receipt of the last correct response from the RADIUS server.
2. After the receipt of the last correct response from the RADIUS server, the number of requests (including retransmitted requests) without a response reaches the value configured by using the **radius-server dead-criteria tries** *number* command.

For an unreachable RADIUS server, the device will consider this RADIUS server reachable if any of the following conditions is met:

67) A correct response is received from this RADIUS server.
68) The duration that this RADIUS server remains unreachable exceeds the time set by using the **radius-server deadtime** command, and proactive detection of this RADIUS server is not enabled.
69) The authentication port or accounting port of this RADIUS server is updated on the device.

RADIUS server reachability detection allows the user to judge whether a RADIUS server is unreachable and to configure proactive detection.

To configure RADIUS server reachability detection, run the following commands in global configuration mode:

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **radius-server dead-criteria time** *seconds* **tries** *number*	Configures global criteria for judging whether a RADIUS server is reachable. The default value of *seconds* is **60**, and the default value of *number* is **10**.
Ruijie(config)# **radius-server deadtime** *minutes*	Configures the duration for the device to stop sending request packets to the RADIUS server in unreachable state (default value: 0 minutes).

Command	Function
Ruijie(config)# **radius-server host** *ip-address* [**auth-port** *port*] [**acct-port** *port*] [**test username** *name* [**idle-time** *time*] [**ignore-auth-port**] [**ignore-acct-port**]]	Configures the IP address of a remote RADIUS server, specifies the authentication port and accounting port, and specify relevant parameters of proactive detection (testing user name, interval for proactive detection of reachable RADIUS servers, and whether the authentication port or the accounting port shall be neglected).

Caution

In the configuration, a special testing user name shall be used. This user name cannot be used by other authorized users, avoiding adverse impact on authentication, authorization or accounting of these users.

Monitoring RADIUS

To monitor RADIUS, run the following command in privileged user mode:

Command	Function
debug radius { **event** | **detail** }	Turns on the Radius debug switch to view the Radius debug information.

Radius Configuration Example

In a typical Radius network configuration diagram, the RADIUS server performs authentication for the users who are attempting to access, enables the accounting function for these users and records the network service usage of them.

Note

The RADIUS server can be a component that comes with the Windows 2000/2003 server (IAS) or the Unix system, or special certified server software of some manufacturers.

The following example shows how to configure the Radius on the network device:

```
Ruijie# configure terminal
Ruijie(config)# aaa new-model

RADIUS IPv6 Configuration Example

In the typical RADIUS network configuration diagram, the RADIUS server performs authentication and accounting of users, and records the network service service usage of them.

Note

The RADIUS server is deployed on a Windows 2008 Server or special IPv6 capable server software certified by manufacturers.

The following example shows how to configure RADIUS on the network device:

```
Ruijie# configure terminal
Ruijie(config)# aaa new-model
Ruijie(config)# radius-server host 3000::100 auth-port 1645 acct-port 1646
Ruijie(config)# radius-server key aaa
Ruijie(config)# aaa authentication login test group radius
Ruijie(config)# end
Ruijie# show radius server
Server IP:   3000::100
Accounting Port: 1646
Authen Port:  1645
Test Username:  <Not Configured>
Test Idle Time:  60 Minutes
Test Ports:   Authen and Accounting
Server State:  Active
    Current duration 765s, previous duration 0s
  Dead: total time 0s, count 0
  Statistics:
   Authen: request 15, timeouts 1
   Author: request 0, timeouts 0
   Account: request 0, timeouts 0

Ruijie# configure terminal
Ruijie(config)# line vty 0
Ruijie(config-line)# login authentication test
Ruijie(config-line)# end
Ruijie# show running-config

Configuring TACACS+

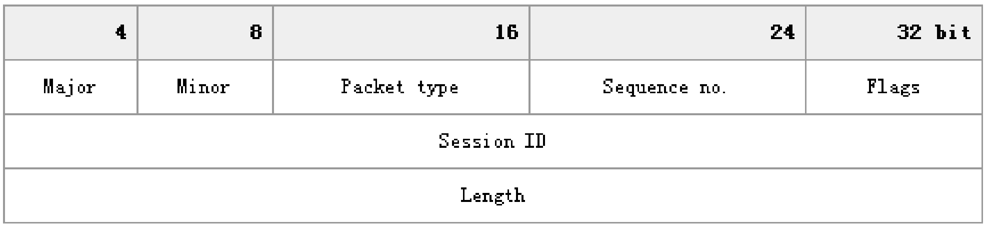
Overview of TACACS+

TACACS+ is an enhancement of Terminal Access Controller Access Control System (TACACS) defined in RFC 1492. It implements authentication, authorization, and accounting (AAA) functions on multiple types of users by communicating with the TACACS server in client-server mode. Before using the TACACS+ server, you need to configure the related functions of the TACACS+ server.

TACACS+ supports user authentication, authorization and accounting. That is, one server is used for authentication, one for authorization, and another for accounting, which proceed concurrently. Each server has its own user data for authentication, authorization, and accounting.

The following table shows the format of a TACACS+ packet:

Figure 36



4	8	16	24	32 bit
Major	Minor	Packet type	Sequence no.	Flags
Session ID				
Length				

- Major Version —TACACS+ Version;
- Minor Version —TACACS+ release;
- Packet Type — Its values are as follows:
  TAC_PLUS_AUTHEN: = 0x01 (Authentication);
  TAC_PLUS_AUTHOR:= 0x02 (Authorization);
  TAC_PLUS_ACCT:= 0x03 (Accounting).
- Sequence Number — packet sequence number in the current session. The sequence number of the first TACACS+ packet in a session must be 1 and those of subsequent packet increment by one. Therefore, the client sends only the packet with an odd sequence number, while TACACS+ Daemon only sends only the packet with an even sequence number.
- Flags — This field includes flags with various bitmap formats. The Flag value indicates whether a packet is encrypted or not.
- Session ID — ID in a TACACS+ session.
- Length —body length of a TACACS+ packet (excluding the header). All the packets are transmitted in the network after being encrypted.

TACACS+ Application

Typically, TACACS+ is used to manage and control the login of terminal users. Network devices work as TACACS+ clients to send user names and passwords to the TACACS+ server for authentication. After authentication and authorization, you can log in to the switch for operation, as shown in Figure 2:

Figure 37

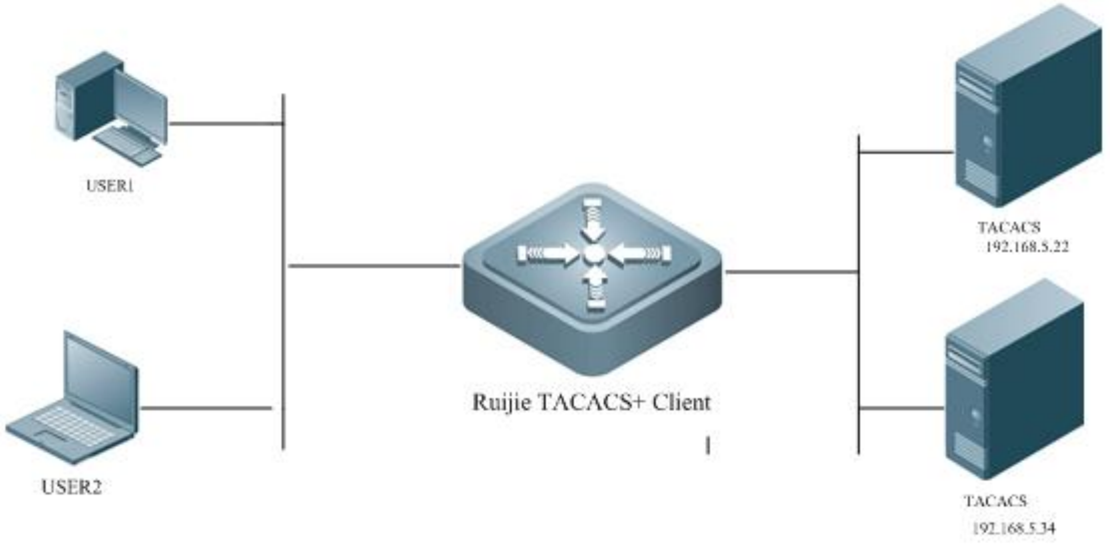


Figure describes the exchange of TACACS+ packets during AAA implementation in a login attempt.

