test@192.168.195.188's password:
config.text                100% 1506    1.5KB/s   00:00
Read from remote host 192.168.195.188: Connection reset by peer
```

Note

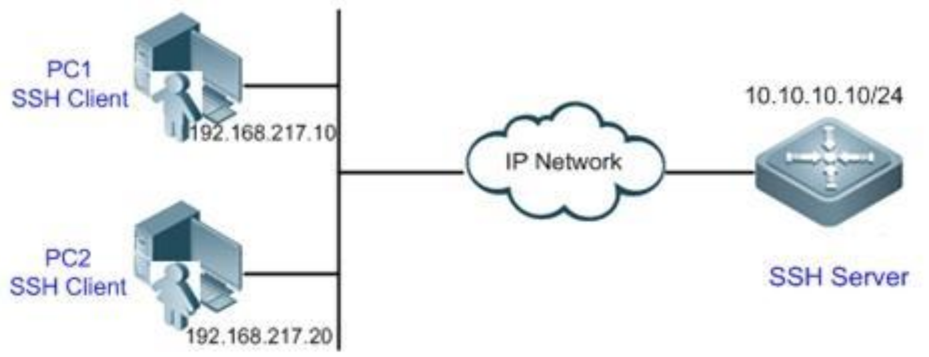
Most options are client related only. And few of these options require support from both client and server. The SCP server on Ruijie Networks' devices do not support -d -p –q –r options. So when user configuring these options, the device indicates unsupported message.

If no rate limitation (-l option) is configured in advance, the CPU usage will rise when the client downloading files from server, and recover after the downloading. The console remains available but other application tasks will be affected.

Typical SSH Configuration Examples

Configuring SSH Local Authentication

Figure 42 Networking diagram for SSH local password protection



Application Requirements

As shown in Figure , to ensure the security of information exchange, PC1 and PC2 serve as SSH clients from which users will log in to the SSH Server through SSH. The specific requirements are shown below:

- SSH users adopt line password authentication.
- Lines 0 to 4 are activated at the same time. The login password for line 0 is "passzero", and the login password for other four lines is "pass". Any user name can be used.

Notes

- Notes on SSH Server configuration are as follows:

98) Globally enable SSH Server. By default, SSH Server supports SSHv1 and SSHv2.
99) Configure a key. The SSH server will use this key to decrypt the encrypted passwords received from the SSH clients, and compare the plain text with the password stored on the server before returning a message that indicates a successful or failed authentication. SSHv1 uses RSA key, while SSHv2 uses RSA or DSA key.
100) Configure the IP address of the Gi 1/1 interface of the SSH server. SSH clients connect to the SSH server through this interface. The routes from SSH clients to the SSH server are reachable.

- Configurations on SSH Clients:

There are many SSH client software, such as Putty, Linux, OpenSSH and etc. In this example, SecureCRT is used as the SSH client software. For configuration details, see the "Configuration Steps" section.

Configuration Steps

- Configure the SSH Server

Before configuring relevant SSH features, make sure the routes from SSH clients to the SSH server are reachable. The IP addresses of respective interfaces are shown in Figure 6, and the IP address and route configuration are omitted herein.

Step 1: Enable SSH Server

```
Ruijie(config)# enable service ssh-server
```

Step 2: Generate an RSA key

```
Ruijie(config)#crypto key generate rsa
% You already have RSA keys.
% Do you really want to replace them? [yes/no]:
```

```
Choose the size of the key modulus in the range of 360 to 2048 for your
Signature Keys. Choosing a key modulus greater than 512 may take
a few minutes.

How many bits in the modulus [512]:
% Generating 512 bit RSA1 keys ...[ok]
% Generating 512 bit RSA keys ...[ok]
```

Step 3: Configure the IP address of Gi 1/1 interface. The client will use this IP address to connect to the SSH server.

```
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if- gigabitEthernet 1/1)#ip address 10.10.10.10 255.255.255.0
Ruijie(config-if- gigabitEthernet 1/1)#exit
```

Step 4: Configure login passwords for lines

! Configure the login password for line 0 as "passzero"

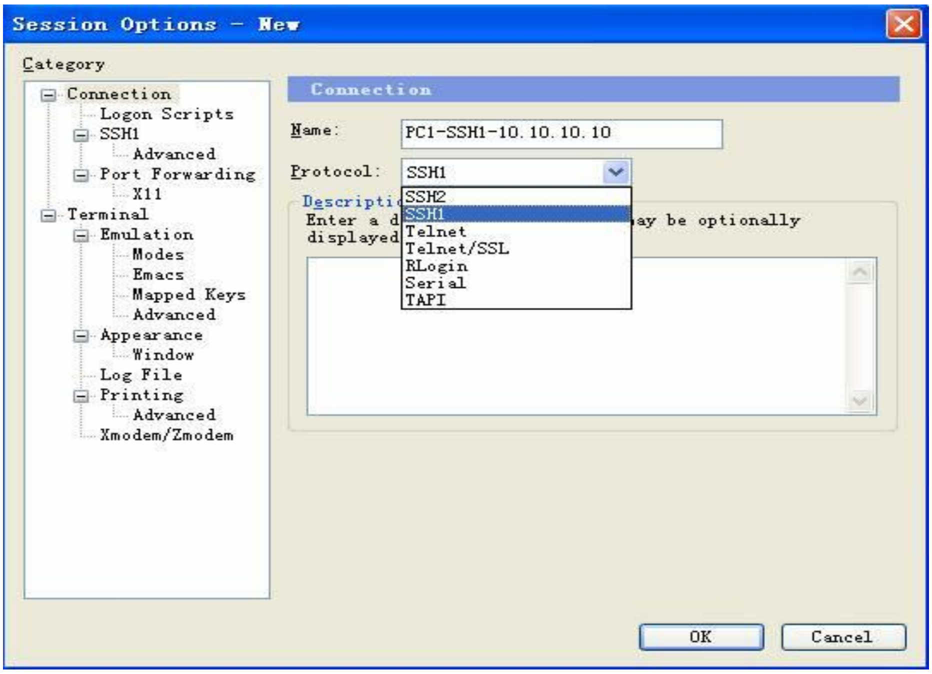
```
Ruijie(config)#line vty 0
Ruijie(config-line)#password passzero
Ruijie(config-line)#privilege level 15
Ruijie(config-line)#exit
```

! Configure the login password for lines 1 to 4 as "pass"

```
Ruijie(config)#line vty 1 4
Ruijie(config-line)#password pass
Ruijie(config-line)#privilege level 15
Ruijie(config-line)#exit
```

■ Configure SSH Clients (PC1 and PC2)

Start SecureCRT, as shown in the following figure. Use SSH1 for login authentication. Any session name can be specified (here the session name is configured as PC1-SSH1-10.10.10.10).

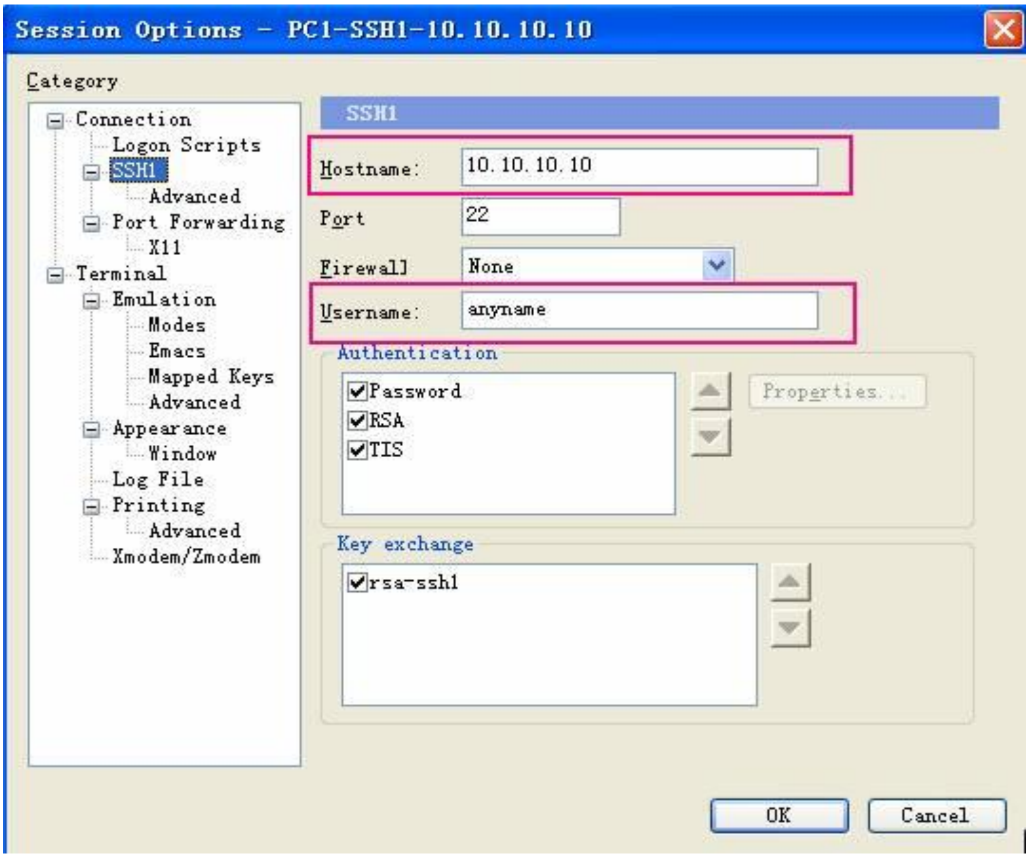


Name: PC1-SSH1-10.10.10.10

Protocol: SSH1

Description: Enter a d... ...ay be optionally displayed

Configure SSH attributes. The host name is the IP address of the SSH server (10.10.10.10 in this example). Since user name is not required, you can type in any user name in the **User Name** field, but this field cannot be left blank (the user name is **anyname** in this example).



Session Options - PC1-SSH1-10.10.10.10

Category

SSH1

Hostname: 10.10.10.10

Port 22

Firewall None

Username: anyname

Authentication

☑Password
☑RSA
☑TIS

Key exchange

☑rsa-ssh1

Verifying the Configuration

- Verify the SSH Server configuration

Step 1: Run the **show running-config** command to verify the current configuration:

```
Ruijie#show running-config

Building configuration...
!
enable secret 5 $1$eyy2$xs28FDw4s2q0tx97
enable service ssh-server
!
interface gigabitEthernet 1/1
 ip address 10.10.10.10 255.255.255.0
line vty 0
privilege level 15
 login
 password passzero
line vty 1 4
privilege level 15
```

```
 login
 password pass
!
end
```

■ Verify the configuration of SSH clients

Step 1: Establish a remote connection.

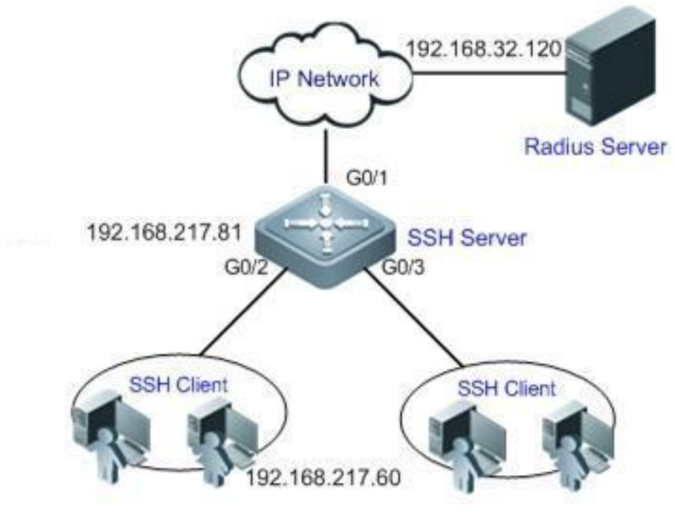
Establish a connection and type in the correct password in order to enter the interface of the SSH Server. The login password for line 0 is "passzero", and the login password for other four lines is "pass".

Step 2: Query the online user.

```
Ruijie#show users
    Line        User        Host(s)             Idle       Location
   0 con 0                  idle               00:03:16
   1 vty 0                  idle               00:02:16   192.168.217.10
*  2 vty 1                  idle               00:00:00   192.168.217.20
```

Example of Configuring SSH AAA Authentication

Figure 43 Networking diagram for SSH AAA authentication



Application Requirements

As shown in Figure 10, to ensure the security of information exchange, PCs serve as SSH clients from which users will log in to the SSH Server through SSH.

To better implement security management, SSH clients adopt AAA authentication. Meanwhile, for stability consideration, two authentication methods are configured in the AAA authentication method list: Radius server authentication and local authentication. Radius server authentication has a higher priority than local authentication unless no response is received during Radius server authentication.

Notes

- The routes from SSH clients to the SSH server and the route from the SSH server to the Radius server shall be reachable.
- SSH Server related configuration is complete on the network device. The configuration tips have been described in the previous example, and are not further described herein.
- AAA authentication related configuration is complete on the network device. AAA defines identity authentication and type by creating a method list, which is then applied to the specific service or interface. For details, see the "Configuration Steps" section.

Configuration Steps

The routes from SSH clients to the SSH server and the route from the SSH server to the Radius server shall be reachable. Route configuration will not be further described. For details, see the section about route configuration in this manual.

- Configure relevant SSH features on the network device

Step 1: Enable SSH Server

```
Ruijie(config)# enable service ssh-server
```

Step 2: Generate a key

! Generate an RSA key

```
Ruijie(config)#crypto key generate rsa
% You already have RSA keys.
% Do you really want to replace them? [yes/no]:
Choose the size of the key modulus in the range of 360 to 2048 for your
Signature Keys. Choosing a key modulus greater than 512 may take
a few minutes.
How many bits in the modulus [512]:
% Generating 512 bit RSA1 keys ...[ok]
% Generating 512 bit RSA keys ...[ok]
```

! Generate a DSA key

```
Ruijie(config)#crypto key generate dsa
Choose the size of the key modulus in the range of 360 to 2048 for your
Signature Keys. Choosing a key modulus greater than 512 may take
a few minutes.
How many bits in the modulus [512]:
% Generating 512 bit DSA keys ...[ok]
```

Step 3: Configure the IP address of the device. The clients will use this address to connect to the SSH server.

```
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-gigabitEthernet 1/1)#ip address 192.168.217.81 255.255.255.0
Ruijie(config-if-gigabitEthernet 1/1)#exit
```

- Configure AAA authentication on the network device

Step 1: Enable AAA on the device

```
Ruijie#configure terminal
Ruijie(config)#aaa new-model
```

Step 2: Configure information about the Radius server (the shared key used by the SSH server for communicating with the Radius server is "aaaradius"

```
Ruijie(config)#radius-server host 192.168.32.120
Ruijie(config)#radius-server key aaaradius
```

Step 3: Configure an AAA authentication method list

! Configure a login authentication method list (Radius server authentication followed by local authentication), and the name of the method list is "method".

```
Ruijie(config)#aaa authentication login method group radius local
```

Step 4: Apply this method list to the lines

```
Ruijie(config)#line vty 0 4
Ruijie(config-line)#login authentication method
Ruijie(config-line)#exit
```

Step 5: Configure a local user database

! Configure a local user database (configure the user name and password, and bind the user to a privilege level)

```
Ruijie(config)#username user1 privilege 1 password 111
Ruijie(config)#username user2 privilege 10 password 222
Ruijie(config)#username user3 privilege 15 password 333
```

! Configure a password for local Enable authentication

```
Ruijie(config)#enable secret w
```

Verifying the Configuration

Step 1: Run the **show running-config** command to verify the current configuration:

```
Ruijie#show run

aaa new-model
!
aaa authentication login method group radius local
!
username user1 password 111
username user2 password 222
username user2 privilege 10
username user3 password 333
username user3 privilege 15

no service password-encryption
!
```

```
radius-server host 192.168.32.120
radius-server key aaaradius
enable secret 5 $1$hbgz$ArCsyqty6yyzzp03
enable service ssh-server
!
interface gigabitEthernet 1/1
 no ip proxy-arp
 ip address 192.168.217.81 255.255.255.0
!
ip route 0.0.0.0 0.0.0.0 192.168.217.1
!
line con 0
line vty 0 4
 login authentication method
!
end
```

Step 2: Configure the Radius Server. This example describes how to configure the SAM server.

Choose **System Management** > **Device Management**, and type in 192.168.217.81 as the IP address of the device and the device key **aaaradius**;

Choose **Security Management** > **Device Management Privilege**, and configure a privilege level for the login user;

Choose **Security Management** > **Device Administrator**, and type in **user** as the user name and **pass** as the password.

Step 3: Establish a remote SSH connection on the PC.

For details about how to set SSH client software and establish a connection, see the previous example.

Type in **user** as the SSH user and **pass** as the password. The user will log in successfully.

Step 4: Query the online user.

```
Ruijie#show users
    Line        User        Host(s)             Idle      Location
   0 con 0                  idle               00:00:31
 * 1 vty 0     user         idle               00:00:33   192.168.217.60
```

Configuring IP Accounting

Understanding IP Accounting

Overview

IP accounting, an easy-to-use traffic management tool, classifies and collects statistics on the traffic passing routers by source IP address and destination IP address. The collected statistics include the number of packets and number of bytes. Traffic accounting and traffic analysis can be implemented on the basis of IP accounting statistics.

Configuring IP Accounting

Enabling IP Accounting

IP accounting is enabled on the inbound or outbound interface. You need to specify an interface and the direction when enabling IP accounting. In addition, you can configure a traffic classification rule while enabling IP accounting. The system will collect statistics on traffic based on the configured rule.

Use the following commands to enable IP accounting.

Command	Function
Ruijie> **enable**	Enters privileged EXEC mode.
Ruijie# **config terminall**	Enters global configuration mode.
Ruijie(config)# **interface** *interface-type interface-number*	Enters interface configuration mode.
Ruijie(config-if)# **ip accounting** { **ingress** | **egress**} **list** { *acl_list_num* | *acl_list_name* }	Enables IP accounting on the interface.
Ruijie(config-if)# **end**	Returns to privileged EXEC mode.
Ruijie# **copy running-config startup-config**	Saves the configuration.

To disable IP accounting on the interface, use the **no ip accounting** { **ingress** | **egress** } command in interface configuration mode.

Configuration example

```
Ruijie# config terminal
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# ip accounting ingress list 20 //Enable IP Accounting on the 0/1 interface
to classify and collect statistics on incoming traffic based on ACL 20.
Ruijie(config-if)# exit
Ruijie(config)# interface gigabitEthernet 0/2
Ruijie(config-if)# ip accounting egress list 10 //Enable IP Accounting on the 0/2 interface
to classify and collect statistics on outgoing traffic based on ACL 10.
Ruijie(config-if)# exit
Ruijie(config)#
```

Displaying IP Accounting Configuration

Use the **show ip accounting config** command to query IP accounting configuration on an interface. For exampe:

```
Ruijie# show ip accounting config
GigabitEthernet 0/1
ip accounting ingress list 20
GigabitEthernet 0/1
ip accounting egress list 10
```

Displaying IP Accounting Statistics

Use the **show ip accounting interface** *interface-type interface-number* { **ingress** | **egress** } { **interior** | **exterior** } command to query IP accounting statistics on the inbound or outbound interface in priveledged, global, or interface mode, with **interior** indicating the statistics matching an ACL rule and **exterior** indicating the statistics not matching the ACL rule.

Command	Function
Ruijie> **enable**	Enters privileged EXEC mode.
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *interface-type interface-number*	Enters interface configuration mode.
Ruijie(config-if)# **show ip accounting** *interface interface-type interface-number* { **ingress** | **egress** } { **interior** | **exterior** }	Displays IP accounting statistics on the interface.
Ruijie(config-if)# **end**	Returns to privileged EXEC mode.

Configuration example

```
Ruijie# config terminal
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# show ip accounting interface gigabitEthernet 0/1 ingress interior
```

Clearing IP Accounting Statistics

Use the **clear ip accounting interface** *interface-type interface-number* { **ingress** | **egress** } command to clear the IP accounting statistics on the specified inteface in priveledge EXEC mode.

The following example clears IP accounting statistics on the outbound interface.

```
Ruijie# clear ip accounting interface gigabitEthernet 0/1 egress
```

Configuring SDG

Understanding SDG

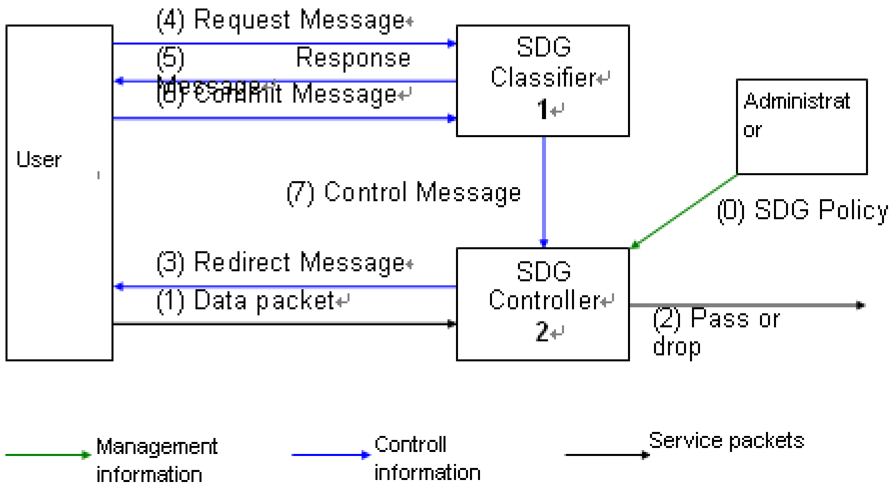
Overview of SDG

To be simple, Security Domain Gateway (SDG) achieves the logical isolation between different security domains. By limiting the user to access only the specified security domain at a time, users can be prevented from accessing different security domains and hence viruses will not spread to other protected domains, or important information will not leak to the insecure domains. SDG has two operating modes: local mode and linked mode.

Working Principle

Working principle of SDG in local mode:

Figure 44



As shown above, the SDG system consists of two parts:

Classifier: Through the interaction with users, the classifier determines the current role of each user, and sends this message to the controller. The classifier is realized by means of Web, so that the user does not need to install the client software.

Controller: The controller is mainly responsible for receiving the user role message sent by the classifier and applying access control to the traffic sent by the user as per the access permission assigned to such role. In addition, the controller is also responsible for triggering a message prompting the user to reselect a role while accessing an unauthorized domain.

User: During the interaction with SDG, the user sends traffic to the controller on one hand and negotiates with the Classifier for role selection on the other hand.

Administrator: It is responsible for establishing SDG policies on the controller. Such a policy determines the access permissions of different user roles, implementing "logical isolation". The policy is generally configured through CLI.

The working procedures of SDG are shown below:

(0): The administrator establishes a SDG policy according to actual needs, covering the user role, isolated domain and the access control rules applied between user roles and isolated domains.

(1) → (2): The Controller receives the traffic sent by the user and applies the access control, so that valid packets can pass and invalid packets failing to trigger "user role selection" will be discarded. A criterion for identifying valid packet depends on an SDG policy: the user role sending this packet is allowed to access the isolated domain.

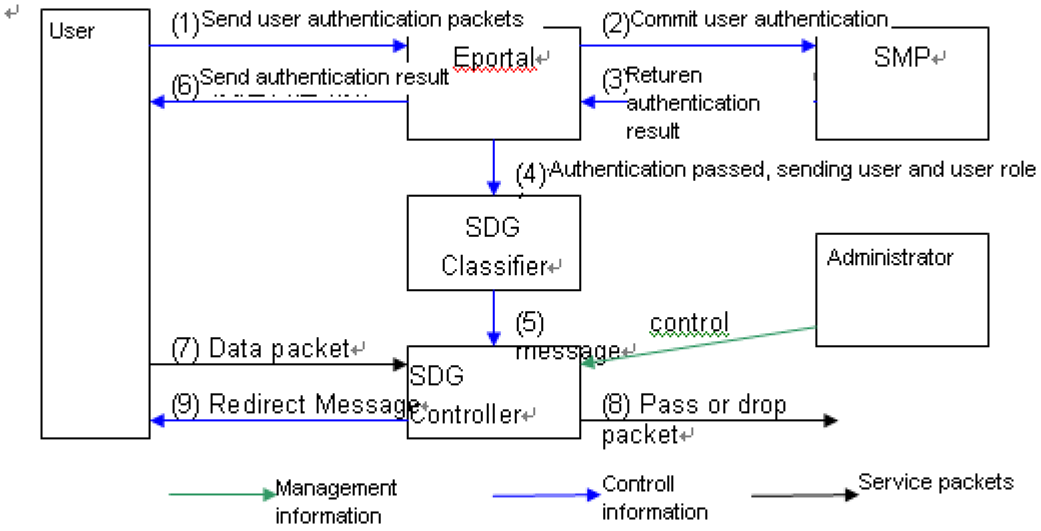
(1) → (3) → (4): As for the invalid packets sent by the user, if such packets are capable of triggering "role selection", then the controller will send an Http redirection packet to the user and redirect the user request to the "user role selection" page on the Classifier. One condition for triggering "user role selection" is that the packet must be a valid http request packet.

(4) → (5) → (6): The user proactively (or through Controller redirection) sends the "user role selection" request to the Classifier, which will reply to the user (browser) with this page. No matter which role is selected by the user on the page, the selection result will be submitted to the Classifier.

(7): The Classifier forwards the user role selection result to the Controller, which will record and use such information as the reference for security check of this user during future access.

Working principle of SDG in linked mode

Figure 45



Eportal: Eportal server

SMP: security authentication server

Other flows are the same as local mode.

The working procedures of SDG are shown below:

(0): The administrator establishes an SDG policy according to actual needs, covering the user role, isolated domain and access control rules applied between user roles and isolated domains.

(1)→(2): The user sends authentication packet to Eportal, which will forward the user authentication packet to SMP.

(3) MP verifies user information and sends the authentication result to Eportal.

(4)→(5): In case of successful authentication, Eportal will send the user and user role to the SDG Classifier, which will update the user role and forward the user role selection result to the Controller. The Controller will record and use such information as the reference for security check of this user during future access.

(6): Eportal will send the authentication result to the user, which will reselect the role or send traffic according to the authentication result.

(7)→(8)→(9): The SDG Controller matches the user role. If the user role does not match and the redirection condition is met, it will send a redirection packet. The user will reselect the role and send a user authentication packet to the Eportal, or else it will discard the packet. If matched, SDG check is passed.

Protocol Specification

N/A

Default Configurations

N/A

Configuring SDG

Configuring SDG Mode

While deploying SDG, you can select different SDG operating modes according to users' security needs. The SDG working in local mode is easy to deploy and will be ready to operate after the router is configured. To deploy SDG working in linked mode, you need to add an SMP server. This mode, however, supports user authentication and hence provides higher security.

To configure SDG mode, run the following commands:

Command	Function
Ruijie> **enable**	Enters privileged command mode.
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **ip sdg mode** *link*	Enables SDG linked mode.

Configuring the IP Address of the SMP Server

In linked mode, you need to configure the IP address of the SMP server for redirection. The user can also use an SMP URL for redirection.

To configure the IP address of the SMP server, run the following commands:

Command	Function
Ruijie> **enable**	Enters privileged command mode.
Ruijie# **config terminal**	Enters global configuration mode.

Ruijie(config)# **ip sdg portal** *ip* [url]	Configures the IP address for connecting to the Eport, namely the IP address of the Eportal server .

Configuring Aging Time for Offline Users

In linked mode, you need to configure aging time for users. A user is considered offline if the user does not initiate a connection request within the aging time.

To configure aging time for offline users, run the following commands:

Command	Function
Ruijie> **enable**	Enters privileged command mode.
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **ip sdg user-timeout** *time*	Configures aging time for offline users.

Configuring Keepalive Duration and Threshold of User Traffic

In association mode, the keepalive duration and threshold of user traffic must be configured. After the keepalive duration and threshold of user traffic are configured, the SDG controller checks whether the user traffic is lower than the configured traffic threshold within the configured keepalive duration. If the user traffic is lower than the configured traffic threshold within the keepalive duration, the user is considered offline. In this case, a trap message is sent to the SMP server to force the user to go offline.

Run the following commands to configure the keepalive duration and threshold of user traffic:

Command	Function
Ruijie> **enable**	Enters the privileged EXEC mode.
Ruijie# **config terminal**	Enters the global configuration mode.
Ruijie(config)# **ip sdg offline-detect idle-timeout** *time-out* **threshold** *flow-num*	Configures the keepalive duration and threshold of user traffic.

Configuring DNS Hijacking

In association mode, DNS hijacking must be configured. DNS hijacking is not configured by default and will be immediately enabled once it is configured. When **action** is **drop**, all DNS query packets except Class A DNS query packets are discarded. When **action** is **permit**, all DNS query except class A query packets are forwarded.

Run the following commands to configure DNS hijacking:

Command	Function
Ruijie> **enable**	Enters the privileged EXEC mode.
Ruijie# **config terminal**	Enters the global configuration mode.
Ruijie(config)# **ip sdg dns-hijack interface loopback** *num* **action** [**drop** | **permit**]	Configures DNS hijacking.

Configure the Default User

In local mode, add the default user into the specified user group. Upon the first access, the user has the permission to access the specified user group.

To configure the default user, run the following commands:

Command	Function
Ruijie> **enable**	Enters privileged command mode.
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)#**ip sdg permit-user** *user-ip user-mask* **user-group** *group-name*	Adds the default user.
Ruijie(config)#**no ip sdg permit-user** *user-ip user-mask* **user-group** *group-name*	Removes the default user.

Configuring SDG Classifiers

To control SDG, you must define SDG classifiers. Each SDG classifier defines a series of user groups (user roles). One user belongs to only one user group at the same time.

The SDG classifier created is applied to SDG policies. When user access violates the SDG policy, the user selection page will be displayed to prompt the user to select a user group.

The user can also take the initiative to access the user selection page to select a user group. The URL of the user selection page is:

"http://" + *device interface address* + "/sdg" + *classifier ID* + ".htm?ruijie_query_id=sdg". For example, if the interface address is 192.168.52.52 and the classifier ID is 1, then the corresponding URL is:

http://192.168.52.52/sdg001.htm

To configure SDG classifiers, run the following commands:

Command	Function
Ruijie> **enable**	Enters privileged command mode.
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **ip sdg classifier** *classifier-id*	Configures SDG classifiers and enters SDG classifier command mode.

Caution Web server must be enabled in order to generate the user role selection page.

```
Ruijie(config)# enable service web-server
```

Configuring User Groups

After creating SDG classifiers, run the **user-group** command to configure user groups to be included in this classifier.

To configure user groups, run the following command:

Command	Function
Ruijie> **enable**	Enters privileged command mode.
Ruijie# **config terminal**	Enters global configuration mode.

Ruijie(config)# **ip sdg classifier** *classifier-id*	Configures SDG classifiers and enters SDG classifier command mode.
Ruijie(config)# **user-group** *group-name*	Configures the user group included in an SDG classifier.

Configuring Static Users

In local mode, add users into the specified user group. The statically configured user will not be changed while the user is selecting a role.

Command	**Function**
Ruijie> **enable**	Enters privileged command mode.
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **user-group** *group-name*	Configures user groups to be included in an SDG classifier.
Ruijie (config-user-group)# **user** ip	Adds a static user.
Ruijie (config-user-group)#**no user** ip	Removes a static user.

Clearing Users in a User Group

In local mode, remove non-static users from a user group; in linked mode, remove all users from a user group.

Command	**Function**
Ruijie> **enable**	Enters privileged command mode.
Ruijie# **clear user-group** *group-name*	Removes users from a user group.

Configuring SDG Control Policies

A SDG policy can be configured in either inbound or outbound direction of an interface. It consists of one ACL and one SDG classifier. The ACL is used to define the isolation policy, which must be based on the user groups included in the SDG classifier. When user access violates the isolation policy, the user selection page defined in SDG classifier will be displayed to prompt the user to select an appropriate user group.

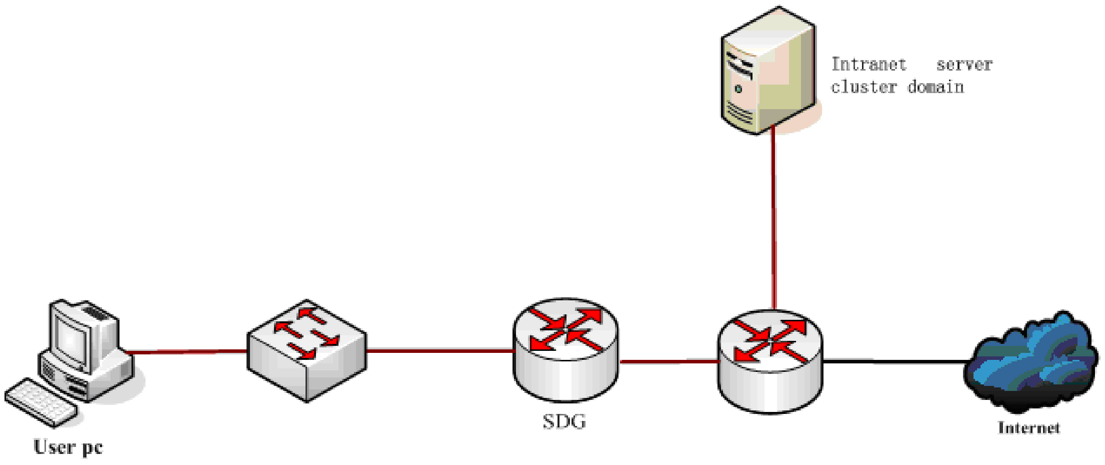
To configure SDG control policies, run the following commands:

Command	**Function**
Ruijie> **enable**	Enters privileged command mode.
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)#**interface** *gigabitEthernet 0/0*	Enters interface configuration mode.
Ruijie(config-if-gigabitEthernet 0/0)#**ip sdg in|out access-group** *acl-no* **trigger** *classifier-id*	Configures an SDG control policy.

Configuration Examples

Local mode

Figure 46



As shown above, after transparent bridge mode is enabled on the SDG device, SDG functions can be realized without changing the network structure.

Configuration:

101) Configure SDG to work in local mode

Command	Function
Ruijie(config)# **ip sdg mode local**	Configures SDG to work in local mode.

102) Configure the SMP address for SDG in linked mode

Command	Function
Ruijie(config)# **ip sdg portal** 10.1.1.2 http:// *xxx.xxx.xxx/eportal*	Configure the IP address for connecting to the Eport, namely the IP address of the Eportal server.

103) Create a user group

Define a user group for each user role, including intranet user group (intranet_user) and internet user group (internet_user).

Command	Function
Ruijie(config)# **user-group** *intranet_user*	Configures the intranet user group.
Ruijie(config)# **user-group** *internet_user*	Configures the internet user group.

104) Configure a static user

In local mode, add a user into the user group

Command	Function
Ruijie(config-user-group)#**user** 192.168.50.18	Adds a user.
Ruijie(config-user-group)# **no user** 192.168.50.18	Removes a user.

105) Create a domain

An intranet server cluster domain (intranet_site) needs to be defined.

Command	Function

Ruijie(config)# **network-region** *intranet _site*	Configures an intranet server cluster domain.
Ruijie(config-network-region)# **network** *192.168.0.0 255.255.0.0* …………	Configures all network segments included in the intranet server cluster domain.

106) Configure an SDG classifier

Define an SDG classifier, which shall include intranet user group (intranet_user) and internet user group (internet_user).

Command	**Function**
Ruijie(config)# **ip sdg classifier** *1*	Defines SDG classifier 1.
Ruijie(config-sdg-classifier)# **user-group** *intranet_user*	Adds intranet_user into the classifier.
Ruijie(config-sdg-classifier)# **user-group** *internet_user*	Adds internet_user into the classifier.

107) Configure an isolated access policy

Use an ACL to define an isolation policy.

Command	**Function**
Ruijie(config)# **ip access-list extend** *100*	Configures extended ACL 100.
Ruijie(config-ext-acl)# **permit ip user-group** *intranet_user* **network-region** *intranet_site*	Allows intranet users to access intranet servers.
Ruijie(config-ext-acl)# **deny ip user-group** *intranet_user* **any**	Prohibits intranet users from accessing other sites.
Ruijie(config-ext-acl)# **deny ip user-group** *internet_user* **network-region** *intranet_site*	Prohibits Internet users from accessing intranet servers.
Ruijie(config-ext-acl)# **permit ip user-group** *internet_user* **any**	Allows Internet users to access other sites.

Note: DNS traffic must not be confined. You can create ACEs at the beginning of the ACL to permit DNS traffic.

108) Configure an SDG policy

Configure an SDG policy on the interface. The SDG policy is associated with one ACL and one SDG trigger. HTTP requests violating this ACL will be redirected to the page configured by the SDG trigger.

Command	**Function**
Ruijie(config)# **Interface** *gi 0/0*	# Enters Gi 0/0 interface.
Ruijie(config-interface)# **ip sdg in access-group** *100* **trigge**r *1*	Configures an SDG policy in the inbound direction and associates the policy with ACL 100 and SDG classifier 1.

109) Enable web-server

Command	**Function**
Ruijie(config)# **enable service web-server**	The SDG user selection page will only be generated only after web-server is enabled.

110) Enable transparent bridge mode

Command	**Function**

Ruijie(config)# transparent	Enables transparent bridge mode.

Note: Only fast forwarding supports transparent bridge mode

111) Authenticating a user

You can directly type the URL of the SMP server in the address box of a Internet Explorer for authentication, or makes SDG trigger authentication upon denial of access.

Configuring Anti-attack Features on Devices

Overview of Device Anti-attack

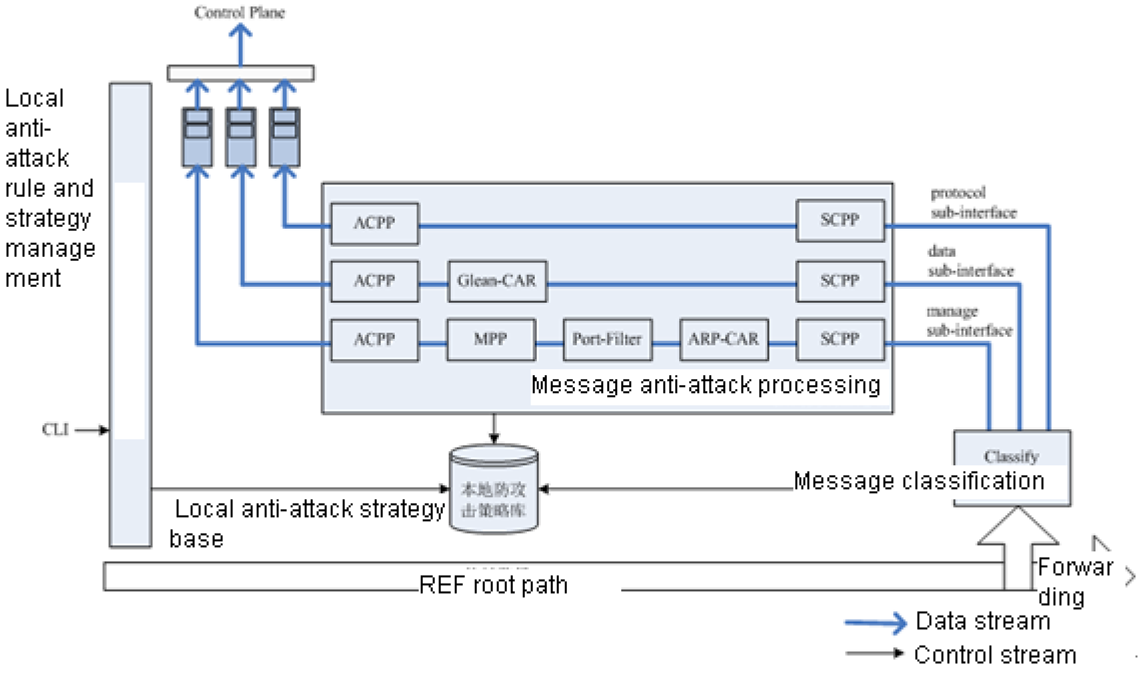
When encountering a network attack or heavy traffic, the device on a complex network may report the following exceptions:

112) Extremely high CPU usage;
113) Slow response or no response of CLI;
114) Loss of link or network control protocol messages, consequently leading to link or network delay variation;
115) Unauthorized occupation of bandwidth, resulting in the failure to process important protocol messages.

Such phenomena are due to the difference in processing capacity of control and forwarding planes on one hand and the lack of protection of the control plane on the other hand. The anti-attack module is to classify, filter and rate-limit the data messages that need to be forwarded to the control layer for processing, protecting the key resources of the control plane.

The following figure illustrates the principle and process of device anti-attack:

Figure 47



As shown in the figure, device anti-attack consists of numerous sub-modules:

Classify: Identify and classify the data traffic destined for the control plane. There are three categories of traffic including protocol, manage and data. The sub-module sets a base for subsequent rate limiting and filtering.

Sub-interface: The three traffic categories correspond to the following three sub-interfaces. The three sub-interfaces and streams through these interfaces are defined as follows:

Protocol sub-interface: All protocol control streams sent to the local device, such as link layer protocol messages, routing protocol messages, etc.

Manage sub-interface: All management protocol streams sent to the local device, such as FTP, TELNET, SNMP streams, etc. In addition, ARP and ICMP traffic also falls into this category.

Data sub-interface: All data streams that cannot be processed by any REF plane.

Note The sub-interface in this manual is different from what is usually regarded. It only represents an internal path through which a type of traffic is sent to the control plane, helping you configure anti-attack and process traffic.

SCPP: protects the control plane by subdividing traffic. SCPP delivers more delicate rate limiting and protection according to user-defined policies.

Glean-CAR: limits the rate of the traffic to the REF plane matching REF Glean adjacency (traffic with a direct route but without a host route matching the destination IP address is diverted to the control plane for destination IP address resolution).

ARP-CAR: Since the REF plane cannot complete processing ARP messages, these messages must be forwarded to the control plane. ARP-CAR can limit the rate of ARP messages from each neighbor.

Port-Filter: checks whether ports have been enabled for local TCP and UDP messages and filters network traffic for which no local network service is enabled.

MPP: Management Plane Protection (MPP) allows administrators to specify one or more interfaces as in-band management interfaces (receiving management messages and forwarding normal service messages). After the MPP function is enabled, only specified in-band management interfaces are allowed to receive the management messages of specified protocol. However, service messages, protocol messages, ARP messages, etc are not affected.

ACPP: Aggregate Control Plane Protection (ACPP) limits, on the basis of classification result by Classify, the rate of traffic on protocol sub-interface, manage sub-interface and data sub-interface with default or users' custom-made rate in order to ensure the traffic does not exceed the processing capacity of the control plane and the control planed is protected as a result.

Configuring Device Anti-attack

Device Anti-attack Configuration Tasks

Note Sub-functions, such as SCPP, Glean-CAR, ARP-CAR, Port-Filter, MPP, and ACPP, are independent from each other. Users may combine and configure them according to their needs and strategies. But it should be noticed that some sub-functions can be applied only to specified sub-interfaces.

Entering Control-plane Configuration Mode

All device anti-attack functions are configured in control-plane configuration mode. To enter control-plane configuration mode, run the following command:

Command	Function
Ruijie(config)# **control-plane** {**protocol** | **manage** | **data**}	Enters control-plane configuration mode and accesses corresponding sub-interfaces.

To exit control-plane configuration mode, run the **exit** command.

Configuring SCPP

SCPP can be used to distinguish and limit the rate of traffic in sub-interfaces according to user-defined policies. Rate limiting is classified into connection limiting and traffic bandwidth limiting. To configure SCPP, run the following commands:

Command	Function
Ruijie(config-cp)# **scpp list** *acl_no* {**bw-rate** bw-rate **bw-burst-rate** *bw-burst-rate* | **conn-total** *conn-num* | **conn-create-rate** conn-*create-rate* **conn-create-burst-rate** *conn-create-burst-rate*}	Configures a SCPP traffic bandwidth limit (unit: pps), a connection limit, etc for the traffic that complies with **acl_no** strategy on the sub-interface. *Acl_no*: ACL rule used to select the traffic in need of SCPP processing. *Bw-rate*: rate limit (unit: pps) *Bw- burst-rate*: burst rate limit (unit: pps) *Conn-num*: limit on the total number of connections *Conn-create-rate*: limit on the rate of connection establishment (unit: connection/s) *Conn-create-burst-rate*: limit on the burst rate of connection establishment (unit: connection/s)
Ruijie(config-cp)# **no scpp list** acl_no	Deletes configured SCPP rules.

SCPP processing can be applied to traffic on all sub-interfaces.

SCPP is disabled by default and will not be enabled until users configure SCPP rules explicitly.

Configuring Glean-CAR

For traffic that has a direct route but does not have its destination IP address resolved, configure Glean-CAR to limit the rate by using the following commands:

Command	Function
Ruijie(config-cp)# **glean-car** *packet_rate_per_group*	Configures a rate limit on Glean adjacency traffic initiated by users hashed to the same group *Packet_rate_per_group:* rate limit (unit: pps)
Ruijie(config-cp)# **no glean-car**	Deletes Glean-CAR rules.

The Glean-CAR function can only be configured on the data sub-interface.

Currently, the hash algorithm extracts the least significant *n* bits (*n* is determined by products) of source address.

It should be noticed that Glean-CAR can limit the rate of Glean adjacency matching traffic initiated by users hashed to the same group. For example, both user of A (192.168.52.57) and user B (192.168.60.57) (with the same hashed result) send traffic to destination host C (172.16.0.5) directly connected to the device. Before ARP messages of host C has been successfully resolved, only a maximum of five messages can be sent by users A and B to the control plane every second for destination IP ARP resolution if glean-car 5 is configured.

Glean-CAR is enabled by default and the rate limit of Glean adjacency matching traffic initiated by users (source) hashed to the same group is configured at 5 pps.

Configuring ARP-CAR

Run the following commands to configure ARP-CAR on ARP traffic reaching the local device.

Command	**Function**
Ruijie(config-cp)# **arp-car** *packet_rate_per_group*	Configures a rate limit of the ARP traffic initiated by users hashed to the same group. *Packet_rate_per_group:* rate limit (unit: pps)
Ruijie(config-cp)# **no arp-car**	Deletes ARP-CAR rules.

The ARP-CAR function can only be configured on the manage sub-interface.

Currently, the hash algorithm extracts the least significant *n* bits (*n* is determined by products) of source address.

It should be noticed that ARP-CAR can limit the rate of ARP traffic initiated by users hashed to the same group. For example, both user A (192.168.52.57) and user B (192.168.60.57) (with the same hashed result) initiate ARP requests of 192.168.52.1 to the device. If ARP-CAR 5 is configured, only a maximum of five messages can be sent by users A and B to the control plane every second for ARP response.

ARP-CAR is enabled by default and the rate limit of the ARP traffic initiated by users (source) hashed to the same group is configured at 5 pps.

Configuring Port-Filter

Run the following commands to configure Port-Filter to filter the transport layer messages that reach the local device yet have no services enabled:

Command	**Function**
Ruijie(config-cp)# **port-filter**	Enables Port-Filter.
Ruijie(config-cp)# **no port-filter**	Disables Port-Filter.

The Port-Filter function can only be configured on the manage sub-interface.

Port-Filter is disabled by default and will not be enabled until users configure Port-Filter rules explicitly..

Configuring MPP

Run the following commands to configure the in-band management interface and the management protocol messages the interface is allowed to receive:

Command	**Function**

Command	Function
Ruijie(config-cp)# **management-interface** *interface* **allow** {**ftp** | **http** | **https** | **ssh** | **snmp** | **telnet** | **tftp**}	Specifies the in-band management interface and configures the management protocol messages supported by the interface *Interface:* in-band management interface
Ruijie(config-cp)# **no management**-**interface** *interface*	Deletes the specified in-band management interface. The MPP function will be disabled if all in-band management interfaces are deleted.

The MPP sub-function can only be configured on the manage sub-interface.

A maximum of 16 in-band management interfaces can be configured and each of them can receive several or all management protocol messages.

After the MPP function is enabled, in-band management interfaces can receive specified management protocol messages and other interfaces do not receive management protocol messages.

MPP is disabled by default and will not be enabled until users configure MPP rules explicitly.

Configuring ACPP

Run the following commands to configure ACPP for the classisified traffic reaching the control plane:

Command	Function
Ruijie(config-cp)# **acpp bw-rate** *rate* **bw-burst-rate** *burst-rate*	Configures ACPP rules for the traffic on sub-interfaces. *Rate:* rate limit (unit: pps) *Burst-rate:* burst rate limit (unit: pps)
Ruijie(config-cp)# **no acpp**	Deletes ACPP rules.

ACPP can be applied to all sub-interfaces.

ACPP is disabled by default and will not be enabled until users configure ACPP rules explicitly.

Enabling Device Anti-attack with Default Rules

Run the following commands in control-plane configuration mode to configure device anti-attack with default rules:

Command	Function
Ruijie(config-cp)# **ef-rnfp enable**	Enables device anti-attack with default rules.
Ruijie(config-cp)# **ef-rnfp disable**	Disables device anti-attack.

Default device anti-attack rules and strategies are configured according to different products and platforms.

Maintaining Device Anti-attack

Maintenance of device anti-attack

To query configurations and statistics of device anti-attack, run the following command:

Command	Function

Ruijie# **show ef-rnfp** { **acpp** {**data** | **manage** | **protocol**}| **scpp** {**data** | **manage** | **protocol**}| **glean-car** | **arp-car** | **port-filter** | **mpp** | **all** }	Views configurations and statistics of device anti-attack.

You can use the **show ef-rnfp { acpp {data | manage | protocol}| scpp {data | manage | protocol}| glean-car | arp-car | port-filter | mpp | all }** command to query configurations and statistics of sub-functions, or the **show ef-rnfp all** command to query the configurations and statistics of available anti-attack functions.

Typical Device Anti-Attack Configuration Example

The following example shows the typical configuration of device anti-attack:

```
Ruijie# config
```

//Enter control-plane configuration mode and protocol sub-interface

```
Ruijie(config)# control-plane protocol
```

// Configure ACPP to set the traffic rate to 500 pps and burst traffic rate to 600 pps on the protocol sub-interface

```
Ruijie(config-cp)# acpp bw-rate 500 bw-burst-rate 600
```

//Enter control-plane configuration mode and data sub-interface

```
Ruijie(config)# control-plane data
```

// Configure ACPP to set the traffic rate to 500 pps and burst traffic rate to 600 pps on the data sub-interface

```
Ruijie(config-cp)# acpp bw-rate 500 bw-burst-rate 600
```

// Configure Glean-CAR, allowing 10 messages from a source to match Glean adjacency per second

```
Ruijie(config-cp)# glean-car 10
```

//Enter control-plane configuration mode and manage sub-interface

```
Ruijie(config)# control-plane manage
```

// Configuring ACPP to set the traffic rate to 500 pps and burst traffic rate to 600 pps on the manage sub-interface

```
Ruijie(config-cp)# acpp bw-rate 500 bw-burst-rate 600
```

// Configure ARP-CAR allowing 10 messages from a source to match Glean adjacency per second

```
Ruijie(config-cp)# arp-car 10
```

// Enable Port-Filter

```
Ruijie(config-cp)# port-filter
```

//Configure MPP rules by specifying gi0/0 interface as the in-band management interface and only allowing it to receive Telnet and SNMP messages

```
Ruijie(config-cp)# management-interface gi0/0 allow telnet snmp
```

Configuring RPL

Understanding RPL

Overview

Reverse path limited (RPL) enables packets to be sent and returned along the same path, ensuring that these packets are not discarded by firewalls that do not allow one-way connection.

When establishing a flow table, a router buffers the inbound port No. of the first packet. Reply packets of a data flow are matched to the flow table preferentially and are forwarded through the inbound port. (Both the routing table and policy-based routing table are not used preferentially, which is similar to the state-based forwarding mechanism of firewalls.)

Basic Concept

RPL

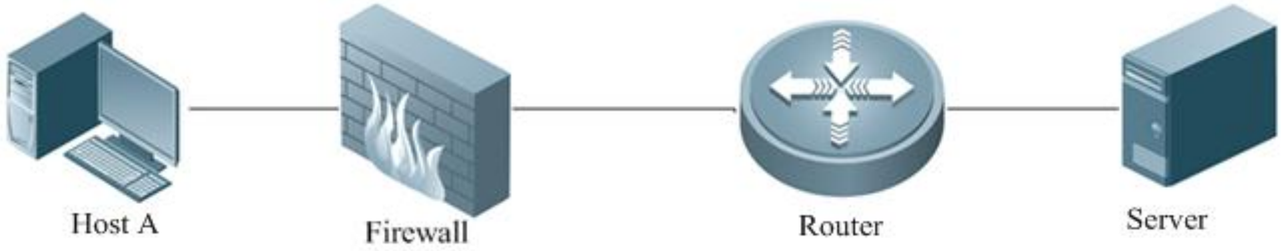
Work Principle

The source port for obtaining a packet is used as the outbound port for replying to the packet.

Typical Application

Figure 4 Networking topology for a terminal to access the server by traversing the firewall

Figure 48



Configuring RPL

Default Configuration

The following table describes the default configuration of RPL.

Feature	Default Setting
RPL	Disabled.

Configuring RPL

Command	Function
Ruijie(config-GigabitEthernet 0/0)#**ip reverse-path** [**access-list**] [*acl_id*]	Enables RPL. The value range of acl_id is as follows: 1 to 99 (IP standard access list) 100 to 199 (IP extended access list) 1300 to 1999 (IP standard access list, expanded range) 2000 to 2699 (IP extended access list, expanded range)
Ruijie(config-GigabitEthernet 0/0)#**no ip reverse-path**	Disables RPL.

Caution

Before enabling RPL on a subinterface, ensure that the subinterface and its peer subinterface are interconnected and the MAC address of the peer subinterface is learnt by this subinterface. If not, the one-way audio failure will occur. You can ping the IP address of the peer subinterface, or use the **shutdown** command to disable the primary interface of the subinterface and then use the **no shutdown** command to enable the primary interface. The preceding restriction does not apply when RPL is configured on other interfaces.

☑ This command is supported by routers only.

Configuration example`# Enable RPL.`

This example shows how to enable RPL on an interface.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface gigabitethernet 0/0/0
Ruijie(config-if)# ip reverse-path
Ruijie(config-if)#exit
Ruijie(config)#end
```

Displaying Device Configurations

Use the following command to show device configurations.