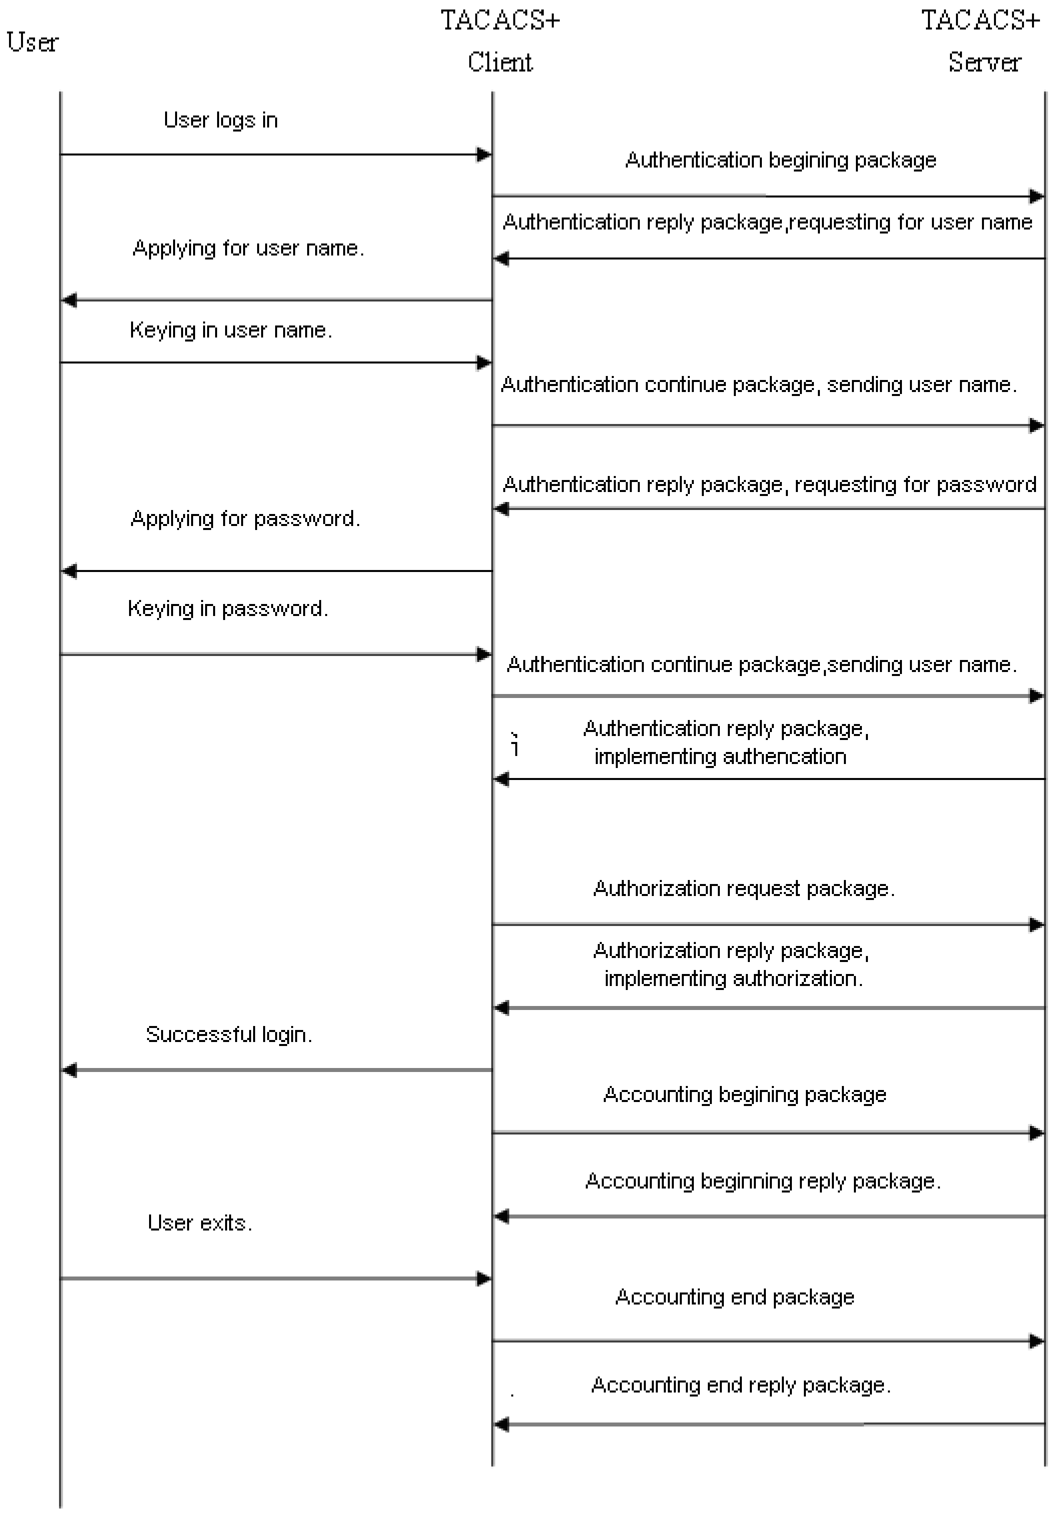
Figure 38



User
TACACS+ Client
TACACS+ Server
User logs in
Authentication begining package
Authentication reply package,requesting for user name
Applying for user name.
Keying in user name.
Authentication continue package, sending user name.
Authentication reply package, requesting for password
Applying for password.
Keying in password.
Authentication continue package,sending user name.
Authentication reply package, implementing authencation
Authorization request package.
Authorization reply package, implementing authorization.
Successful login.
Accounting begining package
Accounting beginning reply package.
User exits.
Accounting end package
Accounting end reply package.

The whole process is divided into three parts:

Authentication:

70) A user sends a login request to the network device;

71) After receiving the request, the TACACS+ client sends a authentication start message to the TACACS+ server;

72) The TACACS+ server sends an authentication reply message, requesting the user name;
73) The TACACS+ client asks the user for the user name.
74) The user enters the login user name;
75) After receiving the user name, the TACACS+ client sends an authentication continue message containing the user name to the TACACS+ server;
76) The TACACS+ server sends an authentication reply message, requesting the login password;
77) The TACACS+ client receives the login password;
78) The user enters the login password;
79) After receiving the login password, the TACACS+ client sends an authentication continue message containing the login password to the TACACS+ server;
80) The TACACS+ server sends an authentication reply message, indicating that the user has been authenticated.

Authorization:

81) The TACACS+ client sends an authorization request message to the TACACS+ server.
82) The TACACS+ server sends an authorization reply message, indicating that the user has been authenticated;
83) The TACACS+ client receives a successful authorization reply message, displaying the interface for configuring the network device.

Accounting:

84) The TACACS+ client sends an accounting start message to the TACACS+ server;
85) The TACACS+ server sends an accounting reply message, indicating that it has received the accounting start message;
86) The user exits;
87) The TACACS+ Client sends an accounting end message to the TACACS+ server;
88) The TACACS+ server sends an accounting end reply message, indicating that it has received the accounting end message.

TACACS+ Configuration Task

The following tasks must be executed before you configure TACACS+ on the network device:

- Use the **aaa new-mode** command to enable AAA. Before using TACACS+, you must enable AAA. For usage of the **aaa new-mode** command, see the “AAA Overview” chapter in *AAA-SCG*.
- Use the **tacacs-server host** command to configure one or multiple TACACS+ servers.
- Use the **tacacs-server key** command to specify the key shared by the server and the network device.
- Use the **tacacs-server timeout** command to specify the timeout time for waiting a reply from the server;
- If authentication is required, use the **aaa authentication** command to define a TACACS+ authentication method list. For details, see the “Configuring Authentication” section in *AAA-SCG*.
- If authorization is required, use the **aaa authorization** command to define a TACACS+ authorization method list. For details, see the “Configuring Authorization” section in *AAA-SCG*.
- If accounting is required, use the **aaa accounting** command to define a TACACS+ accounting method list. For details, see the “Configuring Accounting” section in *AAA-SCG*.
- Apply a specific authentication method list to a specific line. Otherwise, a default method list is used.

Configuring TACACS+ Parameters

Before configuring TACACS+ on a network device, ensure that communication with the TACACS+ server is proper. To configure TACACS+ parameters, run the following commands:

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **tacacs-server host** {*ip-address* | *ipv6-address*} [**port** *integer*] [**timeout** *integer*] [**key** *string*]	Configures the IP address of the remote TACACS+ security server. Different combinations of parameters are used to build parameters of the server. *ip-address*: IP address of the server; *ipv6-address:* IPv6 address of the server; port *intege* [optional]:port used by the server. By default, port 49 is used. The value ranges from 1 to 65535. timeout *integer* [optional]: response timeout time of the server. By default, the timeout time is 5s. The value ranges from 1 to 1000 (in seconds). key *string* [optional]: key shared with the server with the corresponding server.
Ruijie(config)# **tacacs-server key** *string*	Configures the shared key used for communication between the network device and the TACACS+ server. When the corresponding server does not have an independent key, the global configuration is used.
Ruijie(config)# **tacacs-server timeout** *seconds*	Configures the wait time before the network device retransmits a request. It is 5s by default. If no timeout time is specified for a host, the host uses the global configuration.
Ruijie(config)# **ip tacacs source-interface** *interface*	Configures the source IP address used to send a TACACS+ request to the server. By default, the source IP address is not specified.
Ruijie(config)# **aaa group server tacacs+** *group-name*	Configures TACACS+ server groups. Different TACACS+ servers are divided into different groups.
Ruijie(config-gs-tacacs)# **server** {*ip-address* | *ipv6-address*}	Configures IP addresses of servers in a TACACS+ server group.
Ruijie(config-gs-tacacs)# **ip vrf forwarding** *vrf-name*	Configures the VRF instance name used by a TACACS+ server group. This command is available on VRF-capable hosts.

⚠ Caution

When configuring TACACS+, you must configure the TACACS+ key. The network device and the TACACS+ server must use the same shared key.

The **tacacs-server timeout** is affected by **ip tcp syntime-out,** the real valid timeout value is that of the smaller one between the two.

Using TACACS+ for Implementing AAA Functions

In a typical TACACS+ network, the TACACS+ server implements AAA functions on users. The following example shows how AAA functions are implemented through TACACS+.