Command	Function
show running-config	Displays device configurations.

Configuration Examples

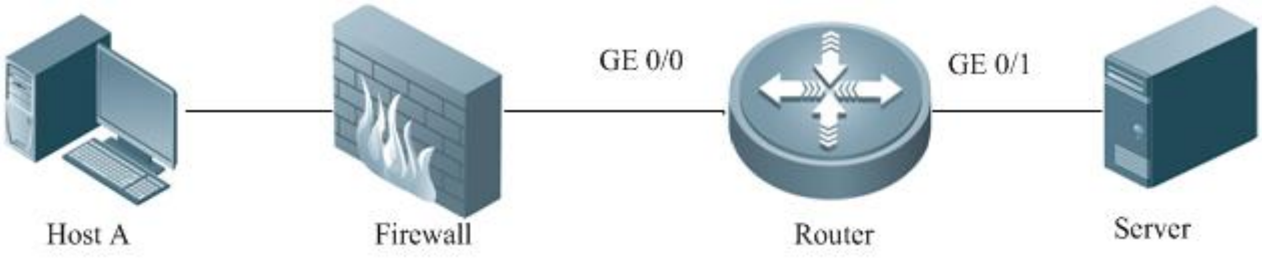
RPL Configuration Example

Networking requirements

Terminals of a network need to traverse the firewall to access the server.

Networking topology

Figure 49 Networking topology for a terminal to access the server through the router and firewall



Configuration Tips

- The router and host A is interconnected.
- IP forwarding is enabled on GE 0/0 and GE 0/1.
- Routes to host A are not required on the router.

Configuration Steps

Enter configuration commands in interface mode to configure RPL.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface gigabitethernet 0/0/0
Ruijie(config-if)# ip reverse-path
Ruijie(config-if)#exit
Ruijie(config)#end
```

Verification

Run the **show running-config** command on the router. **ip reverse-path** is displayed for GE 0/0. Ping the IP address of the server from host A. The server can be successfully pinged.

Configuring QoS

Configuring QOS

What is QOS

In a traditional IP network, the router treats all packets in the same way on a First In First Out (FIFO) basis and sends them to their destinations at best effort. However, it does not provide any assurance for the performances such as reliability and transmission delay of the packets.

As Internet becomes increasingly popular worldwide and IT is more widely used in social activities, people demand more and more from the network. IT needs evolve from the pure data information to the interactive multimedia information, from separate service to integrated transmission of data, voice and image services on a single network. More and more voice and image and other important data that require low bandwidth delay and be jitter sensitive and highly real time are transmitted over the network. On one hand, network resources become much diversified. On the other hand, the assurance of the service quality of the network incurs an important problem since the data, voice and image services have different requirements in delay, throughput or packet loss rate.

One solution to this problem is to increase the network bandwidth, which however is limited and costly as well. Other means to assure the service quality include the use of the techniques such as Policy-Based Routing, Congestion Management, Congestion Avoidance, Traffic Shaping and transmission compression to manage the traffic on the network and meet the needs of the increasing traffic on the network.

QoS (Quality of Service) is the ability of a network to provide better services for the specified network communications by using various basic technologies. To put it in simple way, different network service qualities are provided to suit the specific requirements: better qualities for the packets that are highly real-time and important; lower qualities for the common packets that do not need to be real time. To bear various services on the network, the network must be able to not only provide individual services but also offer different QoSs for them. It can be said for sure that QoS is a basic requirement for future IP networks.

Ruijie devices implement various QoS policies to meet the needs of different services for different QoSs.

Why QoS

QoS allows the network provides services for various network applications and communications in a proactive way. On the network, the QoS can be used to:

- Control resources: Users can control the network resources being used. For example, users can exercise control over the network resources occupied by FTP (File Transfer Protocol) transmission or assign higher priority for important data access.
- Sub-divide services. An ISP as a user can provide services of different QoS for different customers and packets of different requirements.
- In a network environment, different QoSs are provided for different applications to ensure network services for important packets. For example, prudential services are provided for important data; minimum delay is enabled for time-sensitive multimedia and voice applications.
- In addition, QoS lays a good foundation for future integration.

QoS under Differentiated Services

- What are differentiated services

For Differentiated Services (DiffServ), several services with the same feature are converged by using the mechanisms of DSCP (DiffServ CodePoint) and PHB to provide services for the entire converged traffic, instead of individual services.

The following three levels of differentiated services are provided:

1. Expedited Forwarding (EF)
2. Assured Forwarding (AF)
3. Best Effort (BE)

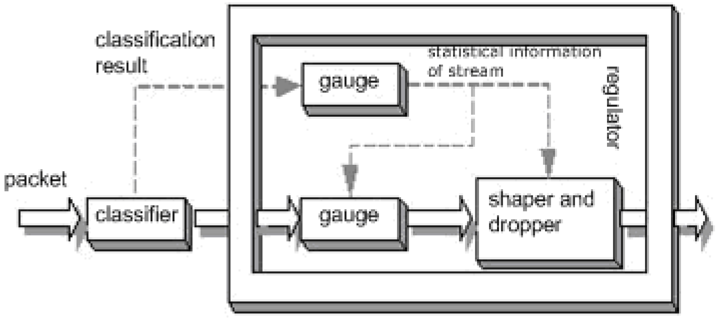
DiffServ greatly reduces the work of signaling and focuses instead on flow convergence and a set of “hop-by-hop behaviors” suitable for networkwide services. Data flows can be classified according to the pre-determined rules in order to converge multiple application traffic into a certain level of data flow.

Therefore, QoS is based on DiffServ system.

- QoS under Differentiated Services

In DiffServ, QoS includes classification/identification, measurement/shaping/packet dropping, and finally congestion management and congestion avoidance. The basic processing is illustrated as below:

Figure 1 Schematic diagram for the border node to classify and adjust the packets



The follow-up chapters separately describe the QoS under differentiated services.

IPv6 QoS

IPv6 QoS supports the 8-bit Traffic Class field, which has the same function as the ToS field of IPv4 to identify the service type of packets. The DSCP of IPv6 takes the first 6 bits in the Traffic Class filed as DHCP value. Thus DSCP=(TC&11111100)>>2. TC value is given by DSCP-to-TC mapping. IPv6 QoS also supports the 20-bit flow label field indicating the traffic belonging to the same classification. Currently, the definition and use of flow label is still in the draft phase, only Traffic Class-based QoS is supported by IPv6 QoS.

Congestion Management

What Is Congestion Management

Congestion occurs in a network node when packets arrive faster than an interface can send them. If the buffer space is insufficient for storing data on the network node, packet loss occurs. Network protocols, such as the Transmission Control Protocol (TCP), provide the data retransmission mechanism, in which the data sender node retransmits data when failing to receive a reply from the peer receiver node. This causes congestion on the peer receiver node and the performance of the entire network deteriorates.

The following are sample causes of congestion:
A packet flow enters **the router** through a high-speed link and leaves the device through a low-speed link;
Packet flows enter **the router** concurrently through multiple interfaces and leaves the device through only one interface;
CPU runs slowly.

Assume that the network needs to transmit some important data as well as much unimportant data. If the device processes all data in the same way with no regard to their importance level, unimportant data uses bulk network bandwidth and transmission of important data is delayed, which may cause tremendous loss.

To resolve these problems, congestion management is introduced. Congestion management features allow you to control congestion by determining the order in which packets are sent out an interface based on priorities assigned to those packets. A network device such as router determines the packet transmission order by controlling which packets are transmitted with priority, ensuring that key services are processed timely.

Policies of Congestion Management

Congestion management performs three tasks:
Create various types of queues.
Classify packets and place them to different queues.
Schedule queues and send packets in queues based on rules. The congestion management QoS features provide five types of queuing. Each type of queuing allows you to create a different number of queues. During periods with light traffic, that is, when no congestion exists, packets are sent out of the interface as soon as they arrive. During periods of transmit congestion at the outgoing interface, packets arrive faster than the interface can send them. If you use congestion management features, packets accumulating at an interface are queued until the interface is free to send them; they are then scheduled for transmission according to their assigned priority and the queuing mechanism configured for the interface. The device determines the packet transmission order by controlling which packets are placed in which queue and how queues are serviced with respect to each other.

This document discusses six types of queuing, which constitute the congestion management QoS features.

Note The NPE80 supports only the First-In, First-Out Queuing (FIFO) and Weighted Fair Queuing (WFQ).

FIFO

FIFO entails no concept of priority or traffic classes. With FIFO, transmission of packets out of the interface occurs in the order the packets arrive. FIFO is the default queuing mechanism that needs no intentional configuration.

WFQ

WFQ offers dynamic, fair queuing that divides bandwidth across queues of traffic based on weights. WFQ ensures that all traffic is treated fairly, given its weight. Given this handling, WFQ ensures satisfactory response time to critical applications, such as interactive, transaction-based applications, which are intolerant of performance degradation.

For WFQ, you define traffic classes based on source addresses, destination addresses, source port numbers, destination port numbers, and protocol types.

CBWFQ

Class-Based Weighted Fair Queuing (CBWFQ) extends the standard WFQ functionality. Same as WFQ, CBWFQ offers dynamic, fair queuing that divides bandwidth across queues of traffic based on weights. The difference lies in classification rules and weight calculation. For WFQ, you define traffic classes based on source addresses, destination addresses, source port numbers, destination port numbers, and protocol types. For CBWFQ, you define traffic classes based on user-defined criteria. WFQ weighs packet priorities based on fixed rules, for example, weighing the priority of an IP packet based on the Type of Service (ToS) domain. CBWFQ assigns communication queue bandwidth by proportion by weighing priorities based on user-defined bandwidth criteria.

CBWFQ allows you to define traffic classes and assign bandwidth in real time. Given these features, CBWFQ allows you to customize bandwidth assignment and ensures that different types of network data traffic acquire bandwidth by proportion.

PQ

With PQ, packets belonging to one priority class of traffic are sent before all lower priority traffic to ensure timely delivery of those packets.

PQ guarantees strict priority for important network data and quickest processing of most-important network data on a network node where PQ is enabled. For PQ, priority can be defined flexibly based on network protocols such as IP, data input interfaces, packet lengths, source addresses, and destination addresses.

LLQ and RTPQ

LLQ indicates Low Latency Queuing. The LLQ feature brings strict Priority Queuing (PQ) to CBWFQ. Strict PQ allows packets that are delay-sensitive and match traffic criteria to be sent and sent before packets in CBWFQ queues.

Functions of Real-time Transport Protocol Priority Queuing (RTPQ) are similar to those of LLQ. Each interface possesses an RTPQ queue exclusively used in the low-delay transmission of RTP packets. RTPQ matches the User Datagram Protocol (UDP) packets of ports in a specified range.

CQ

With Custom Queuing (CQ), each class of traffic acquires bandwidth by proportion. CQ allows you to assign bandwidth to all classes of traffic based on packet importance. Thus, important packets are delivered timely. You can also define the number of the bytes or packets abstracted from queues.

This function is suitable for interfaces that process data at low speeds.

Note You can assign only one queuing mechanism to an interface.

Deciding Which Queuing Policy to Use

Ruijie devices can meet service quality requirements of different services to some degree by implementing FIFO, PQ, CQ, WFQ, CBWFQ, and LLQ&RTPQ. The following section compares the five main queuing strategies.

- FIFO queuing performs the default first-come-first-serviced priorization of packets in user data traffic. It entails no concept of priority or classes of traffic. When FIFO is used, ill-behaved sources can consume available bandwidth, bursty data sources can cause delay in time-sensitive or important traffic, and important traffic may be dropped because less important traffic fills the queue.

- CQ guarantees some level of service to all traffic because you can assign bandwidth to all classes of traffic. You can define the size of the queue by determining its configured packet-count capacity, thereby controlling bandwidth usage.
- PQ guarantees strict priority in that it ensures that one type of traffic will be sent, possibly at the expense of all others. For PQ, a low priority queue can be detrimentally affected, and, in the worst case, never allowed to send its packets if a limited amount of bandwidth is available or if the transmission rate of critical traffic is high.
- WFQ does not use access lists to determine the preferred traffic on an interface. Rather, the fair queue algorithm dynamically sorts traffic into messages that are part of a conversation. Low-volume, interactive traffic gets fair allocation of bandwidth with WFQ, as does high-volume traffic such as file transfers.
- CBWFQ allows you to define traffic classes and assign bandwidth in real time. Specifically, CBWFQ allows you to specify the exact amount of bandwidth to be assigned for a specific class of traffic, which guarantees bandwidth of certain network applications. You can control bandwidth allocation on demand at any time.

The following table compares the main queuing strategies.

	FIFO	**WFQ**	**CBWFQ**	**PQ**	**CQ**
Number of Queues	1	Configurable (default: 256)	320 (64 CBWFQ queues, and 256 WFQ queues)	4	17 (16 user queues, and one system queue)
Advantage	Fast and simple processing	All traffic is treated fairly, given its weight.	Traffic that matches user-defined criteria is placed in CBWFQ queues, and other traffic is placed in WFQ queues. Network packets are delivered in proportion to their configured bandwidth.	High priority queues are serviced first. Absolute prioritization ensures critical traffic of highest priority.	CQ assigns bandwidth by proportion for different types of services. If one queue is empty, its assigned bandwidth is automatically added to another queue that had packets ready to send.
Defect	All packets are treated fairly. Packet delivery sequence is determined by their sequence of arriving at the interface, which may cause delay in delivery of critical applications.	Processing speed is slower than that of FIFO.	Processing speed is slower than that of FIFO.	Processing speed is slow, and a low priority queue can be never allowed to send its packets in the worst case.	Processing speed is relatively slow.
Configuration requirement	No configuration required	Simple configuration required	Configuration required	Configuration required	Configuration required

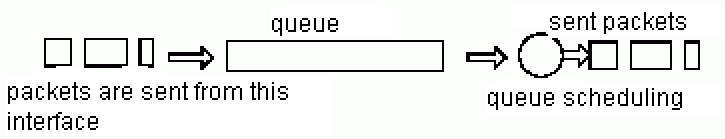
Work Mechanism of Congestion Management

FIFO

Working Principles

FIFO implements a simple service rule and provides only one queue. Packets are delivered based on the first-come-first serviced rule. FIFO does not guarantee delay restrictions or delivery rates, cannot isolate service flows that share a link. Therefore, FIFO cannot fairly treat service flows that share a link.

Figure 2 FIFO queuing



As shown in the preceding figure, packets are sent out an interface in the order in which they arrive. FIFO does not intervene with packets, but allows packets to use bandwidth and other resources in the order in which they arrive. Ill-behaved applications or attacks can consume all the bandwidth and important traffic can be dropped.

Applicable Environment

When there is no other queuing mechanism configured on the network, FIFO is enabled on all interfaces by default. FIFO possesses the quickest processing speed among queuing mechanisms. If congestion rarely occurs, FIFO is the most suitable on the network.

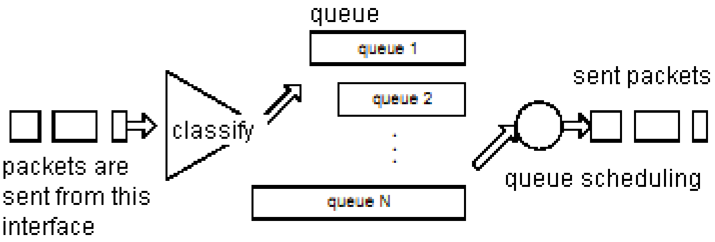
WFQ

Working Principles

WFQ removes FIFO restrictions. When FIFO queuing is enabled, traffic is sent out an interface in the order in which they arrive, disregarding bandwidth consumption and delay. As a result, file transfer and other network applications with large data volumes often generate packet links. A packet link consists of groups of packets and is transferred as a whole. These packet links may consume all available bandwidth and other traffic is dropped.

WFQ ensures that each flow shares link bandwidth fairly and that low-volume traffic gets transmitted in a timely fashion.

Figure 3 WFQ



As shown in the preceding figure, WFQ classifies packets by flow. A flow consists of packets of same source IP address, destination IP address, source MAC address, destination MAC address, source port number, destination port number, protocol type, and ToS. A flow is assigned to a queue with bandwidth in proportion to flow priority during delivery. A flow of high-priority gets more bandwidth than a flow of low-priority. Specifically, bandwidth assigned to a flow divided by the entire bandwidth of the link is equal to the sum (flow priority + 1) divided by the entire bandwidth of the link.

For example, seven flows exist on an interface, with their priority being 1, 2, 3, 4, 5, and 6. The bandwidth assigned to the interface equals the sum of all the flow priorities plus one:

1 + 2 + 3 + 4 + 5 + 6 + 7 = 28

Bandwidth ratio of a flow equals to the sum (flow priority + 1) divided by another sum (sum of all flow priorities + 1). Therefore, bandwidth ratios of flows are 1/28, 2/28, 3/28, 4/28, 5/28, 6/28, and 7/28.

If there are 10 data flows whose priority is 1, the entire bandwidth is:

1 + 2*10 + 3 + 4 + 5 + 6 + 7 = 46

Priority-0 data flows use 1/46 of the entire bandwidth, Priority-1 data flows use 2/46 of entire bandwidth, and accordingly Priority-6 data flows use 7/46 of the entire bandwidth.

When data flows are added or terminated, actual bandwidth changes consequently. By assigning bandwidth of each flow in real time, WFQ is suitable for the network environment that is constantly changing.

Applicable Environment

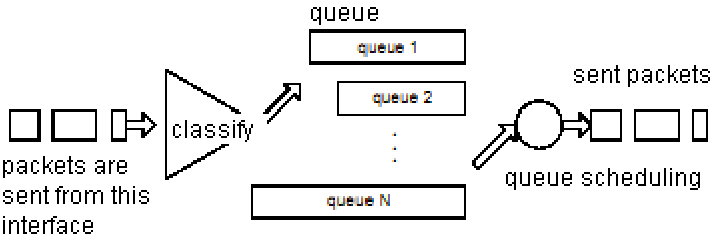
WFQ is suitable for serial interfaces with bandwidth equal to or less than 2.048 Mbps.

CBWFQ

Working Principles

CBWFQ extends the standard WFQ functionality to provide support for assigning bandwidth based on user-defined traffic classes.

Figure 4 CBWFQ



As shown in the preceding figure, CBWFQ defines classes for packets by flow. At first, classes are defined based on user-defined based on user-defined rules. Packets satisfying a same match criterion belong to a network data flow and are placed in a same CBWFQ queue. Packets satisfying no match criterion are classified in WFQ mode. Packets with the same source IP address, destination IP address, source MAC address, source port number, destination port number, protocol type, and ToS field belong to the same flow. When a packet is assigned to a flow, it is placed in the WFQ queue reserved for that flow. During delivery, CBWFQ assigns bandwidth based on the user-defined rules.

When data flows are added or terminated, actual bandwidth assigned by CBWFQ changes consequently. Therefore, CBWFQ is also suitable for the network environment that is constantly changing.

Applicable Environment

CBWFQ is suitable for applying strict classification rules and bandwidth allocation on serial interfaces with bandwidth equal to or less than 2.048 Mbps.

LLQ and RTPQ

Working Principles

LLQ extends the standard CBWFQ functionality. LLQ ensures that delay-sensitive data acquire bandwidth and are sent before packets in other queues are dequeued. The LLQ feature brings strict Priority Queuing (PQ) to CBWFQ. Strict PQ allows packets in LLQ queues to be sent and sent before packets in CBWFQ queues.

For LLQ queues, traffic of different types is monitored separately. If there is no congestion, traffic is allowed for delivery. In the event of congestion, transmission rates of all traffic are monitored, and packets are dropped if the bandwidth is exceeded.

Functions of RTPQ are similar to those of LLQ. Each interface possesses an RTPQ queue exclusively used in the low-delay transmission of RTP packets. RTPQ matches the UDP packets of ports in a specified range.

For RTPQ queues, traffic of different types is monitored separately. If there is no congestion, traffic is allowed for delivery. In the event of congestion, transmission rates of all traffic are monitored, and packets are dropped if the bandwidth is exceeded.

Both an RTPQ queue and an LLQ queue belongs can belong to only one interface, but the priority of an RTPQ queue is higher than that of an LLQ queue.

Applicable Environment

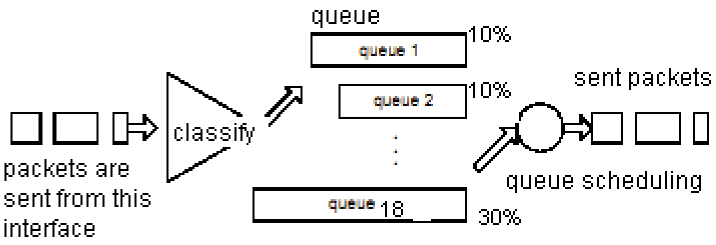
LLQ and RTPQ+CBWFQ are suitable for applying strict classification rules and bandwidth allocation on serial interfaces with bandwidth equal to or less than 2.048 Mbps.

CQ

Working Principles

CQ defines 17 classes for packets, corresponding to 17 CQ queues. Packets enter corresponding CQ queues based on their classes and the FIFO policy. For queues 1 through 16, queue 0 is a system queue; queue 1 through 16 are user queues. Associated with each queue is a configurable byte count, which specifies how many bytes of data the system should deliver from the current queue before it moves on to the next queue. The system queue is emptied before any of the queues 1 through 16 are processed. For queues 1 through 16, the system cycles through the queues using the pre-assigned bandwidth in a round-robin fashion, the system dequeues the configured byte count from each queue in each cycle and delivers packets in the current queue before moving on to the next one.

Figure 5 CQ



CQ ensures that no application or specified group of applications achieves more than a predetermined proportion of overall bandwidth when the line is under stress. Like PQ, CQ is statically configured and does not automatically adapt to changing network conditions. With CQ enabled, the system takes longer and consumes more resources to switch packets because packets need to be queued.

How to Determine Byte Count Values for Queues

In order to assign bandwidth to different queues, you must specify the byte count for each queue. This section describes how to determine byte count values for queues.

When the router cycles through queues in round-robin fashion, the device sends packets from a particular queue until the byte count is exceeded. If the byte count value is exceeded but packets of the queue are not completely sent, the device continues sending until all packets of the queue are sent. Therefore, if you set the byte count to 300 bytes and the packet size of your protocol is 1500 bytes, then every time this queue is serviced, 1500 bytes will be sent, not 300 bytes.

For example, suppose one protocol has 500-byte packets, another has 300-byte packets, and a third has 100-byte packets. If you want to split the bandwidth evenly across all three protocols, you might choose to specify byte counts of 200, 200, and 200 for each queue. However, this configuration does not result in a 33/33/33 ratio. When the device services the first queue, it sends a single 500-byte packet; when it services the second queue, it sends a 300-byte packet; and when it services the third queue, it sends two 100-byte packets. The effective ratio is 50/30/20.

Thus, setting the byte count too low can result in an unintended bandwidth allocation. However, very large byte counts will produce a “jerky” distribution. That is, if you assign 10 KB, 10 KB, and 10 KB to three queues in the example given, each protocol is serviced promptly with equal bandwidth assigned when its queue is the one being serviced, but it may be a long time before the queue is serviced again. A better solution is to specify 500-byte, 600-byte, and 500-byte counts for the queue. This configuration results in a ratio of 31/38/31, which may be acceptable. In order to service queues in a timely manner and ensure that the configured bandwidth allocation is as close as possible to the required bandwidth allocation, you must determine the byte count based on the packet size of each protocol; otherwise your percentages may not match what you configure.

To determine the correct byte counts, perform the following steps:

1. For each queue, divide the percentage of bandwidth you want to assign to the queue by the packet size, in bytes. For example, assume the packet size for protocol A is 1086 bytes, protocol B is 291 bytes, and protocol C is 831 bytes. You want to assign 20 percent for A, 60 percent for B, and 20 percent for C. The ratios would be:
   20/1086, 60/291, 20/831
   or 0.01842, 0.20619, 0.02407

2. Normalize the numbers by dividing by the lowest number:
   1, 11.2, 1.3
   The result is the ratio of the number of packets that must be sent so that the percentage of bandwidth that each protocol uses is approximately 20, 60, and 20 percent.

3. A fraction in any of the ratio values means that an additional packet will be sent. Round up the numbers to the next whole number to obtain the actual packet count. In this example, the actual ratio will be 1 packet, 12 packets, and 2 packets.

4. Convert the packet number ratio into byte counts by multiplying each packet count by the corresponding packet size. In this example, the number of packets sent is one 1086-byte packet, twelve 291-byte packets, and two831-byte packets, or 1086, 3492, and 1662 bytes, respectively, from each queue. These are the byte counts you would specify in your CQ configuration.

5. To determine the bandwidth distribution this ratio represents, first determine the total number of bytes sent after all three queues are serviced:
   (1 x 1086) + (12 x 291) + (2 x 831) = 1086 + 3492 + 1662 = 6240

6. Then determine the percentage of the total number of bytes sent from each queue:
   1086/6240, 3492/6240, 1662/6240 = 17.4, 56, and 26.6 percent
   This result is close to the desired ratio of 20/60/20.

7. If the actual bandwidth is not close enough to the desired bandwidth, multiply the original ratio of1:11.2:1.3 by the best value, trying to get as close to three integer values as possible. Note that the multiplier you use need not be an integer. For example, if we multiply the ratio by two, we get 2:22.4:2.6. You would now send two 1086-byte packets, twenty-three 291-byte packets, and three 831-byte packets, or 2172/6693/2493, for a total of 11,358 bytes. The resulting ratio is 19/59/22 percent, which is much closer to the desired ratio that we achieved.

Window size also affects the bandwidth distribution. If the window size of a particular protocol is set to one, then that protocol will not place another packet into the queue until it receives an acknowledgment. The CQ algorithm moves to the next queue if the byte count is exceeded or no packet is in that queue. Therefore, with a window size of one, only one frame will be sent each time. If your frame count is set to 2 kilobytes, and your frame size is 256 bytes, then only 256 bytes will be sent each time this queue is serviced.

Applicable Environment

This function is suitable for interfaces that process data at low speeds.

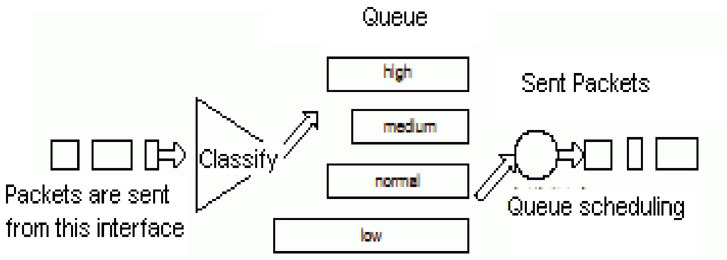
Note CQ is not supported on any tunnels.

PQ

Working Principles

PQ allows you to define how traffic is prioritized in the network. You can configure four traffic priorities. You can define a series of filters based on packet characteristics (source addresses, destination addresses, protocol types, and packet sizes) to place traffic into these four queues; the queue with the highest priority is serviced first until it is empty, then the lower queues are serviced in sequence.

Figure 6 PQ



As shown in the preceding figure, packets are classified and placed in four output types of output queues based on user-defined criteria. The priority queues on that interface are scanned for packets in descending order of priority. The high priority queue is scanned first, then the medium priority queue, and so on. The packet at the head of the highest queue is chosen for transmission. This procedure is repeated every time a packet is to be sent.

When choosing to use PQ, consider that because lower priority traffic is often denied bandwidth in favor of higher priority traffic, use of PQ could, in the worst case, result in lower priority traffic never being sent. PQ introduces extra system resource consumption that is acceptable for slow interfaces, but may not be acceptable for higher speed interfaces such as Ethernet. With PQ enabled, the system takes longer to switch packets, degrading system performance. PQ uses a static configuration and does not adapt to changing network conditions.

Applicable Environment

Although you can enable PQ for any interface, it is best used for low-bandwidth, congested serial interfaces.

Note PQ is not supported on any tunnels.

WFQ

WFQ Configuration Tasks

When standard WFQ is enabled, packets are classified by flow. Packets with the same source IP address, destination IP address, source TCP or UDP port, and destination TCP or UDP port belong to the same flow. WFQ assigns an equal share of bandwidth to each flow. Flow-based WFQ is also called fair queueing because all flows are equally weighted.

Configuring WFQ entails the following two processes:

- Configuring WFQ
- Monitoring fair queuing

Note Memory configuration is different for routers on different platforms. You are advised to run the **fair-queue** command to configure depth and count of different queues.

Configuring WFQ

To configure WFQ, run the following commands in the interface configuration mode:

Command	Function
Ruijie(config-if)# **fair-queue** [*congestive-discard-threshold* [*dynamic-queues*]]	Configure WFQ.
Ruijie(config-if)# **no fair-queue**	Cancel WFQ configuration.

The following table describes parameters related to WFQ configuration.

Command	Function
congestive-discard-threshold	Specify the maximum threshold of packets allowed in each queue. The default value is 64 and the value range is 1–4096. When the packet count reaches the threshold, newly arrived packets will be discarded. This parameter is optional.
dynamic-queues	Specify the number of dynamic queues. The default value is 256 and the value must be 2^n within 16–4096. This parameter is optional.

Note To configure the WFQ congestion management policy, ensure that the fast-switching function configuration (enable or disable the function) is consistent on all system interfaces. Otherwise, the congestion management policy becomes invalid.

Note The value of *dynamic-queues* needs to be adjusted dynamically according to the current service traffic status. Ensure that the value of *dynamic-queues* be greater than the number of service flows; otherwise, multiple service flows enter a same dynamic queue. You are advised to set the *dynamic-queues* to a value greater than both 64 and the number of service flows.

Monitoring WFQ

To view information about WFQ that has been configured, run the following commands in the privileged user mode:

Command	Function

Ruijie# **show queue wfq**	Show configuration information about WFQ queues.
Ruijie# **show queue interface** *interface-name interface-number*	Show interface statistic information about WFQ queues.

For routers of the RSR series, you can view statistic information about fast-switching WFQ queue interfaces by running the **show queue interface** command. "Qos Ref queue information" identifies statistic information about fast-switching WFQ queue interfaces.

WFQ Configuration Example

In the following instance, fair queueing is configured on synchronization port 0. Specifically, serial port 0 is configured with 128 message queues, 512 dynamic queues, and 50 reserved queues.

```
interface Serial 1/0
ip address 1.1.1.1 255.255.255.0
fair-queue 128 512
```

The following are examples of viewing the interface configuration in the privileged user mode:

```
Ruijie# show queue interface serial 1/0
Queuing strategy: weighted fair
Output queue: 0/300/128/0 (size/max total/threshold/drops)
Output queue num: 0/0/512 (now active/max active/max total)
```

The preceding output shows that WFQ is enabled on the interface and the threshold for discarding packets is **128** in the event of congestion.

CBWFQ

CBWFQ Configuration Tasks

By default, the QoS policy of FIFO is enabled on Ruijie network interfaces with bandwidth lower than 4 Mbps.

Configuring CBWFQ

Defining Class-Maps

This function is required for realizing CBWFQ functionality. You can define packet classification rules in class-maps, and specify the class-map names for using them in policy-maps. A class-map can be used by one or more policy-maps. The following table describes the typical configuration of this function.

Command	**Function**
Ruijie(config)# **class-map** *match-all class-map-name*	Access and create the class-map of the "AND" type. That is, all conditions in the class-map must be met.
Ruijie(config)# **class-map** *match-any class-map-name*	Access and create the class-map of the "OR" type. That is, all conditions in the class-map must be met.
Ruijie(config-cmap)# **match access-group** *access-list-number* or Ruijie(config-cmap)# **match input-interface** *interface-name* or Ruijie(config-cmap)# **match protocol** *protocol-name* or Ruijie(config-cmap)# **match cos** *value* or Ruijie(config-cmap)# **Match ip dscp** *value* or Ruijie(config-cmap)# **Match ip precedence** *value* or Ruijie(config-cmap)# **Match not** *match-type value*	Configure the packet classification rules. The rules can be the positive or negative forms of the ACL, packet receiving interface, encapsulation protocol type, COS value, IP DSCP code, and IP Precedence code.
Ruijie(config-cmap)# **exit**	Exit from the configuration layer of class-maps.

Class-map-name: indicates the name of a class-map.

Match-all: All conditions in the class-map must be met. By default, a created class-map is of the **Match-all** type.

Match-any: indicates that only one condition in the class-map needs to be met.

Access- list-number: indicates the number of the access control list (ACL).

Interface- name: indicates the name of a network interface.

Protocol-name: indicates the packet encapsulation protocol.

COS: indicates the COS value of an Ethernet packet.

IP dscp: indicates the DSCP code value of the packet IP TOS domain.

IP Precedence: indicates the Precedence code value of the packet IP TOS domain.

Not match-type: indicates the negative form of a classification rule.

Configuring Rules in Policy-Maps

This function is required for realizing CBWFQ functionality. In a policy-map, you can use all class-maps configured on the router and use a maximum of 64 class-maps concurrently. You can define bandwidth for class-maps that are used under the precondition that the sum of bandwidth for all class-maps is equal to or smaller than the bandwidth assigned to CBWFQ on a specified interface that applies the policy-map. The following table describes the typical configuration of this function.

Command	Function
Ruijie(config)# **policy-map** *policy-map-name*	Access and create a policy-map.
Ruijie(config-pmap)# **class** *class-map-name*	Use class-maps that have been defined.
Ruijie(config-pmap-c)# **bandwidth** { *bandwidth-kbps* | **percent** *percent-number* }	Specify bandwidth assigned to specified types of data flows.
Ruijie(config-pmap-c)# **queue-limit** *number-of-packets*	Set the queue depth.
Ruijie(config-pmap-c)# **exit**	Exit from the configuration layer of class using.
Ruijie(config-pmap)# **exit**	Exit from the configuration layer of policy-maps.

Policy-map-name: indicates the name of a policy-map.

Class-map-name: indicates the name of a class-map.

Bandwidth-kbps: indicates the assigned bandwidth in kbps.

Percent-number: indicates the assigned-bandwidth to all-available-bandwidth ratio.

Number-of-packets: indicates the depth of a CBWFQ queue (the maximum number of packets that are allowed).

Applying Service Rules on Specified Interfaces

This function is required for realizing CBWFQ functionality. If service rules are enabled on specified interfaces, CBFWQ functionality is enabled and classes used in policy-maps obtain their processing queues. The following table describes the typical configuration of this function.

Command	Function
Ruijie(config-if)# **service-policy output** policy-map-name	Enable CBWFQ and specify the policy-maps to be applied.
Ruijie(config-if)# **service-policy input** policy-map-name	Enable the policy-map strategy for interface input packets.

Policy-map-name: indicates the name of a policy-map.

Note

If CBWFQ characteristics (such as the **Bandwidth** command or the **Priority** command) are enabled for a policy-map, the policy-map can be only be used in the **Service-policy Output** command, but not the **Service-policy Input** command.

Note

To configure the policy-map of an interface, ensure that the fast-switching function configuration (enable or disable the function) is consistent on all system interfaces. Otherwise, the functions such as CBWFQ and police of the policy-map become invalid.

Note

Ensure that the fast-switching function is disabled, if an interface configured with an input-direction policy-map or associated with an output-direction policy mapping of the shape and red functions. This is a required in the current software version.

Configuring Bandwidth for Specified Classes

This function is optional for realizing CBWFQ functionality. The following table describes the typical configuration of this function.

Command	Function
Ruijie(config)# **policy-map** *policy-map-name*	Access and create a policy-map.
Ruijie(config-pmap)# **class** *class-name*	Use class-maps that have been defined.
Ruijie (config-pmap-c)# **bandwidth** { bandwidth-kbps | **percent** percent}	Specify bandwidth assigned to specified types of data flows.

Policy-map-name: indicates the name of a policy-map.

Class-map-name: indicates the name of a class-map.

Bandwidth-kbps: indicates the assigned bandwidth in kbps.

Percent-number: indicates the assigned-bandwidth to all-available-bandwidth ratio.

You can specify bandwidth assigned to specified types of data flows. By default, the system assigns 1% of the bandwidth to a specified type of data flow.

Configuring Queue Depth for Specified Classes

This function is optional for realizing CBWFQ functionality. The following table describes the typical configuration of this function.

Command	Function
Ruijie(config)# **policy-map** *policy-map-name*	Access and create a policy-map.
Ruijie(config-pmap)# **class** *class-name*	Use class-maps that have been defined.
Ruijie(config-pmap-c)# **queue-limit** *number-of-packets*	Set the queue depth.

Policy-map-name: indicates the name of a policy-map.

Class-map-name: indicates the name of a class-map.

Number-of-packets: indicates the depth of a CBWFQ queue (the maximum number of packets that are allowed).

You can set the depth of a CBWFQ queue corresponding to a specified type of data flow. The system default value is **64**. That is, the system will discard packets attempting to enter a CBFWQ queue if the queue has got 64 packets. In this case, Ruijie products support the congestion processing only in Tail-Drop mode, not in WRED mode.

Note

Queue depth configuration depends on network requirements. When forwarded data is delay-sensitive, you can decrease the queue depth to lower delay. When the forwarded data is burst or contains many small packets, you can increase the queue depth to improve the system buffer capability.
Do not adjust the queue depth to a value that is too small; otherwise, the bandwidth guarantee function

becomes abnormal.

In an environment where the forwarded data is burst or contains many small packets, bandwidth may fail to be guaranteed. You need to increase the queue depth to improve the system buffer capability.

Configuring the DSCP Code Value of the IP TOS Domain for a Specified Class

This function is optional for realizing CBWFQ functionality. The following table describes the typical configuration of this function.

Command	Function
Ruijie(config)# **policy-map** *policy-map-name*	Access and create a policy-map.
Ruijie(config-pmap)# **class** *class-name*	Use class-maps that have been defined.
Ruijie(config-pmap-c)# **set ip dscp** *values*	Set the packet DSCP value.

Policy-map-name: indicates the name of a policy-map.

Class-map-name: indicates the name of a class-map.

Values: indicates the packet DSCP value to be set.

Configuring the DSCP Code Value of the IPv4 TOS Domain and the IPv6 Traffic Class Domain for a Specified Class

This function is optional for realizing CBWFQ functionality. The following table describes the typical configuration of this function.

Command	Function
Ruijie(config)# **policy-map** *policy-map-name*	Access and create a policy-map.
Ruijie(config-pmap)# **class** *class-name*	Use class-maps that have been defined.
Ruijie(config-pmap-c)# **set dscp** *values*	Set the packet DSCP value.

Policy-map-name: indicates the name of a policy-map.

Class-map-name: indicates the name of a class-map.

Values: indicates the packet DSCP value to be set.

Configuring the Precedence Code Value of the IP TOS Domain for a Specified Class

This function is optional for realizing CBWFQ functionality. The following table describes the typical configuration of this function.

Command	Function
Ruijie(config)# **policy-map** *policy-map-name*	Access and create a policy-map.
Ruijie(config-pmap)# **class** *class-name*	Use class-maps that have been defined.
Ruijie(config-pmap-c)# **set ip precedence** *values*	Set the packet Precedence value.

Policy-map-name: indicates the name of a policy-map.

Class-map-name: indicates the name of a class-map.

Values: indicates the packet Precedence value to be set.

Configuring the Precedence Code Value of the IPv4 TOS Domain and the IPv6 Traffic Class Domain for a Specified Class

This function is optional for realizing CBWFQ functionality. The following table describes the typical configuration of this function.

Command	Function

Ruijie(config)# **policy-map** *policy-map-name*	Access and create a policy-map.
Ruijie(config-pmap)# **class** *class-name*	Use class-maps that have been defined.
Ruijie(config-pmap-c)# **set precedence** *values*	Set the packet Precedence value.

Policy-map-name: indicates the name of a policy-map.

Class-map-name: indicates the name of a class-map.

Values: indicates the packet Precedence value to be set.

Configuring the COS Value of Ethernet Packets for a Specified Class

This function is optional for realizing CBWFQ functionality. The following table describes the typical configuration of this function.

Command	**Function**
Ruijie(config)# **policy-map** *policy-map-name*	Access and create a policy-map.
Ruijie(config-pmap)# **class** *class-name*	Use class-maps that have been defined.
Ruijie(config-pmap-c)# **set cos** *values*	Set the packet COS value.

Policy-map-name: indicates the name of a policy-map.

Class-map-name: indicates the name of a class-map.

Values: indicates the packet COS value to be set.

Configuring Bandwidth Assigned to CBWFQ

This function is optional for realizing CBWFQ functionality. The following table describes the typical configuration of this function.

Command	Function
Ruijie(config-if)# **max-reserved-bandwidth** percent	Set bandwidth assigned to CBWFQ.

Percent: indicates percentage of the bandwidth assigned to CBWFQ on an interface.

You can customize the value of the **percent** parameter. The system default value is **75**. That is, 75% of all available bandwidth of the corresponding network interface will be assigned to CBWFQ queues.

Monitoring CBWFQ

To view information about input and output queues when CBWFQ is enabled on an interface, run the following commands in the privileged user mode:

Command	**Function**
Ruijie# **show class-map**	Show information about all class-maps.
Ruijie# **show class-map** *class-map-name*	Show information about a specified class-map.
Ruijie# show policy-map	Show information about all policy-maps.
Ruijie# **show policy-map name** *policy-map –name*	Show information about a specified policy-map.
Ruijie# **show policy-map name** *policy-map -name* **class** *class-name*	Show information about specified class-maps in a specified policy-map.
Ruijie# **show policy-map interface** interface-name interface-number	Show information about policy-maps applied on a specified interface.
Ruijie# **show queue interface** interface-name *interface-number*	Show interface statistic information about CBWFQ queues.

Class-map-name: indicates the name of a class-map.

Policy-map-name: indicates the name of a policy-map.

Interface-name: indicates the name of a network interface.

Note

For routers of the RSR series, you can view statistic information about fast-switching CBWFQ queue interfaces by running the **show queue interface** command. "Qos Ref queue information" identifies statistic information about fast-switching CBWFQ queue interfaces.

Note

You can run the **show policy-map interface** command to view statistic information about fast-switching policy-maps on routers of the RSR series.

CBWFQ Configuration Example

In the following example, CBWFQ is enabled on a WAN interface Serial1/0 (S1/0) of the router. 30% of all available bandwidth on the interface S0 is used in the IP communication between the host 192.168.201.213 and the host 192.168.12.216. 10% of all available bandwidth on the interface S0 is used in the IP communication between the host 192.168.201.213 and the host 192.168.12.77.

The following is the configuration of the device where CBWFQ is enabled:

```
Ruijie# show running-config
!
.. .. ..
!
class-map class1
match access-group 101
class-map class2
match access-group 102
!
policy-map policy1
class class1
bandwidth percent 30
class class2
bandwidth percent 10
!
interface FastEthernet0/0
ip address 192.168.201.1 255.255.255.0
!
interface Serial1/0
ip address 192.168.20.3 255.255.255.0
encapsulation ppp
service-policy output policy1
clock rate 115200
!
ip route 0.0.0.0 0.0.0.0 Serial1/0
access-list 101 permit ip host 192.168.201.213 host 192.168.12.216
access-list 102 permit ip host 192.168.201.213 host 192.168.12.77
!
.. .. ..
```

In the following example, the DSCP value is set for five types of packets matching the ACL on the ingress interface and the packets are transformed into four types of macro-flows for the differentiated services. The bandwidth assigned to CBWFQ queues is adjusted.

The following is the configuration of the device where CBWFQ is enabled:

```
class-map match-all dlsw
match access-group 101
class-map match-all voip
match access-group 102
class-map match-all notes
match access-group 103
class-map match-all http
match access-group 104
class-map match-all ftp
match access-group 105
class-map match-all ef
match ip dscp 46
```

```
class-map match-all af1
match ip dscp 10
class-map match-all af2
match ip dscp 18
class-map match-all af3
match ip dscp 26
!
!
policy-map 1
class dlsw
set ip dscp 46
class voip
set ip dscp 46
class notes
set ip dscp 10

Configuring LLQ and RTPQ

Configuration Tasks of LLQ and RTPQ

LLQ configuration is combined with CBWFQ configuration, but RTPQ configuration is independent.

Configuring LLQ and RTPQ

To configure LLQ, run the following commands in the configuration mode of the Policy-map command layer:

Command	Function
Ruijie(config)# **policy-map** *policy-map-name*	Access and create a policy-map.

Ruijie(config-pmap)# **class** *class-name*	Use class-maps that have been defined.
Ruijie (config-pmap-c)# **priority** { *bandwidth-kbps* | **percent** *percent*} {*Burst bytes*}	Specify bandwidth assigned to specified types of data flows.
Ruijie(config-if)# service-policy output policy-map-name	Enable CBWFQ and specify the policy-maps to be applied.

Policy-map-name: indicates the name of a policy-map.

Class-map-name: indicates the name of a class-map.

Bandwidth-kbps: indicates the assigned bandwidth in kbps.

Percent-number: indicates the assigned-bandwidth to all-available-bandwidth ratio.

You can specify bandwidth assigned to specified types of data flows. By default, the system assigns 1% of the bandwidth to a specified type of data flow.

Burst bytes: indicates the byte count that can be exceeded.

Note

Queue depth configuration depends on network requirements. When forwarded data is delay-sensitive, you can decrease the queue depth to lower delay. When the forwarded data is burst or contains many small packets, you can increase the queue depth to improve the system buffer capability.
Do not adjust the queue depth to a value that is too small; otherwise, the bandwidth guarantee function becomes abnormal.
In an environment where the forwarded data is burst or contains many small packets, bandwidth may fail to be guaranteed. You need to increase the queue depth to improve the system buffer capability.

To configure RTPQ, run the following commands in the configuration mode of the interface configuration command layer:

Command	Function
Ruijie(config-if)# **ip rtp priority** *starting-rtp-port-number port-number-range bandwidth*	Create RTPQ queues for an interface and assign bandwidth to these queues.

Starting-rtp-port-number: indicates the starting port number among the matching UDP ports.

Port-number-range: indicates the port number range of the matching UDP ports.

Bandwidth-kbps: indicates the assigned bandwidth in kbps.

Note

The following three commands affect the bandwidth assigned for interfaces:
The **Bandwidth** command of CBWFQ
The **Priority** command of LLQ
The **ip rtp priority** command of RTPQ
The **Bandwidth** command of the interface is used to set the entire bandwidth.
That is, Bandwidth = max_reserve +default wfq bandwidth;
max_reserve = bandwidth (policy-map) + priority (policy-map) +ip RTP priority

Note

To configure the interface congestion management policy, ensure that the fast-switching function configuration (enable or disable the function) is consistent on all system interfaces. Otherwise, the congestion management policy becomes invalid.

Monitoring LLQ and RTPQ

To view information about LLQ that has been configured, run the following commands in the privileged user mode:

Command	Function
Ruijie# **show policy-map** *interface-name interface-number*	Show information about policy-maps applied on a specified interface.

To view information about RTPQ that has been configured, run the following commands in the privileged user mode:

Command	Function
Ruijie# **show queue rtpq**	Show information about RTPQ queues.

Note

For routers of the RSR series, you can view statistic information about fast-switching RTPQ queue interfaces by running the **show queue interface** command. "Qos Ref queue information" identifies statistic information about fast-switching RTPQ queue interfaces.

You can run the **show policy-map interface** command to view statistic information about fast-switching policy-maps on routers of the RSR series.

Configuration Examples of LLQ and RTPQ

In the following example, on SYNC port 0, an RTPQ queue is configured for serving RTP of VOIP and an LLQ queue is configured for serving DOSQ office packets. CBFWQ queues process Notes packets and default WFQ queues in CBWFQ process other packets.

Configuring CQ

CQ Configuration Tasks

Configuring CQ

You can configure a maximum of 16 groups for CQ. That is, the List-number range is 1–16. In each group, you can specify queues of packets, queue length, and byte count that can be continuously sent after a queue obtains the controlling right of sending packets.

Determining the Maximum Capacity of CQ

To configure the maximum packet capacity for each queue, run the following commands in the global configuration mode:

Command	Function
Ruijie(config)# **queue-list** *list-number* **queue** *queue-number* limit *limit-number*	Specify the maximum packet count in a CQ queue. The no form of this command can be run to restore the default queue length 20.
Ruijie(config)# **queue-list** *list-number* **queue** *queue-number* **byte-count** *byte-count-number*	Specify the maximum byte count in a queue. The no form of this command can be run to restore the default byte count 1500.

List-number: indicates the number of a queue list within 1–16.

Queue-number: indicates the number of a custom queue number within 1–16.

Limit-number: indicates the maximum packet count in a queue. The value range is 0–32767, and the default value is **20**.

Byte-count-number: specifies how many bytes of data should be delivered from the current queue by the system before the system moves on to the next queue until the value of **Byte-count-number** is exceeded or no packet is in that queue. The value range is 0–16777215, and the default value is **1500**. To determine the correct byte counts, see the related section.

Note

To configure the interface congestion management policy, ensure that the fast-switching function configuration (enable or disable the function) is consistent on all system interfaces. Otherwise, the congestion management policy becomes invalid.

Note

You should configure Byte-count-number based on traffic in each queue. Do not configure a large byte count for a slow traffic queue. Otherwise, the current queue may keep being dispatched, resulting in that other queues cannot be processed.

Assigning Packets to CQ Queues

You can assign a packet to a CQ queue based on the protocol type and the interface where the packet enters the device. You can also configure a default queue with multiple rules for packets matching no allocation criterion.

To configure the CQ queue list, run the following commands in the global configuration mode:

Command	Function
Ruijie(config)# **queue-list** *list-number* **protocol** protocol-name queue-number [queue-keyword] [keyword-value]	Assign a packet to a CQ queue based on the protocol type.
Ruijie(config)# **queue-list** *list-number* **interface** interface-type interface-number queue-number	Assign a packet to a CQ queue based on the type of the interface where the packet enters the device.

Ruijie(config)# **queue-list** *list-number* **default** queue-number	Assign packets matching no assignment rules in the CQ queue list to a CQ queue. The default CQ queue number is **1**.

For the description about **List-number** and **Queue-number**, see the preceding section.

Protocol-name: indicates the type of a protocol. The value can be **IP** (frequently used), **PAD**, and so on.

Queue-keyword and **Keyword-value**: indicates options about protocols. The following table describes values and meanings of the two parameters when IP is used.

queue-keyword	**keyword-value**	**Meaning**
Blank	Blank	All IP packets can enter a specified queue.
fragments	Blank	All fragment IP packets can enter a specified queue.
list	List-number	All packets matching the access-list-number can enter a specified queue.
lt	Byte-count	Packets whose length is smaller than the value of byte-count can enter a specified queue.
gt	Byte-count	Packets whose length is greater than the value of byte-count can enter a specified queue.
tcp	Port	IP packets whose source or destination TCP port number is port can enter a specified queue.
udp	Port	IP packets whose source or destination UDP port number is port can enter a specified queue.

Ensure that the fast-switching function is disabled on an interface when you specify the fragments policy for protocol rules. This is required in the current software version.

Specifying the Lowest CQ Queue Number

By default, you can customize CQ queues numbered 1 to 16. CQ reserves queue 0 for routing protocols and queue 0 functions as the absolute priority queue higher than all customize queues. If there is other traffic that needs to be processed with high priority, CQ allows you to increase the number of absolute priority queues by adjusting the lowest custom queue list number.

By default, the lowest custom queue number is 1. That is, only queue 0 is the absolute priority queue, and queues 1–16 are custom queues.

To configure the lowest CQ queue number, run the following commands in the global configuration mode:

Command	Function
Ruijie(config)# **queue-list** *list-number* **lowest-custom** *queue-number*	Customize the lowest CQ queue number.

List-number: indicates the number of a queue list within 1–16.

Queue-number: indicates the number of a custom queue within 0–16.

Applying the CQ List on an Interface

To apply a CQ list on an interface, run the following command in the interface configuration mode:

Command	Function
Ruijie(config-if)#**custom-queue-list** *list-number*	Set the queueing policy of an interface to a specified CQ list.

Note Each interface can use only one queueing policy and one matching list.

Monitoring CQ

To view information about input and output queues when CQ is enabled on an interface, run the following commands in the privileged user mode:

Command	Function
Ruijie# **show queue cq**	Show configuration information about CQ queues.
Ruijie# **show queue interface** interface-name *interface-number*	Show interface statistic information about CQ queues.
Ruijie# **debug qos cq**	Enable CQ debugging.

Note

For routers of the RSR series, you can view statistic information about fast-switching CQ queue interfaces by running the **show queue interface** command. "Qos Ref queue information" identifies statistic information about fast-switching CQ queue interfaces.

CQ Configuration Examples

Set CQ list 2: Assign IP packets whose length is greater than 200 bytes to queue 12.

```
Ruijie(config)# queue-list 2 protocol ip 12 gt 200
```

Set CQ list 4: Assign IP packets whose length is smaller than 300 bytes to queue 2.

```
Ruijie(config)# queue-list 4 protocol ip 2 lt 300
```

Set CQ list 1: Assign traffic matching IP-access-list 10 to queue 11.

```
Ruijie(config)# queue-list 1 protocol ip 11 list 10
```

Set CQ list 4: Assign Telnet packets to queue 12.

```
Ruijie(config)# queue-list 4 protocol ip 12 tcp 23
```

Set CQ list 4: Assign UDP domain name service packets to queue 2.

```
Ruijie(config)# queue-list 4 protocol ip 2 udp 53
```

Set CQ list 3: Assign packets transmitted from ASNC port 1 to queue 7.

```
Ruijie(config)# queue-list 3 interface serial 1 7
```

Set CQ list 9: Set the byte count of queue 10 to **1800**.

```
Ruijie(config)# queue-list 9 queue 10 byte-count 1800
```

Set CQ list 5: Set the queue length of queue 10 to **40**.

```
Ruijie(config)# queue-list 5 queue 10 limit 40
```

Set the queueing policy of SYNC port 0 to CQ list 5.

```
Ruijie(config)# interface serial 0
Ruijie(config-if)# custom-queue-list 1
```

Configuring PQ

PQ Configuration Tasks

Configuring PQ

You can configure a maximum of 16 groups for PQ. That is, the List-number range is 1–16. In each group, you can specify queues of packets, queue length, and byte count that can be continuously sent after a queue obtains the controlling right of sending packets.

Determining the Maximum Capacity of PQ

There are four queues (each assigned with the high, medium, normal, and low priority) in each group of queue lists. To specify the maximum number of packets allowed in each of the priority queues, run the following command in global configuration mode:

Command	**Function**
Ruijie(config)# **priority-list** *list-number* **queue-limit** [high-limit [medium-limit [normal-limit [low-limit]]]]	Specify the maximum packet count in a PQ queue.