Using TACACS+ for Login Authentication

- Enables AAA:

```
Ruijie# configure terminal
Ruijie(config)# aaa new-model
```

- Configures TACACS+ server information:

```
Ruijie(config)# tacacs-server host 192.168.12.219
Ruijie(config)# tacacs-server key aaa
```

- Configures TACACS+ authentication methods:

```
Ruijie(config)# aaa authentication login test group tacacs+
```

- Applies the authentication method to the interface:

```
Ruijie(config)# line vty 0 4
Ruijie (config-line)# login authentication test
```

Through the above configuration, TACACS+ login authentication is implemented. The configuration is as follows:

```
Ruijie#show running-config
!
aaa new-model
!
aaa authentication login test group tacacs+
!
tacacs-server host 192.168.12.219
tacacs-server key aaa
!
line con 0
line vty 0 4
login authentication test
!
```

Using TACACS+ for Enable Authentication

89) Enables AAA:

```
Ruijie# configure terminal
Ruijie(config)# aaa new-model
```

90) Configures TACACS+ server information:

```
Ruijie(config)# tacacs-server host 192.168.12.219
Ruijie(config)# tacacs-server host 192.168.12.218
Ruijie(config)# tacacs-server host 192.168.12.217
Ruijie(config)# tacacs-server key aaa
```

Configures that some servers in a TACACS+ server group are used:

```
Ruijie(config)# aaa group server tacacs+ tacgroup1
Ruijie(config-gs-tacacs)# server 192.168.12.219
Ruijie(config-gs-tacacs)# server 192.168.12.218
```

91) Configures to use authentication methods of TACACS+ server group 1:

```
Ruijie(config)# aaa authentication enable default group tacgroup1
```

Through the above configuration, TACACS+ Enable authentication is implemented on some servers. The configuration is as follows:

```
Ruijie#show running-config
!
aaa new-model
!
!
aaa group server tacacs+ tacgroup1
server 192.168.12.219
server 192.168.12.218
!
aaa authentication enable default group tacgroup1
!
!
tacacs-server host 192.168.12.219
tacacs-server host 192.168.12.218
tacacs-server host 192.168.12.217
tacacs-server key aaa
!
line con 0
line vty 0 4
!
```

Using TACACS+ for Login Authorization

92) Enables AAA:

```
Ruijie# configure terminal
Ruijie(config)# aaa new-model
```

93) Configures TACACS+ server information:

```
Ruijie(config)# tacacs-server host 192.168.12.219
Ruijie(config)# tacacs-server key aaa
```

94) Configures the authorization method of using tacacs+:

```
Ruijie(config)# aaa authorization exec test group tacacs+
```

95) Applies the authorization method to the interface:

```
Ruijie(config)# line vty 0 4
Ruijie (config-line)# authorization exec test
```

Through the above configuration, TACACS+ Enable authorization is implemented. The configuration is as follows:

```
Ruijie#show running-config
!
```

```
aaa new-model
!
!
aaa authorization exec test group tacacs+
!
tacacs-server host 192.168.12.219
tacacs-server key aaa
!
line con 0
line vty 0 4
authorization exec test
!
```

Using TACACS+ for Level 15 Command Audit

- Enables AAA:

```
Ruijie# configure terminal
Ruijie(config)# aaa new-model
```

- Configures TACACS+ server information:

```
Ruijie(config)# tacacs-server host 192.168.12.219
Ruijie(config)# tacacs-server key aaa
```

- Configures to use the accounting method of TACACS+:

```
Ruijie(config)# aaa accounting commands 15 test start-stop group tacacs+
```

- Applies the accounting method to the interface:

```
Ruijie(config)# line vty 0 4
Ruijie (config-line)# accounting commands 15 test
```

Through the above configuration, TACACS+ Enable accounting is implemented. The configuration is as follows:

```
Ruijie# show running-config
!
aaa new-model
!
!
aaa accounting commands 15 default group tacacs+
!
!
tacacs-server host 192.168.12.219
tacacs-server key aaa
!
line con 0
line vty 0 4
accounting commands 15 test
!
```

Configuring NAT

NAT Overview

Before Network Address Translation (NAT) configuration, it is necessary to understand the allocation of internal local addresses and internal global addresses. Perform the following configuration tasks according to different requirements.

Configuring Static NAT for Internal Source Addresses

To enable an internal network to communicate with an external network, you need to configure NAT to translate internal private IP addresses into a globally unique IP address. In this case, you can choose to configure static NAT or dynamic NAT or even both of them.

Static NAT is to establish a one-to-one permanent mapping between internal local addresses and internal global addresses. It is necessary when an external network uses a fixed global address to access hosts on an internal network. To configure static NAT, run the following commands in global configuration mode:

Command	Function
Ruijie(config)# **ip nat inside source static** *local-address global-address* [**permit-inside**] [**vrf** vrf_*name*]	Defines the static translation relationship of internal source addresses.
Ruijie(config)# **interface** *interface-type interface-number*	Enters interface configuration mode.
Ruijie(config-if)# **ip nat inside**	Defines the internal network the interface connects to.
Ruijie(config)# **interface** *interface-type interface-number*	Enters interface configuration mode.
Ruijie(config-if)# **ip nat outside**	Defines the external network the interface connects to.

The above configuration is the simplest one. You may configure several inside and outside interfaces.

Dynamic NAT is to establish a temporary mapping between internal local addresses and the internal global address pool, which will be deleted after a while. To configure dynamic NAT, run the following commands in global configuration mode:

Command	Function
Ruijie(config)# **ip nat pool** *address-pool start-address end-address* {**netmask** *mask* | **prefix-length** *prefix-length*}	Defines a global IP address pool.
Ruijie(config)# **access-list** *access-list-number* **permit** *ip-address wildcard*	Defines an ACL. Only the IP addresses that match the ACL are translated.
Ruijie(config)# **ip nat inside source list** *access-list-number* **pool** *address-pool* [**vrf** vrf_*name*]	Defines the dynamic translation relationship of internal source addresses.
Ruijie(config)# **interface** *interface-type interface-number*	Enters interface configuration mode.

Command	Function
Ruijie(config-if)# **ip nat inside**	Defines the internal network the interface connects to.
Ruijie(config)# **interface** *interface-type interface-number*	Enters interface configuration mode.
Ruijie(config-if)# **ip nat outside**	Defines the external network the interface connects to.

Note

Only source addresses that match the ACL are translated. Note that the last rule of the ACL contains a deny any statement. The ACL should not permit a wide range of IP addresses to be translated; otherwise, unexpected results will be received.

Configuring NAPT for Internal Source Addresses

Traditional NAT generally defines a one-to-one mapping and cannot enable all hosts on an internal network to communicate with an external network. NAPT allows multiple internal local addresses to be mapped to an internal global address.

NAPT is classified into static NAPT and dynamic NAPT. Static NAPT maps the designated port of a designated internal host to a designated global port, whereas static NAT maps an internal address to a global address.

To configure static NAPT, run the following commands in global configuration mode:

Command	Function
Ruijie(config)# **ip nat inside source static** {**UDP | TCP**} *local-address port global-address port* [**permit-inside**] [**vrf** vrf_*name*]	Defines the static translation relationship of internal source addresses.
Ruijie(config)# **interface** *interface-type interface-number*	Enters interface configuration mode.
Ruijie(config-if)# **ip nat inside**	Defines the internal network the interface connects to.
Ruijie(config)# **interface** *interface-type interface-number*	Enters interface configuration mode.
Ruijie(config-if)# **ip nat outside**	Defines the external network the interface connects to

Dynamic internal source address translation mentioned in previous section has automatically completed the internal source address dynamic NAPT and the configuration is to run the following command in global configuration mode.

Command	Function
Ruijie(config)# **ip nat pool** *address-pool start-address end-address* {**netmask** *mask* | **prefix-length** *prefix-length*}	Defines a global IP address pool. For NAPT, only one IP address is defined.
Ruijie(config)# **access-list** *ccess-list-number* **permit** *ip-address* **wildcard**	Defines an ACL. Only the IP addresses that match the ACL are translated.

Command	Function
Ruijie(config)# **ip nat inside source list** *access-list-number* {[**pool** *address-pool*] | [**interface** *interface-type interface-number*]} **overload** [**vrf** vrf*_name*]	Defines the dynamic translation relationship of source address. The translation effect is the same with or without overload, which is only for compatibility with mainstream manufacturers.
Ruijie(config)# **interface** *interface-type interface-number*	Enters interface configuration mode.
Ruijie(config-if)# **ip nat inside**	Defines the internal network the interface connects to.
Ruijie(config)# **interface** *interface-type interface-number*	Enters interface configuration mode.
Ruijie(config-if)# **ip nat outside**	Defines the external network the interface connects to.

NAPT may use the IP addresses in the address pool or directly uses the IP address of the interface. Generally, one address is enough to meet the address translation need of a network and can be translated into up to 64,512 addresses. In case of insufficient addresses, you can add IP addresses to the address pool.

Configuring NAT Overlap

Address Overlapping refers to the fact that two private networks in need of interconnection are allocated the same IP address or one private network and public network are allocated the same global IP address. Communication is impossible between two network hosts with overlapping addresses since they deem their counterparts are in the local network. NAT overlap is configured to solve this problem by presenting the address of external network host as that of another network host and vice versa.

NAT Overlap configuration is actually divided into two parts: 1) Internal source address translation configuration; and 2) External source address translation configuration, which is only needed by an external network that has addresses overlapped with the inner network. Static NAT or dynamic NAT may be adopted for external source address translation.

To configure static NAT for external source addresses, run the following command in global configuration mode:

Command	Function
Ruijie(config)# **ip nat outside source static** *global-address local-address* [vrf vrf*_name*]	Defines the static translation relationship of external source addresses.
Ruijie(config)# **interface** *interface-type interface-number*	Enters interface configuration mode.
Ruijie(config-if)# **ip nat inside**	Defines the internal network the interface connects to.
Ruijie(config)# **interface** *interface-type interface-number*	Enters interface configuration mode.
Ruijie(config-if)# **ip nat outside**	Defines the external network the interface connects to.

☑ NPE80 does not support NAT overlap.

Configuring TCP Load Balancing

When TCP traffic overload is detected on an internal host, more hosts can be deployed to balance the TCP traffic. In this case, you may use NAT for TCP traffic load balancing. NAT creates a virtual host, which corresponds to several real hosts, to provide TCP services, so that destination addresses are polled for load balancing. To configure destination address polling, run the following commands in global configuration mode:

Command	**Function**
Ruijie(config)# **ip nat pool** *address-pool start-address end-address* {**netmask** *mask* | **prefix-length** *prefix-length*}	Defines an IP address pool. The IP addresses of all real hosts are included in the pool.
Ruijie(config)# **access-list** *access-list-number permit ip-address* **wildcard**	Defines an ACL to match the IP address of a virtual host. The ACL should be an extended ACL used to match destination IP addresses.
Ruijie(config)# **ip nat inside destination list** *access-list-number* **pool** *address-pool* [**vrf** vrf*_name*]	Defines the dynamic translation relationship of internal destination addresses.
Ruijie(config)# **interface** *interface-type* *interface-number*	Enters interface configuration mode.
Ruijie(config-if)# **ip nat inside**	Defines the internal network the interface connects to.
Ruijie(config)# **interface** *interface-type interface-number*	Enters interface configuration mode.
Ruijie(config-if)# **ip nat outside**	Defines the external network the interface connects to.

☑ NPE80 does not support TCP load balancing.

Configuring Special Protocol Gateway

The special protocol gateways are all enabled by default. You can disable a specific special protocol gateway by running a command. All of the special protocols are just switch commands except the File Transfer Protocol (FTP) and DNS protocol, which carry parameters. Run the following commands in global configuration mode:

Command	**Function**
Ruijie(config)# **no ip nat translation ftp**	Disables the FTP gateway.
Ruijie(config)# **ip nat translation ftp**	Enables the FTP gateway. The default port is Port 21.
Ruijie(config)# **ip nat translation ftp 2121**	Enables the FTP gateway and designates Port 2121.

Configuring NAT Static Port Range Mapping

The network address translation (NAT) function can map a TCP/UDP port to an IP address one to one. However, if a continuous range of ports of the internal hosts need to be mapped to an external network, configure the NAT static port range mapping function to map the ports in the range. The port range is 1–65535.

Command	**Function**

Ruijie(config)# **ip nat inside source static** {**UDP** | **TCP**} *local-address global-address* **port-range** *min-port max-port* { [**permit**-**inside**] | [**vrf** vrf_*name*] | [**match** *interface-type interface-number*] }	Defines the static translation relationship of the internal source addresses, for mapping the IP address of an external network.
Ruijie(config)# **ip nat inside source static** {**UDP** | **TCP**} *local-address* **interface** *interface-type interface-number* **port-range** *min-port max-port* [**vrf** vrf_*name*]	Defines the static translation relationship of the internal source addresses, for mapping the interface address of an external network.
Ruijie(config)# **interface** *interface-type interface-number*	Enters the interface configuration mode.
Ruijie(config-if)# **ip nat inside**	Defines the interface for connecting to the internal network.
Ruijie(config)# **interface** *interface-type interface-number*	Enters the interface configuration mode.
Ruijie(config-if)# **ip nat outside**	Defines the interface for connecting to the external network.

Configuring ARP Response Function of NAT

In the VRRP dual-node hot backup scenario, if the same NAT function is configured on both the master and slave devices, when the router initiates an ARP request, both devices receive the ARP request and return an ARP response, causing an ARP conflict. Therefore, the slave device does not respond to the ARP request by default. If NAT configurations on the master and slave devices are different, sometimes the slave device needs to respond to the ARP request. In this case, you can run the ip nat arp reply command, so that the slave device returns a response packet when receiving an ARP request. You can run the no form of this command so that the slave device dose not return a response packet when receiving an ARP request. Run the following commands in global configuration mode:

Command	**Function**
Ruijie(config)# **ip nat arp reply**	Enables the ARP response function of NAT on the slave device.
Ruijie(config)# **no ip nat arp reply**	Disables the ARP response function of NAT on the slave device.

Configuring NAT Keepalive Function

The NAT keepalive function periodically sends ARP requests destined for the addresses in the NAT address pool to verify that the addresses exist. You can run the ip nat keepalive command to enable the keepalive function, or run the no form of this command to send no ARP request packets. The keepalive interval ranges from 1 to 86400 seconds. Run the following commands in global configuration mode:

Command	Function
Ruijie(config)# **no ip nat keepalive**	Disables the NAT keepalive function.
Ruijie(config)# **ip nat keepalive** *interval-num*	Enables the NAT keepalive function.

NAT Configuration Examples

Dynamic translation of internal source addresses

In the following configuration, local and global addresses are allocated from the NAT address pool of Net200, which defines the address range from 200.168.12.2 to 200.168.12.100. A NAT entry is created only when a packet whose internal source address matches ACL 1.

```
!
interface FastEthernet 0/0
ip address 192.168.12.1 255.255.255.0
ip nat inside
!
interface FastEthernet 1/0
ip address 200.168.12.1 255.255.255.0
ip nat outside
!
ip nat pool net200 200.168.12.2 200.168.12.100 netmask 255.255.255.0
ip nat inside source list 1 pool net200
!
access-list 1 permit 192.168.12.0 0.0.0.255
```

Reuse of internal global addresses

Reuse of internal global address is equivalent to NAPT actually. RGOS 8.1 and later versions automatically implement NAPT for dynamic NAT. In the following configuration, local and global addresses are allocated from NAT address pool—Net200, which only defines one IP address 200.168.12.200 that can be reused. A NAT entry is created only when a packet whose internal source address matches ACL 1.

```
!
interface FastEthernet 0/0
ip address 192.168.12.1 255.255.255.0
ip nat inside
```

```
!
interface FastEthernet 1/0
ip address 200.168.12.200 255.255.255.0
ip nat outside
!
ip nat pool net200 200.168.12.200 200.168.12.200 netmask 255.255.255.0

```

Static NAPT for Internal Source Addresses

Static NAPT may be used for creating a virtual server.Creating a virtual server here refers to setting up a server and mapping it to an external network through static NAPT. Thus, access to the virtual server with a global address is diverted to an internal server.

The following example describes how to map IP address 192.168.12.3 of an internal web server to a global IP address 200.198.12.1 of port 80. The configuration script is as follows:

```
!
interface FastEthernet 0/0
ip address 192.168.12.1 255.255.255.0
ip nat inside
!
interface FastEthernet 1/0
ip address 200.198.12.1 255.255.255.0
ip nat outside
!
ip nat inside source static tcp 192.168.12.3 80 200.198.12.1 80
```

For details, see the “Configuring a local server” section.

TCP Load Balancing

A virtual host address is defined in the following configuration so that all TCP connections to this virtual host from external networks will be processed by multiple real hosts for load balancing. **Realhosts** defines a real host address pool, while ACL 1 defines the IP address of the virtual host. Traffic from hosts on an external network must be routed to this virtual host. The following configuration applies only to TCP traffic. Note that an extended ACL must be configured to match destination IP addresses.

```
!
interface FastEthernet 0/0
ip address 10.10.10.1 255.255.255.0
ip nat inside
```

```
!
interface FastEthernet 1/0
ip address 200.198.12.1 255.255.255.0
ip nat outside
!
ip nat pool realhosts 10.10.10.2 10.10.10.3 netmask 255.255.255.0 type rotary
ip nat inside destination list 100 pool realhosts
!
access-list 100 permit ip any host 10.10.10.100
!
```

Whether correct NAT entries can be created can be checked by looking up the NAT mapping table.

```
Ruijie# sh ip nat translations
Pro Inside global Inside local Outside local   Outside global
tcp 10.10.10.100:23 10.10.10.2:23 100.100.100.100:1178 100.100.100.100:1178
tcp 10.10.10.100:23 10.10.10.3:23 200.200.200.200:1024 200.200.200.200:1024
```

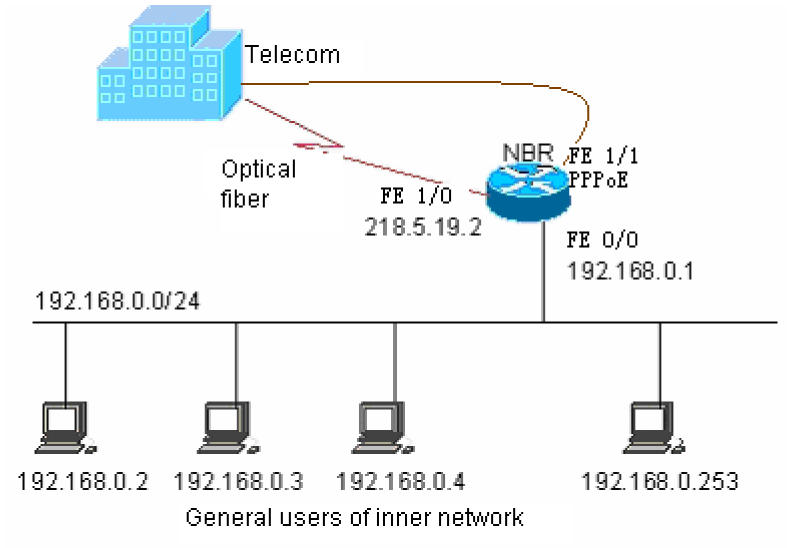
Load balancing among multiple outside interfaces

If several WAN ports of a device are used as outside interfaces, load is balanced among these WAN ports by bandwidth. When one WAN port is faulty, the load will be automatically routed to other normal ports. By default, the load is distributed according to global destination addresses of NAT. In the following example, load is balanced between two WAN ports of a RSR series router.