List-number: indicates the number of a queue list within 1–16.

The following table describes the default queue lengths.

Queue	**Length**
high	20
medium	40
normal	60
Low	80

Note

To configure the interface congestion management policy, ensure that the fast-switching function configuration (enable or disable the function) is consistent on all system interfaces. Otherwise, the congestion management policy becomes invalid.

Assigning Packets to PQ Queues

You can specify multiple assignment rules. The **priority-list** commands are read in order of appearance until a matching protocol or interface type is found. When a match is found, the packet is assigned to the appropriate queue and the search ends. Packets that do not match other assignment rules are assigned to the default queue. To specify which queue to place a packet in, run the following commands in global configuration mode:

Command	**Function**
Ruijie(config)# **priority-list** *list-number* **protocol** *protocol-name* {**high** | **medium** | **normal** | **low**} [queue-keyword] [keyword-value]	Assign a packet to a PQ queue based on the protocol type.
Ruijie(config)# **priority-list** list-number **interface** *interface-type interface-number* {high | medium | normal | low}	Assign a packet to a PQ queue based on the type of the interface where the packet enters the device.
Ruijie(config)# **priority-list** *list-number* **default** {**high** | **medium** | **normal** | **low**}	Assign a default PQ queue with the normal priority for those packets that do not match any other rule in the priority list.

List number indicates the number of a priority queue. **Protocol-name** indicates the name of a protocol, such as IP, PAD, and so on. The values and meanings of **Queue-keyword** and **Eyword-value** are the same as these of CQ.

Applying the PQ List on an Interface

To apply a PQ list on an interface, run the following command in the interface configuration mode:

Command	**Function**
Ruijie(config-if)# **priority-group** *list-number*	Set the queueing policy of an interface to a specified PQ list.

Note

Each interface can use only one queueing policy and one matching list.

Monitoring PQ

To view information about input and output queues when PQ is enabled on an interface, run the following commands in the privileged user mode:

Command	Function
Ruijie# **show queue pq**	Show configuration information about PQ queues.
Ruijie# **show queue interface** interface-name *interface-number*	Show interface statistic information about PQ queues.
Ruijie# **debug qos cq**	Enable PQ debugging.

Note

For routers of the RSR series, you can view statistic information about fast-switching PQ queue interfaces by running the **show queue interface** command. "Qos Ref queue information" identifies statistic information about fast-switching PQ queue interfaces.

PQ Configuration Examples

Set PQ list 3: Assign packets transmitted from ASNC port 1/1 to the medium priority queue.

```
Ruijie(config)# priority-list 3 interface serial 1/1 medium
```

Set PQ list 6: Assign packets with a byte count greater than 250 to the medium priority queue.

```
Ruijie(config)# priority-list 6 protocol ip medium gt 250
```

Set PQ list 11: Assign IP packets with a byte count smaller than 250 to the medium priority queue.

```
Ruijie(config)# priority-list 11 protocol ip medium lt 250
```

Set PQ list 7: Assign packets matching IP access list 101 to the high priority queue.

```
Ruijie(config)# priority-list 7 protocol ip high list 101
```

Set PQ list 6: Assign Telnet packets to the high priority queue.

```
Ruijie(config)# priority-list 6 protocol ip high tcp 23
```

Set PQ list 6: Assign UDP domain name service packets to the low priority queue.

```
Ruijie(config)# priority-list 6 protocol ip low udp 53
```

Set PQ list 1: Assign packets that do not match any other rules in the priority list to the medium priority queue.

```
Ruijie(config)# priority-list 1 default medium
```

Set PQ list 2: set the lengths of the high, medium, normal, and low priority queues to 10, 40, 60, and 80.

```
Ruijie(config)# priority-list 2 queue-limit 10 40 60 80
```

Configuring Hold-queue

Configuring hold-queue

Run this command to set queue length on an interface in interface configuration mode.

Command	Function
Ruijie(config-if)# **hold-queue** *queue length* { **in** | **out** }	Sets queue length on an interface.

Queue length refers to the threshold of packets in a queue. When the number of packets reaches the threshold, the coming packets will be discarded.

The default values for input queue and output queue are 75 and 40 respectively.

Caution This command is used to modify three color-based thresholds of a queue for interface congestion and prevent green packets from being discarded preferentially. The default settings are applied generally. When cached packets exceed the red threshold, you should modify the value to make the number of cached packets below the red threshold.

Monitoring hold-queue

Run this command to show input and output queues information.

Command	Function
Ruijie# **show queue interface** *interface-name interface-number* [*queue-number*]	Shows queue information on an interface.

hold-queque Configuration Example

Configure fair queueing on synchronous interface 0 and set the threshold of packet number in an input queue to 128. When the packet number reaches the threshold, coming packets will be discarded.

```
Ruijie(config)# interface Serial 0
Ruijie(config-if)# hold-queue 128 in
```

Traffic Policing and Shaping

What Are Traffic Policing and Traffic Shaping

Traffic policing is used to control the rate of classified traffic flowing across an interface.

Traffic shaping allows you to control the burst traffic going out an interface to ensure that packets are delivered at stable rates and the network traffic remains stable.

Note NPE80 does not support traffic policing and shaping.

Overview of Traffic Policing and Shaping

- About Traffic Policing

Ruijie series of devices use the committed access rate (CAR) technology to limit the rate of traffic accessing the network to the committed rate. The rate-limiting feature and the packet classification feature can be configured together.

CAR uses the token bucket algorithm. You can set the capacity of the token bucket. If packets satisfy the preconfigured match rules, the token bucket accepts and processes the packets. If packets do not satisfy the preconfigured match rules, the token bucket refuses the packets and they continue to be transmitted. If there are sufficient tokens, packets processed by the token bucket continue to be transmitted. If tokens are insufficient, packets are discarded.

Ruijie series of devices support the configuration of at least 1-KB flow limit, the binding of CAR and ACL, and enable you to perform rate-limiting and traffic classification at the same time.

Ruijie series of devices support the service flow-limiting function based on IP applications. This enables you to limit service traffic flexibly based on IP applications' requirements on service traffic. For example, you can implement the service flow-limiting function based on the IPSec VPN tunnel.

- About Traffic Shaping

Ruijie series of devices shape traffic that is irregular or matches no predefined traffic features through the GTS (Generic Traffic Shaping) to facilitate bandwidth assignment between the upstream and downstream traffic on the network. GTS shapes traffic by buffering high-speed outbound traffic flow in the buffering area by constraining traffic to a particular bit rate using the token bucket.

Traffic shaping of routers is performed based on the following data flows:

1. All data flows passing physical interfaces
2. Data flows that are classified by using the standard or extended ACLs

- About the Token Bucket

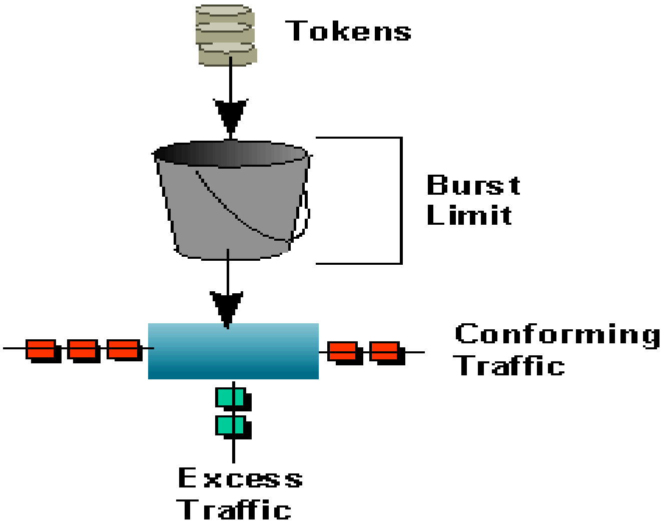
The token bucket algorithm is based on an analogy of a buffer (bucket) into which tokens, normally representing virtual data, are added at a fixed rate.

After entering the bucket, each token collects a packet from data queues and then is deleted from the bucket. This algorithm is associated with the token flow and the data flow. The following are three scenarios:

1. The data flow arrives at TBF using a rate equal to the rate of the token flow. In this case, each packet obtains a token and passes the queue without delay.
2. The data flow arrives at TBF using a rate smaller than the rate of the token flow. In this case, packets use some of the tokens and remaining tokens accumulate in the bucket until the bucket is full. Remaining tokens need to be consumed by the data flow arriving at TF using a rate greater than the rate of the token flow. In this case, burst transmission occurs.
3. The data flow arrives at TBF using a rate greater than the rate of the token flow. In this case, the bucket runs out of tokens quickly. This causes TBF interrupted for a period, namely, "threshold crossing". If packets arrive continuously, packets loss occurs.

The following figure shows the process.

Figure 7



What exactly is a token?

A token is the rate calibrated scale related to the value of CIR. Suppose that you configure an interface with a CIR rate of 8000 bit/s. Then, this interface can send 1000-bytes packets per second. At this time, the token equals to 1000 bytes, indicating that a token equal to 1000 is updated per second. Then, you can use the token to monitor whether packets accessing the interface exceed the committed rate.

Note

Ensure that the capacity of the token bucket is configured based on traffic bursts on the network. You need to expand the capacity of the token bucket to enhance the QoS tolerance capability for burst traffic on the network where burst traffic such as video or file transfer exists. Normally, the token bucket should at least support the 200-ms buffer capacity, that is, (CIR/8)*200ms.

Note

When GTS is used in rate-limiting, the frame gap and CRC are taken into account. The GRS rate limiting calculation is as follows:

1) Packet Per Second (PPS) = GTS rating limiting value in bps / ((packet length + frame gap + CRC) x 8); Round down the result for accuracy.

2) Receiver rate: PPS x actually received packet count in bytes x 8

Configuration Tasks of Traffic Policing

To configure the CAR traffic policing feature, run the following commands in the interface configuration mode:

Command	Function
Ruijie(config)# **interface** *interface-type interface-number*	Specify an interface where CAR rate limiting is to be enabled.
Ruijie(config-if)# **rate-limit** {**input** | **output**} **bps** burst-normal burst-max **conform-action** action exceed-action *action*	Perform packet rate-limiting for input or output packets of all traffic accessing the interface.

Input|output: indicates the input or output traffic that you need to limit.

Bps: indicates the maximum threshold rate (in bps) that you need to set for traffic.

Burst-normal burst-max: indicates the capacity of the token bucket in bytes.

Conform-action: indicates the processing policy for traffic that conforms to the rate limit.

Exceed-action: indicates the processing policy for traffic that exceeds the rate limit.

Action: indicates a processing policy. The processing policies are described as follows:

- Proceed to match the next policy.
- **Continue**: Match the next policy.
- **Drop**: Discard the packet.
- **Set-dscp-continue**: Continue to match the packet with the next policy after the DSCP domain is set for the packet.
- **Set-dscp-transmit**: Transmit the packet after the DSCP domain is set for the packet.
- **Set-prec-continue**: Continue to match the packet with the next policy after the IP Precedence domain is set for the packet.
- **Set-prec-transmit**: Transmit the packet after the IP Precedence domain is set for the packet.
- **Transmit**: Transmit the packet.

Caution

After IPSec encryption is enabled, the inbound traffic monitoring CAR will not support the packet revising policies including **set-dscp-continue**, **set-prec-continue**, **set-dscp-transmit**, and **set-prec-transmit,**

To configure the CAR rate limit feature for different types of traffic based on ACL or DSCP values, run the following commands in the interface configuration mode:

Command	Function
Ruijie(config)# **access-list** *acl-index*	Configure the ACL matching traffic.
Ruijie(config)# **interface** *interface-type* interface-number	Specify an interface where CAR rate limiting is to be enabled.
Ruijie(config-if)# **rate-limit** {**input** | **output**} [**access-group** *acl-index*] *bps* burst-normal burst-max **conform-action** action exceed-action *action*	Perform packet rate-limiting for the input or output packets of the traffic that matches the Acl-index access list.
Ruijie(config-if)# **rate-limit {input | output}** [**dscp** dscp-value] bps *burst-normal burst-max* **conform-action** *action* exceed-action *action*	Perform packet rate-limiting for the input or output packets of the traffic that matches the DSCP code value.

Caution

If multiple ACL CARs are configured and each flow matches an ACL, all matched flows take effect. If a flow is configure with ACL1 and ACL2, ACL1 takes effect. If a flow is configured with the same ACL rules and different action, all ACL rules take effect.

To configure the service rate limiting based on IP applications, run the following commands in the global configuration mode:

Command	Function
Ruijie(config)# **flow-limit** {**input** | **output**} **label** label-num *bps* burst-normal burst-max **conform-action** action **exceed-action** *action*	Configure the global service rate limiting template.
Ruijie(config)# **crypto map** *map-name seq-num* ipsec-isakmp	Enter the IPSec policy-map mode.
Ruijie(config-crypto-map)# **flow-label** *label-num*	Specify the flow label of the IPSec policy-map.

Input|output: indicates the input or output traffic that you need to limit.

label-num: indicates the label number the service rate limiting feature needs to match.

Bps: indicates the maximum threshold rate (in bps) that you need to set for traffic.

Burst-normal burst-max: indicates the capacity of the token bucket in bytes.

Conform-action: indicates the processing policy for traffic that conforms to the rate limit.

Exceed-action: indicates the processing policy for traffic that exceeds the rate limit.

Action: indicates a processing policy. The processing policies are described as follows:

Drop: Drop the packet.

Transmit: Transmit the packet.

Configuration Tasks of Traffic Shaping

To configure the GTS feature, run the following commands in the interface configuration mode:

Command	Function
Ruijie(config)# **interface** *interface-type interface-number*	Specify an interface where traffic shaping is to be enabled.
Ruijie(config-if)# **traffic-shape rate** *bit-rate* [*burst-size*] [*excess-burst-size*] [*buffer-limit*]	Shape the entire traffic of an interface.

Bit-rate: indicates the maximum threshold rate (in bps) that you need to shape. The maximum value is **1000000000**, indicating 1 Gbps.

Burst-size: indicates the size of burst packets that can be transmitted during each interval. The unit is bit.

Excess-burst-size: indicates the size of burst packets that can be exceedingly transmitted during first interval. The unit is bit.

Buffer-limit: indicates the buffer size of a GTS buffer queue. The default value is **1000**.

Note

The system processing traffic shaping policy takes effect based on an interface. After GTS is enabled on the interface, GTS must be enabled on all subinterfaces of the interface. Otherwise, the subinterfaces transmit data unevenly.

Note

After traffic shaping is enabled on an interface, **Burst-size** must be an integral multiple of a certain value (the packet size sent in 10 ms by using the traffic shaping rate). Otherwise, the system invokes the packet configuration parameter to round off **Burst-size** to the certain value to make the parameter take effect legally.

Note

Buffer queue configuration depends on network requirements. When forwarded data is delay-sensitive, you can decrease the queue depth to lower delay. When the forwarded data is burst or contains many small packets, you can increase the queue depth to improve the system buffer capability.

Note

When RSR30-44 performing large MSTP nodes aggregation, GTS rate might be slightly inaccurate for the aggregation capacity of RSR30-44 is limited.

To configure the GTS feature for different types of traffic based on ACLs, run the following commands in the interface configuration mode:

Command	Function
Ruijie(config)# **access-list** *acl-index*	Create the ACL matching traffic.
Ruijie(config)# **interface** *interface-type* interface-number	Specify an interface where GTS is to be enabled.
Ruijie(config-if)# **traffic-shape group** access-list bit-rate [burst-size [excess-burst-size]]	Perform interface traffic shaping for the input or output packets of the traffic that matches the acl-index access list.

Note

The **traffic-shape group** command and the **traffic-shape rate** command are mutually exclusive on an interface**.** That is, you cannot configure the two commands on the same interface.

Note

Ensure that the fast-switching function is disabled on the interface that deploys the traffic shaping function associated with ACL classification. This is required by in the current software version.

Configuration Tasks of Traffic Policing on a Policy-Map

To configure CAR rate limiting of a single rate on a policy-map, run the following commands:

Command	Function
Ruijie(config)# **policy-map** *policy-map-name*	Access and create a policy-map.
Ruijie(config-pmap)# **class** *class-map-name*	Use class-maps that have been defined.
Ruijie(config-pmap-c)# **police cir** [*bps*] [*burst-normal*] [*burst-max*] **conform-action** [*action*] **exceed-action** [*action*] **violate-action** [*action*]	Deploy the token bucket rate limiting of a single rate for this type of traffic.
Ruijie(config-if)# service-policy output policy-map-name	Specify the policy-map to be applied.

CIR: indicates the maximum threshold rate (in bps) that you need to set for traffic.

Burst-normal burst-max: indicates the capacity of the token bucket in bytes.

Conform-action: indicates the processing policy for traffic that conforms to the rate limit.

Exceed-action: indicates the processing policy for traffic that exceeds the rate limit.

violate-action: indicates the processing policy for traffic that exceeds the rate limit set for the second token bucket when there are two token buckets.

Action: indicates a processing policy. The processing policies are described as follows:

- **Drop**: Drop the packet.

- **Set-dscp-transmit**: Transmit the packet after the DSCP domain is set for the packet.
- **Set-prec-transmit**: Transmit the packet after the IP Precedence domain is set for the packet.
- **Transmit**: Transmit the packet.

To configure CAR rate limiting of two rates on a policy-map, run the following commands:

Command	**Function**
Ruijie(config)# **policy-map** *policy-map-name*	Access and create a policy-map.
Ruijie(config-pmap)# **class** *class-map-name*	Use class-maps that have been defined.
Ruijie(config-pmap-c)# **police cir** [bps] **pir** [*bps*] [*burst-normal*] [*burst-max*] **conform-action** [*action*] **exceed-action** [*action*] **violate-action** [*action*]	Deploy the token bucket rate limiting of two rates for this type of traffic.
Ruijie(config-if)# **service-policy output** policy-map-name	Specify the policy-map to be applied on the interface.

CIR: indicates the maximum threshold rate (in bps) that you need to set for traffic.

PIR: indicates the peak maximum threshold rate (in bps) that you need to set for traffic.

Burst-normal burst-max: indicates the capacity of the token bucket in bytes.

Conform-action: indicates the processing policy for traffic that conforms to the rate limit.

Exceed-action: indicates the processing policy for traffic that exceeds the rate limit.

violate-action: indicates the processing policy for traffic that exceeds the rate limit set for the second token bucket when there are two token buckets.

Action: indicates a processing policy. The processing policies are described as follows:

Drop: Drop the packet.

Set-dscp-transmit: Transmit the packet after the DSCP domain is set for the packet.

Set-prec-transmit: Transmit the packet after the IP Precedence domain is set for the packet.

Transmit: Transmit the packet.

Note

You can choose to use one of the four token bucket algorithms for rate limit on a policy-map:
1. Single token bucket algorithm: Use this algorithm if you have not configured **violate-action** and the value of **burst-normal** is equal to the value of **burst-max**.
2. Load mode of the single token bucket algorithm: Use this mode if you have not configured **violate-action** and the value of **burst-normal** is smaller than the value of **burst-max**.
3. Single-rate two-token-buckets algorithm: Use this algorithm if you have configured **violate-action** but not **pir**.
4. Two-rate two-token-bucket algorithm: Use this algorithm if you have configured both **violate-action** and **pir**.

Configuration Tasks of Traffic Shaping on a Policy-Map

To configure traffic shaping with an average rate on a policy-map, run the following commands:

Command	**Function**
Ruijie(config)# **policy-map** *policy-map-name*	Access and create a policy-map.
Ruijie(config-pmap)# **class** *class-map-name*	Use class-maps that have been defined.
Ruijie(config-pmap-c)# **shape average cir** [*bps*] [*bc*] [*be*]	Deploy traffic shaping with an average rate for this type of traffic.
Ruijie(config-if)# service-policy output policy-map-name	Specify the policy-map to be applied on the interface.

Bit-rate: indicates the maximum threshold rate (in bps) that you need to set for traffic shaping.

BC: indicates the size of burst packets that can be transmitted during each interval. The unit is bit.

BE: indicates the size of burst packets that can be exceedingly transmitted during first interval. The unit is bit.

To configure traffic shaping with a peak rate on a policy-map, run the following commands:

Command	Function
Ruijie(config)# **policy-map** *policy-map-name*	Access and create a policy-map.
Ruijie(config-pmap)# **class** *class-map-name*	Use class-maps that have been defined.
Ruijie(config-pmap-c)# **shape peak** [*bps*] [*bc*] [*be*]	Deploy traffic shaping with a peak rate for this type of traffic.
Ruijie(config-if)# **service-policy output** *policy-map-name*	Specify the policy-map to be applied on the interface.

Bit-rate: indicates the maximum threshold rate (in bps) that you need to set for traffic shaping.

BC: indicates the size of burst packets that can be transmitted during each interval. The unit is bit.

BE: indicates the size of burst packets that can be exceedingly transmitted during first interval. The unit is bit.

To configure the buffer size of traffic shaping on a policy-map, run the following commands:

Command	Function
Ruijie(config)# **policy-map** *policy-map-name*	Access and create a policy-map.
Ruijie(config-pmap)# **class** *class-map-name*	Use class-maps that have been defined.
Ruijie(config-pmap-c)# **shape max-buffers** [number-of-buffers]	Configure the buffer size of traffic shaping.
Ruijie(config-if)# **service-policy output** policy-map-name	Specify the policy-map to be applied on the interface.

Number-of-buffers: indicates the buffer size of traffic shaping. The default value is **1000**.

Note

Configurations of **shape average bps** and **shape peak bps** bring different traffic shaping results.
In traffic shaping, the peak rate is greater than the average rate. The calculation is as follows:
Peak rate = cir (1+ bc/be)

Note

Ensure that the fast-switching function is disabled on the interface that deploys the traffic shaping function associated with a policy map. This is required by in the current software version.

Configuring Car Token Bucket Algorithm Mode

There are two modes for calculating Car rate-limit bandwidth: 1) frame-gap-included mode; 2) frame-gap-excluded mode. By default, frame gap is excluded.

To configure car token bucket algorithm mode, perform the following steps:

Command	Function
Ruijie(config)# **bandwidth-mode car** **link-header | frame-gap**	Set Car rate-limit bandwidth calculation mode: link-header means frame gap is excluded when bandwidth is calculated; frame-gap means frame gap is included when bandwidth is calculated; By default, frame gap is excluded under bandwidth calculating mode.

Note

Car token bucket algorithm mode takes effect to both police car and rate-limit in the meantime.

Configuration Examples of Traffic Policing

Configuration Examples of Traffic Policing for Entire Traffic of an Interface

In the following examples, CAR traffic policing is configured on the ingress interface and the egress interface:

# Configure CAR traffic policing of egress interface packets on a serial interface.

# Limit the egress interface traffic to 300 kbps. If the traffic conforms to the rate limit, the traffic is transmitted. If the traffic exceeds the rate limit, the traffic is discarded.

```
interface Serial1/0
ip address 192.168.20.3 255.255.255.0
encapsulation ppp
rate-limit output 300000 3000 3000 conform-action  transmit exceed-action  drop
```

# Configure CAR traffic policing of ingress interface packets on a FastEthernet interface.

# Limit the ingress interface traffic to 2 Mbps. If the traffic conforms to the rate limit, the traffic is transmitted. If the traffic exceeds the rate limit, the traffic is discarded.

```
interface FastEthernet 0/0
ip address 192.168.20.3 255.255.255.0
encapsulation ppp
rate-limit input 2000000 3000 3000 conform-action  transmit exceed-action  drop
```

Configuration Examples of Traffic Policing for Traffic Satisfying Certain Conditions

In the following examples, CAR traffic policing is configured for egress traffic that satisfies certain conditions:

# Configure ACLs based on different TCP and UDP ports.

```
access-list 101 permit tcp any any eq 2065
access-list 102 permit udp any any range 16384 32767
access-list 103 permit tcp any any eq 1352
access-list 104 permit tcp any any eq www
access-list 105 permit tcp any any eq ftp-data
```

# Configure CAR traffic policing of egress interface packets based on ACLs on a serial interface.

```
interface Serial1/0
ip address 192.168.20.3 255.255.255.0
encapsulation ppp
rate-limit output access-group 101 256000 5000 5000 conform-action  transmit exceed-action
set-dscp-transmit 46
rate-limit output access-group 102 200000 3000 3000 conform-action  transmit exceed-action
set-prec-transmit 5
rate-limit output access-group 103 128000 3000 3000 conform-action  transmit exceed-action
set-prec-transmit 1
rate-limit output access-group 104 64000 3000 3000 conform-action  transmit exceed-action
drop
rate-limit output access-group 105 32000 3000 3000 conform-action  transmit exceed-action
drop
```

# Configure CAR traffic policing of egress interface packets based on DSCP code on a serial interface.

# Limit rates of traffic conforming to ACLs to 256 kbps, 200 kbps, 128 kbps, 64 kbps, and 32 kbps.

```
interface Serial1/0
ip address 192.168.20.3 255.255.255.0
encapsulation ppp
rate-limit output dscp 46 256000 5000 5000 conform-action  transmit exceed-action
set-dscp-transmit 46
rate-limit output dscp 10 200000 3000 3000 conform-action  transmit exceed-action
set-prec-transmit 5
rate-limit output dscp 18 128000 3000 3000 conform-action  transmit exceed-action
set-prec-transmit 1
rate-limit output dscp 20 64000 3000 3000 conform-action  transmit exceed-action  drop
```

Note

Do not set **token bucket** to a value that is too small. Otherwise, the system automatically adjust **token bucket** to a default value.

If you do not need to use the exceeding token bucket algorithm, you need to set the value of **Burst-normal** to be equal to or greater than the value of **burst-max**. If is normally feasible when the value of **Burst-normal** is equal to the value of **burst-max**.

Configuration Tasks of Traffic Policing on a Policy-Map

In the following examples, traffic policing based on policy maps is enabled for egress interface traffic satisfying conditions, and rate limit is enabled for each type of traffic using the single-rate two-token-buckets algorithm.

```
access-list 101 permit udp any any eq 100
access-list 102 permit udp any any eq 200
access-list 103 permit udp any any eq 300
access-list 104 permit udp any any eq 400

Configuration Examples of Traffic Shaping

Configuration Examples of Traffic Shaping for Entire Traffic of an Interface

# Configure GTS traffic shaping of egress interface packets on a serial interface.

# Shape the egress interface traffic to 300 kbps. If the traffic conforms to the rate limit, the traffic is transmitted. If the traffic exceeds the rate limit, the traffic is discarded. In this way, traffic is shaped.

```
interface Serial1/0
ip address 192.168.20.3 255.255.255.0
encapsulation ppp
traffic-shape rate 300000 9000 9000 1000
```

Configuration Examples of Traffic Shaping for Traffic Satisfying Certain Conditions

In the following examples, GTS is configured for egress traffic that satisfies certain conditions:

# Configure ACLs based on different TCP and UDP ports.

```
access-list 101 permit tcp any any eq 2065
access-list 102 permit udp any any range 16384 32767
access-list 103 permit tcp any any eq 1352
access-list 104 permit tcp any any eq www
access-list 105 permit tcp any any eq ftp-data
```

# Configure GTS of egress interface packets based on ACLs on a serial interface.

```
# Shape rates of traffic conforming to ACLs to 256 kbps, 200 kbps, 128 kbps, 64 kbps, and 32
kbps.
interface Serial1/0
ip address 192.168.20.3 255.255.255.0
encapsulation ppp
traffic-shape group 101 256000 10240 10240 1000
traffic-shape group 102 200000 8000 8000 1000
traffic-shape group 103 128000 10240 10240 1000
traffic-shape group 104 64000 12800 12800 1000
traffic-shape group 105 32000 12800 12800 1000
```

Note

In traffic policing, tokens are updated in the token bucket every time packets enter the bucket.
In traffic shaping, tokens are updated in the token bucket at each fixed interval.
In traffic policing, you can configure processing polices for input and output packets at the ingress interface and egress interface.
In traffic shaping, buffering and rate limiting can be configured only for egress interface packets.

Configuration Tasks of Traffic Shaping on a Policy-Map

In the following examples, traffic shaping based on a policy map is enabled for egress interface traffic satisfying conditions, and traffic shaping is enabled for each type of traffic using the common single-token-bucket algorithm.

```
access-list 101 permit udp any any eq 100
!
class-map match-all a1
match access-group 101
!
policy-map shape
class a1
shape  average 100000
shape  max-buffers 200  //buffer size: 200
!
interface Serial1/0
ip address 192.168.20.3 255.255.255.0
encapsulation ppp
service-policy output shape
!
```

In the following examples, traffic shaping with a peak rate based on a policy map is enabled for egress interface traffic satisfying conditions, and traffic shaping with a peak rate is enabled for each type of traffic using the common single-token-bucket algorithm.

```
access-list 101 permit udp any any eq 100
!
class-map match-all a1
match access-group 101
!
policy-map shape
class a1
shape  peak 100000
shape  max-buffers 200  //buffer size: 200
!
interface Serial1/0
ip address 192.168.20.3 255.255.255.0
encapsulation ppp
service-policy output shape
!
```

Configuration Examples of Car Token Bucket Algorithm Mode

Configure the car rate limit of out-going interface of GigabitEthernet to be 300kbps

```
Ruijie(config)# int gigabitEthernet 3/1/1
Ruijie(config-if-GigabitEthernet 3/1/1)#rate-limit output 300000 3000 3000 conform-action
transmit exceed-action drop
Ruijie(config)# bandwidth-mode car frame-gap
```

Maintenance and Debugging of Traffic Policing and Shaping

To monitor status of traffic policing and shaping, run the following commands in the privileged user mode:

Command	**Function**
Ruijie# show rate-limit interfaces [*interface-name*]	Show the rate limit of an interface.
Ruijie# **show traffic-shape** [*interface-name*]	Show the traffic shaping configuration policy of an interface.
Ruijie# **show traffic-shape statistics** [interface-name]	Show the packet statistic information about an interface in actual traffic shaping.
Ruijie# **show traffic-shape queue**	Show the queue information of the entire traffic shaping policy that is configured.

The following are examples of **show rate-limit**:

```
Ruijie#show rate-limit
serial 1/0
Output
matches access-group 101
params:  256000 bps, 3000 limit, 3000 extended limit
conformed 0 packets, 0 bytes; action: transmit 0
exceeded 0 packets, 0 bytes; action: drop 0
cbucket 0, cbs 3000; ebucket 0 ebs 0
```

The following are examples of **show traffic-shape interfaces**:

# **Interval** indicates the interval for updating the token bucket. It is set to 30 ms in this example.

# **Byte Limit** indicates the packet count allowed to transmit per second. It is set to 2250 bytes in this example.

```
Ruijie#show traffic-shape
Interface serial 1/0
Access   Target    Byte   Sustain    Excess    Interval    Increment   Adapt
VC     List     Rate    Limit   bits/int   bits/int   (ms)     (bytes)     Active
-    -      300000       2250      9000      9000      30        1125     -
Ruijie#
```

The following are examples of **show raffic-shape statistics**:

```
Ruijie#show traffic-shape statistics
Interface serial 1/0
Acc. Queue   Packets   Bytes   Packets   Bytes      Shaping
List  Depth                  Delayed   Delayed    Active
 -     0          0      0      0      0         no
Ruijie#
```

The following are examples of **show traffic-shape queue**:

```
Ruijie#show traffic-shape queue
Traffic queued in shaping queue on serial 1/0
Traffic shape group: null
Queuing strategy: weighted fair
Output queue: 0/1000/64/0 (size/max total/threshold/drops)
Output queue num: 0/0 (now/max)
Ruijie#
```

To debug packet compression, run the following commands in the privileged user mode:

Command	Function
Ruijie# **debug tc in**	Debug the traffic control for ingress interface packets.
Ruijie# **debug tc out**	Debug the traffic control for egress interface packets.

Note

For routers of the RSR series, you can view the token information about fast-switching traffic shaping interfaces by running the **show queue interface** command. "Qos Ref queue information" identifies the fast-switching statistic information.
You can run the **show rate-limit interface** command to view traffic policing statistic information about fast-switching interfaces on routers of the RSR series.

Congestion Avoidance

Overview

Congestion avoidance techniques monitor network traffic loads in an effort to anticipate and avoid congestion at common network bottlenecks. Congestion avoidance is achieved through packet dropping.

Overdue congestion brings great risks to network resources, and operations must be performed to eliminate congestion. Here, congestion avoidance indicates technologies used to monitor network traffic (such as queues and memory buffer) usage in an effort to avoid network overloading by initiatively dropping packets in the event of network congestion.

Traditional Packet-Drop Policy – Tail-Drop

Traditional packet-drop policy indicates tail-drop. Tail drop treats all traffic equally and does not differentiate between classes of service. Queues fill during periods of congestion. When the output queue is full and tail drop is in effect, packets are dropped until the congestion is eliminated and the queue is no longer full.

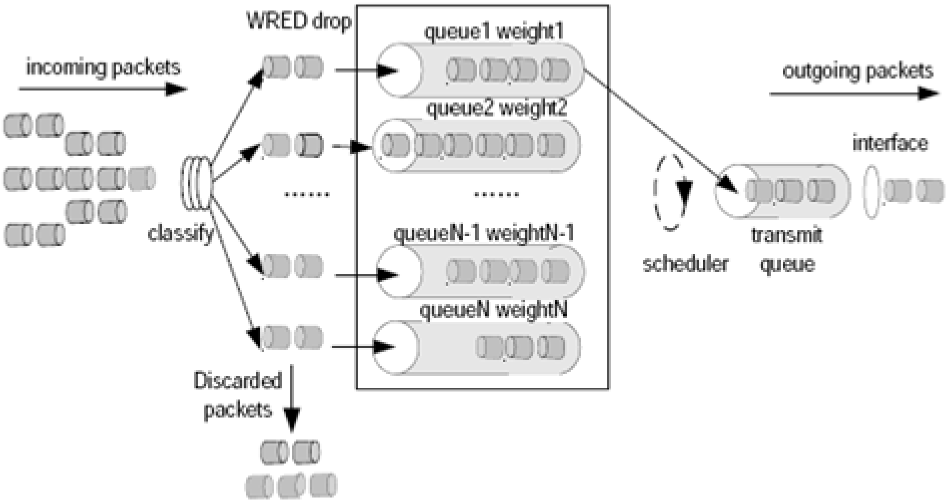
A host running TCP reduces the packet transmission rate when a lot of packets are lost and restore the packet transmission rate when the congestion is eliminated. This causes TCP global synchronization. When queues drop multiple TCP packets, hosts will reduce TCP traffic (referred to as slow start) in response, and then ramp up again simultaneously. When congestion is eased, traffic peaks occur. The two situations repeat one by one, causing cyclical periods of extreme congestion, followed by periods of under-utilization of the link.

WRED

WRED avoids TCP global synchronization by dropping packets randomly. When packets of a TCP connection are dropped and the transmission rate is reduced, other TCP connections still enjoy high transmission rates. In this case, there are TCP connections enjoy high transmission rates at any time, increasing the usage rate of line bandwidth.

WRED randomly drops queued packets after comparing the length, maximum threshold, and minimum threshold of a queue (configuring absolute length of the queue threshold). This is unfair for burst traffic and adverse to transmission. Therefore, the relative length of a queue is compared with the maximum threshold and minimum threshold (configuring the relative value for comparison between the queue threshold and the average length) for dropping packets. The average length of the queue is obtained by using the low-pass filter. It reflects the queue change trend but stays insensitive to the burst change of queue length, avoiding unfair treatment of burst traffic. The following figure shows the relationship between WRED and the queue mechanism.

Figure 8



Each queue is configured with a pair of maximum threshold and minimum threshold values. RED will drop packets using one of three methods:

- **No drop** – used when the queue length is smaller than the minimum threshold.
- **Drop all** – used when the queue length is greater than the maximum threshold.
- **Drop based on the WRED algorithm** – used when the queue length is between the maximum threshold and the minimum threshold.

Specifically: A random number is assigned to each packet that arrives. The random number is compared with the current mark probability denominator (MPD) of the queue. Packets are dropped if the random number is greater than the current MPD. The MPD increases in proportion to queue length, but there is a maximum MPD.

Configuration Tasks of Congestion Avoidance (WRED) Based on an Interface

To configure congestion avoidance based on precedence for an interface, run the following commands in the interface configuration mode:

Command	Function
Ruijie(config)# **interface** *interface-type interface-number*	Specify an interface where congestion avoidance is to be enabled.
Ruijie(config-if)# **random-detect prec-based**	Enable congestion avoidance based on precedence for the entire traffic of an interface.

To configure congestion avoidance based on DSCP classification, for an interface, run the following commands in the interface configuration mode:

Command	Function
Ruijie(config)# **interface** *interface-type interface-number*	Specify an interface where congestion avoidance is to be enabled.
Ruijie(config-if)# **random-detect** *dscp-based*	Enable congestion avoidance based on DSCP for the entire traffic of an interface.

Note

NPE80 does not support WRED congestion avoidance based on precedence and DSCP classification. NPE80 provides only the following command for enabling and disabling WRED:
Ruijie(config-if)# **random-detect**

Note To configure the interface congestion avoidance policy, ensure that the fast-switching function configuration (enable or disable the function) is consistent on all system interfaces. Otherwise, the congestion avoidance policy becomes invalid.

To configure the maximum threshold, the minimum threshold, and the MPD for each type of traffic based on DSCP classification, run the following commands in the interface configuration mode:

Command	Function
Ruijie(config)# **interface** *interface-type interface-number*	Specify an interface where congestion avoidance is to be enabled.
Ruijie(config-if)# **random-detect dscp** [*dscp-value*] [*min-threshold*] [*max-threshold*] [*mark-prob-denominator*]	Configure the maximum threshold, the minimum threshold, and the MPD for each type of traffic based on DSCP classification.

DSCP-value: indicates the value of DSCP. Traffic is classified based on this value.

Min-threshold: indicates the minimum drop threshold. The default values vary by traffic type.

Max-threshold: indicates the maximum drop threshold. The default values vary by traffic type.

Mark-prob-denominator: indicates the MPD that determines the number of packets that will be dropped. This is measured as a fraction, specifically 1/MPD. The greater the MPD is, the smaller the chance of each packet will be dropped. The default MPD is set to **10**, and one out of every 10 packets will be dropped. In other words, the chance of each packet being dropped is 10%.

To configure the maximum threshold, the minimum threshold, and the MPD for each type of traffic based on precedence classification, run the following commands in the interface configuration mode:

Command	Function
Ruijie(config)# **interface** *interface-type interface-number*	Specify an interface where congestion avoidance is to be enabled.
Ruijie(config-if)# **random-detect precedence** [*prec-value*] [*min-threshold*] [*max-threshold*] [*mark-prob-denominator*]	Configure the maximum threshold, the minimum threshold, and the drop probability for each type of traffic based on precedence classification.

Prec-value: indicates the value of Precedence. Traffic is classified based on this value.

Min-threshold: indicates the minimum drop threshold. The default values vary by traffic type.

Max-threshold: indicates the maximum drop threshold. The default values vary by traffic type.

Mark-prob-denominator: indicates the drop probability that determines the number of packets that will be dropped. This is measured as a fraction, specifically 1/MPD. The greater the MPD is, the smaller the chance of each packet will be dropped. The default MPD is set to **10**, and one out of every 10 packets will be dropped. In other words, the chance of each packet being dropped is 10%.

Note NPE80 does not support WRED congestion avoidance based on precedence and DSCP classification. You can run the following command to set the maximum threshold and the minimum threshold:
Ruijie(config-if)# **random-detect** [*min-threshold*] [*max-threshold*] [*mark-prob-denominator*]

To configure the weighting factor of congestion avoidance for an interface, run the following commands in the interface configuration mode:

Command	Function
Ruijie(config)# **interface** *interface-type interface-number*	Specify an interface where congestion avoidance is to be enabled.
Ruijie(config-if)# **random-detect exponential-weighting-constant** [*exponential-value*]	Configure the weighting factor of congestion avoidance for an interface.

Exponential-value: indicates the weighting factor. The default value is **9**. The greater the value is, the smaller the MPD is.

Note If the queueing algorithm of an interface is not FIFO, you need to cancel the current queueing algorithm before configuring WRED congestion avoidance for the interface.

Configuration Tasks of Congestion Avoidance (WRED) Based on a Policy-Map

Note NPE80 does not support congestion avoidance (WRED) based on a policy-map.

To configure congestion avoidance based on precedence for a policy-map, run the following commands:

Command	Function
Ruijie(config)# **policy-map** *policy-map-name*	Access and create a policy-map.
Ruijie(config-pmap)# **class** *class-map-name*	Use class-maps that have been defined.
Ruijie(config-if)# **random-detect prec-based**	Enable congestion avoidance based on precedence for the entire traffic of an interface.

To configure congestion avoidance based on DSCP classification for a policy-map, run the following commands:

Command	Function
Ruijie(config)# **policy-map** *policy-map-name*	Access and create a policy-map.
Ruijie(config-pmap)# **class** *class-map-name*	Use class-maps that have been defined.
Ruijie(config-if)# **random-detect dscp-based**	Enable congestion avoidance based on DSCP for the entire traffic of an interface.

To configure the maximum threshold, the minimum threshold, and the MPD for each type of traffic based on DSCP classification, run the following commands:

Command	Function
Ruijie(config)# **policy-map** *policy-map-name*	Access and create a policy-map.
Ruijie(config-pmap)# **class** *class-map-name*	Use class-maps that have been defined.
Ruijie(config-if)# **random-detect dscp** [*dscp-value*] [*min-threshold*] [*max-threshold*] [*mark-prob-denominator*]	Configure the maximum threshold, the minimum threshold, and the MPD for each type of traffic based on DSCP classification.

DSCP-value: indicates the value of DSCP. Traffic is classified based on this value.

Min-threshold: indicates the minimum drop threshold. The default values vary by traffic type.

Max-threshold: indicates the maximum drop threshold. The default values vary by traffic type.

Mark-prob-denominator: indicates the drop probability that determines the number of packets that will be dropped. This is measured as a fraction, specifically 1/MPD. The greater the MPD is, the smaller the chance of each packet will be dropped. The default MPD is set to **10**, and one out of every 10 packets will be dropped. In other words, the chance of each packet being dropped is 10%.

To configure the maximum threshold, the minimum threshold, and the MPD for each type of traffic based on precedence classification, run the following commands:

Command	Function
Ruijie(config)# **policy-map** *policy-map-name*	Access and create a policy-map.
Ruijie(config-pmap)# **class** *class-map-name*	Use class-maps that have been defined.
Ruijie(config-if)# **random-detect precedence** [*prec-value*] [*min-threshold*] [*max-threshold*] [*mark-prob-denominator*]	Configure the maximum threshold, the minimum threshold, and the MPD for each type of traffic based on precedence classification.

Prec-value: indicates the value of Precedence. Traffic is classified based on this value.

Min-threshold: indicates the minimum drop threshold. The default values vary by traffic type.

Max-threshold: indicates the maximum drop threshold. The default values vary by traffic type.

Mark-prob-denominator: indicates the drop probability that determines the number of packets that will be dropped. This is measured as a fraction, specifically 1/MPD. The greater the MPD is, the smaller the chance of each packet will be dropped. The default MPD is set to **10**, and one out of every 10 packets will be dropped. In other words, the chance of each packet being dropped is 10%.

To configure the weighting factor of congestion avoidance for a policy-map, run the following commands:

Command	Function
Ruijie(config)# **policy-map** *policy-map-name*	Access and create a policy-map.
Ruijie(config-pmap)# **class** *class-map-name*	Use class-maps that have been defined.
Ruijie(config-if)# **random-detect exponential-weighting-constant** [*exponential-value*]	Configure the weighting factor of congestion avoidance for an interface.

Exponential-value: indicates the weighting factor. The default value is **9**. The greater the value is, the smaller the drop probability is.

Configuration Examples of Congestion Avoidance (WRED)

Configuration Examples of Congestion Avoidance for Entire Traffic of an Interface

In the following examples, WRED congestion avoidance is configured on a SYNC interface:

# Configure WRED congestion avoidance based on precedence classification for packets on a serial interface.

# Set that the minimum threshold to **5**, maximum threshold to **100**, and MPD to **10** for traffic with precedence 1.

# Set that the minimum threshold to **10**, maximum threshold to **100**, and MPD to **10** for traffic with precedence 2.

# Set that the minimum threshold to **20**, maximum threshold to **100**, and MPD to **10** for traffic with precedence 3.

# Set that the minimum threshold to **30**, maximum threshold to **100**, and MPD to **10** for traffic with precedence 4.

```
interface Serial1/0
ip address 192.168.20.3 255.255.255.0
encapsulation ppp
random-detect
random-detect precedence 1 5 100 10
random-detect precedence 2 10 100 10
random-detect precedence 3 20 100 10
random-detect precedence 4 30 100 10
```

Configuration Examples of Congestion Avoidance on a Policy-Map

In the following examples, WRED congestion avoidance is configured on a SYNC interface:

# Configure WRED congestion avoidance based on policy-map classification for packets on a serial interface.

# Set that the minimum threshold to **5**, maximum threshold to **100**, and MPD to **10** for traffic with DSCP af11.

# Set that the minimum threshold to **10**, maximum threshold to **100**, and MPD to **10** for traffic with DSCP af21.

# Set that the minimum threshold to **20**, maximum threshold to **100**, and MPD to **10** for traffic with DSCP af31.

# Set that the minimum threshold to **30**, maximum threshold to **100**, and MPD to **10** for traffic with DSCP af41.

Compression Protocol

Packet Compression Protocols

When the TCP and UDP packets carry only a small-size payload but the total amount of IP/TCP or IP/UDP/RTP header information occupies a fixed 40 bytes, the bandwidth of the low-rate link is wasted. Therefore, a series of compression algorithms are needed to compress and decompress the IP/TCP, IP/UDP, or IP/UDP/RTP header information. This is why packet compression protocols are formulated.

Packet compression mainly includes Transmission Control Protocol (TCP) packet compression and User Datagram Protocol (UDP) packet compression. Ruijie products implement the compression in the following two packet formats:

- VJ TCP packet compression: It refers to the compression of TCP packets and is mainly applicable to the low-speed serial links. It complies with the standard RFC 1144 - Compressing TCP/IP Headers for Low-Speed Serial Links.
- IP Header Compression (IPHC): It is IP framework-based packet compression, which consists of three types of packet compression: IP/TCP, IP/UDP, and IP/UDP/RTP. It complies with the standard RFC 2057 - Source Directed Access Control on the Internet.

VJ TCP Packet Compression

VJ TCP packet compression refers to the compression of the TCP packets. It adopts the VJ TCP algorithm and complies with RFC 1144.

A TCP/IP data packet header occupies 40 bytes: 20 bytes for the IP header and 20 bytes for the TCP header. As the TCP and IP headers are not designed by the same organization and all of the fields in the headers are used for a specific purpose, it is impossible to simply ignore the fields for efficiency reasons.

However, TCP connections are created and each connection transmits dozens or even hundreds of packets. Then, how much of the information in each packet in one connection can remain the same? The answer is a half. The sender and receiver can track the connections, and the receiver of each connection can retain a copy of the header of the last received packet. When the sender sends a packet containing a small-size (no more than 8 bits) connection identifier, 20-byte changing content, and 20-byte unchanged content, the receiver can fill only the 20-byte unchanged content into the last saved header. In this way, the data packet is compressed into a half of the original size.

The TCP packet compression can release the bandwidth of the low-speed serial links, which is particularly effective for small packet services such as Telnet.

VJ TCP packet compression supports the following link-layer protocols:

- PPP: Point-to-Point Protocol (PPP): It needs to negotiate the compression protocol option during the IP Control Protocol (IPCP) packet negotiation.
- Serial Line Internet Protocol (SLIP)
- High-Level Data Link Control (HDLC)
- Frame Relay

IPHC

IPHC compresses all TCP and UDP packets in the IPHC format under the IP header compression framework.

At present, IPHC is mainly applied to voice data compression on a low-speed link, including the compression of the real-time transfer (RTP) data, UDP data, and TCP data.

In fact, IPHC can be used to compress the IP, UDP, and RTP headers to achieve a great success similar to that achieved by VJ TCP packet compression in TCP packets. The compression can be applied to the RTP header (in the end-to-end application), or the IP/UDP/RTP combined header (in the link-by-link application). Compressing the 40-byte combined header is more practically effective than compressing only the 12-byte RTP header, because the compressed packages in the two cases both occupy 2–4 bytes. In addition, due to the low packet delay and loss rate, the compression performance in the link-by-link application is better.

The IPHC solution is aimed to compress the IP/UDP/RTP header of most packets into 2 bytes when the UDP checksum is not sent, and into 4 bytes when the UDP checksum is sent.

The IPHC supports the following link-layer protocols:

- PPP: It needs to negotiate the compression protocol option during the IPCP packet negotiation.
- HDLC: Ruijie products support the IPHC compression for the TCP and RTP packets only, and do not support the TCP/RTP packet compression proposed by Cisco.

- Frame Relay: Ruijie products support the TCP/RTP packet compression with the local management interface (LMI) type set to Cisco.

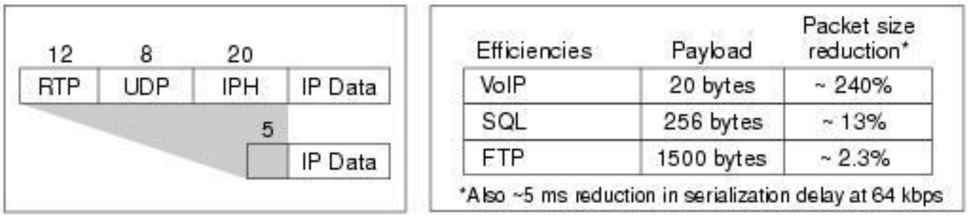
Efficiency and Inapplicable Scenarios of Packet Compression

The following analyzes the efficiency of the packet compression.

- For RTP packet compression, a 40-byte IP/UDP/RTP packet header is compressed to 2–4 bytes. It is assumed that the RTP payload is 24 bytes. In this case, the original 64-byte packet becomes about 27 bytes. The compression ratio is 2.3 times.
- For TCP packet compression, a 40-byte IP/TCP packet header is compressed to 2–4 bytes. It is assumed that the TCP payload is 24 bytes. In this case, the original 64-byte packet becomes about 27 bytes. The compression ratio is 2.3 times.

The following figure shows the efficiency comparison of RTP packet compression.

Figure 9



Efficiencies	Payload	Packet size reduction*
VoIP	20 bytes	~ 240%
SQL	256 bytes	~ 13%
FTP	1500 bytes	~ 2.3%

*Also ~5 ms reduction in serialization delay at 64 kbps

Packet compression protocols are inapplicable to Ruijie products in the following scenarios:

- The Ethernet interface does not support packet compression.
- Serial links with a rate higher than 2 Mbps do not support packet compression.
- Packet compression is not supported in the case with multi-link PPP.
- Fragmented IP packets cannot be compressed.
- Packet compression cannot be configured on the logical interface of the dialer, and must be configured on the physical interface.

Packet Compression Protocol Configuration

To configure TCP packet compression on an interface, run the following commands in interface configuration mode:

Command	Function
Ruijie(config-if)# **ip tcp header-compression**	Configures TCP/IP packet compression.
Ruijie(config-if)# **no ip tcp header-compression**	Cancels TCP/IP packet compression.

To configure the passive mode of TCP packet compression on an interface (the local packets are compressed only when the packets from the peer end are compressed), run the following commands in interface configuration mode:

Command	Function
Ruijie(config-if)# **ip tcp header-compression passive**	Configures the passive mode of TCP/IP packet compression.
Ruijie(config-if)# **no ip tcp header-compression**	Cancels TCP/IP packet compression.

To configure the number of connections for TCP packet compression on an interface, run the following commands in interface configuration mode:

Command	Function
Ruijie(config-if)# **ip tcp compression-connections** *number*	Configures the number of connections for TCP/IP packet compression.
Ruijie(config-if)# **no ip TCP compression-connections**	Cancels the connections for TCP/IP packet compression.

1.

Note The number of connections configured on the compression interfaces at both ends must be the same. Otherwise, the TCP/IP compression module may malfunction or even fail in communication.

To configure RTP packet compression on an interface, run the following commands in interface configuration mode:

Command	Function
Ruijie(config-if)# **ip rtp header-compression**	Configures IP/RTP packet compression.
Ruijie(config-if)# **no ip rtp header-compression**	Cancels IP/RTP packet compression.

To configure the passive mode of RTP packet compression on the interface (the local packets are compressed only when the packets from the peer end are compressed), run the following commands in interface configuration mode:

Command	Function
Ruijie(config-if)# **ip rtp header-compression passive**	Configures the passive mode of the IP/RTP packet compression.
Ruijie(config-if)# **no ip rtp header-compression**	Cancels IP/RTP packet compression.

To configure the number of connections for RTP packet compression on an interface, run the following commands in interface configuration mode:

Command	Function
Ruijie(config-if)# **ip rtp compression-connections** *number*	Configures the number of connections for IP/RTP packet compression.
Ruijie(config-if)# **no ip rtp compression-connections**	Cancels the connections for IP/RTP packet compression.

Note The number of connections configured the compression interfaces at both ends must be the same. Otherwise, the IP/RTP compression module may malfunction or even fail in communication.

Note The compression modes configured on the compression interfaces at both ends must be the same. For example, IP/RTP compression, or TCP/IP compression, or IP/RTP compression, or TCP/IP compression is configured at both ends. In addition, the compression formats of each compression mode must be the same at both ends, that is, both compression formats are IPHC format or IETF format. If the configurations on the compression interfaces at both ends are inconsistent, the communication may fail.

Packet Compression Configuration Examples

PPP-based Packet Compression

The following are examples of PPP-based packet compression:

#Configure the PPP-based RTP packet compression.

```
interface Serial1/0
ip address 192.168.20.3 255.255.255.0
encapsulation ppp
ip rtp header-compression IPHC-format
```

#Configure the PPP-based TCP packet compression.

```
interface Serial1/0
ip address 192.168.20.3 255.255.255.0
```

```
encapsulation ppp
ip tcp header-compression
```

HDLC-based Packet Compression

The following are examples of HDLC-based packet compression.

#Configure the HDLC-based RTP packet compression.