96) Interface GigabitEthernet 0/0 connects to a telecom network.
97) Interface GigabitEthernet 0/1 connects to the education network.

The topology is as follows:

Figure 39



The configuration is as follows:

```
!
```

# Configure an ACL to allow internal network users to access internet.

```
access-list 99 permit 192.168.0.0 0.0.0.255
```

# Configure GigabitEthernet 0/2 to connect to the internal network..

```
interface GigabitEthernet 0/2
ip nat inside
ip address 10.29.0.253 255.255.255.0
!
```

# Configure a static IP address for WAN port 0 which connects to the telecom network.

```
interface GigabitEthernet 0/0
ip nat outside
ip address 218.4.53.238 255.255.255.0
!
```

# WAN port 1 connects to the education network.

```
interface GigabitEthernet 0/1
ip nat outside
ip address 172.16.253.18 255.255.255.0
!
```

# Configure a NAT address pool. NAT provides multiple Outside ports. If GigabitEthernet 0/0 is configured as the Outside port, the IP address of the port is set to 218.4.53.238; if GigabitEthernet 0/1 is configured as the Outside port, the IP address of the port is set to 172.16.253.18.

```
ip nat pool setup_build_pool prefix-length 24
address 61.155.18.17 61.155.18.18 match interface GigabitEthernet 0/0
address 210.28.160.100 210.28.160.110 match interface GigabitEthernet 0/1
```

# Enable internal source address translation of NAT

```
ip nat inside source list 99 pool nbr_setup_build_pool
```

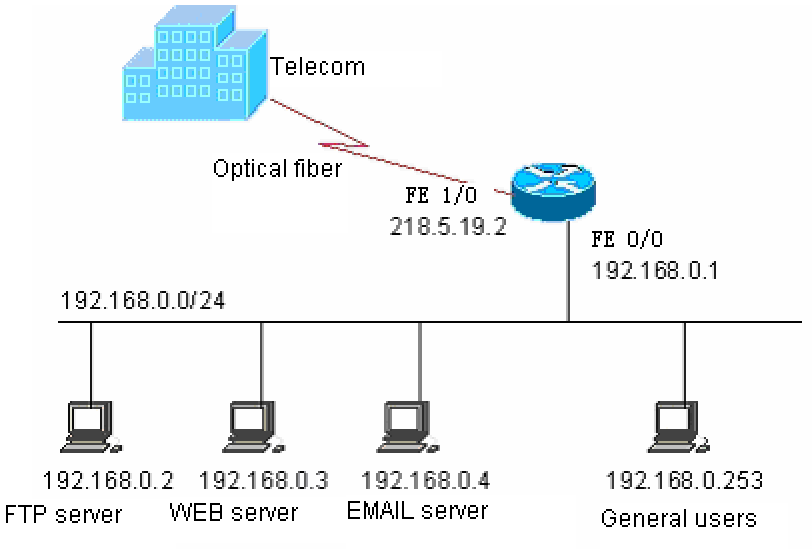
# Configure that traffic is routed to two WAN ports by default.

```
ip route 0.0.0.0 0.0.0.0 FastEthernet 1/0 202.101.98.1
ip route 0.0.0.0 0.0.0.0 dialer 1
!
```

Configuring a local server

To configure a local server means to map one or more hosts to a network access server (NAS), so that users on the WAN can access desired services. As shown in Figure , three servers (an FTP server, a web server, and an E-mail server) are deployed on the internal network. It is expected that hosts on the WAN can access the three servers and common users of the internal network can access Internet by using the gateway as a NAS. For Ruijie products, static NAT is used for server access and dynamic NAT is used for Internet access.

Figure 40 Configuring a local server



To realize these functions, static NAT needs to be configured.

# Enter privileged user mode

```
Ruijie> enable
```

# Enter global configuration mode

```
Ruijie# config terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

# Enter WAN port 0 configuration mode

NAT Configuration in case of multiple VRF instances

The following example shows the NAT implementation when there are multiple VRF instances. An IP address may be found in different VRF instances and needs to be translated into different source IP addresses during NAT. In this case, you must specify the target VRF domain of NAT.

```
access-list 1 permit 192.168.12.0 0.0.0.255

ip vrf 1

ip vrf 2

interface FastEthernet 0/0
ip vrf forward 1
ip address 192.168.12.1 255.255.255.0
ip nat inside
!
interface FastEthernet 0/1
ip vrf forward 1
ip address 100.168.12.200 255.255.255.0
ip nat outside
!
interface FastEthernet 1/0
ip vrf forward 2
ip address 192.168.12.1 255.255.255.0
ip nat inside
!
interface FastEthernet 1/1
ip vrf forward 2
ip address 200.168.12.200 255.255.255.0
ip nat outside
!
ip nat pool net100 100.168.12.200 100.168.12.200 netmask 255.255.255.0
ip nat pool net200 200.168.12.200 200.168.12.200 netmask 255.255.255.0

ip nat inside source list 1 pool net100 vrf 1
ip nat inside source list 1 pool net200 vrf 2
Whether correct NAT entries can be created can be checked by looking up the NAT mapping
table.

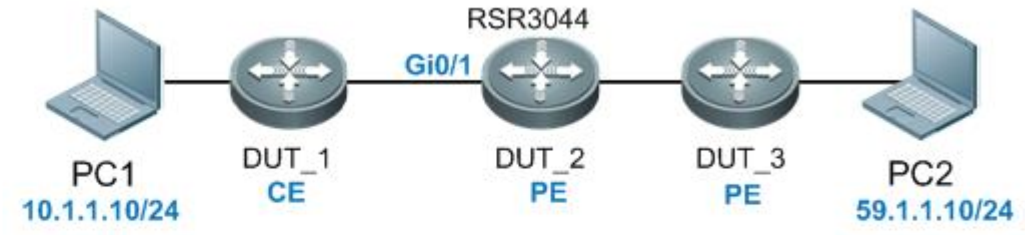
VPN NAT configuration example

On a MPLS network, NAT can be used to implement VRF traversal.

Figure 41



Configure MPLS

```
mpls ip
```

Configure PBR

```
route-map vrfdata permit 10
 match ip address 150
 set vrf data
```

Specify an ACL

```
ip access-list extended 100
 10 permit ip 10.0.0.0 0.255.255.255 any
ip access-list extended 150
 10 permit ip any 20.1.1.0 0.0.0.255
```

Configure VRF domains

```
ip vrf data
 rd 200:1
 route-target both 200:1
ip vrf v1
 rd 100:1
 route-target export 100:1
ip vrf v2
 rd 100:2
 route-target export 100:2
```

Deploy MPLS on a public network interface

```
interface GigabitEthernet 0/0
 ip nat outside
 ip ref
 ip address 10.3.1.3 255.255.255.0
 label-switching
 mpls ip
 duplex auto
 speed auto
```

Configure PBR on a private network interface for NAT deployment

```
interface GigabitEthernet 0/1
 ip vrf forwarding v1
 ip nat inside
 ip policy route-map vrfdata
 ip ref
 ip address 10.1.1.1 255.255.255.0
 duplex auto
 speed auto
interface GigabitEthernet 0/1.1
 encapsulation dot1Q 100
 ip vrf forwarding v2
 ip nat inside
 ip policy route-map vrfdata
 ip address 10.1.1.1 255.255.255.0
```

Configure the loopback interface for advertising routes

```
interface Loopback 0
 ip ref
 ip address 3.3.3.3 255.255.255.255
router bgp 100
 bgp router-id 3.3.3.3
 bgp log-neighbor-changes
 neighbor 4.4.4.4 remote-as 100
 neighbor 4.4.4.4 update-source Loopback 0
address-family ipv4

router ospf 1
 router-id 3.3.3.3
 network 0.0.0.0 255.255.255.255 area 0
mpls router ldp
 ldp router-id interface Loopback 0 force
```

Configure NAT to take effect on VRF data packets

```
ip nat pool abc 100.1.1.1 100.1.1.1 netmask 255.255.255.0
ip nat inside source static 10.1.1.2 100.1.1.1 vrf data
```

Specify a blackhole route

```
ip route vrf data 100.1.1.1 255.255.255.255 Null 0
```

NAT Static Port Range Mapping

```
interface GigabitEthernet 0/0
 ip nat inside
 ip address 11.1.1.1 255.255.255.0
 duplex auto
 speed auto
!
interface GigabitEthernet 0/1
 ip nat outside
 ip address 22.2.2.1 255.255.255.0
 duplex auto
 speed auto
!
ip nat inside source static tcp 11.1.1.2 22.2.2.3 port-range 80 100
```