```
interface Serial1/0
ip address 192.168.20.3 255.255.255.0
ip rtp header-compression iphc-format
```

Note

Ruijie products only support HDLC-based packet compression in the IPHC format. If a Ruijie device interconnects with a Cisco device, packet compression in the IPHC format must also be configured on the Cisco device. If IP/RTP header compression is configured on the Cisco device, compression and decompression will fail, resulting in a communication failure.

Frame Relay-based Packet Compression

The following is an example of Frame Relay-based packet compression:

#Configure Frame Relay-based RTP and TCP packet compression.

```
interface Serial1/0
ip address 1.1.1.1 255.255.255.0
frame-relay map ip 1.1.1.2 20
frame-relay intf-type dce
frame-relay local-dlci 20
frame-relay lmi-type cisco
ip rtp header-compression
ip tcp header-compression
```

Note

Ruijie products and Cisco products both support the Frame Relay-based RTP packet compression with the LMI type set to Cisco.
Cisco products also allow users to enable or disable the compression function on different data links of different data link connection identifiers (DLCIs). Different from Cisco products, the policy of Ruijie products is to compress all, or none.

Packet Compression Maintenance and Debugging

To monitor packet compression, run the following commands in privileged EXEC mode:

Command	Function
Ruijie# **show ip rtp header-compression** *interface*	Displays related information about RTP packet compression and decompression.
Ruijie# **show ip tcp header-compression** *interface*	Displays related information about TCP packet compression and decompression.
Ruijie# **clear rtp-compress** [*interceface*]	Clears the counts of RTP packet compression and decompression.
Ruijie# **clear rtp-compress** [*interceface*]	Clears the counts of TCP packet compression and decompression.

The following is an example of output of the **show ip rtp header-compression** command:

```
RTP/UDP/IP header compression statistics:
Interface serial 1/0: active on
Rcvd:   407 total, 406 compressed, 0 errors
0 dropped, 406 buffer copies, 0 buffer failures
Sent:   406 total, 405 compressed,
14716 bytes saved, 8494 bytes sent
2.73 efficiency improvement factor
```

```
Connect: 256 rx slots, 256 tx slots, 0 long searches, 1 misses
99% hit ratio, five minute miss rate 0 misses/sec, 0 max
```

To debug packet compression, run the following commands in privileged EXEC mode:

Command	Function
Ruijie# **debug ip rtp header-compression**	Debugs the receiving and sending of compressed and decompressed RTP packets.
Ruijie# **debug ip rtp errors**	Debugs RTP packet compression errors.
Ruijie# **debug ip tcp header-compression**	Debugs the receiving and sending of compressed and decompressed TCP packets.

Configuring MPLS QOS

MPLS QOS

MPLS QoS provided by Ruijie Networks supports the following functions:

- Congestion management

Currently, MPLS experimental value based WFQ, CBWFQ, PQ and LLQ queues are supported.

- Traffic policing and traffic shaping

Currently, MPLS experimental value based car is supported to limit the bandwidth of data stream, specify actions for handling excess traffic, and limit traffic burst in respect of MPLS traffic shaping so that message flows can be transmitted at an even rate.

- Congestion avoidance

Currently, MPLS experimental value based RED and WERD are supported.

For more QoS related features, please refer to QoS configuration guideline

Congestion Management

Configuration of Weighted Fair Queuing (WFQ)

WFQ Configuration Tasks

When standard WFQ is used, the data packets will be classified through traffic. Ruijie routers currently support MPLS EXP value based traffic classification. WFQ allocates the same bandwidth for respective traffics. The traffic-based WFQ is also called fair queuing, as all traffic are provided with the same weight.

To configure WFQ, the following tasks need to be completed:

- Configuring WFQ
- Monitoring fair queuing

Note

Since the flash configurations varies from router to router, it is suggested to use "fair-queue" command to configure different queue depth and numbers.

Configuring WFQ

To configure WFQ, execute the following commands in interface configuration mode:

Command	**Function**
Ruijie(config-if)# **fair-queue** [*congestive-discard-threshold* [*dynamic-queues*]]	Configure WFQ
Ruijie(config-if)# no fair-queue	Remove WFQ configurations

WFQ parameters:

Parameter	**Description**
congestive-discard-threshold	The maximum number of packets (threshold) allowed in each queue (64 by default). When the number of packets reaches this threshold, the incoming new packets will be discarded. (This parameter is optional)
dynamic-queues	Number of dynamic queues. Default: 256; scope: integer between 16 and 4096, and must be the power of 2. (This parameter is optional)

Note

To configure WFQ congestion management policy on the interface, all interfaces of the system must enable fast forwarding function, otherwise this function will become invalid.

Note

We can find out the WFQ congestion management configurations of fast-forward IP QoS and MPLS QoS are same. The two functions may overlap on LSP Egress device, and the current software version will give preference to the WFQ function of MPLS QoS under such a circumstance.

Monitoring WFQ

To view WFQ configurations of interface, execute the following commands in privileged user mode.

Command	Function
Ruijie# **show queue interface** *interface–name interface-number [queue-number]*	Display the QoS queue information on the designated network interface.

WFQ Configuration Examples

As shown below, configure fair queuing on the synchronization interface: congestion drop threshold (threshold) being 128 packets and dynamic queues being 512.

```
interface Serial 3/0
 ip ref
 ip address 192.168.200.1 255.255.255.0
 mpls ip
 fair-queue 128 512
An example of viewing interface configurations in privileged user mode is shown below:
Ruijie# show queue interface serial 3/0

  Queueing strategy: weighted fair
  Output queue: 0/300/128/0 (size/max total/threshold/drops)
  Output queue num: 0/0/512 (now active/max active/max total)

  Qos Ref queue information
  Current Policy(s) : WFQ
  interface cir: 2048000
  Queueing strategy: weighted fair
    Dequeue threshold:  Green 25000, Yellow 37500, Red 50000
    Queues: Queues total len 0, MeanBurst 800
    Queues: gts gap 7, deta bits 262, token bucket 51200
    Queues: Max 19353 pkts, used 0 pkts
    Queues: rtpQ: 0 pkts, 0 bytes
    Queues: llQ:  0 pkts, 0 bytes
    Queues: genQ: 0 pkts, 0 bytes
    wfq para: cir(2048000), delta(13/2080)
    wfq_tb para: cir(3938), delta(7/129)
    Output queue: 0/0(send/drops)
```

From the above messages, it can be observed that the queuing policy of interface adopts WFQ and the congestion drop threshold (threshold) is 128.

Configuration of Class-based Weighted Fair Queueing (CBWFQ)

CBWFQ Configuration Tasks

In order to configure CBWFQ, the following tasks need to be completed:

Configuring CBWFQ

Defining Class Maps

This function is required in order to realize CBWFQ function. The user can define network packet classifying policy in the class map, and use these class maps by specifying the name of class map in the policy map. The same class map can be used by one or more policy maps. The typical configurations of this function are shown below:

Command	**Function**
Ruijie(config)# **class-map** *match-all class-map-name*	Enter/create AND-type class map (to meet all conditions in the class map).
Ruijie(config)# **class-map match-any** *class-map-name*	Enter/create OR-type class map (to meet only one condition in the class map).
Ruijie(config-cmap)# **match mpls experimental** *value* or Ruijie(config-cmap)# **match qos-group** *value* Ruijie(config-cmap)# **match not** *match-type value*	Configure network packet classifying policy (according to the group ID of message, EXP value of MPLS message or the false condition of the abovementioned classifying policies.
Ruijie(config-cmap)# **exit**	Exit class map configuration layer

Class-map-name: name of class map;

Match-all: To meet all conditions in the class map; the default type of class map is Match-all;

Match-any: to meet only one condition in the class map;

Mpls Experimental: the value of Experimental field of MPLS packets;

Qos-group: group ID of packets;

Not match-type: false condition of classifying policy.

Configuring Class Policy in the Policy Map

This function is required in order to realize CBWFQ function. In the policy map, the user can use all class maps configured on the device (up to 64 different class maps). The user may allocate bandwidth for the class map used, but the total bandwidth allocated for all used class maps must not exceed the bandwidth allocated to CBWFQ by the interface applied with this policy map. The typical configurations of this function are shown below:

Command	**Function**
Ruijie(config)# **policy-map** *policy-map-name*	Enter/create policy map
Ruijie(config-pmap)# **class** *class-map-name*	Use the class map defined.
Ruijie(config-pmap-c)# **bandwidth** { *bandwidth-kbps* | **percent** *percent-number* }	Allocate bandwidth for specific class of traffic
Ruijie(config-pmap-c)# **queue-limit** *number-of-packets*	Define queue depth
Ruijie(config-pmap-c)# **exit**	Exit class reference configuration layer
Ruijie(config-pmap)# **exit**	Exit policy map configuration layer

Policy-map-name: name of policy map;

Class-map-name: name of class map;

Bandwidth-kbps: bandwidth allocated (unit: kbps);

Percent-number: percentage of bandwidth allocated (in regard to all available bandwidth of network interface);

Number-of-packets: CBWFQ queue depth (maximum number of packets allowed).

Applying Service Policy on the Designated Interface

This function is required in order to realize CBWFQ function. Applying service policy on the designated interface will enable CBWFQ function, after which the class used by the corresponding policy map will have the corresponding queue. The typical configuration of this function is shown below:

Command	**Function**
Ruijie(config-if)# **service-policy output** *policy-map-name*	Enable CBWFQ and specify the policy map to be applied.

Policy-map-name: name of policy map.

Note	To configure policy map on the interface, all interfaces of the system must enable fast forwarding function, otherwise this function will become invalid.

Configuring Bandwidth for an Existing Class

This function is optional for CBWFQ. The typical configurations of this function are shown below:

Command	**Function**
Ruijie(config)# **policy-map** *policy-map-name*	Enter/create policy map
Ruijie(config-pmap)# **class** *class-map-name*	Use the class map defined.
Ruijie (config-pmap-c)# **bandwidth** { *bandwidth-kbps* | **percent** *percent*}	Allocate bandwidth for specific class of traffic

Policy-map-name: name of policy map;

Class-map-name: name of class map;

Bandwidth-kbps: bandwidth allocated (unit: kbps);

Percent-number: percentage of bandwidth allocated (in regard to all available bandwidth of network interface);

The user may allocate bandwidth for the specific type of network traffic. By default, 1% of bandwidth is allocated to the specific type of network traffic.

Configuring the Queue Depth for an Existing Class

This function is optional for CBWFQ. The typical configurations of this function are shown below:

Command	**Function**
Ruijie(config)# **policy-map** *policy-map-name*	Enter/create policy map
Ruijie(config-pmap)# **class** *class-map-name*	Use the class map defined.
Ruijie(config-pmap-c)# **queue-limit** *number-of-packets*	Define queue depth

Policy-map-name: name of policy map;

Class-map-name: name of class map;

Number-of-packets: CBWFQ queue depth (maximum number of packets allowed).

The user may configure queue depth for the corresponding CBWFQ queue of specific network traffic. The default value is 64, which means that after the corresponding CBWFQ queue has 64 packets, the system will discard subsequent network packets entering into this queue. By this time, Ruijie router only supports Tail-Drop congestion management instead of RED/WRED congestion management.

Configuring EXP Value of MPLS Message for an Existing Class

This function is optional for CBWFQ. The typical configurations of this function are shown below:

Command	**Function**

Ruijie(config)# **policy-map** *policy-map-name*	Enter/create policy map
Ruijie(config-pmap)# **class** *class-map-name*	Use the class map defined.
Ruijie(config-pmap-c)# **set mpls experimental** *exp-value*	Configure EXP Value of MPLS Message
Ruijie(config-pmap-c)# **set mpls experimental** *dscp*	Set mpls experimental value to ip dscp value
Ruijie(config-pmap-c)# **set mpls experimental** *precedence*	Set mpls experimental value to ip precedence value

Policy-map-name: name of policy map;

Class-map-name: name of class map;

Exp-values: EXP value of message to be configured.

Note

When MPLS experimental value configured is ip dscp, only the first three bits of dscp will be used for mapping.

Configure EXP Value of MPLS Message for an Existing Class (use table-map)

This function is optional for CBWFQ. The typical configurations of this function are shown below:

Command	**Function**
Ruijie(config)# **table-map** *table-map-name*	Enter/create table-map
Ruijie(config-tablemap)#**map from** *from-value* **to** *to-value*	Add mapping relationship into table-map
Ruijie(config-tablemap)#**default** { *default-value* | **copy** | **ignore** }	Specify the action of table-map when specifying unnecessary mapping relationship for table-map
Ruijie(config)# **policy-map** *policy-map-name*	Enter/create policy map
Ruijie(config-pmap)# **class** *class-map--name*	Use the class map defined.
Ruijie(config-pmap-c)# **set mpls experimental dscp table** *table-map-name*	Set mpls experimental value to ip dscp value according to the configuration of table-map
Ruijie(config-pmap-c)# **set mpls experimental precedence table** *table-map-name*	Set mpls experimental value to ip precedence value according to the configuration of table-map
Ruijie(config-pmap-c)# **set mpls experimental qos-group table** *table-map-name*	Set mpls experimental value to qos-group value according to the configuration of table-map

From-value: value mapped;

To-value: map value;

Default-value: default map value;

Table-map-name: name of table map;

Policy-map-name: name of policy map;

Class-map-name: name of class map;

Configuring DSCP Value of IP Message for an Existing Class

This function is optional for CBWFQ. The typical configurations of this function are shown below:

Command	**Function**

Ruijie(config)# **policy-map** *policy-map-name*	Enter/create policy map
Ruijie(config-pmap)# **class** *class-map-name*	Use the class map defined.
Ruijie(config-pmap-c)# **set dscp** dscp-*value*	Configure dscp Value of IP Message
Ruijie(config-pmap-c)# **set dscp experimental**	Set ip dscp to mpls experimental value

Policy-map-name: name of policy map;

Class-map-name: name of class map;

Dscp-values: dscp value of message to be configured.

Note	When MPLS experimental value configured is ip dscp, only the first three bits of dscp will be used for mapping.

Configuring DSCP Value of IP Message for an Existing Class (use table-map)

This function is optional for CBWFQ. The typical configurations of this function are shown below:

Command	**Function**
Ruijie(config)# **table-map** *table-map-name*	Enter/create table-map
Ruijie(config-tablemap)#**map from** *from-value* **to** *to-value*	Add mapping relationship into table-map
Ruijie(config-tablemap)#**default** { *default-value* | **copy** | **ignore** }	Specify the action of table-map when specifying unnecessary mapping relationship for table-map
Ruijie(config)# **policy-map** *policy-map-name*	Enter/create policy map
Ruijie(config-pmap)# **class** *class-map-name*	Use the class map defined.
Ruijie(config-pmap-c)# **set dscp experimental table** *table-map-name*	Set ip dscp to mpls experimental value according to the configuration of table-map
Ruijie(config-pmap-c)# **set dscp qos-group table** *table-map-name*	Set ip dscp to qos-group value according to the configuration of table-map

From-value: value mapped;

To-value: map value;

Default-value: default map value;

Table-map-name: name of table map;

Policy-map-name: name of policy map;

Class-map-name: name of class map;

Configuring Precedence Value of IP Message for an Existing Class

This function is optional for CBWFQ. The typical configurations of this function are shown below:

Command	**Function**
Ruijie(config)# **policy-map** *policy-map-name*	Enter/create policy map
Ruijie(config-pmap)# **class** *class-map-name*	Use the class map defined.

Ruijie(config-pmap-c)# **set precedence** prec-*value*	Configure prec Value of IP Message
Ruijie(config-pmap-c)# **set precedence experimental**	Set ip prec to mpls experimental value

Policy-map-name: name of policy map;

Class-map-name: name of class map;

Prec-values: precedence value of message to be configured.

Configuring Precedence Value of IP Message for an Existing Class (use table-map)

This function is optional for CBWFQ. The typical configurations of this function are shown below:

Command	Function
Ruijie(config)# **table-map** *table-map-name*	Enter/create table-map
Ruijie(config-tablemap)#**map from** *from-value* **to** *to-value*	Add mapping relationship into table-map
Ruijie(config-tablemap)#**default** { *default-value* | **copy** | **ignore** }	Specify the action of table-map when specifying unnecessary mapping relationship for table-map
Ruijie(config)# **policy-map** *policy-map-name*	Enter/create policy map
Ruijie(config-pmap)# **class** *class-map-name*	Use the class map defined.
Ruijie(config-pmap-c)# **set precedence experimental table** *table-map-name*	Set ip prec to mpls experimental value according to the configuration of table-map
Ruijie(config-pmap-c)# **set precedence qos-group table** *table-map-name*	Set ip prec to qos-group value according to the configuration of table-map

From-value: value mapped;

To-value: map value;

Default-value: default map value;

Table-map-name: name of table map;

Policy-map-name: name of policy map;

Class-map-name: name of class map;

Configuring Group ID of Message for an Existing Class

This function is optional for CBWFQ. The typical configurations of this function are shown below:

Command	Function
Ruijie(config)# **policy-map** *policy-map-name*	Enter/create policy map
Ruijie(config-pmap)# **class** *class-map-name*	Use the class map defined.
Ruijie(config-pmap-c)# set qos-group group-*value*	Set the group ID of message
Ruijie(config-pmap-c)# **set qos-group dscp**	Set group ID of message to ip dscp value.
Ruijie(config-pmap-c)# **set qos-group precedence**	Set group ID of message to ip precedence value.
Ruijie(config-pmap-c)# **set qos-group mpls experimental**	Set group ID of message to mpls experimental value.

Ruijie(config-pmap-c)# **set qos-group cos**	Set group ID of message to cos value.

Policy-map-name: name of policy map;

Class-map-name: name of class map;

Group-values: group ID of message to be configured.

Configuring Group ID of Message for an Existing Class (use table-map)

This function is optional for CBWFQ. The typical configurations of this function are shown below:

Command	Function
Ruijie(config)# **table-map** *table-map-name*	Enter/create table-map
Ruijie(config-tablemap)#**map from** *from-value* **to** *to-value*	Add mapping relationship into table-map
Ruijie(config-tablemap)#**default** { *default-value* | **copy** | **ignore** }	Specify the action of table-map when specifying unnecessary mapping relationship for table-map
Ruijie(config)# **policy-map** *policy-map-name*	Enter/create policy map
Ruijie(config-pmap)# **class** *class-map-name*	Use the class map defined.
Ruijie(config-pmap-c)# **set qos-group dscp table** *table-map-name*	Set group ID of message to ip dscp value according to the configuration of table-map
Ruijie(config-pmap-c)# **set qos-group precedence table** *table-map-name*	Set group ID of message to ip precedence value according to the configuration of table-map
Ruijie(config-pmap-c)# **set qos-group mpls experimental table** *table-map-name*	Set group ID of message to mpls experimental value according to the configuration of table-map
Ruijie(config-pmap-c)# **set qos-group cos table** *table-map-name*	Set group ID of message to cos value according to the configuration of table-map

From-value: value mapped;

To-value: map value;

Default-value: default map value;

Table-map-name: name of table map;

Policy-map-name: name of policy map;

Class-map-name: name of class map;

Configuring the Bandwidth Allocated to CBWFQ

This function is optional for CBWFQ. The typical configurations of this function are shown below:

Command	Function
Ruijie(config-if)# **max-reserved-bandwidth** *percent*	Configure the Bandwidth Allocated to CBWFQ

Percent: Percentage of bandwidth allocated to CBWFQ on the existing network interface.

The user may allocate the available bandwidth percentage allocated to CBWFQ. The default value is 75, which means 75% of gross available bandwidth of network interface will be allocated to CBWFQ.

Monitoring CBWFQ

When CBWFQ becomes valid on a specific interface, to display input and output queues, the user can execute the following commands in privileged user mode:

Command	**Function**
Ruijie# **show class-map**	Display all class maps
Ruijie# **show class-map** *class-map-name*	Display the information of a specific class map
Ruijie# **show policy-map**	Display all policy maps
Ruijie# **show policy-map name** *policy-map –name*	Display the information of a specific policy map
Ruijie# **show policy-map name** *policy-map-name* class *class-name*	Display a specific class map in a specific policy map
Ruijie# **show policy-map interface** *Interface-name interface-number*	Display the policy map applied on a specific network interface
Ruijie# **show queue** *interface-name interface-number*	Display the QoS queue information on the designated network interface.

Class-map-name: name of class map;

Policy-map-name: name of policy map;

Interface-name: name of network interface;

Interface-number: network interface ID.

CBWFQ Configuration Examples

The following example shows how to configure MPLS Experimental based CBWFQ congestion management policy on the synchronization interface:

```
class-map 101
match mpls experimental 1
class-map 102
match mpls experimental 2
class-map 103
match mpls experimental 3
!
policy-map 1
 class 101
  bandwidth 600
 class 102
  bandwidth 400
 class 103
  bandwidth 200
!
interface Serial 3/0
 ip ref
 ip address 192.168.200.1 255.255.255.0
 mpls ip
 service-policy output 1
```

An example of viewing interface configurations in privileged user mode is shown below:

```
Ruijie# show queue interface serial 3/0

  Queueing strategy: cb weighted fair
  Output queue: 0/300/128/0 (size/max total/threshold/drops)
   cb queue_num  0/0 (active/max active)
   wfq queue_num  0/0 (active/max active)
     Reserved queue_num 3/3 (allocated/max allocated)
     Llq is close

  Qos Ref queue information
  Current Policy(s) : CBWFQ
  interface cir: 2048000
  Queueing strategy: cb weighted fair
   Dequeue threshold:  Green 25000, Yellow 37500, Red 50000
```

```
    Queues: Queues total len 0, MeanBurst 800
    Queues: gts gap 7, deta bits 262, token bucket 51200
    Queues: Max 19353 pkts, used 0 pkts
    Queues: rtpQ: 0 pkts, 0 bytes
    Queues: llQ:  0 pkts, 0 bytes
    Queues: genQ: 0 pkts, 0 bytes
   Output Stat.: 0/0/ (send/drops)
    queue_num  128/256 (cb num/wfq num)
    cb packet Stat. 0/0 (send /drop)
    wfq packet Stat. 0/0 (send /drop)
      Reserved queue_num 3/3 (allocated/max allocated)
      Llq is close
```

Configuration of Custom Queueing (CQ)

CQ Configuration Tasks

Custom Queue configuration tasks are shown below:

Configuring CQ

CQ can configure up to 16 groups, namely the scope of List-number is 1-16. Each group specifies the type of queues that can be entered by different kinds of packets, queue length, and byte count that is allowed to be sent.

Determining the Maximum Capacity of Queue Adopting CQ

To configure the maximum packet capacity for each queue, execute the following commands in global configuration mode:

Command	Function
Ruijie(config)# **queue-list** *list-number* **queue** *queue-number* **limit** *limit-number*	Specify the maximum number of packets allowed by each custom queue. The no form of this command can be used to restore the queue length to the default value of 20.
Ruijie(config)# **queue-list** *list-number* **queue** *queue-number* **byte-count** *byte-count-number*	Specify the number of bytes allowed by each queue. The no form of this command can be used to restore the byte count to the default value of 1500.

List-number: number of queue list (any number between 1-16);

Queue-number: queue number (any number between 1-16);

Limit-number: The maximum number of packets allowed by the queue, within the range being from 1 to 32767. The default value is 20.

Byte-count-number: Specify how many bytes of data should be delivered from the current queue by the system before the system moves on to the next queue. When a particular queue is being processed, packets are sent until the number of bytes sent exceeds the byte-count-number configured (within the range of 1 to 16777215, 1500 by default) or until the queue is empty. For how to determine the best byte count of data to be sent, please refer to the foregoing chapters.

Note

To configure CQ congestion management policy on the interface, all interfaces of the system must disable the fast forwarding function, which is not supported by CQ congestion management policy.

Assigning Packets to CQ

You can assign the packets to custom queues based on the protocol type or the interface where the packets enter the device. Additionally, you can set the default queue for the packets that do not match other assignment rules. You can also specify multiple rules.

To define the CQ lists, use the following commands in global configuration mode:

Command	Function

Ruijie(config)# **queue-list** *list-number* **protocol mpls** *queue-number* [**experimental** *exp-value*]	Assign the packets to the specified custom queue based on the protocol type.

Therein, exp-value refers to MPLS experimental value.

Applying CQ List on the Interface

To apply a CQ list to an interface, use the following command in interface configuration mode:

Command	**Function**
Ruijie(config-if)# **custom-queue-list** *list-number*	Set the queuing policy of this interface to a specific CQ list.

Note	You can only specify one queuing policy for each interface, and only one queue list can be specified in the mean time.

Monitoring CQ

To display information about input and output queues when CQ is enabled on an interface, use the following commands in privileged user mode:

Command	**Function**
Ruijie# show queue cq	Display information about CQ.
Ruijie# **show queue interface** *interface-name interface-number* [*queue-number*]	Display information about CQ interface.
Ruijie# **debug qos cq**	Turn on the CQ debug switch if the priority queue is configured.

CQ Configuration Examples

Configure custom list 2, and assign packets with MPLS EXP value being 2 to queue number 12 :

```
Ruijie(config)# queue-list 2 protocol mpls 12 experimental 2
```

Configure custom list 1, and assign packets with MPLS EXP value being 5 to queue number 11:

```
Ruijie(config)# queue-list 1 protocol mpls 11 experimental 5
```

Apply custom list 1 configured previously to the synchronization interface:

```
Ruijie(config)# interface serial 0
Ruijie(config-if)# custom-queue-list 1
```

Configuration of Priority Queueing (PQ)

PQ Configuration Tasks

Priority Queue configuration tasks are shown below:

Configuring PQ

PQ can configure up to 16 groups, namely the scope of List-number is 1-16. Each group specifies the type of queues that can be entered by different kinds of packets, as well as the maximum number of packets allowed by each queue.

Determining the Maximum Capacity of Queue Adopting PQ

In the queue list of each group, there are four queues divided into high, medium, normal and low. The user may configure the maximum packet capacity of each queue. Execute the following commands in global configuration mode:

Command	Function
Ruijie(config)# **priority-list** *list-number* **queue-limit** *high-limit medium-limit normal-limit low-limit*	Specify the maximum number of packets allowed by each priority queue.

List-number: number of queue list (any number between 1-16);

The default length of priority queue is shown below:

Queue	Length
high	20
medium	40
normal	60
Low	80

Note To configure PQ congestion management policy on the interface, all interfaces of the system must enable fast forwarding function, otherwise this function will become invalid.

Assigning Packets to PQ

The system can specify multiple assignment rules. This list will be searched according to the sequence specified by priority-list until a matching protocol or interface type is found. When a matching entry is found, this packet will be allocated to the corresponding queue and the search will end. Packets failing to match other assignment rules can be allocated to the default queue. To specify the queue for assigning packets, execute the following command in global configuration mode:

Command	Function
Ruijie(config)# **priority-list** *list-number* **protocol mpls {high | medium | normal | low}** [**experiemtal** *exp-value*]	Assign packets to a specific PQ according to the EXP value of MPLS message.
Ruijie(config)# **priority-list** *list-number* **default {high | medium | normal | low}**	Assign packets matching no rules to the default PQ (normal).

Therein, List-number is the group ID of PQ, and exp-value refers to MPLS experimental value.

Applying PQ list on the Interface

To apply a PQ list to an interface, execute the following command in interface configuration mode:

Command	Function
Ruijie(config-if)# priority-group *list-number*	Set the queuing policy of this interface to a specific PQ list.

Note You can only specify one queuing policy for each interface, and only one queue list can be specified in the mean time.

Monitoring PQ

When PQ becomes valid on a specific interface, to display input and output queues, the user can execute the following commands in privileged user mode:

Command	Function

Ruijie# **show queue interface** *interface–name interface-number [queue-number]*	Display the PQ information on the designated network interface.

PQ Configuration Examples

Configure priority list 1, and allocate packets with MPLS EXP value being 7 to the medium PQ:

```
priority-list 1 mpls experiemtal 7 medium
```

Configure priority list 1, and allocate packets received by synchronization serial port to the medium PQ:

```
priority-list 1 interface serial 1/1 medium
```

Configure priority list 1, and allocate packets matching no rules in the priority list to the medium PQ:

```
priority-list 1 default medium
```

Configure priority list 1, and configure the length of high, medium, normal and low PQs to 10, 40, 60 and 80 respectively:

```
priority-list 1 queue-limit 10 40 60 80
```

Apply priority list 1 configured previously to the synchronization interface:

```
interface Serial 3/0
```

```
 ip ref
 ip address 192.168.200.1 255.255.255.0
 mpls ip
 priority-group 1
```

An example of viewing interface configurations in privileged user mode is shown below:

```
Ruijie# show queue interface serial 3/0

  Queueing strategy: priority-list 1
  Output queues: (queue #: size/max/send/drops)
  Output queue: high 0/20/0/0, medium 0/40/0/0, normal 0/60/0/0, low 0/80/0/0

  Qos Ref queue information
  Current Policy(s) : PQ
  Queueing strategy: priority-list 1
  interface cir: 2048000
  Dequeue threshold:  Green 25000, Yellow 37500, Red 50000
  Queues: Queues total len 0, MeanBurst 800
  Queues: gts gap 7, deta bits 262, token bucket 51200
  Queues: Max 19353 pkts, used 0 pkts
  Queues: rtpQ: 0 pkts, 0 bytes
  Queues: llQ:  0 pkts, 0 bytes
  Queues: genQ: 0 pkts, 0 bytes
  Threshold: MeanBurst 800, Priority LOW, Dec 4560, Inc 4560, Drop 16720
  Counter:   PriInc 0, PriDec 0, Drop 0
  Queues: Queues len 0, MeanBurst 800, gts token bucket 51200
  Queues: Max 19353 pkts, used 0 pkts, rtpQ: 0 pkts, 0 bytes. genQ: 0 pkts, 0 bytes
  (size/max/send/drops)
  high 0/0/0/0, medium 0/0/0/0, normal 0/0/0/0, low 0/0/0/0
```

Configuration of Low Latency Queuing (LLQ)

LLQ Configuration Tasks

LLQ configuration is performed jointly with CBWFQ configuration. To configure LLQ, the following tasks need to be done:

Configuring LLQ

To configure LLQ, execute the following commands in Policy-map command layer configuration mode:

Command	**Function**
Ruijie(config)# **policy-map** *policy-map-name*	Enter/create policy map
Ruijie(config-pmap)# **class** *class-map-name*	Use the class map defined.
Ruijie (config-pmap-c)# **priority** { *bandwidth-kbps* | **percent** *percent*} [*Burst bytes*]	Allocate bandwidth for specific class of traffic

Ruijie(config-if)# **service-policy output** *policy-map-name*	Enable CBWFQ and specify the policy map to be applied.

Policy-map-name: name of policy map;

Class-map-name: name of class map;

Bandwidth-kbps: bandwidth allocated (unit: kbps);

Percent: percentage of bandwidth allocated (in regard to all available bandwidth of network interface);

The user may allocate bandwidth for the specific type of network traffic. By default, 1% of bandwidth is allocated to the specific type of network traffic.

Burst bytes: number of bytes allowed in a burst above the committed rate limit.

Note

Generally, the bandwidth allocation on the interface will be influenced by the following commands: Bandwidth (CBWFQ), Priority (LLQ), ip rtp priority (RTPQ), and max-reserved-bandwidth (interface). The total bandwidth depends on the "Bandwidth" command of interface. I.e., Bandwidth = max-reserved-bandwidth +default wfq bandwidth; max-reserved-bandwidth = bandwidth(policy-map) +priority(policy-map) +ip RTP priority

Note

To configure PQ congestion management policy on the interface, all interfaces of the system must enable fast forwarding function, otherwise this function will become invalid.

Monitoring LLQ

To view LLQ configurations of interface, execute the following command in privileged user mode.

Command	**Function**
Ruijie# **show policy-map** *interface-name interface-number*	Display the interface information of LLQ.

LLQ Configuration Examples

The following example shows how to configure a LLQ on the synchronization interface to serve packets with MPLS EXP value being 7:

```
class-map match-all 201
 match mpls experimental 7
!
policy-map 1
 class 201
  priority 30 2000
!
interface Serial 3/0
 ip ref
 ip address 192.168.200.1 255.255.255.0
 mpls ip
 service-policy output 1
```

An example of viewing interface configurations in privileged user mode is shown below:

```
Ruijie#show queue interface serial 3/0

  Queueing strategy: cb weighted fair
  Output queue: 0/300/128/0 (size/max total/threshold/drops)
   cb queue_num  0/0 (active/max active)
   wfq queue_num  0/0 (active/max active)
     Reserved queue_num 1/1 (allocated/max allocated)
     Llq is open

  Qos Ref queue information
  Current Policy(s) : CBWFQ
```

```
 interface cir: 2048000
 Queueing strategy: cb weighted fair
  Dequeue threshold:  Green 25000, Yellow 37500, Red 50000
   Queues: Queues total len 0, MeanBurst 800
   Queues: gts gap 7, deta bits 262, token bucket 51200
   Queues: Max 19353 pkts, used 0 pkts
   Queues: rtpQ: 0 pkts, 0 bytes
   Queues: llQ:  0 pkts, 0 bytes
   Queues: genQ: 0 pkts, 0 bytes
  Output Stat.: 0/0/ (send/drops)

Traffic Policing and Traffic Shaping

Introduction to Traffic Policing and Traffic Shaping

In traffic policing, certain actions will be taken to limit the data rate of classified traffics entering the network.

Traffic shaping will restrict the burst of traffics, so that message flows can be transmitted at an even rate and the network traffic can maintain stable.

Traffic Policing Configuration Tasks

To configure Car traffic shaping on the interface, execute the following commands in interface configuration mode:

Command	**Function**
Ruijie(config)# **interface** *interface-type* *interface-number*	Specify the interface for Car traffic policing.
Ruijie(config-if)# **rate-limit {input | output} bps** *burst-normal burst-max* **conform-action** *action* **exceed-action** *action*	Applying rate limiting on all traffics entering the receiving interface or outgoing interface.

Input|output: The input or output data rate to be limited by the user.

Bps: Maximum data rate of the traffic desired by the user (unit: bps).

Burst-normal burst-max: Size of token bucket (unit: bytes).

Conform-action: Traffic handling policy under rate limitation.

Exceed-action: Data rate handling policy when rate limit is exceeded.

Action: Handling policy, including:

Continue to match the next policy

- Drop: drop the packet
- Set-mpls-exp-transmit: transmit this packet after setting mpls experimental field
- Set-mpls-exp-continue: after setting mpls experimental field, this packet continue to match the next policy
- Transmit: transmit this packet

Note To configure traffic policing on the interface, all interfaces of the system must enable fast forwarding function, otherwise this function will become invalid.

Traffic Shaping Configuration Tasks

To configure GTS traffic shaping on the interface, execute the following commands in the interface configuration mode:

Command	**Function**

Ruijie(config)# **interface** *interface-type* *interface-number*	Specify the interface for traffic shaping.
Ruijie(config-if)# **traffic-shape rate** *bit-rate* [*burst-size*] [*excess-burst-size*] [*buffer-limit*]	Carry out traffic shaping of all traffics on the interface.

Bit-rate: the maximum data rate to be shaped by the user (unit: bps).

Burst-size: the maximum traffic size that is permitted in each burst at each interval (unit: bit)

Excess-size: transient burst of traffic that the first interval can forward (unit: bit)

Buffer-limit: buffer size of gts buffer queue (default: 1000).

Note

To configure traffic shaping on the interface, all interfaces of the system must enable fast forwarding function, otherwise this function will become invalid.

Note

The traffic shaping policy handled by the system will function on the interface. When GTS has been configured for the interface, all related sub-interfaces of this interface must enable GTS, otherwise the traffic forwarding will become uneven on related sub-interfaces.

Note

After traffic shaping is enabled on the interface, the burst traffic must be the integral multiple of the data transmitted at 10ms under traffic-shaping rate, otherwise the system will round off the burst traffic configuration parameters according to the data transmitted at 10ms under traffic-shaping rate, so that the parameters can become valid.

Configuring Traffic Policing under Policy-map

To configure single-rate Car traffic limiting in Policy-map, execute the following commands:

Command	**Function**
Ruijie(config)# **policy-map** *policy-map-name*	Enter/create policy map
Ruijie(config-pmap)# **class** *class-map-name*	Use the class map defined.
Ruijie(config-pmap-c)# **police cir** *bps burst-normal burst-max* **conform-action** *action* **exceed-action** *action* **violate-action** *action*	Perform single-rate token bucket limiting of such traffics.
Ruijie(config-if)# **service-policy output** *policy-map-name*	Specify the policy map to be applied to the interface.

CIR: Maximum data rate of the traffic desired by the user (unit: CIR).

Burst-normal burst-max: Size of token bucket (unit: bytes).

Conform-action: Traffic handling policy under rate limitation.

Exceed-action: Data rate handling policy when rate limit is exceeded.

Violate-action: Traffic handling policy when the second token bucket rate limit is exceeded in the case of two token bucket system.

Action: Handling policy, including:

- Drop: drop the packet
- Set-mpls-exp-transmit: transmit this packet after setting mpls experimental field
- Transmit: transmit this packet

To configure dual-rate Car traffic limiting in Policy-map, execute the following commands:

Command	**Function**
Ruijie(config)# **policy-map** *policy-map-name*	Enter/create policy map
Ruijie(config-pmap)# **class** *class-map-name*	Use the class map defined.
Ruijie(config-pmap-c)# **police cir** *bps* **pir** *bps* *burst-normal burst-max* **conform-action** *action* **exceed-action** *action* **violate-action** *action*	Perform dual-rate token bucket limiting of such traffics.
Ruijie(config-if)# **service-policy output** *policy-map-name*	Specify the policy map to be applied to the interface.

CIR: Maximum data rate of the traffic desired by the user (unit: CIR).

PIR: Peak data rate of the traffic desired by the user (unit: CIR).

Burst-normal burst-max: Size of token bucket (unit: bytes).

Conform-action: Traffic handling policy under rate limitation.

Exceed-action: Data rate handling policy when rate limit is exceeded.

Violate-action: Traffic handling policy: when the second token bucket rate limit is exceeded in the case of two token bucket system.

Action: Handling policy, including:

- Drop: drop the packet
- Set-mpls-exp-transmit: transmit this packet after setting mpls experimental field
- Transmit: transmit this packet

Note There are four token bucket algorithms for rate limiting under policy-map. The user may select different token bucket algorithm according to different configurations.

Note Single token bucket algorithm: If violate-action is not configured and the value of burst-normal equals to the value of burst-max, the single token bucket algorithm is adopted.

Note Borrowing mode of single token bucket algorithm: If violate-action is not configured and the value of burst-normal is smaller than the value of burst-max, the borrowing mode of single bucket algorithm is adopted.

Note Single-rate token bucket algorithm: If violate-action is configured but pir is not configured, the single-rate dual token bucket algorithm is adopted.

Note Dual-rate token bucket algorithm: If both violate-action and pir are configured, the dual-rate dual token bucket algorithm is adopted.

Traffic Policing Configuration Examples

Example of Applying Traffic Policing on All Traffics on the Interface

# Configure car traffic policing of incoming messages on Serial interface

# Limit traffics on the receiving interface at 2Mbps; transmit conforming traffics after setting mpls experimental value to 2 and drop excess traffics.

```
interface Serial 3/0
 ip ref
 ip address 192.168.20.3 255.255.255.0
 mpls ip
 rate-limit input 2000000 3000 3000 conform-action set-mpls-exp-transmit 2 exceed-action  drop
```

An example of viewing interface configurations in privileged user mode is shown below:

```
Ruijie#show rate-limit interface serial 3/0
Serial 3/0
  Input
    matches all traffic
      params:  2000000 bps, 3000 limit, 3000 extended limit
      conformed 0 packets, 0 bytes; action: set mpls transmit
      exceeded 0 packets, 0 bytes; action: drop
      cbucket 6000, cbs 6000; ebucket 0 ebs 0
```

Example of Traffic Policing Configuration under Policy-map

The following example shows how to apply Policy-map based traffic limiting on conforming traffics on the outgoing interface. Single-rate dual token bucket algorithm is applied to limit each kind of traffic.

```

Congestion Avoidance

Introduction to Congestion Avoidance

Congestion avoidance is deployed at the network bottle neck to effectively monitor network traffics and avoid anticipated congestion developed at the network bottle neck by dropping information packets.

Excess congestion will cause great harms to network resources, and certain measures shall be taken accordingly. The Congestion Avoidance as mentioned herein refers to the mechanism of actively dropping packets when congestion is expected by monitoring how the network resources are utilized (such as queues or memory buffers), as so to alleviate the load on the network.

WRED

WRED avoids global TCP synchronization by randomly dropping packets. Thus, while the sending rates of some TCP sessions slow down after their packets are dropped, other TCP sessions remain at high sending rates. As there are always TCP sessions at high sending rates, link bandwidth is efficiently utilized.

Before dropping packets, WRED will compare the queue size with lower threshold and upper threshold (the absolute length of queue threshold), and this will result in the unequal treatment of burst traffics and compromise traffic transmission. Therefore, when dropping packets by comparing between lower threshold and upper threshold, the average size of queue will be adopted (this should be the relative value upon comparison between queue threshold and average size). The average queue size is the result of low pass filtering of queue size, and avoids the unequal treatment in the burst of queue size as it reflects the change tendency of queue and is not sensitive to the changes in queue size. The relationship between WRED and queuing mechanism is shown below:

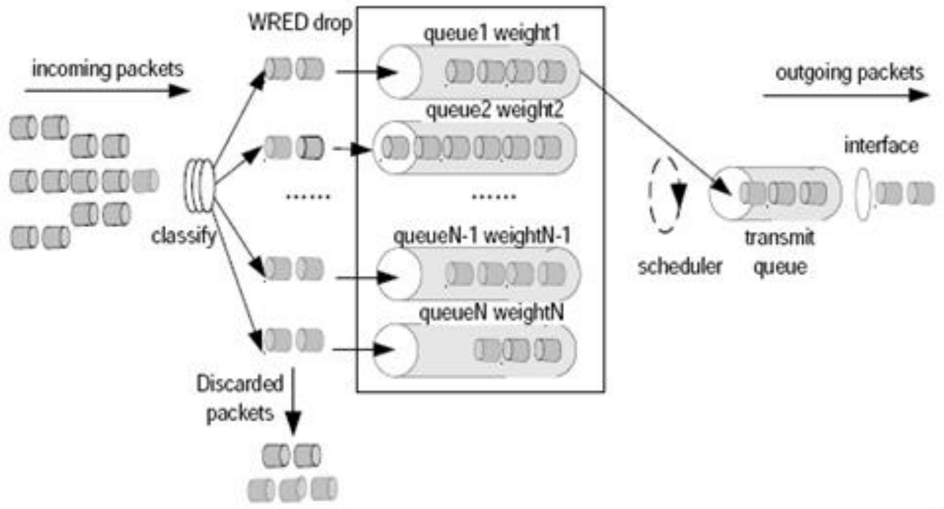

Figure 1

Upper and lower thresholds are set for each queue, and the packets in a queue are processed as follows:

- When the queue size is shorter than the lower threshold, no packet is dropped;
- When the queue size reaches the upper threshold, all subsequent packets are dropped;
- When the queue size is between the lower threshold and the upper threshold, the WRED algorithm will be adopted to determine whether the packets will be dropped or not.

In practice, a random number will be assigned to each incoming packets, and this random number is compared with the drop probability of the existing queue. If this random number is larger than the drop probability, the packets will be dropped. The longer the queue is, the higher the drop probability will be. However, there will be a maximum drop probability.

Configure Congestion Avoidance

Congestion Avoidance (WRED) Configuration Tasks

To enable MPLS EXP value based congestion avoidance on the interface, execute the following command:

Command	Function
Ruijie(config-if)# **random-detect mpls-exp-based**	Enable congestion avoidance based on the EXP value of MPLS packets.

Note

To configure congestion avoidance on the interface, all interfaces of the system must enable fast forwarding function, otherwise this function will become invalid.

To configure the maximum threshold, minimum threshold and drop probability of each kind of traffics classified by experimental, execute the following commands in interface configuration mode:

Command	Function
Ruijie(config)# **interface** *interface-type interface-number*	Specify the interface for congestion avoidance.
Ruijie(config-if)# **random-detect experimental** *exp-value min-threshold max-threshold mark-prob-denominator*	Configure the maximum threshold, minimum threshold and drop probability of each kind of traffics classified by experimental.

Exp-value: experimental value; traffics are classified according to this value.

Min-threshold: the minimum drop threshold; the default value differs from traffic to traffic.

Max-threshold: the maximum drop threshold; the default value differs from traffic to traffic.

Mark-prob-denominator: drop probability; the default value is 10, i.e., 1/10. The larger this value is, the smaller the drop probability will be.

To configure the weight factor for traffic congestion avoidance on the interface, execute the following commands in privileged user mode:

Command	Function
Ruijie(config)# **interface** *interface-type* *interface-number*	Specify the interface for congestion avoidance.
Ruijie(config-if)# **random-detect** **exponential-weighting-constant** *exponential-value*	Configure the weight factor for traffic congestion avoidance on the interface.

Exponential-value: the default value of weight factor is 9; the smaller this value is, the larger the drop probability will be; the larger this value is, the smaller the drop probability will be.

Note

If the queuing algorithm of Ethernet interface is not FIFO, you must "no" the queuing algorithm before configuring WRED congestion avoidance on the interface. If the queuing algorithm of synchronization interface is not FIFO or WFQ, you must "no" the queuing algorithm before configuring WRED congestion avoidance on the interface.

Congestion Avoidance (WRED) Configuration Examples

Example of Configuring Congestion Avoidance on the Interface

# Configure WRED congestion avoidance based on MPLS experimental traffic classification on the synchronization interface.

# Set lower threshold to 5, upper threshold to 100 and drop probability to 10 for packets with experimental value being 1.

# Set lower threshold to 10, upper threshold to 100 and drop probability to 10 for packets with experimental value being 2.

# Set lower threshold to 20, upper threshold to 100 and drop probability to 10 for packets with experimental value being 3.

# Set lower threshold to 30, upper threshold to 100 and drop probability to 10 for packets with experimental value being 4.

QoS Overview

Understanding QoS

QoS Overview

Devices on a conventional IP network equally treat all data packets with a First In First Out (FIFO) policy and deliver each data packet with the best effort to the destination. They do not provide any guarantee for packet transmission performance such as reliability and transmission delay.

As the Internet becomes rapidly popular in the globe and information networks emerge one after another in today's society, people raise increasingly-higher requirements for networks. Today, information requirements are no longer confined to mere data information but also extend to interactive multimedia. Services are developing towards data, voice, unified image, and integrated network transmission. Highly-real-time voice, image, and important data services sensitive to bandwidth delay and jitter tend to be more widely transmitted on networks. On one hand, this helps greatly improve network resources. On the other hand, an issue about how to guarantee network Quality of Service (QoS) arises, since voice, data, and image services have different delay, throughput, and packet loss rate requirements.

The QoS mechanism is intended to provide different QoS to meet diversified service quality requirements.

Basic Concepts

Three QoS models are defined to meet different service quality requirements. They are the Best-Effort Service model, the Integrated Service Model, and the Differentiated Service (DiffServ) model.

Best-Effort Service

The Best-Effort Service model enables a network to transmit packets with the best effort but does not provide any guarantee for transmission performance such as delay and reliability. It is a default service model applied on the conventional Internet.

Integrated Service

In the Integrated Service model, an application program needs to submit a specific QoS request to the network before sending a packet. The request covers the required bandwidth and delay. The application program starts to send the packet only after receiving an acknowledgment from the network (that is, after the network reserves resources for the application program). In addition, packets sent by the application program must be controlled within the traffic range described by traffic parameters.

Differentiated Service

In the Differentiated Service model, an application program does not need to submit a resource request to the network before sending a packet. Instead, it sets QoS parameter information in the IP header of the packet to inform network nodes of its QoS requirements. All routers on the packet propagation path can analyze the IP header to obtain the QoS class of the packet.

Working Principles

Major QoS technologies include traffic classification, traffic policing, traffic shaping, congestion management, and congestion avoidance. The Integrated Service model also introduces a protocol called the Resource Reservation Protocol (RSVP).

Traffic Classification

Objects are identified based on certain matching rules. Traffic classification is a precondition for implementing differentiated services.

Traffic Policing

Traffic policing is used to monitor and control the specifications of specific traffic inbound to routers. It applies when traffic goes beyond specifications.

Traffic Shaping

Traffic shaping is a means to control traffic by actively adjusting the output rate of traffic. In general, it enables traffic to adapt to available network resources on the downstream router so as to avoid packet loss or congestion.

Congestion Management

Congestion management is a measure for solving resource contention in the event of network congestion. In general, packets are cached in queues and a certain scheduling algorithm is applied to arrange the forwarding sequence of packets.

Congestion Avoidance

Excessive congestion will cause great harm to network resources.

RSVP

RSVP is an end-to-end (E2E) resource reservation protocol. Resource requests are transmitted between network nodes. Upon receipt of these requests, a network node needs to allocate resources for these requests.

Ruijie QoS mechanism supports the DiffServ model. The following sections describe how to configure QoS technologies.

Traffic Classification Configuration

Understanding Traffic Classification

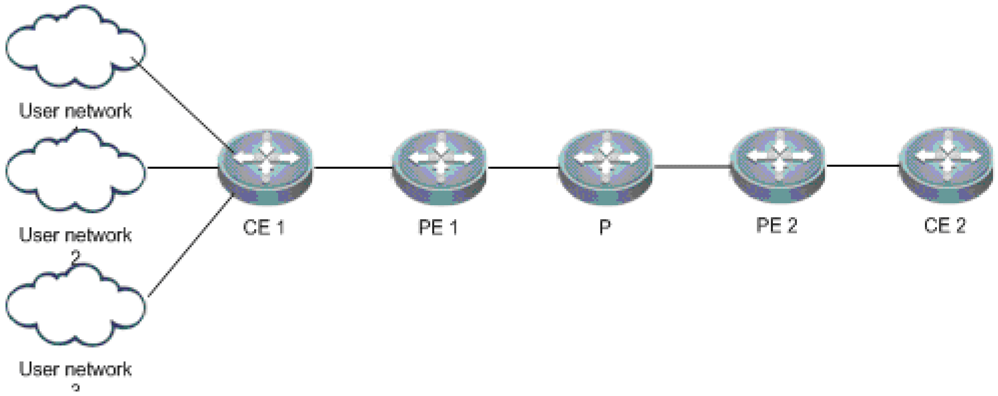
Traffic Classification Overview

When the DiffServ model is applied for QoS implementation, routers need to identify various flows and therefore traffic classification must be performed for packets. Two methods can be used for traffic classification: complex traffic classification and simple traffic classification.

Complex traffic classification is a means to classify packets in a fine manner using complex rules, such as rules based on link layer, network layer, and transport layer information (e.g. source MAC address, destination MAC address, source IP address, destination IP address, user group number, protocol type, or TCP/UDP port number of applications). In general, complex traffic classification is applied to traffic on border routers in the DiffServ domain.

As shown in Figure 9, CE 1, PE 1, P, PE 2, and CE 2 form a service provider network. PE 1, P, and PE 2 establish MPLS neighbors with each other. User networks 1, 2, and 3 access an MPLS network from CE 1 which is a service provider edge device. The traffic of user networks accesses the MPLS network from CE 1. Priority remarking must be performed for traffic of the three user networks, so that the traffic of different users is processed on the MPLS network according to different priorities. CE 1 must support complex traffic classification and related policies in terms of QoS.

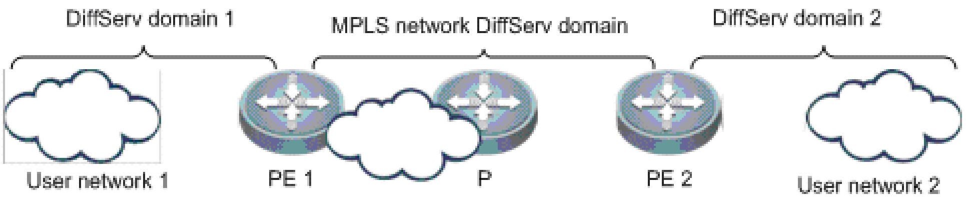
Figure 9 QoS Mapping for User Network Traffic Accessing an MPLS Network



Simple traffic classification is a means to roughly classify packets using simple rules, such as the IP priority or DSCP value of an IP packet, the EXP value of an MPLS packet, or the 802.1p value of a VLAN packet, so as to identify traffic featuring different priorities or Classes of Service (CoSs). In general, simple traffic classification is applied only on core routers in the DiffServ domain.

As shown in Figure 10, PE 1, P, and PE 2 form a backbone network and establish MPLS neighbors with each other. User networks 1 and 2 access the backbone network from the PE. The traffic of user network 1 reaches user network 2 through the backbone network. Service priority mapping must be performed for services between different DiffServ domains.

Figure 10 QoS Mapping for User Network Traffic Across an MPLS Network



Basic Concepts

QoS Priority

Services are classified by QoS requirements into eight types. Packets are first classified and marked after accessing the system. They are treated differently according to packet priorities on the entire forwarding path. The following table defines service priorities.

Table 1 Service Priorities

Code	Service Level		Description
7	CS7		Used for in-band control messages, it represents the highest priority.
6	CS6		Used for protocol packets on the control plane, such as routing protocol packets and Bidirectional Forwarding Detection (BFD) packets.
5	EF (Expedited Forwarding)		Used for services sensitive to delay, jitter, and the packet loss rate, such as VoIP/TDM service packets.
4	AF4	Assured Forwarding	Such services are surely forwarded when they do not exceed the maximum allowed bandwidth. Once the maximum bandwidth is exceeded, however, some packets will be discarded according to a discard priority. Such services are further classified into four types, and different bandwidths are allocated to different service types.
3	AF3		
2	AF2		
1	AF1		
0	BE (Best Effort)		Used for services insensitive to delay, jitter, and the packet loss rate, such as web, FTP, and other Internet services.

QoS Coloring

RFC 2697 and RFC 2698 have defined a service coloring mechanism, which uses three colors Green, Yellow, and Red to implement traffic control for services.

The system colors services based on different service policies to implement different packet discard polices.

Traffic Classifier

In complex traffic classification, it is necessary to define classifiers for various service flows, including classifiers based on different network features such as IPv4, IPv6, MPLS, and VLAN.

In simple traffic classification, traffic classifiers are used to classify traffic based on priorities only, such as DSCP for an IP network, EXP for an MPLS network, and CoS for an 802.1P network.

Traffic Behavior

In complex traffic classification, It is necessary to define the behaviors of various flows, such as Hierarchical QoS (HQoS) marking, priority re-marking, and QoS marking. QoS marking includes priority marking and packet coloring.

In simple traffic classification, however, traffic behaviors support only QoS marking and priority marking.

Traffic Policy

In complex traffic classification, traffic policies are used to associate traffic classifiers with traffic behaviors. One traffic policy can be used to associate multiple traffic classifiers with traffic behaviors so as to perform different operations for different service flows.

In simple traffic classification, a traffic policy consists of an uplink traffic classification mapping table and a downlink traffic classification mapping table. The uplink traffic classification mapping table implements mapping between priorities and QoS levels, whereas the downlink traffic classification mapping table implements mapping from QoS levels to priorities.

⚠ Caution

Simple traffic classification supports mapping between service priorities, CoSs, and discard priorities so as to implement priority bearing and mapping for inter-domain devices.

⚠ Caution

In complex traffic classification, priority marking supports only traffic policies for traffic classification and behaviors on homogeneous networks. For example, the system can perform MPLS priority marking after matching packets with MPLS traffic features.

DiffServ Domain

In the DiffServ model, multiple DiffServ domains are defined and various priority policies are applied. The priority policies for different domains may be different. Therefore, priority mapping must be performed for services across DiffServ domains to guarantee point-to-point QoS.

Universal priority policies are respectively defined for QoS of IP, MPLS, and VLAN networks. DSCP is used for IP networks, EXP for MPLS networks, and CoS for VLAN networks.

Table 2 Default Mapping Between DiffServ Domain DSCP Values and QoS Service Types

DSCP	Service	Color	DSCP	Service	Color
00	BE	Green	32	AF4	Green

Working Principles

Simple Traffic Classification

Ruijie supports the following simple flow classification:

Simple traffic classification for DiffServ domains of VLAN networks

Simple traffic classification for DiffServ domains of MPLS networks

Simple traffic classification for DiffServ domains of IP networks

Uplink traffic mapping from DiffServ priorities to QoS

Downlink traffic mapping from QoS to DiffServ priorities

Applying simple traffic classification policies based on L3 interfaces or virtual templates

Complex Traffic Classification

Ruijie supports the following complex flow classification:

Complex traffic classification based on L2 information for VLAN networks

Complex traffic classification based on L2 information for MPLS networks

Complex traffic classification based on L2 information for IP networks

Traffic classification policies: associated user queues, priority re-marking, and QoS marking

Priority re-marking across DiffServ domains

Applying simple traffic classification policies based on L3 interfaces or virtual templates

Protocols and Specifications

RFC2474: Definition of the Differentiated Services Field (DS Field) in the IPv4 and IPv6 Headers

RFC2597: Assured Forwarding PHB

RFC2598: Expedited Forwarding PHB

RFC2697: A Single Rate Three Color Marker

RFC2698: A Two Rate Three Color Marker

Default Configurations

The following table shows default traffic classification configurations.

Feature	Default
Complex traffic classification	Disabled
Complex traffic behaviors	None
Complex traffic classification polices	None
Simple traffic classification	Disabled
DiffServ domain in simple traffic classification	A default domain is created
Simple traffic classification policies	The default policy is consistent with the default domain

Configuring Complex Traffic Classification

Configuring Traffic Classifiers

Traffic classifiers are configured to distinguish the traffic of different users from one another so as to provide differentiated services for different users. Each traffic classifier may contain multiple matching rules, and the relationship between the matching rules is determined by the classifier type. If the classifier type is "and", all rules apply to the packet. If the rule type is "or", the packet can match any of the rules. If the classifier type is not specified, the "or" relationship applies between the matching rules. To configure traffic classifiers, perform the following steps:

Command	Purpose
Ruijie(config)# **traffic classifier** *classifier-name* [**and** | **or**]	Enter or create a traffic classifier.
Ruijie(config-traffic-classifier)# **if-match acl** *acl-name* **Or:** Ruijie(config-traffic-classifier)# **if-match dscp** *dscp-value* **Or:** Ruijie(config-traffic-classifier)# **if-match ip-precedence** *ip-precedence-value* **Or:** Ruijie(config-traffic-classifier)# **if-match any**	Set an IPv4 packet matching rule, which can be based on ACL, DSCP, or IP precedence, or any IPv4 packet.
Ruijie(config-traffic-classifier)# **if-match ipv6 acl** *ipv6-acl-number* **Or:** Ruijie(config-traffic-classifier)# **if-match ipv6 dscp** *dscp-value* **Or:** Ruijie(config-traffic-classifier)# **if-match ipv6 any**	Set an IPv6 packet matching rule, which can be based on ACL, DSCP, or any IPv6 packet.
Ruijie(config-traffic-classifier)# **if-match mpls-exp** *mpls-exp-value*	Set an MPLS packet matching rule, which can be based on MPLS EXP.
Ruijie(config-traffic-classifier)# **if-match cos** *cos-value* **Or:** Ruijie(config-traffic-classifier)# **if-match source-mac** *mac-address* **Or:** Ruijie(config-traffic-classifier)# **if-match destination-mac** *mac-address*	Set an Ethernet packet matching rule, which can be based on CoS, source MAC address, or destination MAC address.
Ruijie(config-traffic-classifier)#**exit**	Exit the traffic classifier configuration view.

Configuration example:

# Create a traffic classifier and set an IPv4 packet matching rule based on an ACL:

```
Ruijie(config)#traffic classifier tc1
Ruijie(config-traffic-classifier)#if-match acl 100
Ruijie(config-traffic-classifier)#exit
```

Configuring Traffic Behaviors

Traffic behaviors determine traffic scheduling parameters after traffic is classified. To configure traffic behaviors, perform the following steps:

Command	Purpose
Ruijie(config)# **traffic behavior** *traffic-behavior-name*	Enter or create a traffic behavior.
Ruijie(config-traffic-behavior)#**user-queue** *user-queue-name* [**inbound | outbound**]	Set a user queue.
Ruijie(config-traffic-behavior)#**service-class** *service-class-value* **color** *color-value*	Set the service class and discard priority of packets.
Ruijie(config-traffic-behavior)#**remark dscp** *dscp-value* **Or:** Ruijie(config-traffic-behavior)#**remark ip-precedence** *ip-precedence-value*	Set the remark value of IPv4 packets.
Ruijie(config-traffic-behavior)#**remark ipv6 dscp** *dscp-value*	Set the remark value of IPv6 packets.
Ruijie(config-traffic-behavior)#**remark mpls-exp** *mpls-exp-value*	Set the remark value of MPLS packets.
Ruijie(config-traffic-behavior)#**remark cos** *cos-value*	Set the 802.1Q remark value of Ethernet packets.
Ruijie(config-traffic-behavior)#**sub-traffic-policy** *traffic-policy-name*	Set an associated sub-traffic policy.
Ruijie(config-traffic-behavior)#**rtp-shaping delay** *delay-time* **clock-rate** *clock-rate*	Set RTP shaping behavior.

Configuration example:

# Create a traffic behavior.

```
Ruijie(config)#traffic behavior tb1
Ruijie(config-traffic-behavior)#user-queue uq1 inbound
Ruijie(config-traffic-behavior)#service-class ef color green
Ruijie(config-traffic-behavior)#remark dscp 40
```

Configuring Traffic Policies

Traffic policies associate traffic classifiers with traffic behaviors, so that classified traffic is scheduled according to users' configurations. To configure traffic policies, perform the following steps:

Command	Purpose
Ruijie(config)# **traffic policy** *traffic-policy-name*	Enter or create a traffic policy.
Ruijie(config-traffic-policy)# **classifier** *classifier-name* **behavior** *behavior-name* [**precedence** *precedence-value*]	Specify the traffic behavior for a traffic classifier and set the preference. The smaller the precedence value, the higher the preference.

Configuration example:

# Create a traffic policy.

```
Ruijie(config)#traffic policy tp1
Ruijie(config-traffic-policy)#classifier tc1 behavior tb1 precedence 1
```

Applying Traffic Classification Polices

To apply traffic classification policies, perform the following steps:

Command	Purpose
Ruijie(config)# **interface** *interface-name*	Enter interface configuration mode.

Ruijie(config-if)# **traffic-policy** *traffic-policy-name* **{inbound | outbound} [link-layer | all-layer]**	Apply a traffic policy to the interface. You need to specify the layer parameter. By default, a policy takes effect for L3 and MPLS packets only. If the *link-layer* parameter is specified, the policy takes effect for 802.1P L2 packets only. If the *all-layer* parameter is specified, the policy takes effect for both L3 and L2 packets. If you specify the *link-layer* or *all-layer* parameter, the configured traffic policy is applicable to both the interface and all associated subinterfaces but not merely its subinterfaces. ATM interfaces and subinterfaces do not support the *link-layer* or *all-layer* parameter.

Configuration example:

# Apply a traffic policy to an interface.

```
Ruijie(config)#int gigabitethernet 0/1
Ruijie(config-if-Gigabitethernet 0/1)#traffic-policy tp1 inbound
```

Displaying Configurations

Command	Purpose
show traffic classifier [*classifier-name*]	Show traffic classifier configurations in the system.
show traffic behavior [*behavior-name*]	Show traffic behavior configurations in the system.
show traffic policy [*policy-name*]	Show traffic policy configurations in the system.

Configuration example:

# Show information about the interfaces of the port queue in the system.

```
Ruijie# show traffic classifier tc1
traffic classifier tc1 or
  if-match acl 1501
```

Configuring Simple Traffic Classification

Configuring DiffServ Domains and Traffic Policies

You need to first define DiffServ domains and specify traffic policies for the DiffServ domains during simple traffic classification. To configure DiffServ domains and traffic policies, perform the following steps:

Command	Purpose
Ruijie(config)# **diffserv domain {***ds-domain-name* **| default}**	Enter or create a DiffServ domain.
Ruijie(config-diffserv-domain)# **ip-dscp-inbound** *dscpvalue* **phb** *service-class color* **Or:** Ruijie(config-traffic-classifier)# **ip-dscp-outbound** *serviceclass color* **map** *dscp-value*	Configure an IP traffic policy.
Ruijie(config-diffserv-domain)# **mpls-exp-inbound** *exp* **phb** *service-class color* **Or:** Ruijie(config-diffserv-domain)# **mpls-exp-outbound** *service-class color* **map** *exp-value*	Configure an MPLS traffic policy.
Ruijie(config-diffserv-domain)# **8021p-inbound** *cos-value* **phb** *service-class color* **Or:** Ruijie(config-diffserv-domain)# **8021p-outbound** *service-class color* **map** *cos-value*	Configure an 802.1P traffic policy.
Ruijie(config-traffic-classifier)#**exit**	Exit the traffic classifier configuration view.

Configuration example:

# Create a DiffServ domain named "out-ip" and set the mapping from IP DSCP to QoS.

Ruijie(config)# diffserv domain out-ip

```
Ruijie(config-diffserv-domain)# ip-dscp-inbound 34 phb ef green
Ruijie(config-diffserv-domain)#exit
```

Applying Traffic Classification Polices

To apply traffic classification policies, perform the following steps:

Command	**Purpose**
Ruijie(config)# **interface** *interface-name*	Enter interface configuration mode.
Ruijie(config-if)# **trust upstream** **{** *ds-domain-name* **| default }**	Apply a simple traffic classification policy to the interface.
Ruijie(config-if)# **trust 8021p**	Enable 802.1p simple traffic classification. This configuration is applicable to interfaces only. The configured traffic policy is applicable to both the interface and all associated subinterfaces but not merely its subinterfaces. This command is not available for ATM interfaces or subinterfaces.

Configuration example:

# Apply a traffic policy of the DiffServ domain named "out-ip" to an interface.

```
Ruijie(config)#int gigabitethernet 0/1
Ruijie(config-if-Gigabitethernet 0/1)#trust upstream out-ip
```

Displaying Configurations

Command	**Purpose**
show diffserv domain diffserv-domain-name [8021p-inbound | 8021p-outbound | ip-dscp-inbound | ip-dscp-outbound |mpls-exp-inbound | mpls-exp-outbound]	Show DiffServ domain configurations.

Configuration example:

# Show configuration information about the DiffServ domain named "ip-out".

```
Ruijie# show diffserv domain ipdscp

Examples for Configuring Traffic Classification

Configuration Example 1

Networking Requirements

- Device requirements:

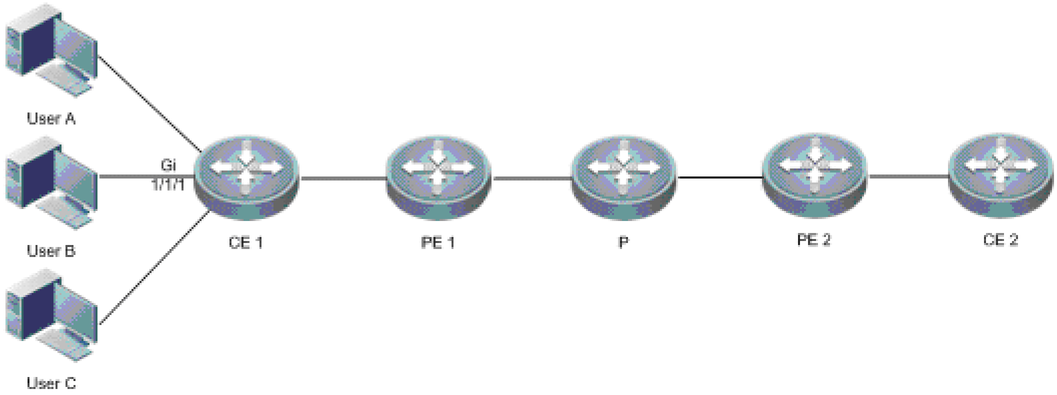
Four routers.

- Configuration requirements:

Two local users access an MPLS backbone network from a CE. The committed access rate of user A is 60 Mbps, and the peak access rate is 80 Mbps. The committed access rate of user B is 30 Mbps, and the peak access rate is 40 Mbps. The IP address of user A is 10.1.10.1, and that of user B is 10.1.10.2.

Network Topology

Figure 11 Network Topology for Complex Traffic Classification



Configuration Tips

Configure traffic classifiers to identify users.

Configure traffic behaviors to monitor and control user traffic.

Configuration Steps

Configure traffic classifiers:

```
# Configure a traffic classifier named "tc1".
Ruijie(config)#access-list 100 permit ip host 10.1.10.1 any
Ruijie(config)#traffic classifier tc1
Ruijie(config-traffic-classifier)#if-match acl 100
Ruijie(config-traffic-classifier)#exit
# Configure a traffic classifier named "tc2".
Ruijie(config)# access-list 110 permit ip host 10.1.10.2 any
Ruijie(config)#traffic classifier tc2
Ruijie(config-traffic-classifier)#if-match acl 110
Ruijie(config-traffic-classifier)#exit
```

Configure user queues:

```
# Configure a user queue named "uq1".
Ruijie(config)#user-queue uq1 inbound
Ruijie(config-user-queue)#cir 60000 pir 80000
Ruijie(config-user-queue)#exit
```

```
# Configure a user queue named "uq2".
Ruijie(config)#user-queue uq2 inbound
Ruijie(config-user-queue)#cir 30000 pir 40000
Ruijie(config-user-queue)#exit
```

Configure traffic behaviors:

```
#Configure a traffic behavior named "tb1".
Ruijie(config)#traffic behavior tb1
Ruijie(config-traffic-behavior)#user-queue uq1 inbound
Ruijie(config-traffic-behavior)#exit
```

```
#Configure a traffic behavior named "tb2".
Ruijie(config)#traffic behavior tb2
Ruijie(config-traffic-behavior)#user-queue uq2 inbound
Ruijie(config-traffic-behavior)#exit
```

Configure a traffic policy:

```
Ruijie(config)#traffic policy tp1
Ruijie(config-traffic-policy)#classifier tc1 behavior tb1
Ruijie(config-traffic-policy)#classifier tc2 behavior tb2
Ruijie(config-traffic-policy)#exit
```

Apply the traffic policy to an interface:

```
Ruijie(config)#int gigabitethernet 1/1/1
Ruijie(config-if-Gigabitethernet1/1/1)#traffic-policy tp1 inbound
```

Verification

Show traffic policy information:

```
Ruijie# show traffic policy tp1
traffic policy tp1
  classifier tc1 behavior tb1 precedence 1
  classifier tc2 behavior tb2 precedence 2
```

Configuration Example 2

Networking Requirements

- Device requirements:

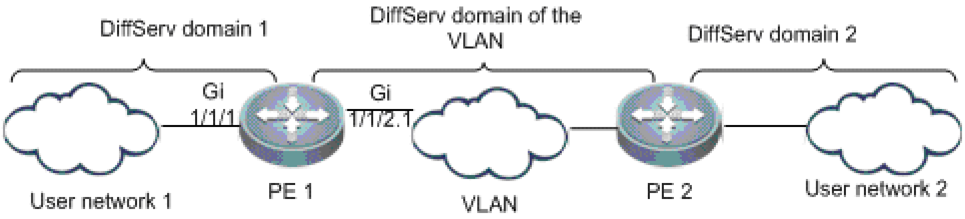
One Ethernet switch and two routers.

- Configuration requirements:

Two routers provide access services for the users of user network 1 and user network 2 respectively. The service priority of users of user network 1 must be able to be carried and transferred to user network 2 to implement DiffServ domain mapping across the VLAN. It is necessary to add HQOS configurations on PE 1.

Network Topology

Figure 12 User Network Interconnection Across a VLAN



Configuration Tips

Configure DiffServ domains on routers.

Apply simple traffic classification to the user networks and VLAN.

Configuration Steps

Create DiffServ domain policies:

```
# Configure a traffic classifier named "usera".
Ruijie(config)# diffserv domain usera
Ruijie(config-diffserv-domain)#ip-dscp-inbound 34 phb ef green
Ruijie(config-diffserv-domain)#ip-dscp-inbound 16 phb be green
# Configure a traffic classifier named "vlan".
Ruijie(config)# diffserv domain vlan
Ruijie(config-diffserv-domain)# 8021p-outbound ef green map 4
Ruijie(config-diffserv-domain)# 8021p-outbound be green map 1
```

Apply simple traffic classifiers to respective interfaces:

```
Ruijie(config)#int gigabitethernet 1/1/1
Ruijie(config-if-Gigabitethernet1/1/1)#trust upstream vlan
Ruijie(config-if-Gigabitethernet1/1/1)#exit

Ruijie(config)#int gigabitethernet 1/1/2.1
Ruijie(config-if-Gigabitethernet1/1/2.1)#trust upstream usera
Ruijie(config-if-Gigabitethernet1/1/2.1)#trust 8021p
Ruijie(config-if-Gigabitethernet1/1/2.1)#exit
```

Verification

Show DiffServ domain configurations:

```
Ruijie# show diffserv domain usera
IP-DSCP map to Server-class and Color:
  0 --> be   green
  1 --> be   green
  2 --> be   green
  3 --> be   green
  4 --> be   green
  5 --> be   green
  6 --> be   green
  7 --> be   green
  8 --> af1  green
  9 --> be   green
 10 --> af1  green
 11 --> be   green
 12 --> af1  yellow
 13 --> be   green
 14 --> af1  red
 15 --> be   green
 16 --> be   green
 17 --> be   green
 18 --> af2  green
 19 --> be   green
 20 --> af2  yellow
 21 --> be   green
 22 --> af2  red
 23 --> be   green
 24 --> af3  green
 25 --> be   green

Configuration Example 3

Networking Requirements

- Device requirements:

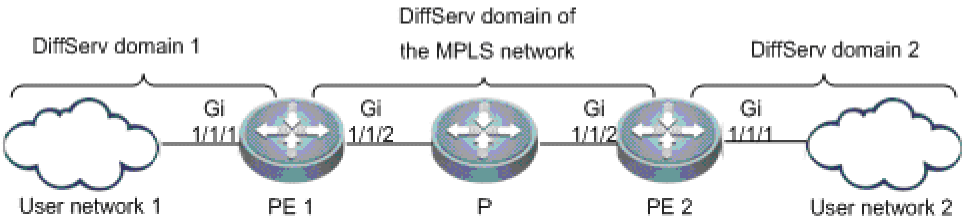
Five routers.

- Configuration requirements:

User network 1 and user network 2 access an MPLS backbone network from PE 1 and PE 2 respectively. The service priority of users of user network 1 must be able to be carried and transferred to user network 2 to implement DiffServ domain mapping across the MPLS network. It is necessary to add HQOS configurations on PE 1 and PE 2.

Network Topology

Figure 13 User Network Interconnection Across an MPLS Network



Configuration Tips

Configure DiffServ domains on routers.

Apply simple traffic classification to the user networks and MPLS network.

Configuration Steps

Configure PE 1 and create DiffServ domain policies:

```
# Configure a traffic classifier named "usera".
Ruijie(config)# diffserv domain usera
Ruijie(config-diffserv-domain)#ip-dscp-inbound 34 phb ef green
Ruijie(config-diffserv-domain)#ip-dscp-inbound 16 phb be green
# Configure a traffic classifier named "mpls".
Ruijie(config)# diffserv domain mplsa
Ruijie(config-diffserv-domain)# mpls-exp-outbound ef green map 4
Ruijie(config-diffserv-domain)# mpls-exp-outbound be green map 1
```

Configure PE1. Apply simple traffic classifiers to respective interfaces:

```
Ruijie(config)#int gigabitethernet 1/1/1
Ruijie(config-if-Gigabitethernet1/1/1)#trust upstream usera
Ruijie(config-if-Gigabitethernet1/1/1)#exit

Ruijie(config)#int gigabitethernet 1/1/2
Ruijie(config-if-Gigabitethernet1/1/2)#trust upstream mplsa
Ruijie(config-if-Gigabitethernet1/1/2)#exit
```

Configure PE 2 and create DiffServ domain policies:

```
# Configure a traffic classifier named "usera".
Ruijie(config)# diffserv domain userb
Ruijie(config-diffserv-domain)# ip-dscp-outbound ef green map
34Ruijie(config-diffserv-domain)# ip-dscp-outbound be green map 16
# Configure a traffic classifier named "mpls".
Ruijie(config)# diffserv domain mplsb
Ruijie(config-diffserv-domain)# mpls-exp-inbound 4 phb ef green
Ruijie(config-diffserv-domain)# mpls-exp-inbound 1 phb be green
```

Configure PE2. Apply simple traffic classifiers to respective interfaces:

```
Ruijie(config)#int gigabitethernet 1/1/1
Ruijie(config-if-Gigabitethernet1/1/1)#trust upstream userb
Ruijie(config-if-Gigabitethernet1/1/1)#exit

Ruijie(config)#int gigabitethernet 1/1/2
Ruijie(config-if-Gigabitethernet1/1/2)#trust upstream mplsb
Ruijie(config-if-Gigabitethernet1/1/2)#exit
```

Verification

Configuring HQoS

Understanding HQoS

HQoS Overview

The traditional QoS offers different treatment to services and ensure QoS needs such as bandwidth and delay by classifying service flows and specifying policies for them. However, the existing user access network is complex, and there are a large number of access devices (such as Layer 2 switches and converters) that do not support complex QoS. Although egress devices of the user access network can ensure QoS for transmitted services as much as possible, they cannot ensure QoS based on the user and user group in a more refined manner.

Hierarchical QoS (HQoS) is different from the traditional QoS, which is specific to services. HQoS can provide QoS for data flows in the network by service, user, floor, and residential area. Service QoS provides quality service for multiple service flows of a single user. User QoS provides quality service for multiple users on a floor, and so on for floor QoS and residential area QoS. HQoS can implement more refined service assurance for data aggregation devices to improve service quality for whole-network users.

Basic Concepts

FQ

The flow queue (FQ) indicates service queues of a user. Each user has eight FQs, which correspond to eight service priorities respectively (BE, AF1, AF2, AF3, AF4, EF, CS6, and CS7). The eight FQs can be configured with Priority Queuing (PQ), Weighted Fair Queuing (WFQ), or Low-priority Queuing (LPQ). Each FQ supports Weighted Random Early Detection (WRED) and traffic shaping.

UQ

The user here indicates one VLAN or VPN. Users can be divided based on the interface, sub-interface, or ACL. Each user has a user queue (UQ), which is aggregated by eight fixed FQs. You can limit the total bandwidth of each user by performing rate limiting to its UQ.

Note

If users belong to different line cards of a distributed device, the UQ function takes effect based on each line card.

GQ

Multiple users can be bound to one user group. Each user group has a group queue (GQ). You can control the traffic of a user group by performing traffic shaping to the GQ.

Note If user groups belong to different line cards of a distributed device, the GQ function takes effect based on each line card.

Destination Interface/Destination Device CQ

Each destination interface has eight queues, which correspond to eight service types respectively. The eight FQs can be configured with SP and WFQ. Each class queue (CQ) supports WRED and traffic shaping.

The destination device CQ can be regarded as an uplink destination interface CQ. They are the same in nature. The difference is that the packets of the destination device CQ are sent to boards instead of interfaces. Each destination device correspond to four queues, which correspond to four service types. The four queues are scheduled in SP mode.

LPQ

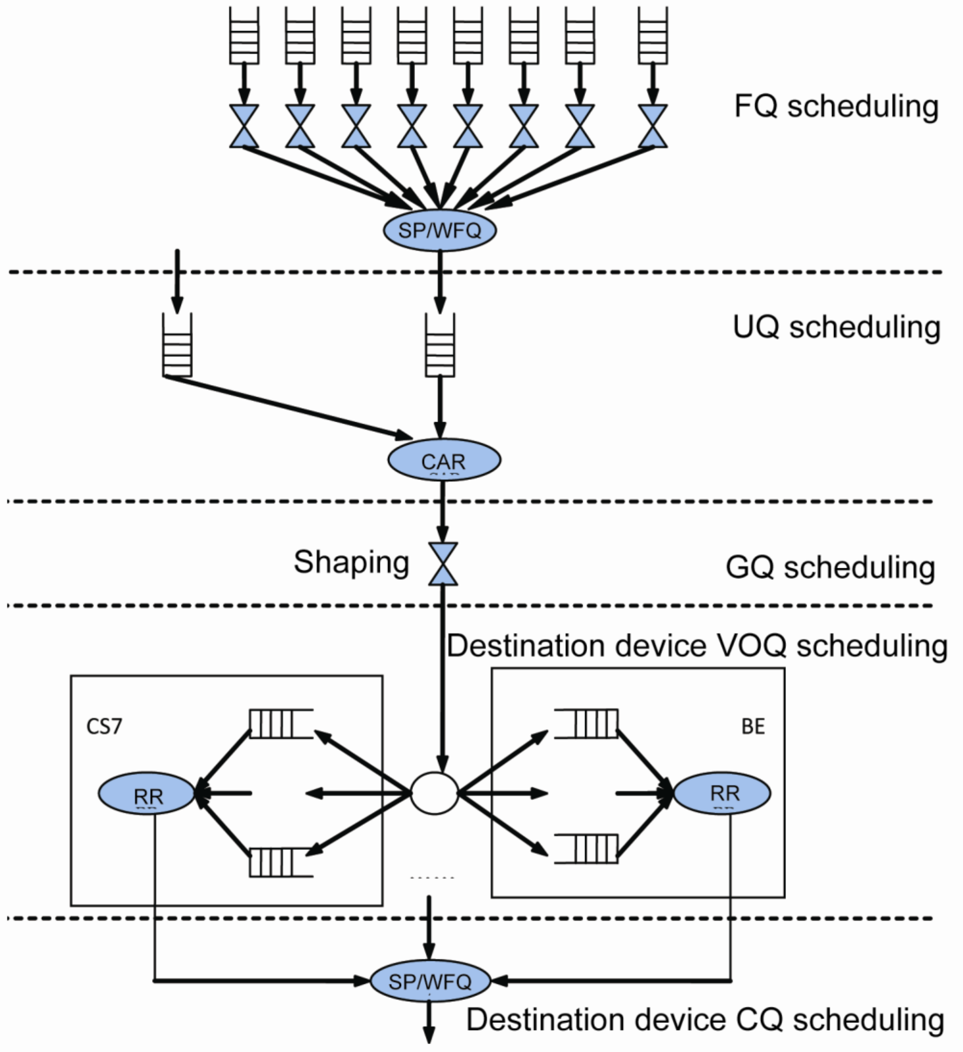
There are three scheduling mechanisms in HQoS: PQ, WFQ, and Low-priority Queue (LPQ), which descend in order of priority. In the case of congestion, PQ queues and WFQ queues can preempt the bandwidth of LPQ queues.

How HQoS Works

Uplink HQoS Scheduling

Uplink HQoS scheduling is divided into five levels: CQ > UQ > GQ > Destination device VOQ > Destination device CQ, as shown in the following figure:

Figure 1 Uplink HQoS scheduling process



Level 1 scheduling is FQ scheduling. The FQ is an entity queue, that is, the packets are cached in an FQ. FQ includes FQ WRED, FQ shaping, and FQ scheduling. WERD congestion avoidance is required before a packet enters a FQ. The system supports discarding priorities of three colors: red, yellow, and green. Red indicates the highest discarding priority, and green indicates the lowest one. Each FQ sets the minimum threshold, maximum threshold, and discarding probability for each discarding priority. The higher the discarding priority, the greater the maximum threshold and minimum threshold, and the greater the discarding probability of packets. Traffic shaping is performed via token bucket after WRED for FQ. Finally, FQ scheduling is performed by using Strict Priority (SP)+WFQ. SP includes PQ and LPQ. CS7, CS6, EF, AF, and BE are scheduled in sequence. Low-priority queues are scheduled only when there are no packets in high-priority queues. AF includes four types, which are scheduled according to their respective weights.

Level 2 scheduling is UQ scheduling. The UQ is a virtual queue, that is, the packets are not cached in a UQ. UQ scheduling is only an HQoS scheduling level. Each UQ includes eight FQs that share the bandwidth of the UQ. The UQ supports committed interface rate (CIR) only. Each UQ can invoke zero to one GQ.

Level 3 scheduling is GQ scheduling. The GQ is a virtual queue. Multiple UQs can be bound to a GQ for scheduling. The GQ supports traffic shaping only. If no UQ is bound to a GQ, GQ scheduling will be skipped.

Level 4 scheduling is VoQ scheduling. VoQ scheduling is the uplink traffic scheduling among line cards. The VoQ breaks into four groups by service priority, with one queue for each destination device in each group. When packets pass through UQ scheduling, they enter different VoQs based on their destination devices and priorities. VoQ scheduling is configured by the system, and no additional user configuration is required.

Level 5 scheduling is CQ scheduling. The CQ is a virtual queue, instead of an entity queue that caches packets. Each CQ, however, maintains information such as scheduling priority and weigh, and supports SP/WFQ scheduling. CQ scheduling for uplink HQoS is configured by the system, and no additional user configuration is required.

- CoS-based uplink HQoS processing:

Flows are classified based on configured flow classification rules, and are prioritized at eight levels.

The UQ, GQ, WRED parameters, and scheduling policies of packets are determined based on flow behavior rules. Then, packets are passed to corresponding FQs.

- FQ scheduling can be performed according to user configuration to avoid congestion.
- An FQ can be scheduled as a PQ, WFQ, or LPQ. The PQ and WFQ can preempt the bandwidth of the LPQ.

The remaining bandwidth for the GQ is checked. If the remaining bandwidth for the GQ is insufficient, the UQ included in the GQ is not scheduled. Otherwise, the UQ included in the GQ is scheduled. The bandwidth for the GQ is configurable.

The remaining bandwidth for the UQ is checked. If the remaining bandwidth for the UQ is insufficient, the FQ included in the UQ is not scheduled. Otherwise, the FQ is scheduled. The bandwidth for the UQ is configurable.

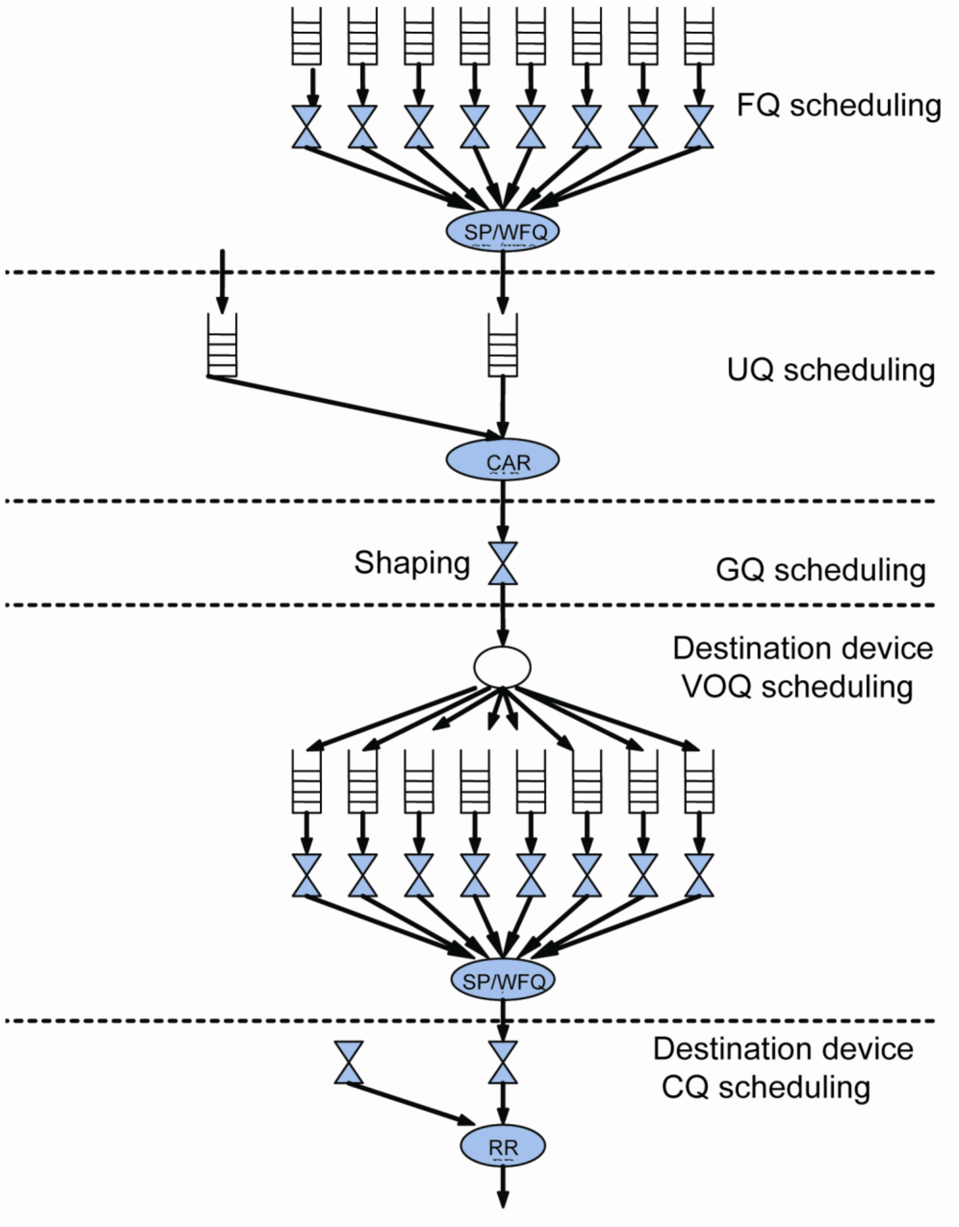
After scheduling, packets in the FQ enter the VoQs on destination devices or destination interfaces.

CQ scheduling is performed in SP mode among four queues. After scheduling, packets are forwarded.

Downlink HQoS Scheduling

Downlink HQoS scheduling is divided into five levels: FQ > UQ > GQ > Interface CQ > Destination interface, as shown in the following figure:

Figure 2 Downlink HQoS Scheduling Process



Level 1 FQ scheduling, level 2 UQ scheduling, and level 3 GQ scheduling are identical with those of uplink HQoS scheduling.

Level 4 scheduling is CQ scheduling. There are eight CQs on each interface, corresponding to eight service priorities. Different from the case of uplink HQoS scheduling, you can configure CQ congestion avoidance parameters and the traffic shaping value. The CQ is scheduled in SP + WFQ mode.

Level 5 scheduling is destination interface scheduling. The system polls interfaces for scheduling. Level 5 scheduling is configured by the system, and no additional user configuration is required.

Protocol Specifications

TR-059: A layered QoS model defined by the DSL Forum

Default Configuration

The following table describes the default HQoS configurations:

Function	Default
WRED queue lower threshold	20
WRED queue upper threshold	40
WRED queue discarding probability	100

Configuring CoS-based HqoS

Configuring a Traffic Classifier Rule

Configuring a traffic classifier rule is to distinguish between user flows to provide differentiated services for different users. Each traffic classifier rule can contain multiple match rules, the relationship among which is determined by the rule type. If the rule type is "and", the packet must match all rules; if the rule type is "or", the packet can match any one of the rules. If no rule type is specified, "or" rule type is adopted by default. Configure this function as follows:

Command	Purpose
Ruijie(config)# **traffic classifier** *classifier-name* [**and** | **or**]	Enters/Creates a traffic classifier rule.
Ruijie(config-traffic-classifier)# **if-match acl** *acl-number* Or: Ruijie(config-traffic-classifier)# **if-match dscp** *dscp-value* Or: Ruijie(config-traffic-classifier)# **if-match ip-precedence** *ip-precedence-value* Or: Ruijie(config-traffic-classifier)# **if-match any**	Sets IPv4 packet match rules. Supports matching packets based on ACL, DSCP, and IP precedence and matching all IPv4 packets (any).
Ruijie(config-traffic-classifier)# **if-match ipv6** *ipv6-acl-number* Or: Ruijie(config-traffic-classifier)# **if-match ipv6 dscp** *dscp-value* Or: Ruijie(config-traffic-classifier)# **if-match ipv6 any**	Sets IPv6 packet match rules. Supports matching packets based on ACL and DSCP, and matching all IPv6 packets (any).
Ruijie(config-traffic-classifier)# **if-match mpls-exp** *mpls-exp-value*	Sets MPLS packet match rules. Supports matching packets based on MPLS EXP.
Ruijie(config-traffic-classifier)# **if-match cos** *cos-value* Or: Ruijie(config-traffic-classifier)# **if-match source-mac** *mac-address* Or: Ruijie(config-traffic-classifier)# **if-match destination-mac** *mac-address*	Sets Ethernet packet match rules. Supports matching packets based on CoS, source MAC address, and destination MAC address.
Ruijie(config-traffic-classifier)#**exit**	Exits the traffic classifier rule configuration.

Configuration example:

# Create a traffic classifier rule and set the IPv4 packet match rule to be based on ACL.

```
Ruijie(config)#traffic classifier tc1
Ruijie(config-traffic-classifier)#if-match acl 100
Ruijie(config-traffic-classifier)#exit
```

Configuring an FQ WRED Template

Configuring a WRED template is to configure congestion avoidance parameters, including upper threshold, lower threshold, and discarding probability, for packets in three colors. When the number of packets in a queue is smaller than the lower threshold, packets are not discarded. When the number of packets in a queue is larger than the lower threshold and smaller than the upper threshold, packets are discarded at certain probability. When the number of packets in a queue is larger than the upper threshold, packets are discarded. You can configure different WRED templates and apply them to different FQs.

Configure this function as follows:

Command	Purpose
Ruijie(config)# **wred** *wred-template-name*	Creates/Enters a WRED template.

Ruijie(config-wred)#**color green low-limit** *low-limit-threshold* **high-limit** *high-limit-threshold* **discard-percent** *discard-percent-value* Ruijie(config-wred)#**color yellow low-limit** *low-limit-threshold* **high-limit** *high-limit-threshold* **discard-percent** *discard-percent-value* Ruijie(config-wred)#**color red low-limit** *low-limit-threshold* **high-limit** *high-limit-threshold* **discard-percent** *discard-percent-value*	Sets the upper threshold, lower threshold, and probability for queues in three colors.
Ruijie(config- wred)#**exit**	Exits the WRED template configuration.

Configuration example:

# Create a WRED template and set congestion avoidance parameters.

```
Ruijie(config)#wred wt1
Ruijie(config-wred)#color green low-limit 40 high-limit 60 discard-percent 10
Ruijie(config-wred)#color yellow low-limit 30 high-limit 50 discard-percent 10
Ruijie(config-wred)#color red low-limit 20 high-limit 40 discard-percent 10
Ruijie(config-wred)#exit
```

Configuring an FQ Template

Configuring an FQ template is to configure the scheduling mode (PQ, WFQ, and LPQ), traffic shaping value, and WRED parameters of eight kinds of PQs. PQ scheduling is performed on queues with the priority as ef, cs6, or cs7. WFQ scheduling is performed on queues with the priority as be, af1, af2, af3, or af4. Traffic shaping is not performed by default and the default discarding policy is tail discarding. You can configure multiple FQ templates and apply them to different FQs.

Configure this function as follows:

Command	**Purpose**
Ruijie(config)# **flow-queue** *flow-queue-template-name*	Enters/Creates an FQ template.
Ruijie(config-flow-queue)# **queue** *cos-value* {**pq** | **wfq weight** *weight-value* | **lpq**} [**shaping** *shaping-value*] [**wred** *wred-name*] [**depth** *depth-value*]	Set FQ scheduling parameters.
Ruijie(config- flow-queue)#**exit**	Exits the FQ template configuration.

Configuration example:

# Create an FQ template and set FQ scheduling parameters.

```
Ruijie(config)#flow-queue fqt1
Ruijie(config-flow-queue)# queue be lpq
Ruijie(config-flow-queue)# queue af1 wfq weight 10 shaping 100000 wred wt1
Ruijie(config-flow-queue)# queue cs7 pq shaping wred wt1
Ruijie(config-flow-queue)#exit
```

Configuring an FQ Mapping Template

Configuring an FQ mapping template is to configure the mapping from eight kinds of PQs to CQs.

Configure this function as follows:

Command	**Purpose**
Ruijie(config)# **flow-mapping** *flow-mapping name*	Enters/Creates an FQ mapping template.
Ruijie(config-flow-mapping)# **map flow-queue** *cos-value* **to port-queue** *cos-value*	Sets the mapping from FQ to CQ.
Ruijie(config- flow-mapping)#**exit**	Exits the FQ mapping template configuration.

Configuration example:

# Create a FQ mapping template and set the mapping from FQ to CQ.

```
Ruijie(config)#flow-mapping fmt1
Ruijie(config-flow-mapping)# map flow-queue af1 to port-queue ef
Ruijie(config-flow-mapping)#exit
```

Configuring a UQ

Configuring a UQ consists of configuring the CIR, configuring the FQ template, and associating a GQ.

Configure this function as follows:

Command	Purpose
Ruijie(config)# **user-queue** *user-queue-name* **inbound | outbound**	Enters/Creates a UQ.
Ruijie(config-user-queue)# **cir** *vir-value* **pir** *pir-value*	Sets UQ traffic shaping parameters. By default, the CIR of the UQ is 0.
Ruijie(config-user-queue)# **flow-queue** *flow-queue-template-name*	Sets UQ FQ scheduling parameters.
Ruijie(config-user-queue)# **user-group-queue** *user-group-queue-name*	Associates the UQ with a GQ.
Ruijie(config-user-queue)# **flow-mapping** *flow-rmap-name*	Sets an FQ mapping template.

Configuration example:

# Create a UQ and set scheduling parameters.

```
Ruijie(config)#user-queue uq1 inbound
Ruijie(confg-user-queue)#cir 100000 pir 100000
Ruijie(config-user-queue)#flow-queue fqt1
Ruijie(config-user-queue)#user-group-queue ugq1
Ruijie(config-user-queue)#flow-mapping fmt1
```

Configuring a GQ

A GQ is a bundle of multiple UQs for centralized traffic shaping.

Configure this function as follows:

Command	Purpose
Ruijie(config)# **user-group-queue** *user-group-queue-name* [**inbound | outbound**]	Enters/Creates a GQ.
Ruijie(config-user-group-queue)# **shaping** *shaping-value*	Sets the traffic shaping value of the GQ.

Configuration example:

# Create a GQ and set the traffic shaping value.

```
Ruijie(config)#user-group-queue ugq1 inbound
Ruijie(config-user-group-queue)#shaping 100000
```

Configuring a Traffic Behavior Rule

The traffic behavior rule determines traffic scheduling parameters after classification. Configure this function as follows:

Command	Purpose
Ruijie(config)# **traffic behavior** *traffic-behavior-name*	Enters/Creates a traffic behavior rule.
Ruijie(config-traffic-behavior)#**user-queue** *user-queue-name* [**inbound | outbound**]	Sets the UQ.
Ruijie(config-traffic-behavior)#**service-class** *service-class-value* **color** *color-value*	Sets the color of packets with different priorities.
Ruijie(config-traffic-behavior)#**remark dscp** *dscp-value* **Or:** Ruijie(config-traffic-behavior)#**remark ip-precedence** *ip-precedence-value* **Or:** Ruijie(config-traffic-behavior)#**remark mpls-exp** *mpls-exp-value*	Sets the remark value of IPv4 packets.
Ruijie(config-traffic-behavior)#**remark ipv6 dscp** *dscp-value*	Sets the remark value of IPv6 packets.
Ruijie(config-traffic-behavior)#**remark mpls-exp** *mpls-exp-value*	Sets the remark value of MPLS packets.

Ruijie(config-traffic-behavior)#**remark cos** *cos-value*	Sets the 802.1Q remark value of Ethernet packet.
Ruijie(config-traffic-behavior)#**sub-traffic-policy** *traffic-policy-name*	Sets a sub-traffic policy.
Ruijie(config-traffic-behavior)#**rtp-shaping delay** *500* **clock-rate** *9000*	Set TRP shaping behavior.

Configuration example:

# Create a traffic behavior rule.

```
Ruijie(config)#traffic behavior tb1
Ruijie(config-traffic-behavior)#user-queue uq1 inbound
Ruijie(config-traffic-behavior)#service-class ef color green
Ruijie(config-traffic-behavior)#remark dscp 40
```

Configuring a Traffic Policy Rule

The traffic policy rule associates traffic classes and traffic behaviors, thus scheduling classified traffic according to user configurations. Configure this function as follows:

Command	Purpose
Ruijie(config)# **traffic policy** *traffic-policy-name*	Enters/Creates a traffic policy.
Ruijie(config-traffic-policy)# **classifier** *classifier-name* **behavior** *behavior-name* **precedence** *precedence-value*	Specifies a traffic behavior rule for a traffic class and sets the precedence. The smaller the value of the precedence, the higher the precedence is.

Configuration example:

# Create a traffic policy.

```
Ruijie(config)#traffic policy tp1
Ruijie(config-traffic-policy)#classifier tc1 behavior tb1 precedence 1
```

Applying a Traffic Policy to an Interface

Configure this function as follows:

Command	Purpose
Ruijie(config)# **interface** *interface-name*	Enters the interface configuration mode.
Ruijie(config-if)# **traffic-policy** *traffic-policy-name* **[inbound | outbound] [link-layer | all-layer]**	To apply a traffic policy, the layer parameter needs to be specified. Only Layer 3 policies and MPLS take effect by default. The link-layer parameter specified takes effect to only 802.1P Layer 2 packets. The all-layer parameter specified takes effect to both Layer 2 and Layer 3 packets. The link-layer and all-layer parameters can be specified for main interfaces only. The parameters take effect to the main interface and its associated sub-interfaces after specified. They cannot be specified for sub-interfaces.

Configuration example:

# Apply a traffic policy to an interface.

```
Ruijie(config)#int gigabitethernet 0/1
Ruijie(config-if-Gigabitethernet 0/1)#traffic-policy tp1 inbound
```

Configuring a CQ Template

Configuring an CQ template is to configure the scheduling mode (PQ, WFQ, and LPQ), traffic shaping value, and WRED parameters of eight kinds of PQs. PQ scheduling is performed on queues with the priority as ef, cs6, or cs7. WFQ scheduling is performed on queues with the priority as be, af1, af2, af3, or af4. Traffic shaping is not performed by default and the default discarding policy is tail discarding. You can configure multiple CQ templates and apply them to different interfaces. CQ scheduling takes effect on outbound traffic only.

Configure this function as follows:

Command	Purpose

Ruijie(config)# **port-queue** *port-queue-template-name*	Enters/Creates a CQ template.
Ruijie(config-port-queue)# **queue** *cos-value* {**pq** | **wfq weight** *weight-value* | **lpq**} [**shaping** *shaping-value*] [**wred** *wred-name*] [**depth** *depth-value*]	Sets CQ scheduling parameters.
Ruijie(config-port-queue-template)#**exit**	Exits the CQ template configuration.

Configuration example:

# Create a CQ template and set CQ scheduling parameters.

```
Ruijie(config)#port-queue pqt1
Ruijie(config-port-queue)# queue be lpq outbound
Ruijie(config-port-queue)# queue af1 wfq weight 10 shaping 100000 wred pwt1
Ruijie(config-port-queue)# queue cs7 pq shaping wred pwt1
Ruijie(config-port-queue)#exit
```

Applying the CQ to an Interface

The CQ applied to an interface takes effect on outbound traffic only.

Configure this function as follows:

Command	Purpose
Ruijie(config)# **interface** *interface-name*	Enters the interface configuration mode.
Ruijie(config-if)# **port-queue** *port-queue-template-name* [**shaping** *shaping-value*]	Applies the CQ to an interface.

Configuration example:

# Apply the CQ to an interface.

```
Ruijie(config)#int gigabitethernet 0/1
Ruijie(config-if-Gigabitethernet 0/1)#port-queue pqt1
```

Applying Resource Reservation Queue to Interface

The resource reservation queue applied to the interface is scheduled for outbound traffic only.

Run the following commands to configure this function:

Command	Purpose
Ruijie(config)# **interface** *interface-name*	Enters the interface configuration mode.
Ruijie(config-if)# **port-res-queue** *shaping-value* [**depth** *depth-value*]	Applies the resource reservation queue to the interface.

Configuration example:

#Apply the class queue to the interface.

```
Ruijie(config)#int gigabitethernet 0/1
Ruijie(config-if-Gigabitethernet 0/1)# port-res-queue 5000 depth 300
```

Note

The resource reservation queue takes effect only after the **port-queue** command is run on the interface.
The shaping value for the resource reservation queue is allocated form the shaping value configured in the **port-queue** command on the interface. The shaping value is automatically allocated only when there is a flow passing the resource reservation queue. When the flow stops for 3 minutes, the shaping value allocated to the resource reservation queue is invalidated.

Configuring HQoS Policy for AP Scenario

The bandwidth committed by the operator is configured for an AP member. The HQoS distributes load according to the physical link bandwidth corresponding to an AP member when scheduling traffic between AP members for routing. The physical bandwidths of a gigabit interface and a 10-gigabit interface are respectively 1000 Mbps and 10,000 Mbps. However, though the bandwidth allocated by the operator may be less than the committed bandwidth, the configuration is still performed according to the bandwidth committed by the operator. In this way, the HQoS schedules traffic for routing based on the actual available bandwidth of the egress, so that traffic on the operator links is controllable.

Run the following commands to configure this function:

Command	Purpose
Ruijie(config)# **interface** *interface-name*	Enters the interface configuration mode.
Ruijie(config-if)# **port-bandwidth** *bandwidth-value1*	Configures the maximum available bandwidth committed by the operator for the current AP member of traffic management.

Configuration example:

#Configure 100 Mbps available bandwidth on the link corresponding to Interface Gi0/0.

```
Ruijie(config)#int GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#port-bandwidth 100000
```

Note This command is available only on AP members.

An AP is configured to schedule traffic for routing. The AP is a logical port, and does not forward traffic. All traffic is forwarded by the physical member port. When the HQoS policy is applied to the AP, the HQoS policy schedules traffic between the AP members by the source or destination IP address for routing.

Run the following commands to configure this function:

Command	Purpose
Ruijie(config)# **interface AggregatePort-L3** *interface-name*	Enters the layer 3 AP configuration mode.
Ruijie(config-if-AggregatePort-L3 1)# **traffic-balance** { dst-ip | src-ip}	Schedules traffic between AP members by the source or destination IP address.

Configuration example:

#Perform traffic managment on the layer 3 AP by the source IP address.

```
Ruijie(config)#int AggregatePort-L3 1
Ruijie(config-if-AggregatePort-L3 1)#traffic-balance src-ip
```

Note This command is available only on the AP.

Configuring a Static VoQ Credit Point

By default, the VoQ credit point of a device is calculated dynamically based on the processing capability of the device, FAP bandwidth, and flow control. This configuration is to specify a static credit point for the destination device, so that VoQ requests are not updated dynamically during VoQ scheduling.

Configure this function as follows:

Command	Purpose
Ruijie(config)# **credit** {*device-id* *credit-value*}	Specifies the VoQ credit point for the destination device.

Configuration example:

# Set the VoQ credit point of the destination device with the ID as 4 to 10,000.

```
Ruijie(config)#credit 4 10000
```

Configuring System VoQ Scheduling

By default, system VoQ scheduling is disabled.

Configure this function as follows:

Command	Purpose
Ruijie(config)# **voq enable**	Enables system VoQ scheduling.

Configuration example:

# Enable system VoQ scheduling.

```
Ruijie(config)#voq enable
```

Clearing Queue Statistics

Command	Function
clear port-queue statistics interface *interface-name*	Clears CQ statistics.
clear user-queue statistics ***user-queue-name*** **{inbound | outbound}** devid *devid*	Clears UQ statistics.
clear user-group-queue statistics *user-group-queue-name* **{inbound | outbound} devid** *devid*	Clears GQ statistics.
clear voq statistics *class-queue-priority* **devid** *devid*	Clears VoQ statistics.

Showing Configurations

Command	Function
show wred [*wred-name*]	Displays WRED configuration information on the system.
Show flow-queue [*flow-queue-name*]	Displays FQ configuration information
show user-queue statistics *user-group-queue-name* **{inbound | outbound} [devid** ***devid*****]**	Displays UQ statistics.
show user-group-queue statistics *user-group-queue-name* **{inbound | outbound} [devid** *devid*]	Displays GQ statistics on the system.
show port-queue [*port-queue-name*]	Displays port-queue configuration information on the system.
show port-queue statistics [interface *interface*]	Displays port-queue statistics on the system.
show credit status [devid *devid*]	Displays credit system information.

Configuration example:

# Display the port-queue information on a system interface.