You can check whether the translation record is established correctly by displaying the NAT mapping table.

```
RSR10X#show ip nat translations

Configuring SSH Terminal Service

Overview of SSH

A Secure Shell (SSH) connection functions like a Telnet connection, except that all transmissions based on the connection are encrypted. When a user logs in to the device from an insecure network, the SSH feature provides information security guarantee and powerful authentication function to protect the devices from IP spoofing, plain password interception and other kinds of attacks.

Ruijie SSH service supports both the IPv4 and IPv6 protocols.

SSH Algorithms Supported by Ruijie Products

Supported Algorithm	SSH1	SSH2
Signature authentication algorithm	RSA	RSA, DSA
Key exchange algorithm	RSA public key encryption based key exchange algorithm	KEX_DH_GEX_SHA1 KEX_DH_GRP1_SHA1 KEX_DH_GRP14_SHA1
Encryption algorithm	DES, 3DES, Blowfish	DES, 3DES, AES-128, AES-192, AES-256
User authentication algorithm	User password based authentication method	User password based authentication method
Message authentication algorithm	Not supported	MD5, SHA1, SHA1-96, MD5-96
Compression algorithm	NONE	NONE

SSH Configuration

Default SSH Configurations

Item	Default Value
SSH server status	Off
SSH version	Compatible mode (supporting versions 1 and 2)
SSH user authentication timeout period	120s
SSH user re-authentication times	3

Configuring User Authentication

- Considering the SSH connection security, the login without authentication is forbidden. Therefore, in the login authentication of the users, the login authentication mode must have password configured (authentication-free login allowed for telnet).

- The username and password entered every time must be set. If the current authentication mode does not need the username, the username can be entered randomly but the length must be greater than zero.

Enabling SSH Server

The SSH Server is disabled by default. To enable the SSH Server, run the **enable service ssh-server** command in global configuration mode while generating a SSH key.

Command	Description
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **enable service ssh-server**	Enables the SSH Server.
Ruijie(config)# **crypto key generate** {**rsa|dsa**}	Generates a key

Caution

To delete a key, use the crypto key zeroize command rather than the [no] crypto key generate command. The SSH module does not support hot standby. For products supporting management module hot standby, after the management module is switched over, if the current primary board has no SSH key file, the crypto key generate command must be used to regenerate a key in order to use SSH.

Shutting Down the SSH Server

To disable the SSH Server, run the **no enable service ssh-server** command in global configuration mode:

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **no enable service ssh-server**	Disables the SSH Server.

Configuring the Supported SSH Server Version

By default, the SSHv1 and SSHv2 are compatible. Run the following commands to configure the SSH version.

Command	Function
Ruijie# **configure terminal**	Enters configuration mode.
Ruijie(config)# **ip ssh version** {**1 | 2**}	Configures the supported SSH version.
Ruijie(config)# **no ip ssh version**	Restore the default SSH version. By default, SSHv1 and SSHv2 are supported.

Configuring SSH User Authentication Timeout Period

By default, the user authentication timeout period of the SSH server is 120 seconds. Run the following commands to configure the SSH user authentication timeout period.

Command	Function
Ruijie# **configure terminal**	Enters configuration mode.
Ruijie(config)# **ip ssh time-out** *time*	Configures the SSH timeout period (ranging from 1 to 120 seconds).
Ruijie(config)# **no ip ssh time-out**	Restores the default SSH user authentication timeout period to 120 seconds.

Configuring SSH Re-authentication Times

This command is used to set the authentication attempts for SSH users requesting connections to prevent illegal actions such as malicious guesswork. By default, three authentication attempts can be made for the SSH Server. In other words, it allows the user to enter the username and password for three times to attempt the authentication. Run the following commands to configure the SSH re-authentication times:

Command	**Function**
Ruijie# **configure terminal**	Enters configuration mode.
Ruijie(config)# **ip ssh authentication-retries** *retry times*	Configures SSH re-authentication times (ranging from 0 to 5).
Ruijie(config)# **no ip ssh authentication-retries**	Restores the default SSH re-authentication times to 3.

Caution For details of the preceding commands, see SSH Command Reference Manual.

Configuring SSH Public Key Based Authentication

Only the version 2 of the SSH protocol supports public key based authentication. The following commands associate a public key file with a username. When processing client authentication, the server uses a specified public key file according to the username of the client.

Command	**Function**
Ruijie# configure terminal	Enters configuration mode.
Ruijie(config)# **ip ssh peer** *test* **public-key rsa flash**:*rsa.pub*	Configures the RSA public key file that is associated with the username *test*.
Ruijie(config)# ip ssh peer *test* **public-key dsa flash**:*dsa.pub*	Configures the DSA public key file that is associated with the username *test*.

Configuring the SCP Server Function

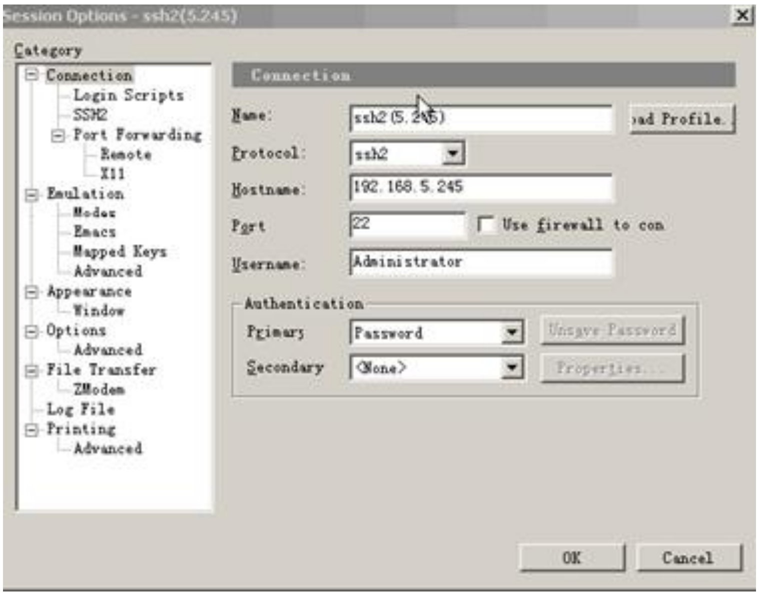
With the SCP server enabled on a network device, the user can directly download files from the network device and upload local files to the network device. Meanwhile, the user can transfer all interactive data in encrypted text manner, featuring authentication and security.

Command	Function
Ruijie# **configure terminal**	Enters configuration mode..
Ruijie(config)#**ip scp server enable**	Enable the SCP server function.
Ruijie(config)# **no ip scp server enable**	Disable the SCP server function.

Note For details of the above commands, see *SSH Command Reference Manual*.

Using SSH for Device Management