```
Ruijie# show port-queue interface gigabitethernet 1/1/1
[be]
 Pass:     42900556 packets,   2745666258 bytes

Typical HQoS Configuration Examples

Configuration Example 1

Networking Requirement

- Device requirement

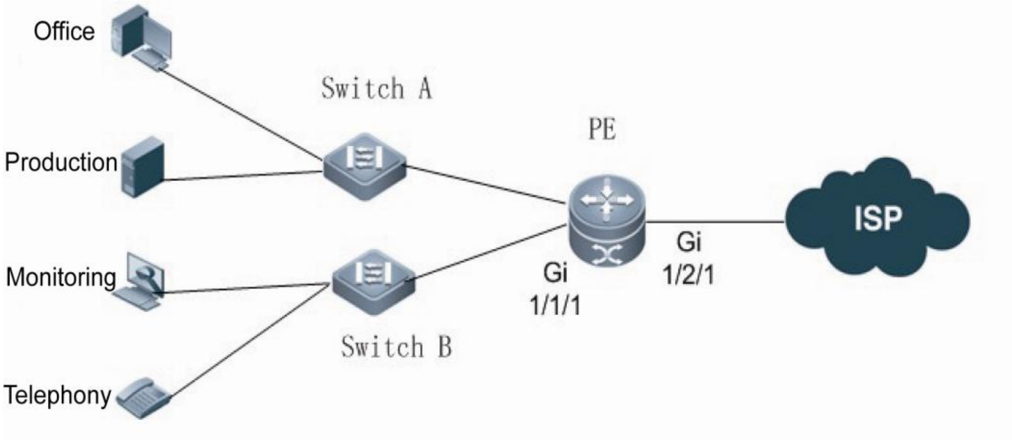
Two Ethernet switches and one router

- Configuration requirement

Each switch is connected to one user to provide two services. For user A, the CIR is 60 Mbit/s and peak bandwidth is 80 Mbit/s. For user B, the CIR is 30 Mbit/s and peak bandwidth is 40 Mbit/s. Both users are bound to a user group with the CIR as 90 Mbit/s and peak bandwidth as120 Mbit/s. Four services are identified by four IP addresses, that is, 10.1.10.1, 10.1.10.2, 10.1.20.1, and 10.1.20.2.

Networking Topology

Figure 3 HQoS Access Networking



Configuration Points

Configure traffic classification rules to distinguish between services.

Configure traffic behavior rules to perform traffic shaping on UQ and GQ.

Configuration Steps

Configure traffic classification rules.

```
# Configure traffic behavior rule tc1.
Ruijie(config)#access-list 100 permit ip 10.1.10.0 0.0.0.255  any
Ruijie(config)#traffic classifier tc1
Ruijie(config-traffic-classifier)#if-match acl 100
Ruijie(config-traffic-classifier)#exit
# Configure traffic behavior rule tc2.
Ruijie(config)#access-list 110 permit ip 10.1.20.0 0.0.0.255 any
Ruijie(config)#traffic classifier tc2
Ruijie(config-traffic-classifier)#if-match acl 110
Ruijie(config-traffic-classifier)#exit
```

Configure an FQ WRED template.

```
Ruijie(config)#wred-template wt1
Ruijie(config-wred-template)#color green low-limit 40 high-limit 60 discard-percent 10
Ruijie(config-wred-template)#color yellow low-limit 30 high-limit 50 discard-percent 10
Ruijie(config-wred-template)#color red low-limit 20 high-limit 40 discard-percent 10
Ruijie(config-wred-template)#exit
```

Configure FQ scheduling parameters.

```
Ruijie(config)#flow-queue-template fqt1
Ruijie(config-flow-queue-template)# queue be lpq
Ruijie(config-flow-queue-template)# queue af1 wfq weight 10 shaping 100 flow-wred wt1
Ruijie(config-flow-queue-template)# queue cs7 pq shaping shaping-percentage 20 flow-wred wt1
Ruijie(config-flow-queue-template)#exit
```

Configure an FQ mapping template.

```
Ruijie(config)#flow-mapping-template fmt1
Ruijie(config-flow-mapping-template)# map flow-queue af1 to port-queue ef
```

Configure a GQ.

```
Ruijie(config)#user-group-queue ugq1 inbound
Ruijie(config-user-group-queue)#shaping 120000
Ruijie(config-user-group-queue)#exit
```

Configure a UQ.

```
# Configure UQ uq1.
Ruijie(config)#user-queue uq1 inbound
Ruijie(confg-user-queue)#cir 60000 pir 80000
Ruijie(config-user-queue)#flow-queue-template fqt1
Ruijie(config-user-queue)#flow-mapping-template fmt1
Ruijie(config-user-queue)#user-group-queue ugq1
Ruijie(config-user-queue)#exit
# Configure UQ uq2.
Ruijie(config)#user-queue uq2 inbound
Ruijie(config-user-queue)#cir 30000 pir 40000
Ruijie(config-user-queue)#flow-queue-template fqt1
Ruijie(config-user-queue)#user-group-queue ugq1
Ruijie(config-user-queue)#exit
```

Configure traffic behavior rules.

```
# Configure traffic behavior rule tb1.
Ruijie(config)#traffic behavior tb1
Ruijie(config-traffic-behavior)#user-queue uq1 inbound
Ruijie(config-traffic-behavior)#exit
# Configure traffic behavior rule tb2.
Ruijie(config)#traffic behavior tb2
Ruijie(config-traffic-behavior)#user-queue uq2 inbound
Ruijie(config-traffic-behavior)#exit
```

Configure a traffic policy.

```
Ruijie(config)#traffic policy tp1
Ruijie(config-traffic-policy)#classifier tc1 behavior tb1
Ruijie(config-traffic-policy)#classifier tc2 behavior tb2
Ruijie(config-traffic-policy)#exit
```

Apply the policy to an interface.

```
Ruijie(config)#int gigabitethernet 1/1/1
Ruijie(config-if-Gigabitethernet1/1/1)#traffic-policy tp1 inbound
```

Configure a CQ WRED template.

```
Ruijie(config)# port-wred-template pwt1
Ruijie(config-port-wred-template)#color green low-limit 40 high-limit 60 discard-percent 10
Ruijie(config-port-wred-template)#color yellow low-limit 30 high-limit 50 discard-percent 10
Ruijie(config-port-wred-template)#color red low-limit 20 high-limit 40 discard-percent 10
Ruijie(config-port-wred-template)#exit
```

Configure a CQ.

```
Ruijie(config)#port-queue-template pqt1
Ruijie(config-port-queue-template)# queue be lpq outbound
Ruijie(config-port-queue-template)# queue af1 wfq weight 10 shaping 100000000 port-wred pwt1
Ruijie(config-port-queue-template)# queue cs7 pq shaping shaping-percentage 20 port-wred pwt1
Ruijie(config-port-queue-template)#exit
```

Apply the CQ to an interface.

```
Ruijie(config)#int gigabitethernet 1/2/1
Ruijie(config-if-Gigabitethernet 1/2/1)#port-queue pqt1 outbound
```

Verification

Display traffic policy statistics on an interface.

```
Ruijie#show user-queue statistics uq1 inbound devid 4
Ruijie#show user-queue statistics uq2 inbound devid 4
```

Display CQ statistics on an interface.

```
Ruijie# show port-queue interface gigabitethernet 1/2/1
```

Configuration Example 2

Networking Requirement

- Device requirement

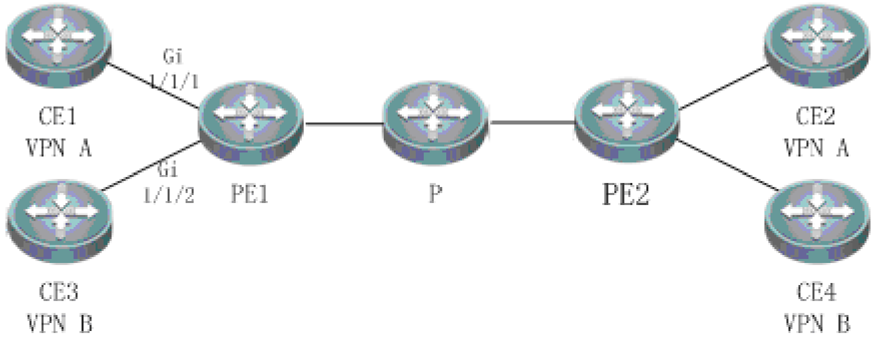
Seven routers

- Configuration requirement

Three routers constitute an MPLS backbone network. Two routers provide user access for VPN A, and two routers provide users access for VPN B. On each of the networks connected to CE1 and CE3, there is a multicast source with the multicast address as 232.0.0.1. For CE1, the CIR is 60 Mbit/s and peak bandwidth is 80 Mbit/s. For CE2, the CIR is 30 Mbit/s and peak bandwidth is 40 Mbit/s.

Networking Topology

Figure 4 HQoS Multicast Networking



Configuration Points

Configure traffic classification rules to distinguish between multicast addresses.

Configure traffic behavior rules to restrict the bandwidth of uplink multicast UQ.

Configuration Steps

Configure traffic classification rules.

```
# Configure traffic classification rule tc1.
Ruijie(config)#access-list 100 permit ip any host 232.0.0.1
Ruijie(config)#traffic classifier tc1
Ruijie(config-traffic-classifier)#if-match acl 100
Ruijie(config-traffic-classifier)#exit
# Configure traffic classification rule tc2.
Ruijie(config)#traffic classifier tc2
Ruijie(config-traffic-classifier)#if-match acl 100
Ruijie(config-traffic-classifier)#exit
```

Configure a UQ.

```
# Configure UQ uq1.
Ruijie(config)#user-queue uq1 inbound
Ruijie(confg-user-queue)#cir 60000 pir 80000
Ruijie(config-user-queue)#exit
# Configure UQ uq2.
```

```
Ruijie(config)#user-queue uq2 inbound
Ruijie(config-user-queue)#cir 30000 pir 40000
Ruijie(config-user-queue)#exit
```

Configure traffic behavior rules.

```
# Configure traffic behavior rule tb1.
Ruijie(config)#traffic behavior tb1
Ruijie(config-traffic-behavior)#user-queue uq1 inbound
Ruijie(config-traffic-behavior)#exit
# Configure traffic behavior rule tb2.
Ruijie(config)#traffic behavior tb2
Ruijie(config-traffic-behavior)#user-queue uq2 inbound
Ruijie(config-traffic-behavior)#exit
```

Configure a traffic policy.

```
Ruijie(config)#traffic policy tp1
Ruijie(config-traffic-policy)#classifier tc1 behavior tb1
Ruijie(config-traffic-policy)#exit

Ruijie(config)#traffic policy tp2
Ruijie(config-traffic-policy)#classifier tc2 behavior tb2
Ruijie(config-traffic-policy)#exit
```

Apply the policy to an interface.

```
Ruijie(config)#int gigabitethernet 1/1/1
Ruijie(config-if-Gigabitethernet1/1/1)#traffic-policy tp1 inbound

Ruijie(config)#int gigabitethernet 1/1/2
Ruijie(config-if-Gigabitethernet1/1/2)#traffic-policy tp2 inbound
```

Verification

Display traffic policy statistics on an interface.

```
Ruijie# show traffic policy tp1

Ruijie# show traffic policy t
```

VDA Configuration Example

Networking Requirements

- Device requirement

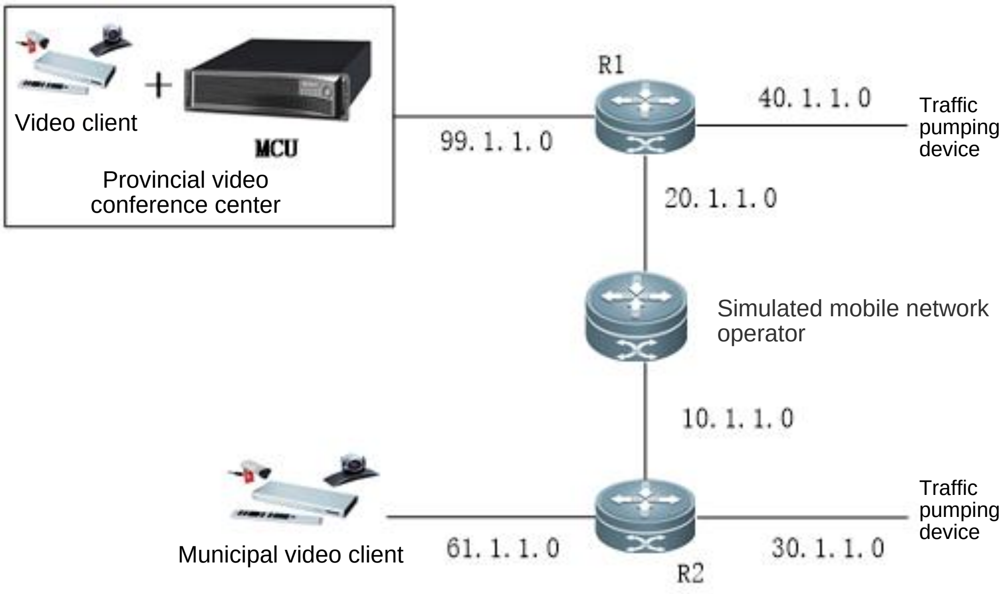
Three routers are required

- Configuration requirement

The provincial video conference center and the municipal video conference center are simulated. These two centers are connected via a 20 mbps dedicated line, to provide the video conference service and other production and office services. It is required to reserve bandwidth for a video conference and isolate the video conference service from other services. After the video conference ends, the reserved bandwidth is automatically released. Configurations in the two centers are the same, only the municipal egress device is described.

Network Topology

Figure 5 VDA Application



Configuration Key Points

1. Configure flow identification for the resource reservation queue.
2. Configure the resource reservation queue on an interface.

Configuration Steps

1. Configure the traffic classifier.

#Configure the traffic classifier for matching based on the interface and any ACL.

```
ip access-list extended 101
 10 permit ip any any
traffic classifier tc or
 if-match acl 101
```

2. Configure the traffic behavior.

#Configure the traffic behavior.

```
traffic behavior tb
 port-res-queue
```

3. Configure the traffic policy.

#Configure the traffic policy and the traffic behavior.

```
traffic policy tp
 classifier tc behavior tb precedence 1
```

4. Apply the traffic policy to an interface.

#Interface 0/0/2 is directly connected to the municipal conference center. Apply the traffic policy to this interface.

```
interface GigabitEthernet 0/0/2
 ip address 61.1.1.1 255.255.255.0
 traffic-policy tp inbound
```

5. Configure the resource reservation queue on the outbound interface.

#Connect Interface 0/0/1 (egress of the municipal network) to the operator device. Configure the resource reservation queue on this interface.

```
interface GigabitEthernet 0/0/1
 ip address 10.1.1.2 255.255.255.0
 port-queue pq shaping 20000
 port-res-queue 12000
```

Displaying

Display the user queue statistics on the device.

```
Ruijie# show port-queue statistics interface gi 0/0/1
```

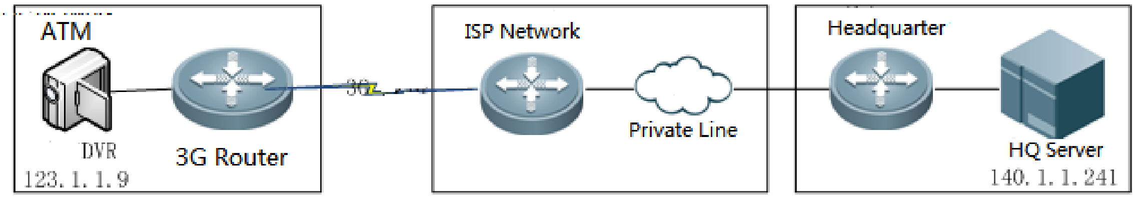
Examples for Configuring RTP Traffic Shaping

Networking Requirements

1. Off-bank ATMs adopt Ruijie routers as access routers that are connected to servers in headquarters via 3G circuit.
2. Monitoring videos are transmitted between routers of branches and the servers of the headquarters by application of TCP and converged by RSR77 in the headquarters.
3. Data flows are not encrypted or encapsulated by other tunnels before reaching the routers adopting optimizing strategies.

Network Topology

Figure 6 RTP Shaping Application Network Topology



Configuration Tips

1. Turn on WAN-TA function.
2. Identify characteristics of data flows to realize RTP business.
3. Configure RTP shaping behavior.

Configuration Steps

1. Transmitted optimization should be turned on when RSR77 of the headquarters are configured.

Configure video transmitted optimization to transit monitoring videos between routers and servers. ACL101configues RTP data flows from the branches to the headquarters. With video data flows of off-bank ATMs reaching the servers in the headquarters, the transmitted optimization of convergence routers is enabled. And wan-ta policy is applied on the in-coming interface gigaethernet2/1/1.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#ip access-list extended 101
Ruijie(config-ext-nacl)# 10 permit tcp any eq 554 any
Ruijie(config)#wan-ta enable
Ruijie(config)# wan-ta policy video
Ruijie(config-if-GigabitEthernet 2/1/1)#wan-ta-policy video list 101
```

2. RTP Traffic Shaping to RSR77 of the Headquarters

Configuring RTP Traffic Shaping to RSR77 of the Headquarters

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#
Ruijie(config)#traffic classifier tc1 or
Ruijie(config-traffic-classifier)# if-match acl 101
Ruijie(config-traffic-classifier)#
Ruijie(config-traffic-classifier)#traffic behavior tb1
Ruijie(config-traffic-behavior)# rtp-shaping delay 500 clock-rate 89950
Ruijie(config)#traffic policy tp1
Ruijie(config-traffic-policy)# classifier tc1 behavior tb1 precedence 1
Ruijie(config-if-GigabitEthernet 2/1/1)#traffic-policy tp1 inbound
```

Verification

1. Displaying WAN-TA Policy Configuration

```
Ruijie#show wan-ta policy video
wan-ta policy: video
    Congestion Control : low-bandwidth-delay
    SACK Support: TRUE
    Initial Congest Window: 10 MSS
    Maxitum Segment Size: 1460
```

```
   Keepalvie Interval(retry): 120(9)

apply on interfaces:
interface name                      list
GigabitEthernet 2/1/1                 101
```

2. Displaying RTP-shaping Statistics

```
Ruijie#show rtp-shaping statistics
hqos_rtp_dump[185566fc][1]
rtp-que[184bdec0]:
       delay[1000],clock_rate[89950]
       flow[10.255.255.91,10.255.255.213,6,554,49419]
       que-pkts[0],pass_pkts[6050],drop_pkts[0],disorder_pkts[0],none_video_pkts[5692]
       last_rtp_time[3933490296],last_sys_time[2267149741]
```

Configuring IP Multicast

Configuring IP Multicast Routing

Overview

This chapter describes how to configure IPv4 multicast routing protocols. To obtain complete descriptions of multicast routing commands, see the "Multicast Routing Commands" section.

The traditional IP transmission only allows one host to transmit packets to a single host (unicast communication) or all hosts (broadcast communication). Multicast, however, allows one host to send the packets to some hosts (also known as group members).

The destination addresses of packets sent to the group member are Class-D network addresses (224.0.0.0–239.255.255.255). Multicast packets are UDP packets with best effort service. It does not provide reliable transmission and error control as TCP.

The multicast application consists of the sender and receiver. The sender can send multicast packets without needing to join a group. In contrast, the receiver can receive the multicast packets from the group only after joining the group.

Group members are dynamic. A host can join or leave a group at any time. Furthermore, there is no limit on the position or number of group members. A host can join more than one group simultaneously if necessary. Consequently, the active status and the number of members of a group vary from time to time.

Devices run a multicast routing protocol such as the Protocol-Independent Multicasting-Dense Mode (PIM-DM) and the Protocol-Independent Multicasting-Sparse Mode (PIM-SM) to maintain their routing tables to forward multicast messages, and use the Internet Group Management Protocol (IGMP) to learn the status of the members within a group on their directly attached subnets. A host can join or leave an IGMP group by sending IGMP Report messages.

IP multicast applies to one-to-many multimedia applications.

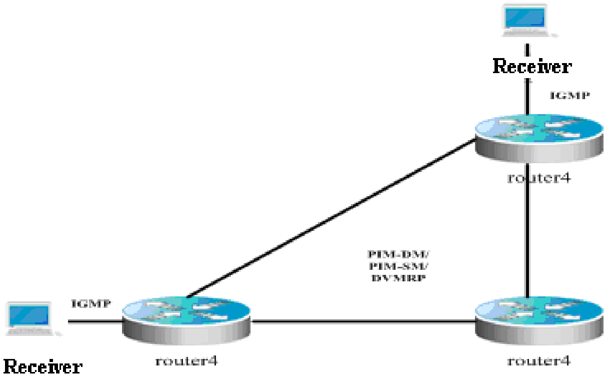
Implementation of IP Multicast Routing

Multicast routing protocols include:

- IGMP: Runs between the routers and the hosts to trace the relationship of group members.
- PIM-DM: A multicast routing protocol in dense mode, which runs between multicast devices to establish the multicast routing table for forwarding.
- PIM-SM: A multicast routing protocol in sparse mode, which runs between multicast devices to establish the multicast routing table for forwarding.
- DVMRP: Distance Vector Multicast Routing Protocol, which runs between multicast devices to establish the multicast routing table for forwarding.

Figure 1 shows IP multicast routing protocols used within the IP multicast environment.

Figure 1 IP Multicast Routing Protocols within the IP Multicast Environment



IGMP

To enable IP multicast, hosts and routers must support the IGMP protocol. This protocol is used by hosts to report their group memberships to multicast routers on the directly-connected network, allowing the multicast routers to determine how to forward multicast traffic.

By using the information obtained from IGMP, multicast routers create an interface-based multicast group member list. The list is activated only when at least one host on an interface is a member of the group. IGMPv1, IGMPv2 and IGMPv3 are currently supported.

IGMPv1

There are only two types of IGMP messages defined in IGMPv1:

- Membership query
- Membership report

A host sends a membership report to indicate that it is interest in joining a group, and the router sends membership queries periodically to ensure that the group has at least one host. When there is no hosts in that group, the device will delete it.

IGMPv2

In IGMPv2, there are only four types of IGMP messages:

- Membership query
- Version 1 membership report
- Version 2 membership report
- Leave group

IGMPv2 is basically the same as IGMPv1, except that IGMPv2 creates a Leave group message for hosts. For IGMPv2, hosts report leave messages to routers which then send queries to check whether there is a host in the multicast group. This makes joining and leaving a group more efficient.

In the multicast network running IGMP, a multicast router is dedicated for sending IGMP query messages. This router is called a querier which is selected through an election mechanism. At first, all routers are queriers. If a router receives a query message from another router with a lower IP address, it becomes a non-querier. Consequently, there is only one querier which has the lowest IP address among all multicast routers on the network.

If a querier is invalid, new querier will be elected. Non-queriers keep a timer for Other Querier Present Interval. Every time when a router receives a membership query packet, it resets the timer. If the timer expires, the router starts to send query messages and selects new querier again.

Queriers must periodically send membership queries to ensure that other routers on the network know that the querier still works. For this purpose, the querier maintains one query interval timer. When it sends membership query messages, this timer will be reset. When the interval timer times out, the querier sends another membership query.

When a new router appers, it sends a series of general query messages to solicit membership information. The number of general query packets depends on the Startup Query Count configured on the router. The initial general query interval is defined by the Startup Query Interval.

When a querier receives a leave group message from a host, it must send a group-specific membership query to see whether the host is the last one to leave the group. Before the querier stops forwarding packets to the group, it sends a series of such packets, the number of which is equal to the Last Member Query Count. The querier sends multiple group-specific membership queries to ensure that there is no member in the group. Such a query is sent every other the Last Member Query Interval seconds. When no response is received, the querier stops forwarding multicast packets to the group on the specified interface.

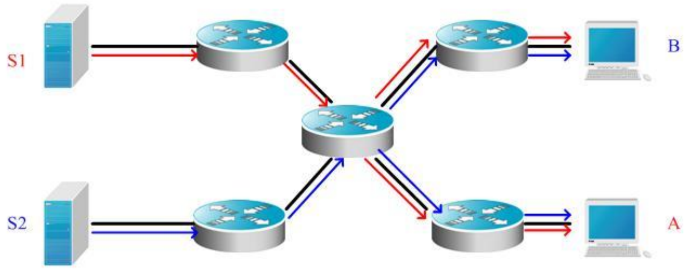
IGMPv3

Both IGMPv1 and IGMPv2 have the following defects:

- Lack of efficient measures to control multicast sources
- Difficult to establish multicast paths due to ignorance of multicast source locations.
- Difficult to find a unique multicast address. It is possible that multicast groups are using the same multicast address.

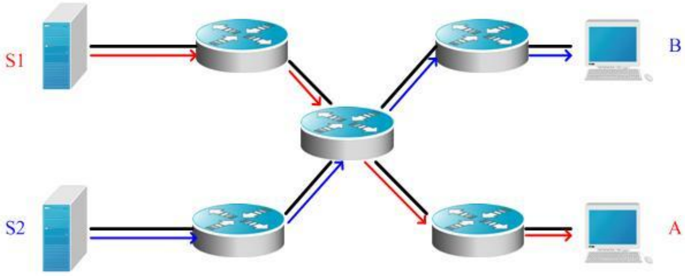
On the basis of IGMPv1 and IGMPv2, IGMPv3 provides an additional source filtering multicast function. In IGMPv1 or IGMPv2, hosts determines whether to join a group by group address and, once it joins the group, it receives multicast traffic forwarded from any source to that group address. In IGMPv3, hosts are enabled to report the multicast group they desire to join in and the multicast source from which they expect to receive traffic. A host specifies sources from which they want to receive multicast traffic through an INCLUDE list or an EXCLUDE list. Besides, IGMPv3 saves bandwidth by preventing unnecessary, illegal multicast data flows from occupying network bandwidth. It is particularly useful in the case where multiple multicast sources share one multicast address. IGMPv1 and IGMPv2 can also implement "source address filtering" in some sense, which, however, is performed on hosts receiving multicast traffic. As shown in the following diagram, two multicast sources (S1 and S2) send out traffic directed to the same multicast group address (G). This multicast traffic from S1 and S2 will be sent to all hosts receiving traffic from G. If host A only wants to receive multicast traffic from S1, it has to filter out traffic from S2 by running approriate client software.

Figure 2 Multicast traffic forwarded without source filtering



If multicast routers on the network support IGMPv3, host A wants to receive traffic from S1 only, it sends out an IGMPv3 packet in the form of “join G include S1”. host B wants to receive traffic from S2 only, it sends out an IGMPv3 packet in the form of “ join G include S2”. In this way, the traffic is forwarded as shown in Figure 3. This saves bandwidth.

Figure 3 Multicast traffic forwarded with source filtering



Based on IGMPv2, IGMPv3 adds the following two kinds of messages:

- Membership query
- Version 3 membership report

There are three types of membership query:

- General Query: used to learn information of all multicast members on an interface.
- Group-Specific Query: used to learn information of members of a specific group on an interface.
- Group-and-Source-Specific Query: a new type specified in IGMPv3 used to learn whether there is a member on an interface wants to receive group-specific multicast traffic from sources in the specified source list.

Membership report in IGMPv3 is different from that defined in IGMPv2. The IGMPv3 membership reports are always sent with an destination address of 224.0.0.22. Besides, an IGMPv3 membership report can contain one or more group records, containing a group address and an list of source addresses. Group records have the following types.

- IS_IN: indicates that the filter mode between a multicast group and the multicast source list is INCLUDE, that is, only multicast data sent from the specified multicast source list to the multicast group is received. If the specified multicast source list is empty, it indicates leaving the multicast group, which is equivalent to the leave packet in IGMPv2.
- IS_EX: indicates that the filter mode between a multicast group and the multicast source list is EXCLUDE, that is, only multicast data sent from the multicast sources not included in the specified multicast source list to the multicast group is received.
- TO_IN: indicates that the filter mode between a multicast group and the multicast source list is changed from EXCLUDE to INCLUDE.
- TO_EX: indicates that the filter mode between a multicast group and the multicast source list is changed from INCLUDE to EXCLUDE.

- ALLOW: indicates that multicast data from certain multicast sources are allowed. If the current relationship is INCLUDE, these multicast sources are added to the existing multicast source list. If the current relationship is EXCLUDE, these multicast sources are deleted from the existing multicast source list.
- BLOCK: indicates that multicast data from certain multicast sources are prohibited. If the current relationship is INCLUDE, these multicast sources are deleted from the existing multicast source list. If the current relationship is EXCLUDE, these multicast sources are added to the existing multicast source list.

For compatibility consideration, IGMPv3 can identify packets of IGMPv1 and IGMPv2.

PIM-DM

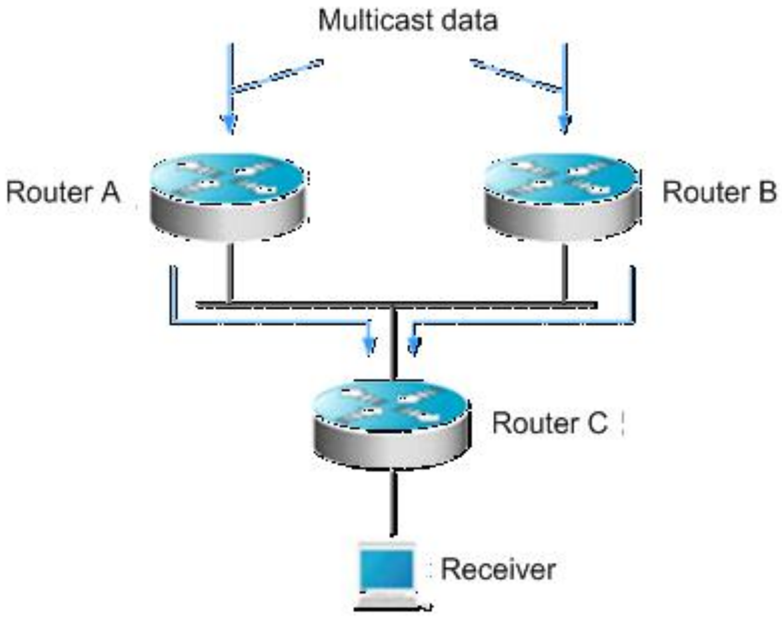
Protocol Independent Multicast-Dense Mode (PIM-DM) is a dense-mode multicast routing protocol, which is suitable for small-sized networks with densely distributed multicast members. As PIM-DM does not rely on any specific unicast routing protocol, it is called protocol independent multicast routing protocol. PIM-DM is defined in RFC 3973.

PIM-DM devices discover neighbors through Hello messages. After startup, a PIM-DM device sends a Hello message to each PIM-DM enabled interface periodically. The Hello message has a field of **Hello Hold Time**, which defines the maximum duration that a neighbor waits for the next message. If the neighbor does not receive another Hello message from the sender within this duration, this device will be removed from the adjacency list.

PIM-DM builds a shortest path tree (SPT) through flood and prune. PIM-DM assumes that when a multicast source begins to send a multicast packet, all the systems in the network need to receive this packet. As a result, this packet is forwarded to every system. The reverse path forwarding (RPF) check is performed for the packets received from the upstream interface. Those packets that fail to pass the check will be discarded. For the packets passing the check, the outgoing interface is computed based on the (S, G) pair of the packets, that is, source address and group address. If the outgoing interface is not null, an outgoing interface entry is created from the (S, G) pair and the multicast packet is forwarded through this outgoing interface. If the computed outgoing interface is null, a prune message is sent to the RPF neighbor, informing the upstream neighbor not to forward the multicast packets from the (S, G) pair to this interface. After the prune message is received on the upstream interface, the device marks the sending interface as pruned state and sets a pruned state timer. In this way, an SPT is created with the multicast source as its root.

PIM-DM uses the Assert mechanism to eliminate redundant routes.

Figure 4 Assert mechanism of PIM-DM



As shown in Figure-4, the multicast data arrives at Routers A and B at the same time, which forward the data to Router C. In this case, Router C receives duplicated data, which is not allowed. So there must be a mechanism to select Router A or B to forward the multicast data to Router C. This is the Assert mechanism of PIM-DM.

PIM-DM uses the state refresh message to update network state. The device directly connected to the multicast source sends the state refresh message to the downstream devices periodically to advertise the network topology changes. The devices receiving the message add their topology state to the state refresh message by modifying some fields, and then send it to the downstream devices. When the refresh message arrives at the leaf devices, the entire network state is updated.

PIM-DM uses the Graft mechanism to reestablish the connection with upstream devices. If the network topology of a downstream device in pruned state changes and the device needs to receive multicast data from a (S, G) pair, it sends the graft message to the upstream device. Upon receiving the graft message, the upstream device responds with a Graft-Ack message and forwards the multicast data to the downstream device again.

DVMRP

The Distance Vector Multicast Routing Protocol (DVMRP) is the first widely used multicast routing protocol in the Internet. It is also in dense mode. Like PIM-DM, DVMRP also uses the reverse path multicast mechanism to establish a distribution tree to forward multicast packets. The difference between the two protocols is that PIM-DM does not rely on specific unicast routing protocols and DVMRP replies on RIP.

A DVMRP device advertises itself, learns neighbor addresses and establishes adjacency through Probe packets. The DVMRP device establishes the adjacency relationship when the Probe packet received from a neighbor contains the IP address of the DVMRP device.

DVMRP neighbors exchange source route information by periodically sending Report packets. The information includes the source network mask and hop count. Such information is stored in the DVMRP routing table that is independent of the unicast routing table and used for RPF check during source tree creation.

DVMRP is also a multicast routing protocol in dense mode and creates SPTs for each multicast source. Initial multicast traffic is forwarded along the entire SPT, but DVMRP does not forward redundant paths. For the specified SPT, the device will send Prune packets to the upstream device after acknowledging that it does not need to receive multicast traffic. The device does not need to receive specified multicast traffic if no downstream neighbor exists and no multicast member information exists. As DVMRP is a multicast routing protocol in dense mode, multicast traffic is redistributed once pruning times out.

In addition, to enable the multicast receiver to join the SPT quickly, DVMRP supports the Graft and Graft-Ack mechanisms. The Graft mechanism adds the pruned paths to the SPT quickly, while the Graft-Ack mechanism avoids loss of Graft messages due to busy networks.

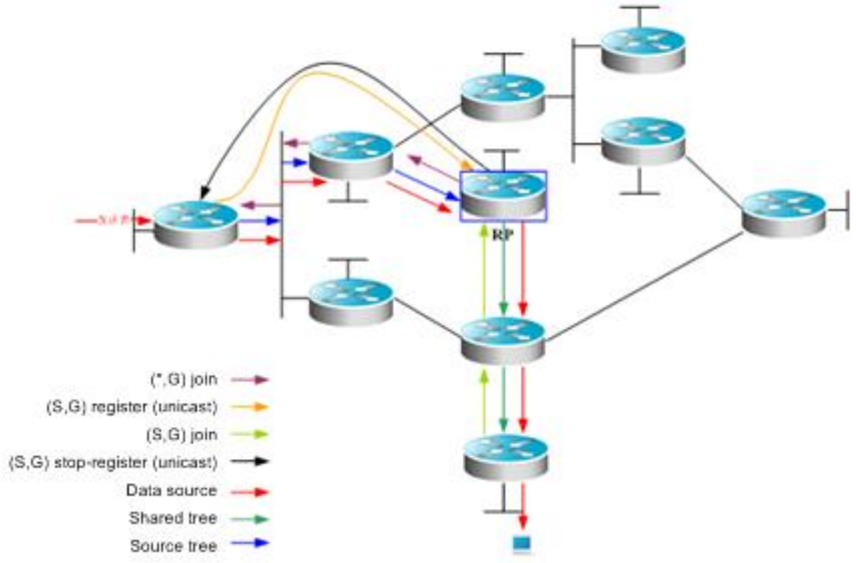
This product supports the complete DVMRP protocol.

PIM-SM

The Protocol Independent Multicast (PIM) is designed by the Inter-Domain Multicast Routing (idmr) working group. As its name implied, PIM does not rely on any specific unicast routing protocol. It can use a unicast routing table established by any unicast routing protocol to perform the RPF check function, instead of maintaining separate multicast routing tables to implement multicast forwarding. As PIM is not required to receive or distribute route updates, compared to other multicast routing protocols, it costs much less. PIM is designed to support shortest path trees (SPTs) and rendezvous point trees (RPTs) simultanenously and enable flexible conversion between them, so that their advantages can be used to improve multicast efficiency. There are two PIM modes: dense mode and sparse mode.

The Protocol Independent Multicast – Sparse Mode (PIM-SM) is a multicast routing protocol of sparse mode. In a PIM-SM domain, the PIM-SM-enabled device periodically sends Hello messages to discover adjacent PIM-SM devices and selects a designated router (DR) in a multi-access network. The DR is responsible for sending Join/Prune messages towards the root of themulticast distribution tree from its directly connected group member, or itsdirectly connected multicast source.

Figure 5 Explicit join mechanism of PIM-SM



PIM-SM forwards multicast data packets by establishing a multicast distribution tree. The multicast distribution tree is divided into two types: Shared Tree that takes the RP of the group G as the root and Shortest Path Tree that takes the multicast source as the root. PIM-SM establishes and maintains the multicast distribution tree by use of the explicit join/prune mechanism. As shown in Figure-5,

When the DR at the receiving end receives a report packet from the receiving end, it sends a (*.G)join packet towards the RP of group G to join the shared tree.

When the DR at the data source receives multicast data from the source host, it encapsulates the multicast data into a register message and unicasts it to the RP. Then the RP will forward the decapsulated data packets to group members along the shared tree.

The RP sends an (S, G)join packet to the first-hop device in the source direction to join the shortest path tree of this source. In this way, the source’s packets are sent to the RP without encapsulation along its shortest path tree.

When the first multicast data reaches along the SPT, the RP sends the stop-register message to the DR at the source, notifying the DR of stopping register encapsulation. Afterwards, the DR at the source does not encapsulate register packets but sends them to the RP along its shortest path tree, which then forwards the packets to group members along the shared tree. When no multicast data is required, the DR at the receiving end multicasts the prune message to group G’s RP hop by hop to prune the shared tree.

PIM-SM also offers a mechanism of selecting the root point (RP). One or more Candidate-BSRs are configured in a PIM-SM domain. PIM-SM selects a BSR by following a certain rule. There are also Candidate-RPs in a PIM-SM domain that unicast the packets including their IP addresses and available multicast groups to the BSR. The BSR will periodically generate a BSR message which includes a series ofcandidate RPs and corresponding multicast group addresses. The BSR messages are sent hop-by-hop within the entire domain. The device receives and saves these BSR messages. If the DR receives a report on the member relationship of a multicast group from its directly connected host but has no route entries of the multicast group, the DR will use a Hash algorithm to map the multicast group address to a candidate RP that can serve this group. Then, the DR multicasts the Join/Prune message to the RP hop-by-hop. If the DR receives multicast data packets from its directly connected host but has no route entries of the multicast group, the DR will usea Hash algorithm to map the multicast group address to a candidate RP that can serve this group. Then the DR encapsulates multicast data packets into a register message and unicasts it to the RP.

The main difference between PIM-SM and the flood/prune model-based PIM-DM is that PIM-SM is based on the explicit join model. In other words, the receiver sends the join message to the RP, while the router only forwards the packets of that multicast group on the outgoing interface that has joined a multicast group. PIM-SM uses the shared tree to forward multicast packets. Each group has a Rendezvous Point (RP). The multicast source sends data to the RP along the shortest path, and then the RP sends the data to the receivers along the shortest path. This is similar to CBT, but PIM-SM does not use the concept of core. One of the major advantages of PIM-SM is that it not only receives multicast messages through the shared tree but also provides a shared tree-to-SPT conversion mechanism. Such conversion reduces network delay and possible congestion on the RP, but it consumes enormous router resources. So it is suitable for the case where there are only a few multicast data sources and network groups.

PIM-SM uses the shared tree and SPT to distribute multicast frames. At this time, it is assumed that other devices don't want to receive these multicasts unless otherwise stated definitely. When a host joins a group, the equipment connected to the host must notify the root (or the RP) by using the PIM join message. This join message is transferred one after another through the routers to create a shared tree structure. Therefore, the RP records the transfer path and also the register message from the first hop router (DR) of the multicast source, and improves the shared tree upon these two messages. The branch/leaf messages are updated by periodically querying messages. With the shared tree, the multicast source first sends multicast packets to the RP, guaranteeing that all the receivers can receive them. The notation (*.G) represents a tree. The asterisk (*) represents all sources and G represents a specific multicast address. The prune message is also used in the shared tree. That is, the branch/leaf will send prune messages once it is not expecting to receive multicast frames.

PIMv2 BSR is a method of distributing group-to-RP messages to all devices without the need of setting an RP for them. BSR distributes mapping information by propagating BSR messages hop by hop. At first, BSR is selected among routers in the same process as selecting a root bridge based on priority level among layer 2 bridges. Each BSR checks the BSR messages and only forwards those having a priority higher than or equal to its own (higher IP address). The selected BSR sends its BSR message to the all-PIM-routers multicast group (224.0.0.13), where TTL is 1. After the adjacent PIMv2 router receives the message, it multicasts it while setting the TTL to 1. In this way, the BSR message is received by all devices hop by hop. Since the message contains the IP address of the BSR, the candidate BSR can know which router is the current BSR based on this message. The candidate RPs send candidate RP advertisements to announce in which address ranges they can become an RP. The BSR stores them in its local candidate RP cache. The BSP notifies all PIM routers of its local candidate RPs periodically. These messages reach various devices hop by hop in the same way.RPF Check

Multicast routing protocols depend on existing unicast route messages, MBGP routes or static multicast routes to create multicast routing entries. When creating multicast routing entries, multicast routing protocols run the Reverse Path Forwarding (RPF) check mechanism to ensure that multicast packets are transmitted along proper paths while avoiding loops.

RPF check is on the basis of unicast routes, MBGP routes or static multicast routes.

- The unicast routing table summarizes the shortest paths to each destination network segment.
- The MBGP routing table directly offers multicast routes.
- The multicast static routing table lists the RPF route messages that the user configures statically and manually.

RPF Check Process

The multicast routing protocol searches the unicast routing table, the MBGP routing table and the static multicast routing while performing an RPF check. The process is as follows:

1) First of all, select an optimal route from the unicast routing table, the MBGP routing table and the static multicast routing table, respectively.

- Select an optimal route from the unicast routing table for RPF check:
  - Use the IP address of the packet source as the destination address to search the unicast routing table and select an optimal unicast route.
  - If the unicast route has only one next hop, check whether multicast is enabled on the egress of the next hop.
    - If no, the unicast route is not suitable for RPF check.
    - If yes, the unicast route is suitable for RPF check and the egress serves as the RPF interface.
  - If the unicast route has more than one next hop, traverse all next hops and check whether multicast is enabled on the egress of one next hop.
    - If no, traverse the next hop.
    - If yes, the unicast route is suitable for RPF check and the egress serves as the RPF interface.
    - If no multicast is enabled on the egress after all next hops are traversed, there is no unicast route suitable for RPF check.
  - If no optimal route exists, there is no unicast route suitable for RPF check.
- Select an optimal route from the MBGP routing table for RPF check:
  - Use the IP address of the packet source as the destination address to search the MBGP routing table and select an optimal MBGP route.
  - The MBGP route has only one next hop. Check whether multicast is enabled on the egress of the next hop.
    - If no, the MBGP route is not suitable for RPF check.
    - If yes, the MBGP route is suitable for RPF check.
  - If no optimal route exists, there is no MBGP route suitable for RPF check.
- Select an optimal route from the static multicast routing table for RPF check:
  - Use the IP address of the packet source as the destination address to search the static multicast routing table and select an optimal static multicast route.
  - If the static multicast route has only one next hop, check whether multicast is enabled on the egress of the next hop.
    - If no, the static multicast route is not suitable for RPF check.
    - If yes, further check whether there is a unicast route available for RPF check.
      - If the next hop does not associate with the unicast protocol number, the static multicast route is suitable for RPF check.
      - If there is no unicast route available for RPF check, the static multicast route is suitable for RPF check.
      - If there is a unicast route available for RPF check, but the unicast protocol number is inconsistent with the one associated with the next hop of the static multicast route, the static multicast route is not suitable for RPF check.
      - If there is a unicast route available for RPF check, and the unicast protocol number is consistent with the one associated with the next hop of the static multicast route, the static multicast route is suitable for RPF check.
  - If the static multicast route has more than one next hop, traverse all next hops and check whether multicast is enabled on the egress of one next hop.
    - If no, traverse the next hop.
    - If yes, further check whether there is a unicast route available for RPF check.
      - If the next hop does not associate with the unicast protocol number, the static multicast route is suitable for RPF check. The outbound interface is the RPF interface.

- If there is no unicast route available for RPF check, the static multicast route is suitable for RPF check. The outbound interface is the RPF interface.
- If there is a unicast route available for RPF check, but the unicast protocol number is inconsistent with the one associated with the next hop of the static multicast route, traverse the next hop.
- If there is a unicast route available for RPF check, and the unicast protocol number is consistent with the one associated with the next hop of the static multicast route, the static multicast route is suitable for RPF check. The outbound interface is the RPF interface.
- If no multicast is enabled on the egress after all next hops are traversed, there is no static multicast route suitable for RPF check.

■ If no optimal route exists, there is no static multicast route suitable for RPF check.

Select one from these three optimal routes for RPF check.

■ If the longest match routing rule is configured, select the longest match route; if these three routes are of the same mask, select the one of the highest priority; if they are of the same priority, select the one in the order of static multicast route, MBGP route and unicast route.

■ If the longest match routing rule is not configured, select the one of the highest priority; if they are of the same priority, select the one in the order of static multicast route, MBGP route and unicast route.

⚠ Caution

The effectiveness of MBGP routes recurs on unicast routes rather than distance. The implementation of current MBGP protocols does not support equal-cost routes.

The effectiveness of static multicast routes recurs on unicast routes rather than distance.

If the static unicast route is selected as RPF route, the route must be configured with the next hop IP address. The PIM protocol will select RPF neighbors based on this next hop IP address. If the static unicast route is not configured with the next hop IP address, the PIM protocol cannot obtain RPF neighbors.

☑ For the commands including the VRF parameters, only the RSR20, RSR30, RSR50 and RSR50E devices support the VRF parameters.

Configuring IP Multicast Routing

Enabling IP Multicast Forwarding

Multicast data packets and protocol packets can be received and processed by related multicast protocols only after the multicast routing forwarding function is enabled.

Command	Function
Ruijie(config)# **ip multicast-routing** [**vrf** *vrf-name*]	Enables multicast routing forwarding. Enable multicast routing based on VRF if it is carried; Enable the default multicast routing globally if VRF is not carried.

Enabling IP Multicast Routing Protocols

Use the following commands to enable the IP multicast function on an interface.

Command	Function

Command	Function
Ruijie(config-if)# **ip pim dense-mode**	Enters the interface on which PIM-DM is to be enabled and enables PIM-DM in interface configuration mode. This command must be configured on a layer 3 interface.
Ruijie(config-if)# **ip pim sparse-mode**	Enters the interface on which PIM-SM is to be enabled and enables PIM-SM in interface configuration mode. This command must be configured on a layer 3 interface.
Ruijie(config-if)# **ip dvmrp enable**	Enters the interface on which DVMRP is to be enabled and enables DVMRP in interface configuration mode. This command must be configured on a layer 3 interface.

The following example shows how to configure PIM-DM on interface GE 0/3:

```
Ruijie(config)# ip multicast-routing
Ruijie(config)# interface  gigabitEthernet 0/3
Ruijie(config-if)# ip address 192.168.194.2 255.255.255.0
Ruijie(config-if)# ip pim dense-mode
```

Note

If IPv4 multicast routing is enabled globally, enabling IP multicast routing protocols on an interface will also enable the IGMP function. Only the IP multicast routing protocols of one mode can be enabled on one interface.

Caution

After the layer 3 multicasting is enabled on the Private VLAN and Super VLAN, if the multicast source exists in the sub-VLAN, one more route entry must be duplicated and the ingress is the sub-VLAN in which the multicast streams enter as the ingress validity check is required for multicast forwarding. As a result, one more multicast hardware entry is occupied, that is, multicast capacity is reduced by 1.

Enabling IGMP

The IGMP protocol is enabled with the enabling of IP multicast route forwarding and IP multicast routing protocols.

Configuring IP Multicast Routing

Configuring TTL Threshold

To limit the TTL of the data packets allowed to pass an interface, configure the TTL threshold.

Use the following command to configure the TTL threshold of multicast packets allowed to pass an interface. Use the **no** form of this command to restore the default value. The default value is **0**.

Command	Function

Command	Function
Ruijie (config-if) # **ip multicast ttl-threshold** *ttl-value*	Configures the TTL threshold of an interface. *ttl-value* ranges from 0 to 255.

Limiting the Number of Entries to Be Added to the IP Multicast Routing Table

Use the following command to limit the number of entries to be added to the IP multicast routing table in global configuration mode. Use the **no** form of this command to restore the default value. The default value is **1024**.

Command	Function
Ruijie (config) # **ip multicast route-limit** *limit* [*threshold*]	Limits the number of entries to be added to the IP multicast routing table. *limit* specifies the number of entries to be added to the multicast routing table. The range is from 1 to 2147483647. The default is 1024. *threshold* (optional) specifies the number of routes triggering alarm. The default is 2147483647.

Caution

As the hardware is limited for different models, the routes exceeding the hardware entry threshold need to be forwarded through software, resulting in performance degrade.

Configuring IP Multicast Boundary for a Specific IP Group

Use the following command to set IP multicast boundary for a specific IP group in interface configuration mode. Use the **no** form of this command to restore the default value.

Command	Purpose
Ruijie (config-if) # **ip multicast boundary** *access-list* [**in** | **out**]	Sets IP multicast boundary for a specific IP group. Numerical standard ACL or name can be used to specify an IP group.

This command filters the IGMP, PIM-SM and PIM-DM packets associated with the IP group. Multicast packets will not flow in or out through the multicast boundary interface.

Note

The ACL in this command supports matching of destination IP addresses, not group IP addresses or source IP addresses.

Configuring IP Multicast Static Route

IP static multicast route enables multicast packet forwarding through a path different from IP unicast path. RPF check is always performed for IP multicast packet forwarding. The real interface receiving packets is the expected one, namely the next hop interface of IP unicast route used to transmit to the sender. The check is reasonable when IP unicast topology is consistent with IP multicast topology. In some cases, however, it is better to make difference between IP unicast path and IP multicast path.

Static multicast route enables devices to execute RPF check according to configurations rather than the IP unicast routing table. Consequently, tunnel technology is used for IP multicast packet forwarding, not IP unicast packet forwarding. IP static multicast route is stored locally rather than be advertised or forwarded.

Use the following command to configure IP multicast static routes.

Command	**Function**
Ruijie (config) # **ip mroute** [**vrf** *vrf-name*] *source-address mask* { **fallback-lookup** { **global** | **vrf** *vrf-name* } | [**bgp** | **isis** | **ospf** | **static**] {*v4rpf-address* | *interface-type interface-number* } } [*distance*]	Configures IP multicast static route. The routing protocol type can be set. *distance*: In the range of 0 to 255

Caution

To set the egress of the static multicast route not to be the next hop IP address, the egress must be a point-to-point interface.

Configuring Longest-match-based Routing

Use the following command to configure longest-match-based routing.

Command	**Function**
Ruijie(config)# **ip multicast** [**vrf** *vrf-name*] **rpf longest-match**	Selects an optimal route from the static multicast, MBGP and unicast routing tables respectively in compliance with the RPF rules. Select the one with the longest mask matching from the three routes as the RPF route. If the three are of the same priority, select one in the order of multicast static route, MBGP route and unicast route.

The static multicast route, MBGP route and unicast route used for RPF check are elected from the static multicast routing table, MBGP routing table and unicast routing by RPF rules, respectively.

- By default, the one of highest priority is selected from these three routes. If they are of the same priority, select one in the order of static multicast route, MBGP route and unicast route.
- If the route selection based on the longest match has been configured, the one with the longest mask matching is selected from the three routes as the RPF route. If the masks of the three routes are the same, the one of the highest priority will be selected; if the three are of the same priority, a route is selected in the order of multicast static route, MBGP route and unicast route.

Configuring the Selection Method for PROXY in RPF Vector

Use the following commands to configure the selection method for proxy in RPF vector in global configuration mode.

Command	Function
ip multicast [**vrf** *vrf-name*] **rpf proxy** [**rd**] {**vector |** **disable**}	Configures the selection method for proxy. There are three selection methods for proxy: When the **rd** parameter is configured, the RPF Vector with RD information carried is used. This parameter takes effect only when the vrf is specified. When the **vector** parameter is configured, RFP Vector is used. When the **disable** parameter is configured, receiving RPF Vector is prohibited.
no ip multicast [**vrf** *vrf-name*] **rpf proxy** [**rd**] {**vector |** **disable**}	Deletes the selection method for proxy.

☑ Currently, this function is supported by RSR20. RSR30, RSR50 and RSR50E.

Configuring the Multicast Hardware Table Overflow Override Mechanism

This command deletes the hardware forwarding entry created earliest if the number of hardware forwarding table is full during creation of a new entry.

Command	Function
Ruijie(config)# **msf ipmc-overflow override**	Deletes the hardware forwarding entry created earliest and adds the new entry if the hardware forwarding table is full during creation of a new entry.

Monitoring and Maintaining IP Multicast Routing

Use the following command to show the IPv4 multicast forwarding table in privileged EXEC mode.

Command	Function
show ip mroute [**vrf** *vrf-name*] [*group-or-source-address* [*group-or-source-address*]] [**dense** | **sparse**] [**summary** | **count**]	Shows the IPv4 multicast forwarding table.

Use the following command to delete the IPv4 multicast forwarding table in privileged EXEC mode.

Command	Function
clear ip mroute [vrf *vrf-name***]** {*** |** *v4group-address* [*v4source -address*]}	Deletes the IPv4 multicast forwarding table.

Use the following command to reset the IPv4 multicast forwarding table statistics in privileged EXEC mode.

Command	Function
clear ip mroute [vrf *vrf-name***] statistics** {* | *v4group-address* [*v4source-address*]}	Resets the IPv4 multicast forwarding table statistics.

Use the following command to show the IPv4 static multicast routing information in privileged EXEC mode.

Command	Function
show ip mroute [**vrf** *vrf-name*] **static**	Shows the IPv4 static multicast routing information.

Use the following command to show the IPv4 static multicast routing information in privileged EXEC mode.

Command	Function
show ip rpf [**vrf** *vrf-name*] { *source-address* [*group-address*] [**rd** *route-distinguisher*] } [**metric**]	Shows the RPF information of specific IPv4 source address.

☑ Only RSR20, RSR30, RSR50 and RSR50E support the parameters of **group address**, **rd** and **metric**.

Use the following command to show the IPv4 static multicast interface information in privileged EXEC mode.

Command	Function
show ip mvif [**vrf** *vrf-name*] [*interface-type interface-number*]	Shows the IPv4 multicast interface information.

Use the following command to show the IPv4 layer 3 multicast forwarding table in privileged EXEC mode.

Command	Function
show ip mrf [**vrf** *vrf-name*] **mfc**	Shows the IPv4 layer 3 multicast forwarding table.

Use the following command to show the operation of multicast core in privileged mode.

Command	Function
debug nsm mcast [**vrf** *vrf-name*] **all**	Shows the operation of multicast core.

Use the following command to show the communication between the core of IPv4 multicast and multicast protocols in privileged mode.

Command	Function
debug nsm mcast [**vrf** *vrf-name*] **fib-msg**	Shows the communication between the core of IPv4 multicast and multicast protocols.

Use the following command to show the operation on the interface of the core of IPv4 multicast in privileged mode.

Command	Function
debug nsm mcast [**vrf** *vrf-name*] **vif**	Shows the operation on the interface of the core of IPv4 multicast.

Use the following command to show the operation of interface and statistics of the core of IPv4 multicast in privileged mode.

Command	Function
debug nsm mcast [**vrf** *vrf-name*] **stats**	Shows the operation of interface and statistics of the core of IPv4 multicast.

Use the following command to show the packet forwarding on Layer 3 of IPv4 multicast in privileged mode.

Command	Function

debug ip mrf [**vrf** *vrf-name*] **forwarding**	Shows the packet forwarding on Layer 3 of IPv4 multicast.

Use the following command to show the operation of forwarding entries on Layer 3 of IPv4 multicast in privileged mode.

Command	Function
debug ip mrf [**vrf** *vrf-name*] **mfc**	Shows the operation of forwarding entries on Layer 3 of IPv6 multicast.

Use the following command to show the operation of forwarding events on Layer 3 of IPv4 multicast in privileged mode.

Command	Function
debug ip mrf [**vrf** *vrf-name*] **event**	Shows the operation of forwarding events on Layer 3 of IPv4 multicast.

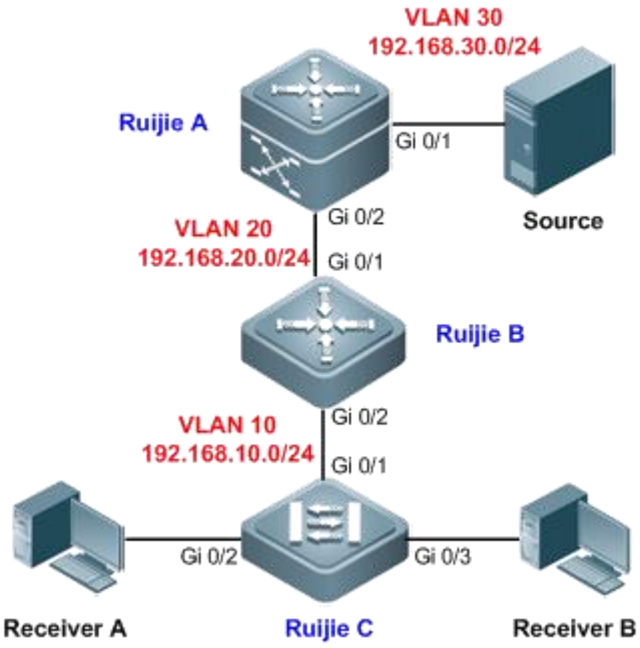
Configuration Examples

PIM-DM Configuration Example

Networking Topology

As shown in Figure 6, Ruijie A and Ruijie B are layer 3 devices; Ruijie C is a layer-2 access device, with downlink users belonging to VLAN 10. The multicast source belongs to VLAN 30, and resides in a network segment different from the multicast receivers.

Figure 6 Topology for multicast routing network



Networking Requirements

- IGMP is running between multicast source and multicast receiver to establish and maintain the membership of a multicast group. For a dense-mode multicast network, PIM-DM can be applied to realize layer-3 routing of multicast data, while IGMP Snooping can be applied on the layer-2 device to realize layer-2 forwarding of multicast data.
- Only hosts belonging to VLAN 10 can join the multicast group 225.0.0.0/8, and a host can join up to 200 multicast groups.
- PIM adjacency established between the edge multicast router (Ruijie B) and the downlink device by receiving PIM data packets should be avoided.

Configuration Tips

- Configure unicast routing protocol on the layer-3 devices (Ruijie A and Ruijie B in this example), and ensure the route connectivity between different network segments. Static route is configured in this example.
- On the layer-3 interface of multicast routing devices (SVI of VLANs 10, 20 and 30), configure PIM-DM to enable IGMP automatically (IGMPv2 is the default version).
- Configure IGMP Snooping on the layer-2 device (Ruijie C in this example). Here only the IVGL mode of IGMP Snooping is enabled, and detailed configurations are not provided here. For details, see *Configuring IGMP Snooping*.
- Configure multicast group access control on the layer-3 interface (SVI for VLAN 10 of Ruijie B) of multicast router to limit the range of multicast groups the downlink hosts can join. Configure the maximum number of IGMP group members on this interface (in this example, the maximum number is set to 200).
- Configure PIM neighbor filtering on the layer-3 interface of Ruijie B for connecting to the layer-2 device. By setting up filtering conditions for ACL, only the PIM packets from uplink neighbors can be received.

Configuration Steps

- Step 1: Configure SVI for each VLAN.

! On Ruijie A, create VLAN 20 and VLAN 30, and configure the SVI for VLAN 20 as 192.168.20.1/24 and the SVI for VLAN 30 as 192.168.30.1/24.

```
RuijieA#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
RuijieA(config)#vlan 20
RuijieA(config-vlan)#exit
RuijieA(config)#vlan 30
RuijieA(config-vlan)#exit
RuijieA(config)#interface vlan 20
RuijieA(config-if-VLAN 20)#ip address 192.168.20.1 255.255.255.0
RuijieA(config-if-VLAN 20)#exit
RuijieA(config)#interface vlan 30
RuijieA(config-if-VLAN 30)#ip address 192.168.30.1 255.255.255.0
RuijieA(config-if-VLAN 30)#exit
```

! On Ruijie B, create VLAN 10 and VLAN 20, and configure the SVI for VLAN 10 as 192.168.10.1/24 and the SVI for VLAN 20 as 192.168.20.2/24.

```
RuijieB#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
RuijieB(config)#vlan 10
RuijieB(config-vlan)#exit
RuijieB(config)#vlan 20
RuijieB(config-vlan)#exit
RuijieB(config)#interface vlan 10
RuijieB(config-if-VLAN 10)#ip address 192.168.10.1 255.255.255.0
RuijieB(config-if-VLAN 10)#exit
RuijieB(config)#interface vlan 20
RuijieB(config-if-VLAN 20)#ip address 192.168.20.2 255.255.255.0
RuijieB(config-if-VLAN 20)#exit
```

- Step 2: Configure the attributes of each port.

! On Ruijie A, configure Gi 0/1 as an access port belonging to VLAN 30 and Gi 0/2 as a trunk port.

```
RuijieA(config)#interface gigabitEthernet 0/1
RuijieA(config-if-GigabitEthernet 0/1)#switchport access vlan 30
RuijieA(config-if-GigabitEthernet 0/1)#exit
RuijieA(config)#interface gigabitEthernet 0/2
RuijieA(config-if-GigabitEthernet 0/2)#switchport mode trunk
RuijieA(config-if-GigabitEthernet 0/2)#exit
```

! On Ruijie B, configure Gi 0/1 and Gi 0/2 as trunk ports.

```
RuijieB(config)#interface range gigabitEthernet 0/1-2
RuijieB(config-if-range)#switchport mode trunk
RuijieB(config-if-range)#exit
```

! On Ruijie C, configure Gi 0/1 as a trunk port and Gi 0/2-3 as an access port belonging to VLAN 10.

```
RuijieC(config)#interface gigabitEthernet 0/1
RuijieC(config-if-GigabitEthernet 0/1)#switchport mode trunk
RuijieC(config-if-GigabitEthernet 0/1)#exit
RuijieC(config)#interface range gigabitEthernet 0/2-3
RuijieC(config-if-range)#switchport access vlan 10
RuijieC(config-if-range)#exit
```

- Step 3: Configure static route on the layer-3 device.

! On Ruijie B, configure the next-hop IP address for 192.168.30.0 as 192.168.20.1.

```
RuijieB(config)#ip route 192.168.30.0 255.255.255.0 192.168.20.1
```

! On Ruijie A, configure the next-hop IP address for 192.168.10.0 as 192.168.20.2.

```
RuijieA(config)#ip route 192.168.10.0 255.255.255.0 192.168.20.2
```

- Step 4: Enable multicast routing on the layer-3 interface.

! On Ruijie A, enable multicast routing globally, and enable PIM-DM on each interface.

```
RuijieA(config)#ip multicast-routing
RuijieA(config)#interface vlan 20
RuijieA(config-if-VLAN 20)#ip pim dense-mode
RuijieA(config-if-VLAN 20)#exit
RuijieA(config)#interface vlan 30
RuijieA(config-if-VLAN 30)#ip pim dense-mode
RuijieA(config-if-VLAN 30)#exit
```

! On Ruijie B, enable multicast routing globally, and enable PIM-DM on each interface.

```
RuijieB(config)#ip multicast-routing
RuijieB(config)#interface vlan 10
RuijieB(config-if-VLAN 10)#ip pim dense-mode
RuijieB(config-if-VLAN 10)#exit
RuijieB(config)#interface vlan 20
RuijieB(config-if-VLAN 20)#ip pim dense-mode
RuijieB(config-if-VLAN 20)#exit
```

- Step 5: Enable IGMP Snooping on the layer-2 device.

! In global configuration mode, configure IGMP Snooping to operate in IVGL mode.

```
RuijieC(config)#ip igmp snooping ivgl
```

- Step 6: Configure multicast group access control on the layer-3 interface and configure the maximum number of IGMP group members.

! On Ruijie B, create ACL to permit the IP address 225.0.0.0/8.

```
RuijieB(config)#ip access-list standard 1
RuijieB(config-std-nacl)#permit 225.0.0.0 0.255.255.255
RuijieB(config-std-nacl)#exit
```

! On the SVI for VLAN 10, configure multicast group access control and associate ACL.

```
RuijieB(config)#interface vlan 10
RuijieB(config-if-VLAN 10)#ip igmp access-group 1
```

! On the SVI for VLAN 10, configure the maximum number of allowed multicast groups as 200.

```
RuijieB(config-if-VLAN 10)#ip igmp limit 200
RuijieB(config-if-VLAN 10)#exit
```

- Step 7: Configure PIM neighbor filtering.

! On Ruijie B, create the ACL to deny all IP addresses.

```
RuijieB(config)#ip access-list standard 2
RuijieB(config-std-nacl)#deny any
RuijieB(config-std-nacl)#exit
```

! Configure PIM neighbor filtering on the SVI for VLAN 10 and associate ACL so that this interface does not receive PIM packets from other devices or establish adjacencies with them.

```
RuijieB(config)#interface vlan 10
RuijieB(config-if-VLAN 10)#ip pim neighbor-filter 2
RuijieB(config-if-VLAN 10)#exit
```

Verification

- Step 1: Display device configurations.

! Configurations on Switch A

```
RuijieA#show running-config
!
vlan 20
!
vlan 30
!
ip multicast-routing
!
interface GigabitEthernet 0/1
 switchport access vlan 30
!
interface GigabitEthernet 0/2
 switchport mode trunk
!
interface VLAN 20
 ip pim dense-mode
 no ip proxy-arp
 ip address 192.168.20.1 255.255.255.0
!
interface VLAN 30
 ip pim dense-mode
 no ip proxy-arp
 ip address 192.168.30.1 255.255.255.0
!
ip route 192.168.10.0 255.255.255.0 192.168.20.2
```

! Configurations on Switch B

```
SwtichB#show running-config
!
vlan 10
!
vlan 20
!
ip multicast-routing
!
ip access-list standard 1
 10 permit 225.0.0.0 0.255.255.255
!
ip access-list standard 2
 10 deny any
!
interface GigabitEthernet 0/1
 switchport mode trunk
!
interface GigabitEthernet 0/2
 switchport mode trunk
!
interface VLAN 10
 ip pim dense-mode
 ip pim neighbor-filter 2
 ip igmp access-group 1
 ip igmp limit 200
 no ip proxy-arp
 ip address 192.168.10.1 255.255.255.0
!
interface VLAN 20
 ip pim dense-mode
 no ip proxy-arp
 ip address 192.168.20.2 255.255.255.0
!
ip route 192.168.30.0 255.255.255.0 192.168.20.1
```

- Step 2: Display PIM-DM information of the interface (Ruijie A is used as an example).

```
RuijieA#show ip pim dense-mode interface detail
VLAN 20 (vif-id: 1):
  Address 192.168.20.1
  Hello period 30 seconds, Next Hello in 30 seconds
  Over-ride interval 2500 milli-seconds
  Propagation-delay 500 milli-seconds
  Neighbors:
    192.168.20.2
VLAN 30 (vif-id: 2):
  Address 192.168.30.1
  Hello period 30 seconds, Next Hello in 25 seconds
  Over-ride interval 2500 milli-seconds
  Propagation-delay 500 milli-seconds
  Neighbors: none
```

The preceding information shows the ID and address of the PIM-DM enabled interface and the corresponding PIM-DM neighbor.

- Step 3: Display the next hop information of PIM-DM (Ruijie B is used as an example).

```
RuijieB#show ip pim dense-mode nexthop
Destination   Nexthop   Nexthop       Nexthop       Metric Pref
              Num       Addr          Interface
192.168.30.2   1      192.168.20.1   VLAN 20           0     1
```

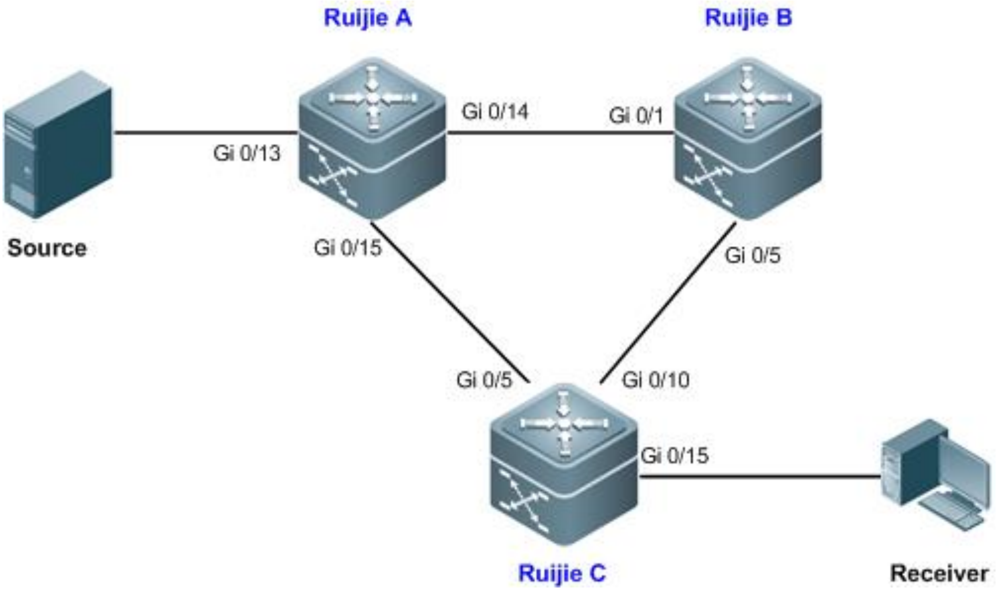
☑ This example applies to both layer-3 switches and routers. However, VLAN-related configuration commands are not supported on routers. Therefore, to establish the topology in this example on routers, directly replace the SVI interfaces with use common layer-3 interfaces.

PIM-SM Configuration Example (I)

Networking Topology

As shown in Figure 7, three layer-3 devices are interconnected through the routed ports. Multicast source and receiver are in different network segments.

Figure 7



The interface addresses of the devices are listed in the following table.

Device	Port Number	IP Address
Ruijie A	Gi 0/13	192.168.1.1/24
	Gi 0/14	192.168.2.1/24
	Gi 0/15	192.168.3.1/24
Ruijie B	Gi 0/1	192.168.2.2/24
	Gi 0/5	192.168.4.1/24
	Loopback1	10.1.1.1/24
Ruijie C	Gi 0/5	192.168.3.2/24
	Gi 0/10	192.168.4.2/24
	Gi 0/15	192.168.5.1/24

Networking Requirements

- IGMP is running between multicast source and multicast receiver to establish and maintain the membership of a multicast group. For a sparse-mode multicast network, PIM-SM can be applied to realize layer-3 routing of multicast data.
- Unauthenticated multicast source should be avoided from sending multicast data in the PIM-SM domain.

Configuration Tips

- Configure unicast routing protocols on the layer-3 devices, and ensure the route connectivity between different network segments. This example configures the OSPF protocol. For details, see *Configuring OSPF*.
- After enabling PIM-SM on each interface, IGMP will be enabled automatically (IGMPv2 is the default version).
- In the entire PIM-SM domain, at least one RP must be configured (serving all multicast groups by default) to act as the root node of shared tree (in this example, one interface of Ruijie B is configured as static RP).
- On the RP, configure address filtering of register messages (on Ruijie B in this example).

Configuration Steps

- Step 1: Configure the IP address on the interface of each device.

! Configure the IP address of Ruijie A's interface.

```
RuijieA#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
RuijieA(config)#interface gigabitEthernet 0/13
RuijieA(config-if-GigabitEthernet 0/13)#no switchport
RuijieA(config-if-GigabitEthernet 0/13)#ip address 192.168.1.1 255.255.255.0
RuijieA(config-if-GigabitEthernet 0/13)#exit
RuijieA(config)#interface gigabitEthernet 0/14
RuijieA(config-if-GigabitEthernet 0/14)#no switchport
RuijieA(config-if-GigabitEthernet 0/14)#ip address 192.168.2.1 255.255.255.0
RuijieA(config-if-GigabitEthernet 0/14)#exit
RuijieA(config)#interface gigabitEthernet 0/15
RuijieA(config-if-GigabitEthernet 0/15)#no switchport
RuijieA(config-if-GigabitEthernet 0/15)#ip address 192.168.3.1 255.255.255.0
RuijieA(config-if-GigabitEthernet 0/15)#exit
```

! Configure the IP address of Ruijie B's interface, and configure a Loopback interface as well.

```
RuijieB(config)#interface gigabitEthernet 0/1
RuijieB(config-if-GigabitEthernet 0/1)#no switchport
RuijieB(config-if-GigabitEthernet 0/1)#ip address 192.168.2.2 255.255.255.0
RuijieB(config-if-GigabitEthernet 0/1)#exit
RuijieB(config)#interface gigabitEthernet 0/5
RuijieB(config-if-GigabitEthernet 0/5)#no switchport
RuijieB(config-if-GigabitEthernet 0/5)#ip address 192.168.4.1 255.255.255.0
RuijieB(config-if-GigabitEthernet 0/5)#exit
RuijieB(config)#interface loopback 1
RuijieB(config-if-Loopback 1)#ip address 10.1.1.1 255.255.255.0
RuijieB(config-if-Loopback 1)#exit
```

! Configure the IP address of Ruijie C's interface.

```
RuijieC(config)#interface gigabitEthernet 0/5
RuijieC(config-GigabitEthernet 0/5)#no switchport
RuijieC(config-GigabitEthernet 0/5)#ip address 192.168.3.2 255.255.255.0
RuijieC(config-GigabitEthernet 0/5)#exit
RuijieC(config)#interface gigabitEthernet 0/10
RuijieC(config-GigabitEthernet 0/10)#no switchport
RuijieC(config-GigabitEthernet 0/10)#ip address 192.168.4.2 255.255.255.0
RuijieC(config-GigabitEthernet 0/10)#exit
RuijieC(config)#interface gigabitEthernet 0/15
RuijieC(config-GigabitEthernet 0/15)#no switchport
RuijieC(config-GigabitEthernet 0/15)#ip address 192.168.5.1 255.255.255.0
```

- Step 2: Interconnect devices and configure the corresponding OSPF protocol on the devices.

! Configure Switch A

```
RuijieA(config)#route ospf 1
RuijieA(config-router)#network 192.168.1.0 0.0.0.255 area 0
RuijieA(config-router)#network 192.168.2.0 0.0.0.255 area 0
RuijieA(config-router)#network 192.168.3.0 0.0.0.255 area 0
RuijieA(config-router)#exit
```

! Configure Ruijie B

```
RuijieB(config)#route ospf 1
RuijieB(config-router)#network 10.1.1.0 0.0.0.255 area 0
RuijieB(config-router)#network 192.168.2.0 0.0.0.255 area 0
RuijieB(config-router)#network 192.168.4.0 0.0.0.255 area 0
RuijieB(config-router)#exit
```

! Configure Ruijie C

```
RuijieC(config)#route ospf 1
RuijieC(config-router)#network 192.168.3.0 0.0.0.255 area 0
RuijieC(config-router)#network 192.168.4.0 0.0.0.255 area 0
RuijieC(config-router)#network 192.168.5.0 0.0.0.255 area 0
RuijieC(config-router)#exit
```

- Step 3: Globally enable multicast routing on the devices and enable PIM-SM on each interface.

! Configure Ruijie A

```
RuijieA(config)#ip multicast-routing
RuijieA(config)#interface gigabitEthernet 0/13
RuijieA(config-if-GigabitEthernet 0/13)#ip pim sparse-mode
RuijieA(config-if-GigabitEthernet 0/13)#exit
RuijieA(config)#interface gigabitEthernet 0/14
RuijieA(config-if-GigabitEthernet 0/14)#ip pim sparse-mode
RuijieA(config-if-GigabitEthernet 0/14)#exit
RuijieA(config)#interface gigabitEthernet 0/15
RuijieA(config-if-GigabitEthernet 0/15)#ip pim sparse-mode
RuijieA(config-if-GigabitEthernet 0/15)#exit
```

! Configurations on Ruijie B and Ruijie C (including the Loopback interface on Ruijie B) are the same as the preceding configurations.

- Step 4: Configure RP.

! Select the Loopback interface of Switch B as the static RP of PIM-SM domain. Note: Static RP must be configured identically on all PIM devices.

```
RuijieA(config)#ip pim rp-address 10.1.1.1
```

! Configurations on Ruijie B and Ruijie C are the same as the preceding configuration.

- Step 5: Configure address filtering of register messages on RP.

! On Ruijie B, create ACL to permit register messages with source IP address being 192.168.1.2 and group address range being 225.0.0.0/8–226.0.0.0/8.

```
RuijieB(config)#ip access-list extended 100
RuijieB(config-ext-nacl)#permit ip host 192.168.1.2 225.0.0.0 0.255.255.255
RuijieB(config-ext-nacl)#permit ip host 192.168.1.2 226.0.0.0 0.255.255.255
RuijieB(config-ext-nacl)#deny ip any any
RuijieB(config-ext-nacl)#exit
```

! Associate this ACL with the register message address filtering of RP.

```
RuijieB(config)#ip pim accept-register list 100
```

Verification

- Step 1: Display device configurations.

! Configurations on Ruijie A.

```
RuijieA#show running-config
!
ip pim rp-address 10.1.1.1
!
ip multicast-routing
!

 network 192.168.5.0 0.0.0.255 area 0
```

- Step 2: Display PIM-SM interface information (Ruijie B is used as an example).

```
RuijieB#show ip pim sparse-mode interface detail
GigabitEthernet 0/1 (vif 1):
  Address 192.168.2.2, DR 192.168.2.2
  Hello period 30 seconds, Next Hello in 1 seconds
  Triggered Hello period 5 seconds
  Neighbors:
   192.168.2.1
GigabitEthernet 0/5 (vif 2):
  Address 192.168.4.1, DR 192.168.4.2
  Hello period 30 seconds, Next Hello in 10 seconds
  Triggered Hello period 5 seconds
  Neighbors:
   192.168.4.2
Loopback 1 (vif 3):
  Address 10.1.1.1, DR 10.1.1.1
  Hello period 30 seconds
  Triggered Hello period 5 seconds
  Neighbors:
```

The preceding information shows the IP address of each interface and the IP addresses of the DR and PIM-SM neighbor in the corresponding network segment.

- Step 3: Display current RP information (Ruijie B is used as an example).

```
RuijieB#show ip pim sparse-mode rp mapping
PIM Group-to-RP Mappings
Group(s): 224.0.0.0/4, Static
   RP: 10.1.1.1 , Static
        Uptime: 01:43:07
```

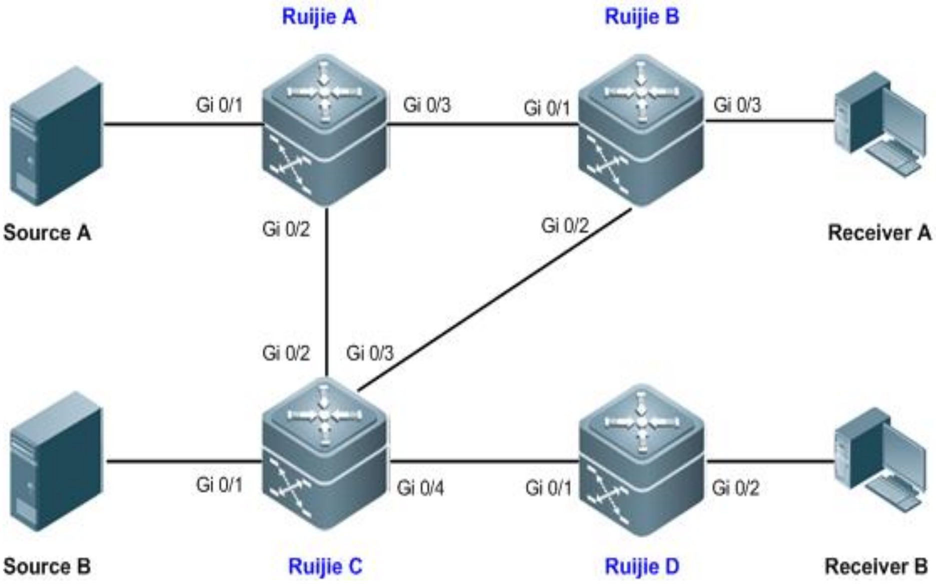
☑ This example applies to both layer-3 switches and routers. However, if you need to configure the switch port as a layer-3 port, you must run the **no switchport** command (not needed for routers).

PIM-SM Configuration Example (II)

Networking Topology

As shown in Figure 8, four layer-3 devices are interconnected through the routed ports. Multicast sources (Source A and Source B) and receivers (Receiver A and Receiver B) are in different network segments.

Figure 8



The interface addresses of each device are listed in the following table.

Device	Port Number	IP Address
Ruijie A	Gi 0/1	192.168.1.1/24
	Gi 0/2	192.168.2.1/24
	Gi 0/3	192.168.3.1/24
Ruijie B	Gi 0/1	192.168.3.2/24
	Gi 0/2	192.168.4.1/24
	Gi 0/3	192.168.5.1/24
	Loopback 1	10.1.1.1/24
	Loopback 2	10.1.2.1/24
Ruijie C	Gi 0/1	192.168.6.1/24
	Gi 0/2	192.168.2.2/24
	Gi 0/3	192.168.4.2/24
	Gi 0/4	192.168.7.1/24
	Loopback 1	10.1.3.1/24
Ruijie D	Gi 0/1	192.168.7.2/24
	Gi 0/2	192.168.8.1/24

Networking Requirements

- Multicast data forwarding between multicast routers is achieved through PIM-SM. One BSR in the PIM-SM domain is responsible for collecting and advertising RP information in the domain, while multiple candidate RPs serve different multicast groups to divert network traffic.
- The multicast router receives only BSM messages from a valid BSR.
- The BSR receives only advertisement packets from valid candidate RPs.

Configuration Tips

- Enable multicast routing on all multicast routers and enable PIM-SM multicast routing protocol on the interconnected interface. Note: Enabling PIM-SM will automatically enable IGMP.
- Specify one interface (Loopback 1 on Ruijie B) as the candidate BSR and two other interfaces (Loopback 2 on Ruijie B and Loopback 1 on Ruijie C) as the candidate RPs, and configure the multicast groups served by the candidate RPs.
- On the multicast router needing to filter BSM messages, configure the range of valid BSR (in this example, enable Ruijie C to permit only the BSM messages sent from Loopback 1 of Ruijie B).
- On BSR (Ruijie B in this example), configure the elected BSR to limit the valid C-RP address range and the multicast group range served.

Configuration Steps

- Step 1: Configure the interface IP addresses of each device.

! Configure Ruijie A

```
RuijieA#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
RuijieA(config)#interface gigabitEthernet 0/1
RuijieA(config-if-GigabitEthernet 0/1)#no switchport
RuijieA(config-if-GigabitEthernet 0/1)#ip address 192.168.1.1 255.255.255.0
RuijieA(config-if-GigabitEthernet 0/1)#exit
RuijieA(config)#interface gigabitEthernet 0/2
RuijieA(config-if-GigabitEthernet 0/2)#no switchport
RuijieA(config-if-GigabitEthernet 0/2)#ip address 192.168.2.1 255.255.255.0
RuijieA(config-if-GigabitEthernet 0/2)#exit
RuijieA(config)#interface gigabitEthernet 0/3
RuijieA(config-if-GigabitEthernet 0/3)#no switchport
RuijieA(config-if-GigabitEthernet 0/3)#ip address 192.168.3.1 255.255.255.0
RuijieA(config-if-GigabitEthernet 0/3)#exit
```

! Configurations on Ruijie B, Ruijie C and Ruijie D are the same as the preceding configurations.

! On Ruijie B, configure the IP address of Loopback 1 as 10.1.1.1/24 and the IP address of Loopback 2 as 10.1.2.1/24.

```
RuijieB(config)#interface loopback 1
RuijieB(config-if-Loopback 1)#ip address 10.1.1.1 255.255.255.0
RuijieB(config-if-Loopback 1)#exit
RuijieB(config)#interface loopback 2
RuijieB(config-if-Loopback 2)#ip address 10.1.2.1 255.255.255.0
RuijieB(config-if-Loopback 2)#exit
```

! On Ruijie C, configure the IP address of Loopback 1 as 10.1.3.1/24.

```
RuijieC(config)#interface loopback 1
RuijieC(config-Loopback 1)#ip address 10.1.3.1 255.255.255.0
RuijieC(config-Loopback 1)#exit
```

- Step 2: Interconnect devices and configure the corresponding OSPF protocol on the devices.

! Configure Ruijie A

```
RuijieA(config)#route ospf 1
RuijieA(config-router)#network 192.168.1.0 0.0.0.255 area 0
RuijieA(config-router)#network 192.168.2.0 0.0.0.255 area 0
RuijieA(config-router)#network 192.168.3.0 0.0.0.255 area 0
RuijieA(config-router)#exit
```

! Configurations on Ruijie B, Ruijie C and Ruijie D are the same as the preceding configurations.

Step 2: Enable multicast routing on each device and enable PIM-SM multicast routing protocol on each interface.

! Configure Ruijie A

```
RuijieA(config)#ip multicast-routing
RuijieA(config)#interface range gigabitEthernet 0/1-3
RuijieA(config-if-range)#ip pim sparse-mode
```

! Configurations on Ruijie B, Ruijie C and Ruijie D are the same as the preceding configurations. Note: PIM-SM must be enabled on the Loopback interface.

- Step 3: Configure the candidate BSR and candidate RP.

! On Ruijie B, configure Loopback 1 as the candidate BSR.

```
RuijieB(config)#ip pim bsr-candidate loopback 1 24
```

! On Ruijie B, create standard ACL to permit the address range of 225.0.0.0/8 to 226.0.0.0/8.

```
RuijieB(config)#ip access-list standard 1
RuijieB(config-std-nacl)#permit 225.0.0.0 0.255.255.255
RuijieB(config-std-nacl)#permit 226.0.0.0 0.255.255.255
RuijieB(config-std-nacl)#exit
```

! Configure Loopback 2 of Ruijie B as the candidate RP and associate the ACL.

```
RuijieB(config)#ip pim rp-candidate loopback 2 group-list 1
```

! On Ruijie C, create the standard ACL to permit the address range of 227.0.0.0/8 to 228.0.0.0/8.

```
RuijieC(config)#ip access-list standard 1
RuijieC(config-std-nacl)#permit 227.0.0.0 0.255.255.255
RuijieC(config-std-nacl)#permit 228.0.0.0 0.255.255.255
RuijieC(config-std-nacl)#exit
```

! On Ruijie C, configure Loopback 1 as the candidate RP and associate the ACL.

```
RuijieC(config)#ip pim rp-candidate loopback 1 group-list 1
```

- Step 4: Configure the range of valid BSR.

! On Ruijie C, create the standard ACL named "bsr_acl" to permit only packets with IP address being 10.1.1.1.

```
RuijieC(config)#ip access-list standard bsr_acl
RuijieC(config-std-nacl)#permit host 10.1.1.1
RuijieC(config-std-nacl)#exit
```

! On Ruijie C, configure the range of valid BSR and associate ACL "bsr_acl".

```
RuijieC(config)#ip pim accept-bsr list bsr_acl
```

- Step 5: Configure the elected BSR to limit the valid C-RP address range and the multicast group range served.

! On Ruijie B, create extended ACL named "rp_acl" to permit only packets with IP address being 10.1.3.1 and multicast address range being 227.0.0.0/8–228.0.0.0/8.

```
RuijieB(config)#ip access-list extended rp_acl
RuijieB(config-ext-nacl)#permit ip host 10.1.3.1 227.0.0.0 0.255.255.255
RuijieB(config-ext-nacl)#permit ip host 10.1.3.1 228.0.0.0 0.255.255.255
RuijieB(config-ext-nacl)#exit
```

! On Ruijie B, configure the elected BSR to limit the valid C_RP.

```
RuijieB(config)#ip pim accept-crp list rp_acl
```

Verification

- Step 1: Display device configurations.

! Configurations on Ruijie A.

```
RuijieA#show running-config
!
ip multicast-routing
```

```
!
interface GigabitEthernet 0/1

 network 192.168.8.0 0.0.0.255 area 0
```

- Step 2: Display RPs in the PIM-SM domain and the corresponding service multicast information (Ruijie A is used as an example).

```
RuijieA#show ip pim sparse-mode rp mapping
PIM Group-to-RP Mappings
Group(s): 225.0.0.0/8
  RP: 10.1.2.1
    Info source: 10.1.1.1, via bootstrap, priority 192
         Uptime: 01:15:16, expires: 00:02:00
Group(s): 226.0.0.0/8
  RP: 10.1.2.1
    Info source: 10.1.1.1, via bootstrap, priority 192
         Uptime: 01:15:16, expires: 00:02:00
Group(s): 227.0.0.0/8
  RP: 10.1.3.1
    Info source: 10.1.1.1, via bootstrap, priority 192
         Uptime: 01:13:30, expires: 00:02:00
Group(s): 228.0.0.0/8
  RP: 10.1.3.1
    Info source: 10.1.1.1, via bootstrap, priority 192
         Uptime: 01:13:30, expires: 00:02:00
```

By limiting the multicast address range served by each candidate RP, the multicast sources in the PIM-SM domain can be limited. The receiver cannot receive multicast data sent from a multicast source that is not within the address range served (225.0.0.0/8–228.0.0.0/8).

In addition, invalid BSMs (the source address is not 10.1.1.1) are directly dropped on the device configured with valid BSR limitation. If invalid C_RP advertisement messages are sent to BSR, after valid C_RP limitation is configured, BSR will filter invalid C_RP advertisement messages.

☑ This example applies to both layer-3 switches and routers. However, if you need to configure the switch port as a layer-3 port, you must run the **no switchport** command (not needed for routers).

Configuring IPv6 Multicast

Overview

Traditional IP transmission allows one host to transmit packets to a single host (unicast communication) or all hosts (broadcast communication). (Note that IPv6 no longer supports broadcast). Multicast, however, allows one host to send packets to some hosts (also known as group members).

The multicast application consists of the sender and the receiver. The sender can send multicast packets without needing to join a group. In contrast, the receiver can receive the multicast packets from the group only after joining the group.

Group members are dynamic. A host can join in or leave from a group at any time. Furthermore, there is no limit on the position and number of group members. A host can join in more than one group simultaneously if necessary. Consequently, the active status and the number of members of a group vary with time.

The device maintains the routing table for forwarding multicast packets by running IPv6 multicast routing protocol (for instance, PIM-SMv6) and learns the status of group members on the direct segment by running the MLDv1/v2 protocol. The device joins inan IPv6 multicast group by sending the MLD report message.

IPv6 multicast applies to one-to-many multimedia applications.

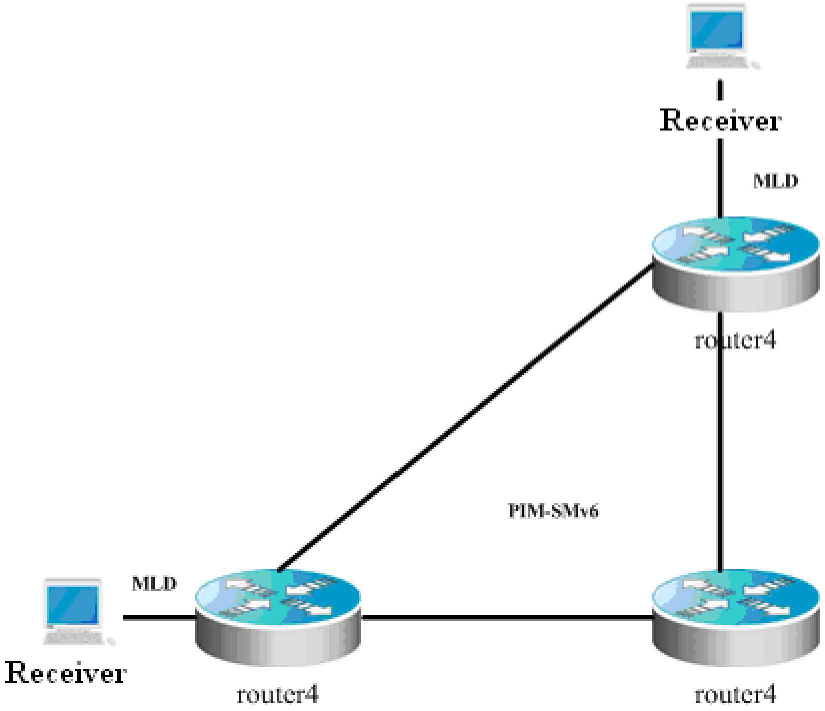
Implementation of IPv6 Multicast Routing

The IPv6 multicast routing protocol includes:

- MLD: Runs between the multicast deivce and the host to learn the relation of group members.
- PIM-SMv6: Runs between the multicast devices to enable multicast packet forwarding by setting up the multicast routing table.

The following figure illustrates the function of the multicast protocols used in IPv6 multicast packet forwarding:

Figure 1 Multicast protocols used in IPv6 multicast environment



MLD Overview

To enable IPv6 multicast, the multicast hosts and devices must support the MLD protocol, which maintains the multicast group member relation between the multicast device and the unicast device to determine the forwarding of multicast streams.

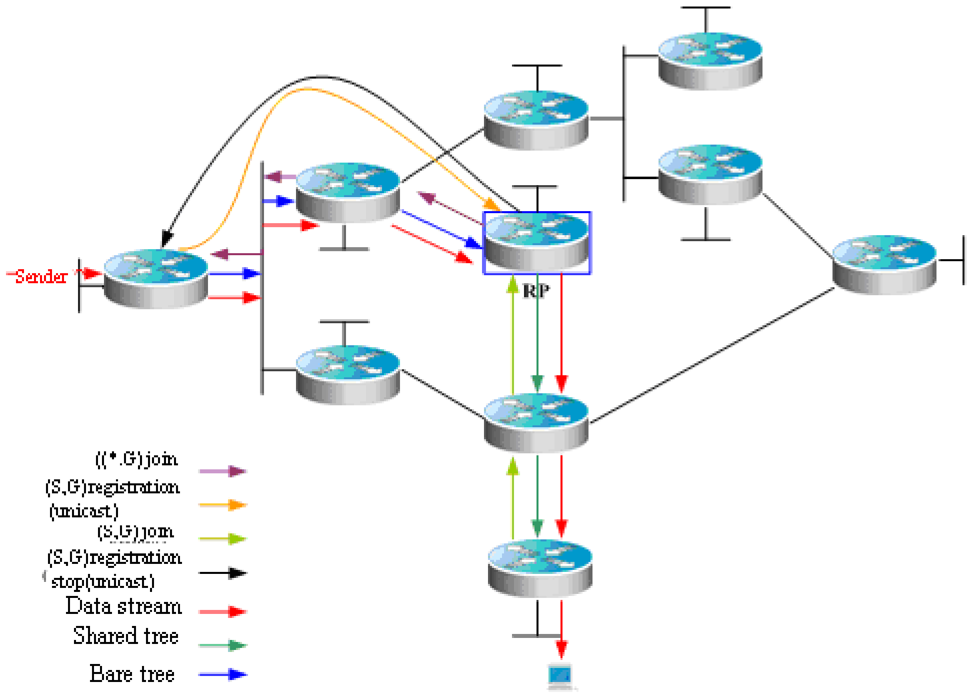
Based on the messages obtained from the MLD protocol, the device maintains a multicast group member table per interface, which is activated when at least one host on the interface is group member.

PIM-SMv6 Overview

PIM (Protocol Independent Multicast) is designed by IDMR (Inter-domain Multicast Routing) working group. As its name implied, PIM does not depend on a specific unicast routing protocol. It utilizes the unicast routing table established by various unicast routing protocols to enable the RPF check function instead of maintaining a separate multicast routing table for forwarding multicast packets. Compared with other multicast protocols, PIM overhead falls down at large extent for PIM does not need to receive and send multicast route update. The concept behind PIM design is that support and flexible transformation between SPT and the shared tree is enabled for higher multicast efficiency. There are two kinds of PIM modes-dense mode and sparse mode.

PIM-SMv6 (Protocol Independent Multicast Sparse Mode) is a multicast routing protocol in sparse mode. In the PIM-SMv6 domain, the device running PIM-SMv6 sends the Hello message at a specific interval to discover adjacent devices running PIM-SMv6 and be in charge of DR election. Here DR sends the “join/prune” message to its direct group members in the direction of the root node of the multicast distribution tree or sends the data from the direct multicast source to the multicast distribution tree.

Figure 2 PIM-SMv6 explicit join mechanism



PIM-SMv6 forwards multicast data packets by setting up a multicast distribution tree. There are two kinds of multicast distribution tree: the shared tree using G's RP as root and the shortest path tree using the multicast source as root. With the explicit join/prune mechanism, PIM-SMv6 sets up and maintains the multicast distribution tree. As shown in the above figure, when the DR receives a join report message from the receiver, it multicasts a (*.G) join message in the direction of G's RP hop by hop to join the shared tree. The source host sends multicast packets. Upon receiving the packets, its DR encapsulates them in the registration message, and then unicasts to the RP. Then the RP forwards the decapsulated packets to every group member along the shared tree. The RP sends the (S,G) join message to the first hop device along the source direction to join the shortest path tree of the source. In this way, the source sends packets along the shortest path tree to the RP without encapsulation. Upon receiving the first multicast data, the RP sends the registration stop message to the source DR to stop encapsulation. After that, the source sends multicast packets without registration and encapsulation alogn its shortest path tree to the RP, which then forwards the packets to every group members. When there is no necessary to receive multicast packets, the DR on the receiving side sends the multicast prune message to G's RP hop by hop to prune the shared tree.

RP election is also involved in PIM-SMv6. when there is one or more candidate BSRs configured in the PIM-SMv6 domain, some rule is applied to elect BSR. Candidate RPs are also configured in the PIM-SMv6 domain, which send the packets containing their addresses and serviceable multicast groups to BSRs in unicast form. BSRs generate bootstrap messages with a series of candidate RPs and the addresses of corresponding multicast groups periodically. These bootstrap messages are transmitted in the overall domain hop by hop. Devices will receive and save these bootstrap messages. Upon receiving the member relation report of a multicast group from the directly connected device, the DR will use a hash algorithm and map the multicast group address to a candidate RP who can serve this group if it has not the routing entry of this group. Then the DR will send the join/prune message in multicast form hop by hop along the way to the RP. On the other hand, upon receiving multicast packets from the directly connected device, the DR will use a hash algorithm and map the multicast group address to a candidate RP who can serve this group, and then encapsulate these multicast packets in the registration message and send it to the PR in unicast form.

The essential difference between PIM-SMv6 and PIM-DM is that PIM-SMv6 is based on explicit join mode and PIM-DM is based on flood/prune mode. For PIM-SMv6, the receiver sends a join message to the PR, but the device forwards the packets of a multicast group only on the interface joining this multicast group. PIM-SMv6 forwards multicast packets through the shared tree. Each multicast group has a rendezvous point. The multicast source sends packets to the RP along the shortest path, and then the RP sends the packets to every receiver along the shortest path. This process is similar to CBT. However, the core concept is not used in PIM-SMv6. One of the main advantages of PIM-SMv6 is that it not only receives multicast packets through the shared tree but also offers the shared tree-to-SPT transformation mechanism. This transformation consumes a lot number of resources, even though it reduces network delay and possible block on the RP. It is suitable for the environment where there are many pairs of multicast sources yet fewer networks.

PIM-SMv6 distributes multicast packets through the shared tree and SPT. Assume that other devices do not need to receive these multicast packets, unless otherwise specified. When a host joins a multicast group, the devices connecting to the host notify the root (or RP) through the PIM join message. This message is transferred among these devices in order to set up the structure of a shared tree. So, the RP records this transmission path and the registration message from the first hop device (DR) of the sending multicast source, and perfects the shared tree based on these two messages. Update of leaf messages is enabled on periodic query message. For the shared tree, the multicast source sends multicast packets to the RP so that all receivers can receive these multicast packets.

PIMv2 BSR distributes the group-to-RP message to all devices without the necessity for configuring RP for every device. The BSR distributes the mapping message through the hop-by-hop flooding BSR message. First of all, the BSR is elected among devices. This election procedure is similar to electing the root bridge in STP by priority. Every BSR device checks the BSR message, and only forwards the BSR messages with higher or equivalent priority (or higher IP address). The elected BSR sends the BSR message to the all-PIM-routers multicast group (ff02::d) with TTL 1. Upon receiving the BSR message, the adjacent PIMv2 device sents it out in multicast form and then reset TTL to 1. In this way, the BSR message is sent to all devices hop by hop. Since the BSR message includes the IP addresses of BSR devices, the candidate BSR can determine which device is the current BSR device. The candidate RP sends the candidate RP advertisement and alleges in which address ranges it can become RP. The BSR stores the advertisement message in its local candidate RP cache, and notifies all PIM devices of local candidate RPs periodically. Also in this way, the message is sent to all devices hop by hop.

RPF Rules

Multicast routing protocols depend on existing unicast route messages, MBGP routes or static multicast routes to create multicast routing entries. When creating multicast routing entries, multicast routing protocols run the Reverse Path Forwarding (RPF) check mechanism to guarantee that multicast packets are transmitted along proper paths while avoiding loops.

RPF check is on the basis of unicast routes, MBGP routes or static multicast route:

- The unicast routing table summarizes the shortest paths to each destination segments.
- The MBGP routing table directly offers multicast routes.
- The static multicast routing table lists the RPF route messages that user configures statically and manually.

The multicast routing protocol searches the unicast routing table, the MBGP routing table and the static multicast routing while run RPF check, as shown below:

1. First of all, select an optimal route from the unicast routing table, the MBGP routing table and the static multicast routing table, respectively.

a. Select an optimal route from the unicast routing table for RPF check:

- Use the IP address of the packet source as the destination address to search the unicast routing table and select an optimal unicast route.
- If the unicast route has only one next hop, check whether multicast is enabled on the egress of the next hop or not.
  - If not, the unicast route is not suitable for RPF check.
  - If so, the unicast route is suitable for RPF check and the egress serves as the RPF interface.
- If the unicast route has more than one next hop, traverse all next hops and check whether multicast is enabled on the egress of one next hop.
  - If not, traverse the next hop.
  - If so, the unicast route is suitable for RPF check and the egress serves as the RPF interface.
  - If no multicast is enabled on the egress after traversing all next hops, there is no unicast route suitable for RPF check.
- If no optical route exists, there is no unicast route suitable for RPF check.

2. Select an optimal route from the MBGP routing table for RPF check:

- Use the IP address of the packet source as the destination address to search the MBGP routing table and select an optimal MBGP route.
- The MBGP route has only one next hop. Check whether multicast is enabled on the egress of the next hop or not.
  - If not, the MBGP route is not suitable for RPF check.
  - If so, the MBGP route is suitable for RPF check.
- If no optical route exists, there is no MBGP route suitable for RPF check.

3. Select an optimal route from the static multicast routing table for RPF check:

- Use the IP address of the packet source as the destination address to search the static multicast routing table and select an optimal static multicast route.
- If the static multicast route has only one next hop, check whether multicast is enabled on the egress of the next hop or not.
  - If not, the static multicast route is not suitable for RPF check.
  - If so, further check whether there is a unicast route available for RPF check.
    - If the next hop does not associate with the unicast protocol number, the static multicast route is suitable for RPF check.
    - If there is no unicast route available for RPF check, the static multicast route is suitable for RPF check.
    - If there is a unicast route available for RPF check, but the unicast protocol number is inconsistent with the one associated with the next hop of the static multicast route, the static multicast route is not suitable for RPF check.

    - ➢ If there is a unicast route available for RPF check, and the unicast protocol number is consistent with the one associated with the next hop of the static multicast route, the static multicast route is suitable for RPF check.

- ◆ If the static multicast route has more than one next hop, traverse all next hops and check whether multicast is enabled on the egress of one next hop.

  - ■ If not, traverse the next hop.
  - ■ If so, further check whether there is a unicast route available for RPF check.
    - ➢ If the next hop does not associate with the unicast protocol number, the static multicast route is suitable for RPF check.
    - ➢ If there is no unicast route available for RPF check, the static multicast route is suitable for RPF check.
    - ➢ If there is a unicast route available for RPF check, but the unicast protocol number is inconsistent with the one associated with the next hop of the static multicast route, traverse the next hop.
    - ➢ If there is a unicast route available for RPF check, and the unicast protocol number is consistent with the one associated with the next hop of the static multicast route, the static multicast route is suitable for RPF check.
    - ➢ If no multicast is enabled on the egress after traversing all next hops, there is no static multicast route suitable for RPF check.

- ◆ If no optical route exists, there is no static multicast route suitable for RPF check.

4. Then, select one from these three optimal routes for RPF check.

   a. If the longest match routing rule is configured, select the longest match route; if these three routes are of the same mask, select the one of the highest priority; if they are of the same priority, select the one in the order of static multicast route, MBGP route and unicast route.

   b. If the longest match routing rule is not configured, select the one of the highest priority; if they are of the same priority, select the one in the order of static multicast route, MBGP route and unicast route.

Caution

The effectiveness of MBGP routes recurs on unicast routes rather than distance. The implementation of current MBGP protocols does not support equal-cost routes.

Caution

The effectiveness of static multicast routes recurs on unicast routes rather than distance.

Caution

If the static unicast route is selected as RPF route, the route must be configured with the next hop IP address. PIM protocol will select RPF neighbors based on this next hop IP address. If the static unicast route is not configured with the next hop IP address, PIM protocol can get RPF neighbors.

Basic IPv6 Multicast Route Configuration

Basic IPv6 multicast route configuration includes:

- Enable IPv6 multicast route forwarding (mandatory)
- Enable IPv6 multicast route protocol (mandatory)

Enabling IPv6 Multicast Route Forwarding

This function enables software to forward multicast packets.

To enable IPv6 multicast route forwarding, run the following command in the global configuration mode:

Command	Function
Ruijie(config)# **ipv6 multicast-routing**	Enable IPv6 multicast routing.

Enabling IPv6 Multicast Route Protocol

To enable IPv6 PIM-SM multicast route protocol, run the following command in the interface configuration mode:

Command	Function
Ruijie(config-if)# **ipv6 pim sparse-mode**	Enable PIM-SM. This command should run on Layer 3 interfaces.

The following example configures PIM-SM on GigabitEthernet 0/3.

```
Ruijie(config)# ipv6 multicast-routing
Ruijie(config)# interface  gigabitEthernet 0/3
Ruijie(config-if)# ipv6 address 3333::3333/64
Ruijie(config-if)# ipv6 pim sparse-mode
```

Note

When IPv6 multicast route is enabled globally, enabling PIM-SMv6 on an interface will enable MLD on the corresponding interface. Only one kind of multicast routing protocol is allowed to run on an interface.

Caution

After enabling the layer3 multicasting on the Private VLAN and Super VLAN, if the multicast source exists in the Sub-VLAN, one more route entry is needed to be duplicated and the ingress is the Sub-VLAN in which the multicast streams enter as the ingress validity check is required when multicast forwarding, resulting in occupying one more multicast hardware entry with 1 less multicast capacity.

Caution

S5760 supports running RPF check on SVI interface, not on routed interface. Consequently, if the routed interface becomes RPF interface, multicast streams from a non-RPF interface can also be forwarded according to route entries.

Enabling MLD

Enabling IPv6 multicast route forwarding and IPv6 multicast route protocol will enable MLD.

Advanced IPv6 Multicast Core Function Configuration

Advanced IPv6 multicast core function configuration includes:

- Limit the number of the routes that are allowed to join the IPv6 multicast routing table (optional)
- Set the IPv6 multicast border for the specific IPv6 group range (optional)
- Configure static IPv6 multicast route (optional)
- IPV6 multicast route monitoring and maintenance (optional)

Limiting the Number of the Routes That are Allowed to Join the IPv6 Multicast Routing Table

In the global configuration mode, use the **ipv6 multicast route-limit** *limit* [*threshold*] command to limit the number of the routes that are allowed to join the multicast routing table. Use the no form of this command to restore it to the default value, or 1024.