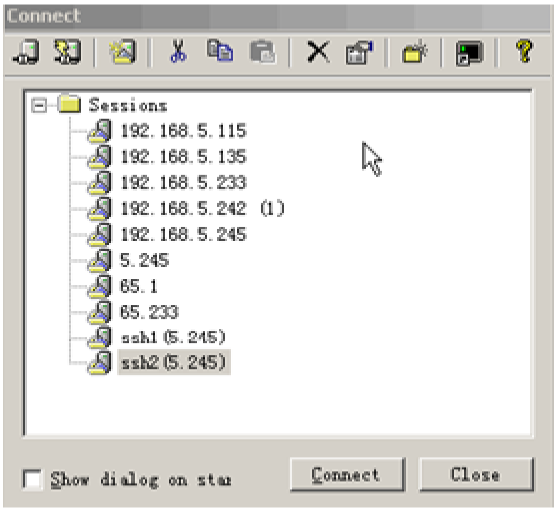
You may use SSH for device management after enabling the SSH Server function that is disabled by default. Since Telnet that comes with the Windows does not support SSH, third-party client software must be used. Currently, the clients with sound forward compatibility include Putty, Linux and SecureCRT. With the client software SecureCRT as an example, the SSH client configuration is described as follows (see the UI below):



Name: ssh2 (5.245)
Protocol: ssh2
Hostname: 192.168.5.245
Port 22 □ Use firewall to con
Username: Administrator
Primary Password
Secondary <None>

As shown in the figure, protocol 2 is used for login, so **SSH2** is selected for **Protocol**. **Hostname** indicates the IP address of the host the user will log in, 192.168.5.245. Port 22 is the default port listened by SSH. **Username** indicates the username, and does not take effect when the device only requires a password. **Authentication** indicates the authentication mode, and the username/password authentication is supported here. The used password is the same as the password used for Telnet.

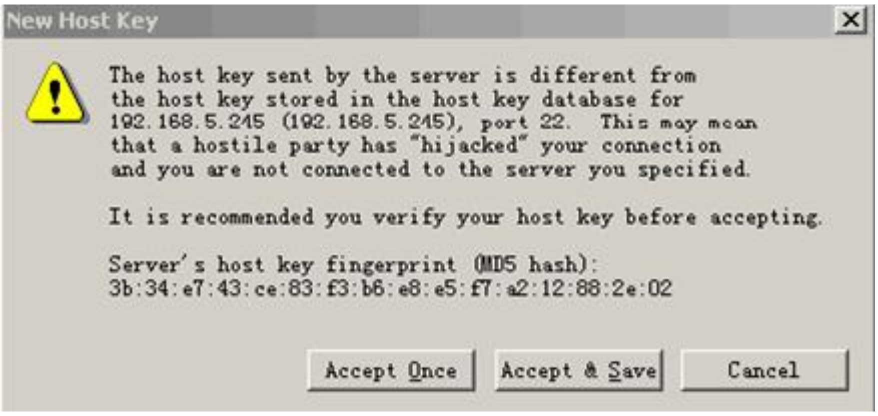
Click **OK**. The following dialog box pops up:



Sessions
192.168.5.115
192.168.5.135
192.168.5.233
192.168.5.242 (1)
192.168.5.245
5.245
65.1
65.233
ssh1 (5.245)
ssh2 (5.245)

□ Show dialog on star

Click **Connect** to log in to the host, as shown below:

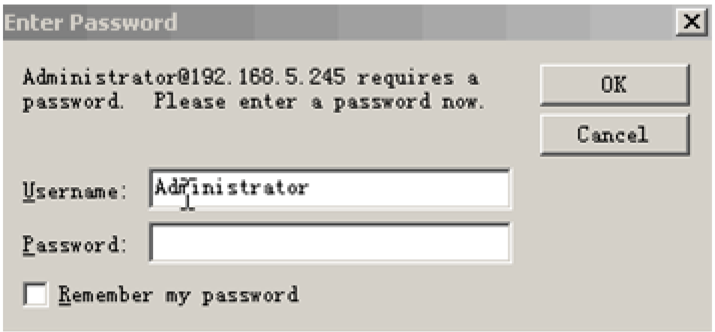


The host key sent by the server is different from the host key stored in the host key database for 192.168.5.245 (192.168.5.245), port 22. This may mean that a hostile party has "hijacked" your connection and you are not connected to the server you specified.

It is recommended you verify your host key before accepting.

Server's host key fingerprint (MD5 hash):
3b:34:e7:43:ce:83:f3:b6:e8:e5:f7:a2:12:88:2e:02

Ask the user whose is logging in to the host 192.168.5.245 whether to receive the key from the server. Select **Accept & Save** or **Accept Once**. A dialog box, prompting you to enter a password, pops up as follows:



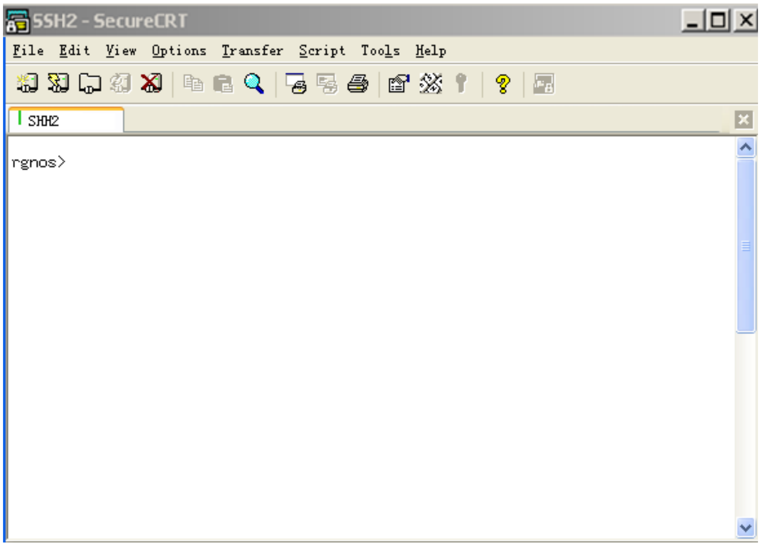
Administrator@192.168.5.245 requires a password. Please enter a password now.

Username: Administrator

Password:

□ Remember my password

Enter the Telnet login password. A window pops up as follows:



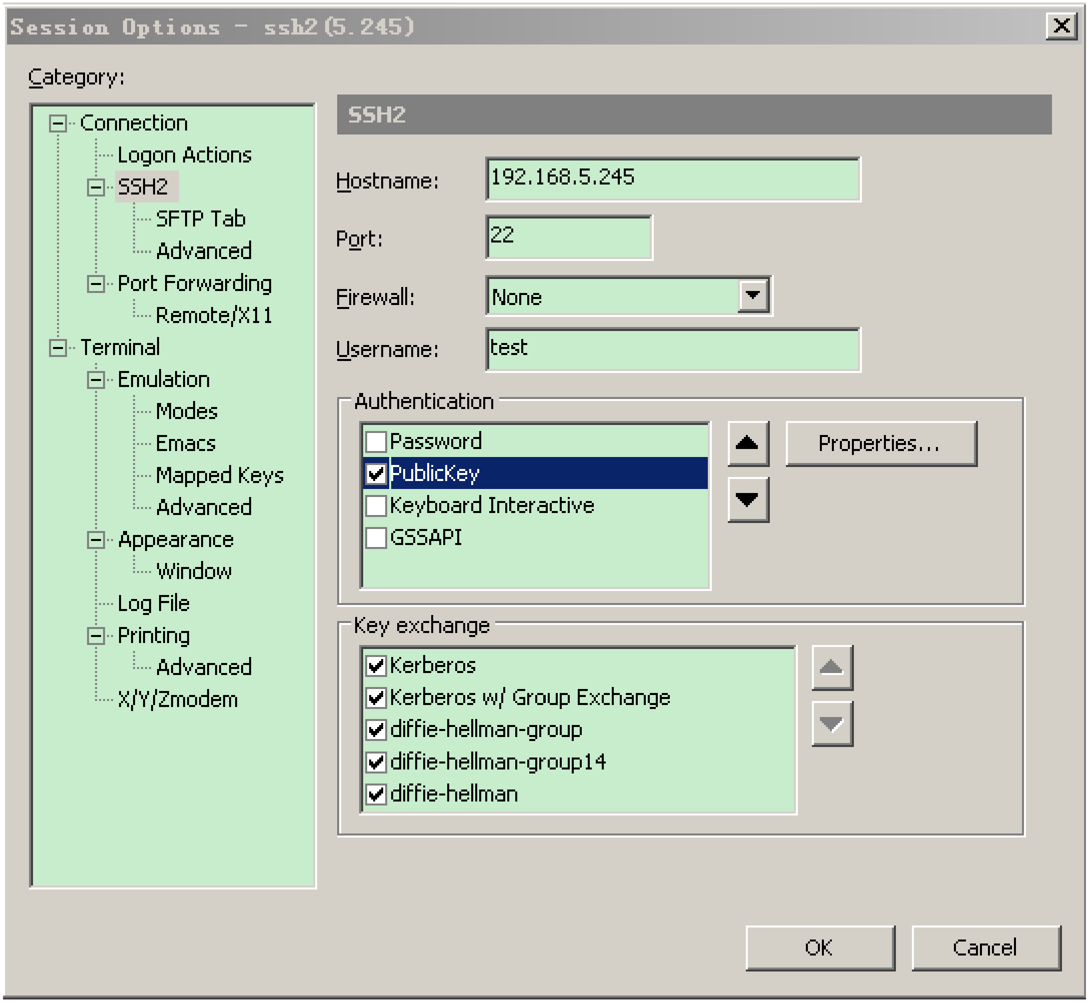
```
rgnos>
```

Enabling SSH public key based authentication

Operations on the SSH Client:

To enable SSH public key authentication, generate a key pair (RSA or DSA) on the SSH client and put the public key on the SSH server. And then enabling SSH public key based authentication on SSH server. The following section takes client software SecureCRT for an instance to demonstrate how to generate key pair on SSH client.

Firstly, click PublicKey in Authentication on Session Option, and then click Properties. as Shown below.



Session Options - ssh2(5.245)

SSH2

Hostname: 192.168.5.245

Port: 22

Firewall: None

Username: test

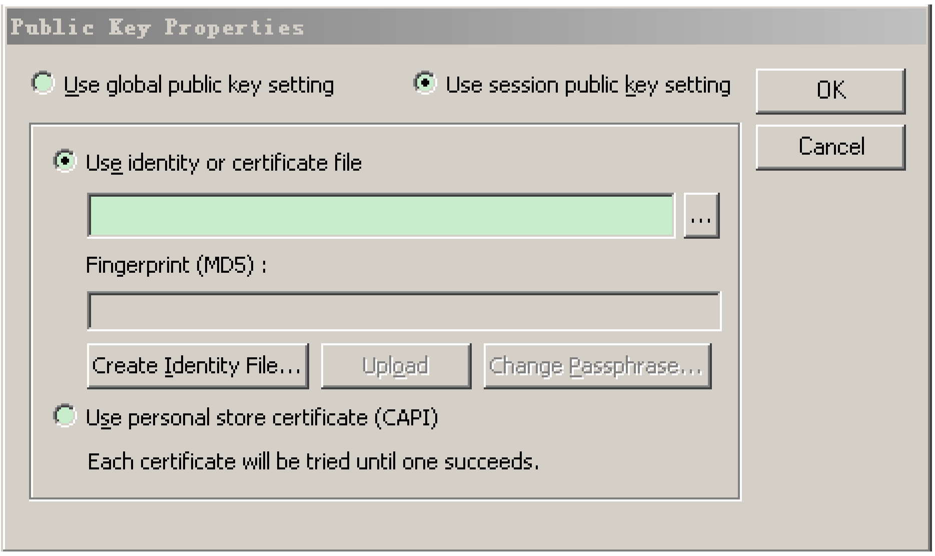
Authentication

- □ Password
- ☑ PublicKey
- □ Keyboard Interactive
- □ GSSAPI

Key exchange

- ☑ Kerberos
- ☑ Kerberos w/ Group Exchange
- ☑ diffie-hellman-group
- ☑ diffie-hellman-group14
- ☑ diffie-hellman

If the key pair is generated before, use the private key （Use identity or certificate file）. Note that this private key must be paired with the public key on the SSH server, otherwise the authentication fails. As shown below.



Public Key Properties

○ Use global public key setting ● Use session public key setting

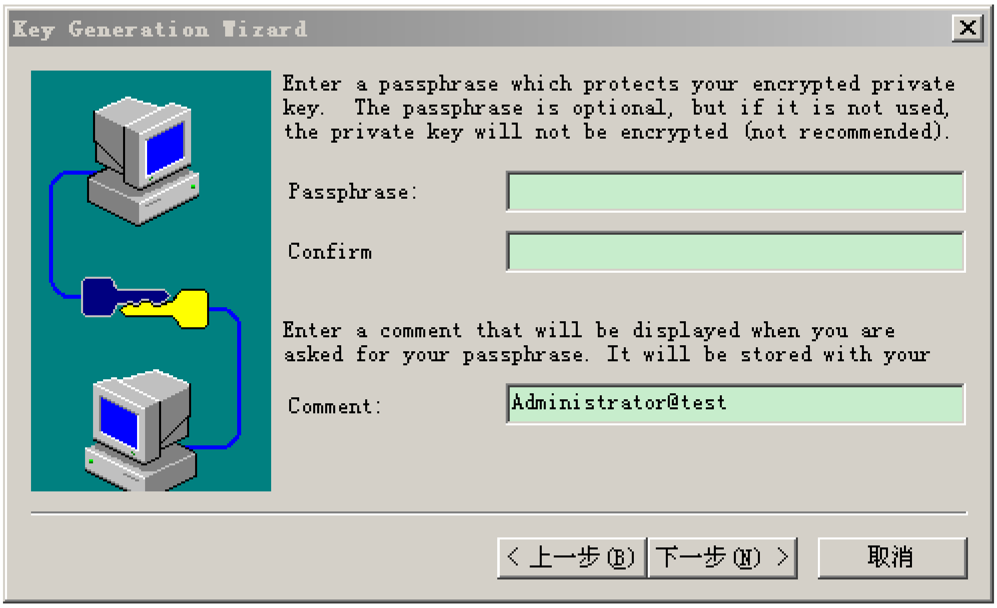
● Use identity or certificate file

Fingerprint (MD5) :

○ Use personal store certificate (CAPI)

Each certificate will be tried until one succeeds.

If no key pair is generated before, generate a new key pair. (Optional) set a passphrase for the private key. Once the passphrase is set, you should key in this passphrase for authentication. As shown below.



Enter a passphrase which protects your encrypted private key. The passphrase is optional, but if it is not used, the private key will not be encrypted (not recommended).

Passphrase:

Confirm

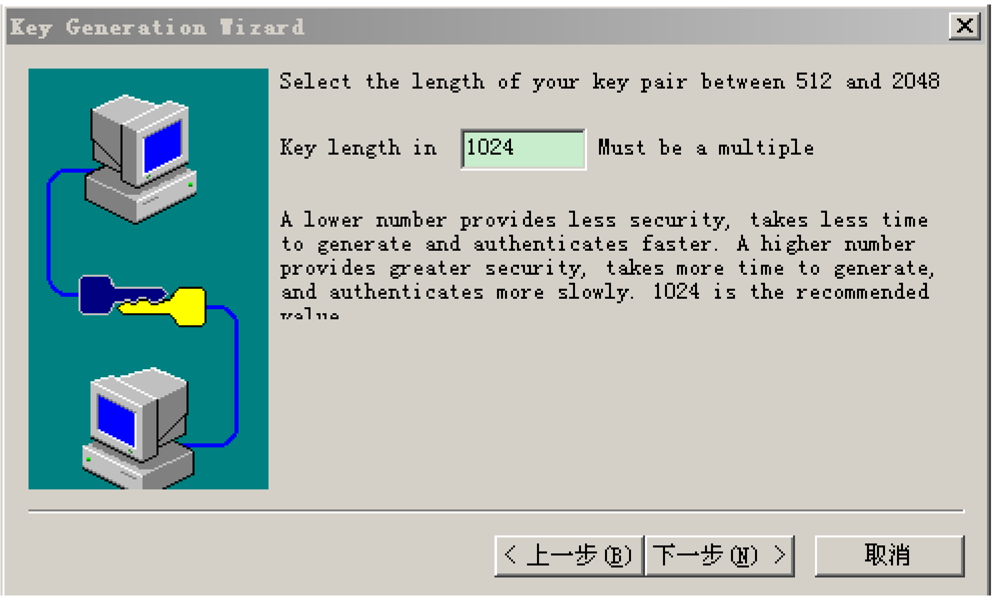
Enter a comment that will be displayed when you are asked for your passphrase. It will be stored with your

Comment: Administrator@test

Note

Shaking the mouse when the SSH client is generating the key pair, otherwise the generating rate will be slow.

The key files must be stored in OpenSSH key format, otherwise the files cannot be used. If the Putty is adopted as the client software, still the private key is required to turn into the Putty format by puttygen.exe.(Puttygen.exe can generate key pair in OpenSHH format, but Putty cannot use key pair in OpenSHH format directly). However, the public key files generated in OpenSSH format do not need transformation.



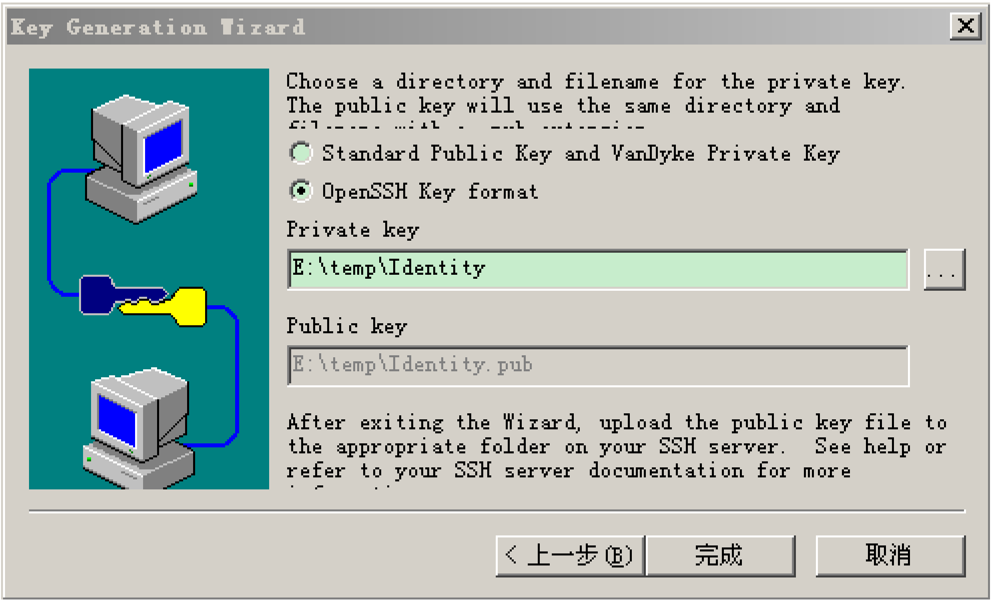
Select the length of your key pair between 512 and 2048

Key length in 1024 Must be a multiple

A lower number provides less security, takes less time to generate and authenticates faster. A higher number provides greater security, takes more time to generate, and authenticates more slowly. 1024 is the recommended value

Note

To guarantee the security of RSA public key based authentication, make sure the key length is longer or equivalent to 768.



Choose a directory and filename for the private key. The public key will use the same directory and

○ Standard Public Key and VanDyke Private Key

● OpenSSH Key format

Private key

E:\temp\Identity

Public key

E:\temp\Identity.pub

After exiting the Wizard, upload the public key file to the appropriate folder on your SSH server. See help or refer to your SSH server documentation for more

Operations on the SSH server

When the key pair is generated on the SSH client, the SSH server (network device) copies the public key files into flash, and associated these public key files with SSH clients' username. Each username can be associated with one RSA public key and one DSA public key. As shown below:

```
Ruijie# configure terminal
Ruijie(config)# ip ssh peer test public-key rsa flash:rsa.pub
Ruijie(config)# ip ssh peer test public-key dsa flash:dsa.pub
```

By doing so, SSH clients can log into network devices through public key based authentication.

Transferring files through SSH

Operation on the SSH server:

SSH transfers files by means of the SCP protocol (Secure Copy). The client can upload files to the network device or download files from the network device through SCP. To realize such function, enable the SCP server function, as shown below.

```
Ruijie# configure terminal
Ruijie(config)# ip scp server enable
```

By doing so, client can connect server and transfer files through SCP. SCP server use SSH thread. So when a client connects the network device transferring files through SCP, it will takes up a VTY line. (when using the command show user, you can see the user type is SSH).

Operation on the SSH server:

Both Unix and Linux platform carries SCP command. Taking Ubuntu Linux as an example to demonstrate the use of SCP command, as shown below:

```
Grammar of SCP command:
    scp [-1246BCpqrv] [-c cipher] [-F ssh_config] [-i identity_file]
       [-l limit] [-o ssh_option] [-P port] [-S program]
       [[user@]host1:]file1 [...] [[user@]host2:]file2
Explanation for some options:
-1 : Use SSH version 1 (by default, use SSH version 2);
-2 :  Use SSH version 2 (by default);
-C :  Specify compressed transmission;
-c :  Specify encryption algorithm;
-r :  Transmit all files under this content;
-i :  Specify key pair;
-l :  Limit the transmission rate (measured by Kbits);
For other detailed parameters, see als the scp.0.
```

Take Ubuntu 7.10 as an example to demonstrate file transferring.

The designated user named *test copies config.text* file from a network device with an IP address 192.168.195.188 to the local /*root*. As shown below:

```
root@dhcpd:~# scp test@192.168.195.188:/config.text /root/config.text