Command	Function
Ruijie(config-if)# **ipv6 multicast route-limit** *limit* [*threshold*]	Limits the number of the routes that are allowed to join the multicast routing table. *limit*: Number of the routes that are allowed to join the multicast routing table in the range 1 to 2147483647, 1024 by default. Threshold: (optional) Number of multicast routes triggering alarm, 2147483647 by default. Note: Given the hardware resource for different models of devices, the routes exceeding the hardware entry threshold need to be forwarded through software, and resulting in decrease in performance.

Setting IPv6 Multicast Border for Specific IPv6 Group Range

In interface configuration mode, use the **ipv6 multicast boundary** *access-list-name* command to set IPv6 multicast border for specific IPv6 group range. Use no form of this command to restore it to the default value, namely no multicast border.

Command	Function
Ruijie(config-if)# **ipv6 multicast boundary** *access-list-name* [**in | out**]	Set IPv6 multicast border for specific IPv6 group range. ACL can be used to specify the IPv6 group range. Note: The ACL associated with this command supports only matching destination IP address, not multicast IP address and source IP address.

This command filters MLD and PIM-SMv6 protocol packets correlating with the specific IPv6 group range. Multicast streams will income and outgoing through the multicast border interface.

Configuring Static IPv6 Multicast Route

IPv6 static multicast route enables multicast packet forwarding through a path different from IPv6 unicast path. RPF check is always performed while forwarding. The real interface receiving packets is the expected one, namely the next hop interface of IPv6 unicast route used to transmit to the sender. The check is reasonable when IPv6 unicast topology is in accord with IPv6 multicast topology. In some cases, however, it is better to make difference between IPv6 unicast path and IPv6 multicast path.

Static multicast route enables devices to execute RPF check according to configurations rather than the IPv6 unicast routing table. Consequently, tunnel technology is used for IPv6 multicast packet forwarding, not IPv6 unicast packet forwarding. IPv6 static multicast route is stored locally rather than be advertised or forwarded.

In the global configuration mode, use the following command to configure IPv6 static multicast route.

Command	Function
Ruijie(config)# **ipv6 mroute** *ipv6-prefix/prefix-length* [**bgp | isis | ospfv3 | ripng | static**]{ *ipv6-prefix* | *interface-type interface-number*} [*distance*]	Configures IPv6 static multicast route. Routing protocol can be set at the same time. Distance: <1-255>

Note

To set the egress of the static multicast route not to be the IPv6 address of next hop, the egress must be an point-to-point interface.

Configuring Longest-match-based Routing

The static multicast route, MBGP route and unicast route used for RPF check are elected from the static multicast routing table, MBGP routing table and unicast routing by RPF rules, respectively.

By default, the one of highest priority is selected from these three routes. If they are of the same priority, select one in the order of static multicast route, MBGP route and unicast route.

Use this command to select the route matching the longest mask from these three routes. If they are of the same priority level, the order of choice is: multicast static route, MBGP route and unicast route.

Command	Function
Ruijie(config)# **ipv6 multicast rpf longest-match**	Selects the route matching the longest mask.

Multicast Route Monitoring and Maintenance

In the privileged EXEC configuration mode, run the following command to show the information of IPv6 multicast forwarding table.

Command	Function
show ipv6 mroute [*v6group-address*] [*v6source-address*] [**dense**]|[**sparse**] } {[**summary**]|[**count**]}	Show the information of IPv6 multicast forwarding table.

In the privileged EXEC configuration mode, run the following command to delete the IPv6 multicast forwarding table.

Command	Function
clear ipv6 mroute {* | *v6group-address* [*v6source -address*]}	Delete the IPv6 multicast forwarding table.

In the privileged EXEC configuration mode, run the following command to reset the statics of the IPv6 multicast forwarding table.

Command	Function
clear ipv6 mroute statistics {* | *v6group-address* [*v6source-address*]}	Reset the statics of the IPv6 multicast forwarding table.

In the privileged EXEC configuration mode, run the following command to show the RPF information of the specific IPv6 source address.

Command	Function
show ipv6 rpf *v6source-address*	Show the RPF information of the specific IPv6 source address.

In the privileged EXEC configuration mode, run the following command to show the information of static IPv6 multicast route.

Command	Function
show ipv6 mroute static	Show the information of static IPv6 multicast route.

In the privileged EXEC configuration mode, run the following command to show the information of IPv6 multicast interface.

Command	Function

show ipv6 mvif [*interface-type interface-number*]	Show the information of IPv6 multicast interface.

In the privileged EXEC configuration mode, run the following command to show the IPv6 Layer 3 multicast forwarding table.

Command	Function
show ipv6 mrf mfc	Show the IPv6 Layer 3 multicast forwarding table.

In the privileged EXEC configuration mode, run the following command to show the operation of the core of IPv6 multicast.

Command	Function
debug nsm mcast6 all	Show the operation of the core of IPv6 multicast.

In the privileged EXEC configuration mode, run the following command to show the communication between the core of IPv6 multicast and multicast protocols.

Command	Function
debug nsm mcast6 fib-msg	Show the communication between the core of IPv6 multicast and multicast protocols.

In the privileged EXEC configuration mode, run the following command to show the operation on the interface of the core of IPv6 multicast.

Command	Function
debug nsm mcast6 mif	Show the operation on the interface of the core of IPv6 multicast.

In the privileged EXEC configuration mode, run the following command to show the operation of interface and statistics of the core of IPv6 multicast.

Command	Function
debug nsm mcast6 stats	Show the operation of interface and statistics of the core of IPv6 multicast.

In the privileged EXEC configuration mode, run the following command to show the packet forwarding on Layer 3 of IPv6 multicast.

Command	Function
debug ipv6 mrf forwarding	Show the packet forwarding on Layer 3 of IPv6 multicast.

In the privileged EXEC configuration mode, run the following command to show the operation of forwarding entries on Layer 3 of IPv6 multicast.

Command	Function
debug ipv6 mrf mfc	Show the operation of forwarding entries on Layer 3 of IPv6 multicast.

In the privileged EXEC configuration mode, run the following command to show the operation of forwarding events on Layer 3 of IPv6 multicast.

Command	Function
debug ipv6 mrf event	Show the operation of forwarding events on Layer 3 of IPv6 multicast.

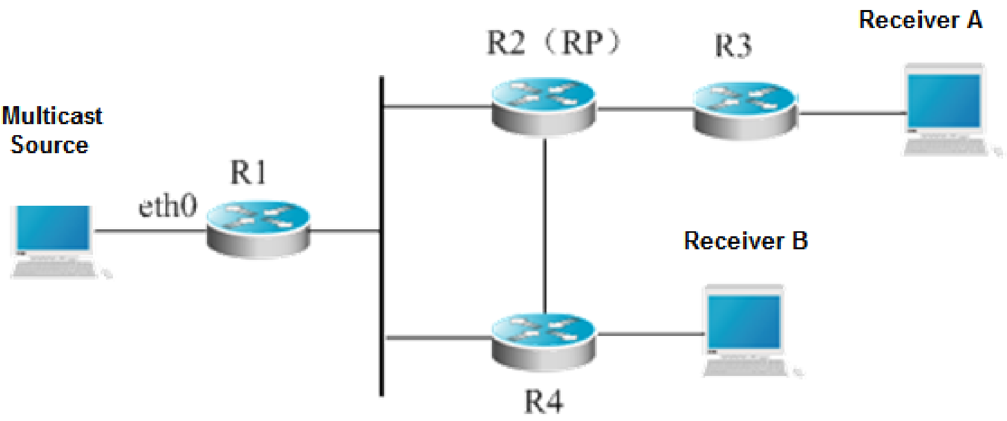
Multicast Route Configuration Example

PIM-SMv6 Configuration Example

Configuration Requirements

Figure 3 is network topology. R1 and the multicast source are located in one network. R2 is set to be RP. R3 and the Receiver A are located in the same network. R4 and the Receiver B are located in the same network. Assume that devices and hosts are connected properly, IPv6 is enabled on every interface and IPv6 unicast is enabled on every device.

Figure 3 Network topology of PIM-SMv6 configuration example



Device Configuration

Step1: Enable IPv6 multicast route.

Enable IPv6 multicast route on R1. The configurations on R2, R3 and R4 are similar.

```
Ruijie# configure terminal
Ruijie(config)# ipv6 multicast-routing
```

Step 2: Enable PIM-SMv6 on the interface.

Enable PIM-SMv6 on R1’s Gi 0/1. The configurations on R2, R3 and R4 are similar.

```
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if)# ipv6 pim sparse-mode
Ruijie(config-if)# end
```

Step 3: Configure the candidate BSR and the candidate RP.

Set R2’s loopback1 to be C-BSR and C-RP

```
Ruijie(config)# interface loopback 1
Ruijie(config-if)# ipv6 address 2008:1::1/64
Ruijie(config-if)# ipv6 pim sparse-mode
Ruijie(config-if)# exit
Ruijie(config)# ipv6 pim bsr-candidate loopback 1
Ruijie(config)# ipv6 pim rp-candidate loopback 1
Ruijie(config-if)# end
```

Add the receiver into the multicast group. After the multicast source sends multicast streams, you can run **show** commands to monitor operation.

Note

When you enable PIM-SMV6, MLD automatically runs on every interface, respectively.

Configuring IGMP

IGMP Overview

IP multicast refers to a network technology that allows one or more sender (multicast source) to send one packet to more than one receiver simultaneously. The multicast source sends packets to a specific multicast group and only hosts joining the group can receive the packets. Multicast can save network bandwidth greatly because there is only a single packet transmitted on any link of the network, no matter how many receivers are deployed.

Multicast uses Class-D IP addresses specified by the Internet Assigned Numbers Authority (IANA). The four high-order bits of Class-D IP addresses are binary 1110. So, the range of multicast address is from 224.0.0.0 to 239.255.255.255. However, not all addresses in this range can be assigned to users. Some addresses are reserved for protocols or other use. For instance, the address 224.0.0.1 is assigned to all multicast hosts and 224.0.0.2 is assigned to all multicast routers.

Any hosts, no matter whether they are multicast group members or not, can be multicast sources. However, only multicast group members can receive multicast frames. A multicast group member is able to dynamically join or leave the group. Forwarding of multicast frames in the network is implemented by multicast routers running multicast routing protocols.

To enable IP multicast, hosts and routers must support the Internet Group Management Protocol (IGMP). This protocol is used by hosts to report their group memberships to multicast routers on the directly-connected network, allowing the multicast routers to determine how to forward multicast traffic. By using the information obtained from IGMP, multicast routers create an interface-based multicast group member list. The list is activated only when at least one host on an interface is a member of the group.

IGMPv1, IGMPv2 and IGMPv3 are currently supported. On the basis of IGMPv1, IGMPv2 adds a leave message for a host to actively request to leave a multicast group. IGMP behaviors includes behaviors of hosts and devices.

IGMPv1

There are only two types of IGMP messages defined in IGMPv1:

- Membership query
- Membership report

A host sends a membership report to indicate that it is interest in joining a group, and the router sends membership queries periodically to ensure that the group has at least one host. When there is no hosts in that group, the device will delete it.

IGMPv2

In IGMPv2, there are only four types of IGMP messages:

- Membership query
- Version 1 membership report
- Version 2 membership report
- Leave group

IGMPv2 is basically the same as IGMPv1, except that IGMPv2 creates a Leave group message for hosts. For IGMPv2, hosts report leave messages to routers which then send queries to check whether there is a host in the multicast group. This makes joining and leaving a group more efficient.

In the multicast network running IGMP, a multicast router is dedicated for sending IGMP query messages. This router is called a querier which is selected through an election mechanism. At first, all routers are queriers. If a router receives a query message from another router with a lower IP address, it becomes a non-querier. Consequently, there is only one querier which has the lowest IP address among all multicast routers on the network.

If a querier is invalid, new querier will be elected. . Non-queriers keep a timer for Other Querier Present Interval. Every time when a router receives a membership query packet, it resets the timer. If the timer expires, the router starts to send query messages and selects new querier again.

Queriers must periodically send membership queries to ensure that other routers on the network know that the querier still works. For this purpose, the querier maintains one query interval timer. When it sends membership query messages, this timer will be reset. When the interval timer times out, the querier sends another membership query.

When a new router appers, it sends a series of general query messages to solicit membership information. The number of general query packets depends on the Startup Query Count configured on the router. The initial general query interval is defined by the Startup Query Interval.

When a querier receives a leave group message from a host, it must send a group-specific membership query to see whether the host is the last one to leave the group. Before the querier stops forwarding packets to the group, it sends a series of such packets, the number of which is equal to the Last Member Query Count. The querier sends multiple group-specific membership queries to ensure that there is no member in the group. Such a query is sent every other the Last Member Query Interval seconds. When no response is received, the querier stops forwarding multicast packets to the group on the specified interface.

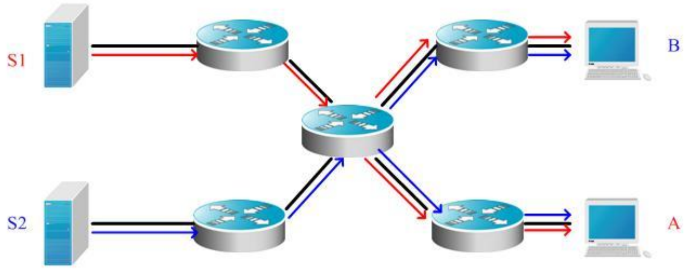
IGMPv3

Both IGMPv1 and IGMPv2 have the following defects:

- Lack of efficient measures to control multicast sources
- Difficult to establish multicast paths due to ignorance of multicast source locations.
- Difficult to find a unique multicast address. It is possible that multicast groups are using the same multicast address.

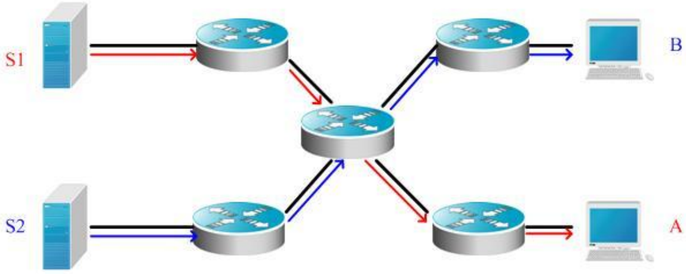
On the basis of IGMPv1 and IGMPv2, IGMPv3 provides an additional source filtering multicast function. In IGMPv1 or IGMPv2, hosts determines whether to join a group by group address and, once it joins the group, it receives multicast traffic forwarded from any source to that group address. In IGMPv3, hosts are enabled to report the multicast group they desire to join in and the multicast source from which they expect to receive traffic. A host specifies sources from which they want to receive multicast traffic through an INCLUDE list or an EXCLUDE list. Besides, IGMPv3 saves bandwidth by preventing unnecessary, illegal multicast data flows from occupying network bandwidth. It is particularly useful in the case where multiple multicast sources share one multicast address. IGMPv1 and IGMPv2 can also implement "source address filtering" in some sense, which, however, is performed on hosts receiving multicast traffic. As shown in the following diagram, two multicast sources (S1 and S2) send out traffic directed to the same multicast group address (G). This multicast traffic from S1 and S2 will be sent to all hosts receiving traffic from G. If host A only wants to receive multicast traffic from S1, it has to filter out traffic from S2 by running approriate client software.

Figure 9 Multicast traffic forwarded without source filtering



If multicast routers on the network support IGMPv3, host A wants to receive traffic from S1 only, it sends out an IGMPv3 packet in the form of “join G include S1”. host B wants to receive traffic from S2 only, it sends out an IGMPv3 packet in the form of “ join G include S2”. In this way, the traffic is forwarded as shown in Figure 2. This saves bandwidth.

Figure 10 Multicast traffic forwarded with source filtering



Based on IGMPv2, IGMPv3 adds the following two kinds of messages:

- Membership query
- Version 3 membership report

There are three types of membership query:

- General Query: used to learn information of all multicast members on an interface.
- Group-Specific Query: used to learn information of members of a specific group on an interface.
- Group-and-Source-Specific Query: a new type specified in IGMPv3 used to learn whether there is a member on an interface wants to receive group-specific multicast traffic from sources in the specified source list.

Membership Report in IGMPv3 is different from that defined in IGMPv2. The IGMPv3 membership reports are always sent with an destination address of 224.0.0.22. Besides, an IGMPv3 membership report can contain information of multiple groups.

IGMPv3 can identify membership report messages of IGMPv1 and IGMPv2 and leave group messges of IGMPv2.

IGMPv3 works the same way as IGMPv2. It is backward compatible with IGMPv1 and IGMPv2.

Caution

At most 1017 sources are allowed to forward traffic to a specific multicast group on Layer-3 interfaces of Ruijie’s switching routers. You can configure unicasting traffic from a specific allowed source. At most 1017 sources can be filtered from forwarding traffic to a specific multicast group on Layer-3 interfaces of Ruijie’s switching routers. You cannot configure unicasting traffic from the filtered sources.

IGMP Configuration Tasks

This section describes IGMP configuration tasks. Only some tasks are mandatory, and other tasks are optional depending on network requirements.

Caution All commands described in this section must be configured on layer-3 interfaces.

Default Configuration

The following table describes the default configuration of IGMP.

Feature	Default Setting
IGMP version	IGMPv2 is supported on all interfaces.
Query response interval	10 seconds
Query interval	125 seconds
Access to multicast group	All multicast groups are permitted.
Other querier present interval	255 seconds
Robustness variable	2
Last member query interval	1 second
Last member query count	2
IGMP	Disabled

Enabling IGMP

Use the following commands to enable IGMP in interface configuration mode.

Command	Function
Ruijie (config-if) # **ip pim** { **sparse-mode** | **dense-mode** }	Enables IGMP.
Ruijie (config-if) # **no ip pim** { **sparse-mode** | **dense-mode** }	Disables IGMP.

Configuring IGMP Version

Use the following commands to configure the IGMP version in interface configuration mode.

Command	Function
Ruijie (config-if) # **ip igmp version** { 1 | *2* | 3 }	Configures the IGMP version, version 2 by default.
Ruijie (config-if) # **no ip igmp version**	Restores to the default value.

Configuring Last Member Query Interval

After receiving a leave message from a multicast group, the querier sends a group-specific membership query to verify whether there is any member in the group. If no report is received during the last member query interval, the querier will regard the host that is leaving the group is the last member of that group, and then delete the information of the group. The default value of the last member query interval is 10, in units of 1/10 second. .

Use the following commands to configure the last member query interval in interface configuration mode.

Command	Function
Ruijie (config-if) # **ip igmp last-member-query-interval** *interval*	Configures the last member query interval. The *interval* specifies the range from 1 to 255. The unit is 1/10 second.
Ruijie (config-if) # **no ip igmp last-member-query-interval**	Restores to the default value.

Configuring Last Member Query Count

To prevent loss of group-specific membership query packets, it is required to send the packets for several times to ensure reliability. Therefore, you are advised to configure the last member query count to greater than 1.

Use the following commands to configure the last member query count in interface configuration mode.

Command	Function
Ruijie (config-if) # **ip igmp last-member-query-count** *count*	Configures the last member query count. The range is from 2 to 7. The default is 2.
Ruijie (config-if) # **no ip igmp last-member-query-count**	Restores to the default value.

Configuring General Query Interval

A querier sends general query messages at intervals to all hosts to verify the current membership. The destination address of the messages is the all-hosts group address, 224.0.0.1, Time To Live (TTL) is 1 and the default value is 125 seconds.

Use the following commands to configure the general query interval in interface configuration mode.

Command	Function
Ruijie (config-if) # **ip igmp query-interval** *seconds*	Configures the general query interval in seconds. The range is from 1 to 18000 seconds. The default is 125 seconds.
Ruijie (config-if) # **no ip igmp query-interval**	Restores to the default value.

Configuring the Max Response Time

The max response time is specified in the membership query message sent by the querier. Shortening this response time can allow the querier to know change of members earlier. However, it can also result in increase of the member reports diffusing in the network. Network administrators can consider a tradeoff between the two factors and then decide a proper value for the period, 10 seconds by default. Another consideration in configuring the response time is that it must be shorter than the query interval.

Use the following commands to configure the max response time in interface configuration mode.

Command	Function
Ruijie (config-if) # **ip igmp query-max-response-time** *seconds*	Configures the max response time in seconds. The range is from 1 to 25 seconds. The default value is 10 seconds.
Ruijie (config-if) # **no ip igmp query-max-response-time**	Restores to the default value.

Configuring Other Querier Present Interval

Once the timer times out, the querier considers that there is no other queriers on the network. This is helpful for the election of querier. You can reduce the value of this timer in the circumstance where the querier changes frequently to speed up response.

Use the following commands to configure the other querier present interval in interface configuration mode.

Command	Function
Ruijie (config-if) # **ip igmp query-timeout** *seconds*	Configures other querier present interval in seconds. The range is from 60 to 300 seconds. The default is 255 seconds.
Ruijie (config-if) # **no ip igmp query-timeout**	Restores to the default value.

Configuring Access Control to Multicast Groups

By default, hosts on an interface can join any multicast group. You can limit the range of multicast groups that hosts can join by configuring a standard IP ACL and applying it to the specific interface.

Use the following commands to create a standard access control list.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie (config) # **access-list** *access-list-num* **permit** *A.B.C.D A.B.C.D*	Defines an ACL.
Ruijie (config)# **interface** *interface-id*	Enters interface configuration mode.
Ruijie (config-if) # **ip igmp access-group** *access-list-name*	Applies the access control list to an interface. The *access-list-name* specifies the range of group addresses that hosts on the interface can join.
Ruijie (config-if) # **no ip igmp access-group**	Deletes the access control list.

Caution

Suppose this command is associated with extended ACL. When the received IGMP report message is (S1,S2,S3…Sn,G), this command has to use an ACL entry to match the (0, G) message. Therefore you must explicitly configure an extended ACL with the (0,G) entry so that the (S1,S2,S3…Sn,G) message can be filtered.

Configuring Immediate-leave Group

In IGMPv2, you can execute this command to r reduce the leave latency of multicast group members . After this command is enabled, a host leaves a multicast group as long as it sends a leave message, without waiting the querier to send a group-specific query message. This command is available only when there is only one receiver host on an interface.

Use the following commands to configure an immdiate-leave group list. .

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.

Command	Function
Ruijie (config) # **access-list** *access-list-num* **permit** *A.B.C.D A.B.C.D*	Defines an ACL.
Ruijie (config)# **interface** *interface-id*	Enters interface configuration mode.
Ruijie(config-if)# **ip igmp immediate-leave group-list** *access-list-name*	Creates an immediate-leave group list.
Ruijie (config-if) # **end**	Enters privileged EXEC mode.

Configuring Join-Group

This command configures a routeras a member of a multicast group. Use the **no** form of this command to remove the router from the multicast group.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie (config)# **interface** *interface-id*	Enters interface configuration mode.
Ruijie(config-if)# **ip igmp join-group** *group-address*	Configures a router to join a multicast group.
Ruijie (config-if) # **end**	Enters privileged EXEC mode.

Use the **no ip igmp join-group** *group-address* command to remove the router from the multicast group.

Configuring Static-Group

This command configures a statically joined group. Use the **no** form of this command to remove the statically joined multicast group.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie (config)# **interface** *interface-id*	Enters interface configuration mode.
Ruijie(config-if)# **ip igmp static-group** *group-address*	Configures a statically joined group.
Ruijie (config-if) # **end**	Enters privileged EXEC mode.

Use the **no ip igmp static-group** *group-address* command to remove the statically joined group. .

Configuring Limit on the Number of IGMP Group Members

Use this command to limit the number of IGMP group members globally. Membership messages that exceed the limit will not be cached or forwarded.

You can configure this command on each interface in interface or global configuration mode.

Command	Function
Ruijie(config) # **ip igmp limit** *number*	Limits the number of IGMP members in global configuration mode. The range depends on specific products.
Ruijie(config-if) # **ip igmp limit** *number*	Limits the number of IGMP members in interface

Command	Function
	configuration mode. . The range depends on specific products. By default, it is 1024.

Use the **no ip igmp limit** command to restore the default configuration.

Configuring IGMP PROXY-SERVICE

This command enables services on all the downlink mroute-proxy interfaces. After you configure this command on an interface, the interface becomes the uplink interface of the corresponding mroute-proxy service. Moreover, it associates all its downlink interfaces and maintains their propagated multicast group information.

Up to 32 proxy services can be configured using this command. The interface number with the IGMP Proxy enabled is limited by the multicast interface number supported by the device. Upon the receipt of query message, the proxy-service interface responds accordingly based on the member information that it maintains from the interfaces with mroute-proxy configured. Consequently, configuring proxy-service on an interface equals to performing host behaviors rather than router behaviors on the interface. Use the following command to configure IGMP proxy-service in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip igmp proxy-service**	Configures proxy-service on the interface.

Configuring IGMP MROUTE-PROXY

This command lets an interface to forward messages to its corresponding uplink interface. The uplink interface can forward IGMP messages received from its members only when it is set to a proxy-service interface.

Use the following command to configure IGMP mroute-proxy in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip igmp mroute-proxy** *interfacename*	Configures mroute-proxy on the interface. *interfacename* specifies the name of the uplink interface.

Enabling IGMP SSM-MAP

This command forcibly appends the relevant multicast source messages to the dynamically learned multicast group messages. It is usually used in conjunction with the **ip igmp ssm-map static** command.

Use the following command to enable IGMP SSM-MAP in global configuration mode.

Command	Function
Ruijie(config)# **ip igmp** [**vrf** *vrf-name*] **ssm-map enable**	Enables the SSM-MAP function under specified VRF.

Configuring IGMP SSM-MAP STATIC

This command is used in conjunction with the **ip igmp ssm-map enable** command. After this command is configured, the received messages whose version is earlier than version 3 will be mapped to the corresponding multicast source record.

Use the following command to configure IGMP SSM-MAP static in global configuration mode.

Command	Function

Command	Function
Ruijie(config)# **ip igmp** [**vrf** *vrf-name*] **ssm-map static** *access-list-num A.B.C.D*	Maps all groups matched ACL *access-list-num* under specified VRF to source address *A.B.C.D*.

Monitoring and Maintaining IGMP and Membership Information

Clearing the Dynamic Group Member Messages Obtained from the Response Message in the IGMP Cache

Use the following command to clear the dynamic group member messages obtained from the response message in the IGMP cache in privileged EXEC mode.

Command	Function
Ruijie# **clear ip igmp** [**vrf** *vrf-name*] **group**	Clears the dynamic group member messages obtained from the response message in the IGMP cache in the specified VRF.

Clearing All the Information on the Interface in IGMP Cache

Use the following command to clear all the information on the interface in IGMP cache in privileged EXEC mode.

Command	Function
Ruijie# **clear ip igmp** [**vrf** *vrf-name*] **interface** *interface-type interface-number*	Clears all the information on the interface in IGMP cache in the specified VRF.

Displaying the Status of All IGMP Group Members in the Directly-Connected Subnet

Use the following command to show the status of all IGMP group members in the directly-connected subnet in privileged EXEC mode.

Command	Function
Ruijie# **show ip igmp** [**vrf** *vrf-name*] **groups**	Shows the status of all IGMP groups under the specified VRF in the directly-connected subnet.
Ruijie# **show ip igmp** [**vrf** *vrf-name*] **groups detail**	Shows the details of all IGMP groups under the specified VRF in the directly-connected subnet.
Ruijie# **show ip igmp** [**vrf** *vrf-name*] **groups** *A.B.C.D*	Shows the status of the specified group under the specified VRF in the directly-connected subnet.
Ruijie# **show ip igmp** [**vrf** *vrf-name*] **groups** *A.B.C.D* **detail**	Shows the details of the specified group under the specified VRF in the directly-connected subnet.
Ruijie# **show ip igmp** [**vrf** *vrf-name*] **interface** *interface-type interface-number*	Shows the information of the specified interface under the specified VRF in the directly-connected subnet.
Ruijie# **show ip igmp** [**vrf** *vrf-name*] **groups** *interface-type interface-number* **detail**	Shows the details of all the groups of the specified interface under the specified VRF in the directly-connected subnet.
Ruijie# **show ip igmp** [**vrf** *vrf-name*] **groups** *interface-type interface-number A.B.C.D*	Shows the information of the specific group of the specified interface under the specified VRF in the directly-connected subnet.

Command	Function
Ruijie# **show ip igmp** [**vrf** *vrf-name*] **groups** *interface-type interface-number A.B.C.D* **detail**	Shows the details of the specific group of the specified interface under the specified VRF in the directly-connected subnet.

Displaying IGMP Interface Configuration

Use the following commands to show the IGMP interface configuration in privileged EXEC mode.

Command	Function
Ruijie# **show ip igmp** [**vrf** *vrf-name*] **interface** [*interface-type interface-number*]	Shows the configuration information of the IGMP interface in the specified VRF.
Ruijie# **show ip igmp** [**vrf** *vrf-name*] **interface**	Shows the configuration information of all the IGMP interfaces in the specified VRF.

Displaying IGMP SSM-MAP Configuration

Use the following commands to show the IGMP SSM-MAP configuration in privileged EXEC mode.

Command	Function
Ruijie# **show ip igmp** [**vrf** *vrf-name*] **ssm-mapping**	Shows the configuration information of IGMP SSM-MAP under the specified VRF.
Ruijie# **show ip igmp ssm-mapping** *A.B.C.D*	Shows the mapping information from IGMP SSM-MAP under the specified VRF to the multicast group *A.B.C.D*.

Displaying the Status of the IGMP Debugging Switch

Use the following command to show the status of the IGMP debugging switch in privileged EXEC mode.

Command	Function
Ruijie# **show debugging**	Shows the status of the IGMP debugging switch.

Turning on IGMP Debugging Switches

Use the following commands to turn on IGMP debugging switches to observe IGMP behaviors in privileged EXEC mode.

Command	Function
Ruijie# **debug ip igmp** [**vrf** *vrf-name*] **all**	Turns on all IGMP debugging switches in the specified VRF.
Ruijie# **debug ip igmp** [**vrf** *vrf-name*] **decode**	Turns on decode debugging switch in the specified VRF.
Ruijie# **debug ip igmp** [**vrf** *vrf-name*] **encode**	Turns on encode debugging switch in the specified VRF.
Ruijie# **debug ip igmp** [**vrf** *vrf-name*] **events**	Turns on event debugging switch in the specified VRF.
Ruijie# **debug ip igmp** [**vrf** *vrf-name*] **fsm**	Turns on final-state-machine debugging switch in the specified VRF.
Ruijie# **debug igmp** [**vrf** *vrf-name*] **tib**	Turns on tree debugging switch in the specified VRF.
Ruijie# **debug ip igmp** [**vrf** *vrf-name*] **warning**	Turns on warning debugging switch in the specified VRF.

Configuring MLD

MLD Overview

IPv6 multicast is a network technology allowing one or more senders (multicast sources) to send a single packet to multiple receivers (once and simultaneous). The multicast source sends the packet to a specific multicast group, and only hosts having addresses of this multicast group can receive the packet. Multicasting can substantially save network bandwidth, because only one packet is sent on any link of the entire network no matter how many destination addresses exist.

The format of IPv6 multicast address is different from that of IPv6 unicast address, and can only be used for destination address. The first byte of address format all consists of "1" (multicast address). The multicast address occupies 1/256 of the IPv6 address space. Except for parts other than the first byte, the multicast address format includes the following fields:

```
|   8    |  4 |  4 |                  112 bits                   |
 +--------+----+----+---------------------------------------------+
|11111111|flgs|scop|                  group ID
|+--------+----+----+---------------------------------------------+
```

- Flag field: (starting from high-order bit) The first bit is the reserved bit set to 0; the second bit is R flag: R = 1 indicates a multicast address that embeds the address of the RP, while R = 0 indicates a multicast address that does not embed the address of the RP; the third bit is P bit: R = 1 indicates a multicast address is created on basis of unicast prefix, otherwise it is set to 0.
- The scop field has 4 bits and indicates the scope of multicasting. According to the definition given in RFC 4291: 1 (hexadecimal number system) indicates interface-local scope, 2 indicates link-local scope, 4 indicates admin-local scope, 5 indicates site-local scope, 8 indicates organization-local scope, and E indicates global scope.
- Group ID has 112 bits, and is used to identify the multicast group. According to the multicast address (transient or well-known) and the scope of address, the same multicast ID can indicate different groups. Well-known multicast address uses specific group ID with special meanings.

No matter whether a member of multicast group or not, any host can be a multicast source. However, only the member of multicast group can receive the multicast frames. Members of the multicast group are determined dynamically, and the host can dynamically join or leave the group. The multicast frames are forwarded by the multicast device, which will run the multicast routing protocol.

To participate in IPv6 multicast, the multicast host/device shall be able to support MLD operations. This protocol allows the interactive multicasting of member relationship between host and routing device, so as to decide on the forwarding of multicast steam. By utilizing the information obtained from MLD, the device will maintain a multicast listener state table, which is based on each interface. When the local link of an interface has at least one host being a member of the group, the multicast listener state table will then be activated.

Currently, MLD has to versions. MLDv2 was developed on the basis of MLDv1 by adding the source filtering mechanism. The behaviors of MLD protocol can be divided into two parts: host behavior and router behavior.

Introduction to Messages of Different MLD versions

MLD Version 1

In MLDv1, there are three types of messages:

- Multicast Listener Query
- Multicast Listener Report
- Multicast Listener Done

In the multicast network running MLD protocol, there will be querier responsible for sending MLD query messages. Such querier is determined through election. In the beginning, all devices are of the querier state. When the devices receives multicast listener query from a device with a lower IP address, they will change from querier state to non-querier state. Therefore, only one device will be of the querier state, and this device has the lowest IP address among all multicast devices on the network.

MLDv1 also has the corresponding mechanism to handle the failure of querier device. Non-querier devices will maintain the current interval timer of other queriers. The device will reset this timer when every time it receives the multicast listener query message. If this timer times out, then the corresponding device will restart sending query message, and the new round of querier device election will begin again.

The querier device must periodically send out the multicast listener query to ensure that non-querier devices on the network know that the querier device is still workable. In realize this function, the querier device maintains a query interval timer, which will be reset when the multicast listener query message is sent out. When the query interval timer is set to zero or no longer useful, the querier device will send out another multicast listener query.

When MLD protocol is initiated, it will send a number of general query messages to discover which multicast groups shall be forwarded on the specific interface. The number of ordinary query messages sent by the device will be based on the Startup Query Count configured by the current device. The space between startup general queries will be determined by the value of Startup Query Interval. 。

When the querier device receives the leave message, it must send a group-specific multicast listener query message to see whether the host is the last listener to leave the group. The device will send a number of group-specific query messages before it stops forwarding data messages for the specific group, and the number of messages equals to the number of last listener queries. The device will send multiple group-specific multicast listener queries to ensure there is no more listener in that group. A group-specific query will be sent at every other last listener query interval in order to partition the queries. When no response is received, the device will delete the corresponding group record, and stop forwarding multicast data messages on that specific interface for this group address.

MLD Version 2

MLDV1 has the following defects in application:

- Lack of effective means to control multicast sources.
- Being unaware of the location of multicast source, it is comparatively difficult to establish the multicast route.
- It is very difficult to discover an only multicast address. Multiple multicast groups may use the same multicast address.

On the basis of MLDv1, MLDv2 provides the additional multicast source filtering mode (INCLUDE/EXCLUDE). In MLDv1, the host determines to join a certain group only according to the group address, and receives multicast streams sent from any source to this group address. In MLDv2, the host informs the host of the multicast group it desires to join in, and also notifies this host of addresses of multicast sources that it is willing/unwilling to receive. The host can indicate which sources to receive multicast streams via an INCLUDE list or an EXCLUDE list. When the host joins a multicast group:

- If the host only needs to receive the data streams sent from source { s1,s2,s3…}, then its Report message can contain the information of INCLUDE{ s1,s2,s3…}.
- If the host doesn't want to receive the data streams sent from source { s1,s2,s3…}, then its Report message can contain the information of EXCLUDE{ s1,s2,s3…}.

Through source address filtering, MLDv2 can save network bandwidth and prevent unnecessary and invalid multicast data streams from occupying the network bandwidth. This is especially useful when multiple multicast sources are sharing one multicast address. Although MLDv1 can also realize "source address filtering" in a certain sense, it is done on the receiving end of multicast streams. As shown in Fig 1, S1 and S2 are multicast sources sending data streams with the same multicast address of G. The multicast streams of S1 and S2 will be sent to all hosts receiving G. If host A only wants to receive the data streams of S1, in order to avoid the disturbance of data streams from S2, we can only use the corresponding Client software to perform filtering.

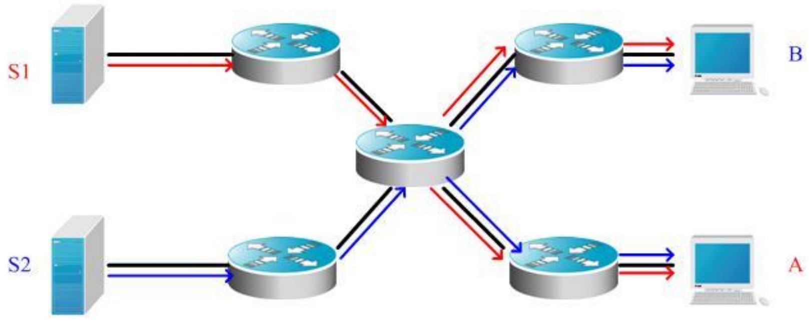


Fig 4 MLDv1 forwarding diagram

If the devices on network can support MLDv2: host A can send the MLDv2 message of join G include { S1 } if it only wants to receive data streams from S1, and host B can send the MLDv2 message of join G include { S2 } if it only wants to receive data streams from S2. The forwarding of data streams will be shown as follows, allowing the saving of partial bandwidth.

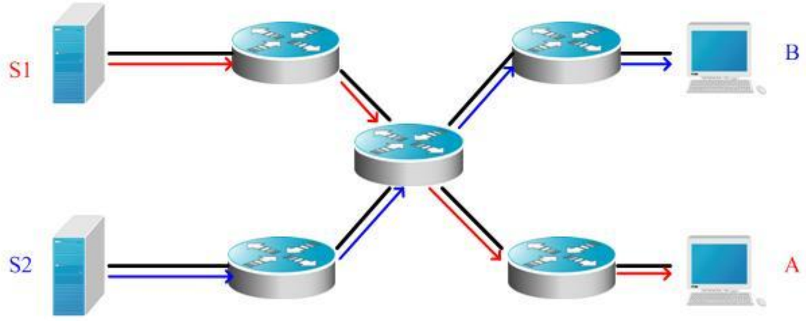

Fig 5 MLDv2 forwarding diagram

Compared with version 2, version 2 defines the following two types of messages:

- Membership Listener Query
- Membership Listener Report

Membership Query can be classified into:

- General Query: Used to learn the information of all multicast listeners on the attached link;
- Group-Specific Query: Used to learn the information of group-specific listeners on the attached link;
- Group-and-Source-Specific Query: This type is newly added by MLDv2, and is used to learn if any of listeners on the attached link needs to receive the group-specific multicast streams sent by the specified source list.

Different from the Membership Report described in MLD Version1, the Membership Report message sent by MLD Version2 may contain the information of multiple groups. The destination address of Report message is FF02::16 in MLDv2, and can carry one ore more group records, each of which contains the group address and source address. The types of group records are shown below:

- IS_IN: indicates that filtering mode between multicast group and multicast source list is INCLUDE, i.e., only the multicast data sent from the specified multicast source list to this multicast group will be received.
- IS_EX: indicates that filtering mode between multicast group and multicast source list is EXCLUDE, i.e., only the multicast data sent from multicast sources outside the specified multicast source list to this multicast group will be received.
- TO_IN: indicates that the filtering mode between multicast group and multicast source list will change from EXCLUDE mode to INCLUDE mode.
- TO_EX: indicates that the filtering mode between multicast group and multicast source list will change from INCLUDE mode to EXCLUDE mode.
- ALLOW: allows the receipt of multicast data from certain multicast sources. If the current corresponding relationship is INCLUDE, these multicast sources will be added into the existing multicast source list; if the current corresponding relationship is EXCLUDE, these multicast sources will be deleted from the existing multicast source list.
- BLOCK: no longer expects to receive multicast data from certain multicast sources. If the current corresponding relationship is INCLUDE, these multicast sources will be deleted from the existing multicast source list; if the current corresponding relationship is EXCLUDE, these multicast sources will be added into the existing multicast source list.

In consideration of compatibility, MLD Version2 can also recognize the Membership Report message and Done message of version 1.

Caution

The multicast layer-3 interface of Ruijie router can only allow up to 253 specific sources for specific groups. The user can perform the unicast of allowed specific sources.

Caution

The multicast layer-3 interface of Ruijie router can only filter up to 253 specific sources for specific groups. The user cannot perform the unicast of filtered specific sources.

MLD Protocol Specifications

The current MLD protocols include:

- RFC2710: Multicast Listener Discovery (MLD) for IPv6
- RFC3810: Multicast Listener Discovery Version 2 (MLDv2) for IPv6

MLD Configuration Task List

MLD configuration tasks include the following items, but only some configurations are compulsory, while other tasks are optional according to the specific needs of the network. Note: The following command must be configured on the layer-3 interface.

- (mandatory) Enabling MLD protocol
- (mandatory) Configuring MLD version
- (optional) Configuring Last Listener Query Interval
- (optional) Configuring Last Listener Query Count
- (optional) Configuring General Listener Query Interval
- (optional) Configuring Maximum Response Interval
- (optional) Configuring Other Querier Timer Interval
- (optional) Configuring Multicast Group Access Control
- (optional) Configuring Immediate Leave Group
- (optional) Configuring MLD Listener Number Limit
- (optional) Configure Host-Behavior Multicast Group Joining
- (optional) Configuring Static Multicast Group Joining
- (optional) Configuring MLD P
- (optional) Configuring MLD P
- (optional) Enabling MLD SSM-MAP
- (optional) Configuring MLD SSM-MAP S

Default MLD Configurations

Function	Default setting
MLD version	All interfaces support version 2
Query Response Interval	10 seconds
Query Interval	125 seconds
Multicast Group Access Control	All groups allowed
Other Querier Present Interval	255 seconds
Robustness Variable	2
Last Listener Query Interval	10 (0.1s)
Last Listener Query Count	2
MLD state	Disabled

Enabling MLD Protocol

MLD needs to be used with multicast routing protocol. If the multicast routing protocol is enabled, the MLD protocol will also be enabled. Run the following command in the interface configuration mode:

Command	Function
Ruijie (config-if) # **ipv6 pim sparse-mode**	Enable the multicast routing protocol and MLD.
Ruijie (config-if) # **no ipv6 pim sparse-mode**	Disable the multicast routing protocol and MLD.

Configuring MLD Version

To configure MLD version, run the following command in the interface configuration mode:

Command	Function
Ruijie (config-if) # **ipv6 mld version** {**1|2**}	Configure the MLD version.
Ruijie (config-if) # **no ipv6 mld version**	Recover the MLD version to the default version2.

Configuring Last Listener Query Interval

After receiving a group leave message, the querier device will send a group-specific listener query to identify that whether there are still listeners in the group. During the interval of sending last listener query, if no report is received, the device will assume that the leaving device is the last listener of the group, and will the information of this group. The default value is 1s. The Last Listener Query Interval determines the leaving speed of listeners.

Run the following command in the interface configuration mode:

Command	Function
Ruijie (config-if) # **ipv6 mld last-member-query-interval** *interval*	Configure the last listener query interval *interval*: the valid range is 1-255, in 0.1s.
Ruijie (config-if) # **no ipv6 mld last-member-query-interval**	Configure Last Listener Query Interval to default value.

Configuring Last Listener Query Count

To avoid the loss of group-specific listener query messages sent by the querier device, the messages need to be sent for several times to guarantee reliability. Therefore, the Last Listener Query Count shall be configured.

Run the following command in the interface configuration mode:

Command	Function
Ruijie(config-if) # **ipv6 mld last-member-query-count** *count*	Configure the last listener query count. *count:* the valid range is 2-7, and the default value is 2.
Ruijie(config-if) # **no ipv6 mld last-member-query-count**	Configure the last listener query count to the default value.

Configuring General Listener Query Interval

At every other listener query interval, the querier will periodically send out the listener query messages to verify the relationship of current listeners. The destination address of listener query message is all-hosts, the multicast address is FF02::1, and the TTL is 1. The default value is 125 seconds.

Run the following command in the interface configuration mode:

Command	Function
Ruijie (config-if) # **ipv6 mld query-interval** *seconds*	Configure the general listener query interval. *seconds:* the valid range is 1-18000.
Ruijie (config-if) # **no ipv6 mld query-interval**	Configure the general listener query interval to the default value of 125s.

Configuring Maximum Response Interval

This means the maximum response time required in the multicast listener query messages sent by the querier device. Less time can allow the device to rapidly learn the changes in listeners but will lead to corresponding increase in the number of potential listener reports. The network administrator can consider both factors to determine the most appropriate value, which is 10 seconds by default. Furthermore, this time shall be less than the Query Interval.

Run the following command in the interface configuration mode:

Command	Function
Ruijie (config-if)**# ipv6 mld query-max-response-time** *seconds*	Configure the maximum response time. *seconds:* the valid range is 1-25.
Ruijie (config-if)**# no ipv6 mld query-max-response-time**	Configure the maximum response time to the default value of 10s.

Configuring Other Querier Timer Interval

The configuration of other querier timer interval can help adjust the querier device election time. This value can be decreased to increase the response speed when the querier devices are prone to change.

Run the following command in the interface configuration mode:

Command	Function
Ruijie (config-if)# **ipv6 mld query-timeout** *seconds*	Configure other querier timer interval. *seconds:* the valid range is 60-300, and the default value is 255s.
Ruijie (config-if)# **no ipv6 mld query-timeout**	Configure other querier timer interval to the default value.

Configuring Multicast Group Access Control

By default, the host on one interface can join any multicast group. This feature can be used when the administrator expects to limit the scope of multicast groups which can be joined by the host. Configure an IP access list to allow and limit the scope of multicast group addresses, and apply the list to the specific interface.

Run the following commands:

Command	Function
Ruijie# **config terminal**	Enter the global configuration mode.
Ruijie (config) # **ipv6 access-list** *access-list-name* Ruijie (config-std-nacl) # **permit ipv6** source_address *group_address*	Define an access control list.
Ruijie (config)# **interface** *interface-type interface-id*	Enter the interface configuration mode.
Ruijie (config-if) # **ipv6 mld access-group** *access-list-name*	Configure the group addresses or source addresses so that multicast groups covered by the address scope of access-list-name can access this interface.
Ruijie (config-if) # **no ipv6 mld access-group**	Delete the access control list and allow the access of all groups.

Caution The Multicast Group Access Control is associated with Extended ACL. When the MLD report message received is (S1,S2,S3…Sn,G), this command will perform the corresponding ACL based check of (0,G) information. Therefore, an explicit entry of (0,G) shall be configured for extended ACL to allow the normal filtering of (S1,S2,S3…Sn,G). This (0,G) mentioned herein refers to all sources of the specific group.

Configuring Immediate Leave Group

In MLD, this command can reduce the leave latency. When there is only one host on the attached link needs to receive group information, after the host sends out the leave message, it can leave immediately without the need for the querier to device to send group-specific query. This command is used when one interface has only one receiver host.

Command	Function
Ruijie# **config terminal**	Enter the global configuration mode.
Ruijie (config)# **interface** *interface-id*	Enter the interface configuration mode.
Ruijie (config-if)# **ipv6 mld immediate-leave group-list** *access-list-name*	Configure the immediate leave group list to access-list-name.
Ruijie (config-if) # **exit**	Return to the global configuration mode.
Ruijie (config)# **ipv6 access-list** *access-list-name* Ruijie (config-std-nacl)#**permit** *x:x:x:x::x:x/< 0-128>*	Configure the address scope of group list.

Configuring MLD Listener Number Limit

This command can be used to limit the number of listeners that can be learned by MLD. Listener messages will not be learned after the listener number has exceeded the limit, and no group record will be generated.

This command can be used to configure each interface, and the interface and global can be configured separately. If exceeding the number limit of interface or global configuration, the listener messages will be dropped. Run the following commands:

Command	Function
Ruijie (config)# **ipv6 mld limit** *number*	Global configuration of MLD listener number limit Please note that different models provide different limit ranges. Please identify the default value according to the capacity indicator of different models.
Ruijie (config-if) **# ipv6 mld limit** *number*	Interface configuration of MLD listener number limit Please note that different models provide different limit ranges. The default value is 1024.
Ruijie (config-if) **# ipv6 mld limit** *number* **except** *access-list-name*	The key word of Except indicates that groups covered by ACL will be limited in number.

Use the **no ipv6 mld limit** command to restore the relevant configurations to the default values.

Configuring Host-Behavior Multicast Group Joining

Use this command to configure relevant switch interfaces to implement host behavior and join the corresponding multicast group. In this way, the sub-switches can initiatively learn the corresponding group information. This configuration can be used when a listener is required to be assigned to the interface. Use the **no** form of this command to cancel the joining operation.

Command	Function
Ruijie# **config terminal**	Enter the global configuration mode.
Ruijie (config)# **interface** *interface-id*	Enter the interface configuration mode.
Ruijie (config-if)# **ipv6 mld join-group** *group-address*	Enable the interface to join host group.
Ruijie (config-if) # **exit**	Return to the global configuration mode.

Use the **no ipv6 mld join-group** *group-address* command to leave the corresponding multicast group.

Caution

Some of the local link addresses have been reserved for use by the IP layer. If such addresses are used as the local link address, no group record will be generated.

Configuring Static Multicast Group Joining

Use this command to directly assign a listener to the relevant switch interface when a listener is required to be assigned to the interface. Use the **no** form of this command to cancel the joining operation.

Command	Function
Ruijie# **config terminal**	Enter the global configuration mode.
Ruijie (config)# **interface** *interface-id*	Enter the interface configuration mode.
Ruijie (config-if)# **ipv6 mld static-group** *group-address*	Enable the interface to join static group.
Ruijie (config-if) # **exit**	Return to the global configuration mode.

Use the **no ipv6 mld static-group** *group-address* command to delete the static group assigned to the interface.

Configuring MLD Proxy-service

Use this command to enable the service of all downlink mroute-proxy interfaces, enabling the interface to become the uplink interface of corresponding mroute-proxy. It will bind all attached downlink interfaces and maintain the group information advertised by the downlink interface.

The maximum configurable number of this command is limited to 32. The number of interfaces with MLD Proxy function enabled depends on the number of multicast interfaces supported by the device. When the interface receives the query message, the proxy-service interface will give the corresponding reply according to the listener information it maintains. Such information is acquired from the mroute-proxy interface. Therefore, proxy-service interface means that it will only implement host behavior instead of router behavior. Run the following command in the interface configuration mode:

Command	Function
Ruijie (config-if)# **ipv6 mld proxy-service**	Configure the interface to proxy-service state.

Use the **no ipv6 mld proxy-service** command to disable the proxy function on the corresponding interface.

Configuring MLD Mroute-proxy

This command will allow the interface to forward messages to the corresponding uplink interface. When the corresponding uplink interface is configured to proxy-service interface, this interface can then forward various MLD protocol messages forwarded by its listeners.

Run the following command in the interface configuration mode:

Command	Function
Ruijie (config-if ）# **ipv6 mld mroute-proxy** *interfacename*	Enables the interface to forward messages to the correspongding uplink interface.

Use the **no ipv6 mld mroute-proxy** command to cancel the binding between downlink interface and uplink interface, and disable the proxy function of downlink interface.

Enabling MLD SSM-MAP

Use this command to add the dynamically learned group information to the bound source record information, and is generally co-used with the **ipv6 mld ssm-map static** command.

Run the following command in the global configuration mode:

Command	Function
Ruijie (config)# **ipv6 mld ssm-map enable**	Enable the ssm-map function.

Use the **no ipv6 mld ssm-map enable** command to disable the SSM-MAP function.

Configuring MLD SSM-MAP Static

Use this command together with the **ipv6 mld ssm-map enable** command. After configuring this command, the MLDv1 messages received will be mapped to the corresponding source records.

Run the following command in the global configuration mode:

Command	Function
Ruijie (config ）# **ipv6 mld ssm-map static** *acl_name src_address*	Map all group records complying with acl_name to the source address of src_address.

Use the **no ipv6 mld ssm-map static** command to cancel the mapping relationship between related group record and source address.

Monitoring and Maintaining MLD State and Listener Information

Clearing the Dynamic Listener Information in the MLD Cache

Use this comamnd to clear the dynamic listener information in the MLD cache. Note that this command cannot delete the statically added listener information. Run the following command in the privilege mode:

Command	Function

Ruijie# **clear ipv6 mld group** [group-address] [interface-type interface-number]	Clear all dynamic listener information in the MLD cache learned from response message. Clear all mld group information if there is no parameter.

Clearing All Information in MLD Cache on the Specific Interface

To clear all information in MLD cache on the specific interface, run the following command in the privilege mode:

Command	Function
Ruijie# **clear ipv6 mld interface** *interface-type*	Clear all information in MLD cache on the interface.

Displaying the State of Listeners on the Attached Subnetwork

To display the state of all listeners on the attached subnetwork, run the following commands in the privilege mode:

Command	Function
Ruijie# **show ipv6 mld groups**	Display the information of all listeners learned by MLD.
Ruijie# **show ipv6 mld groups detail**	Display the detailed information of all listeners learned by MLD.
Ruijie# **show ipv6 mld groups** *x:x:x:x::x*	Display the information of group-specific listeners learned by MLD.
Ruijie# **show ipv6 mld groups** *x:x:x:x::x* detail	Display the detailed information of group-specific listeners learned by MLD.
Ruijie# **show ipv6 mld ssm-mapping**	Display the configuration information of ssm-mapping.
Ruijie# **show ipv6 mld ssm-mapping** *x:x:x:x::x*	Display the source address mapping information of specific group.
Ruijie# **show ipv6 mld groups** *interface-type interface-number* **detail**	Display the detailed information of all groups on the specific interface.
Ruijie# **show ipv6 mld groups** *interface-type interface-number x:x:x:x::x*	Display the information of specific groups on the specific interface.
Ruijie# **show ipv6 mld groups** *interface-type interface-number x:x:x:x::x* **detail**	Display the detailed information of specific groups on the specific interface.

Displaying the Configuration Information of MLD Interface

To display the configuration information of MLD interface, run the following commands in the privilege mode:

Command	Function
Ruijie# **show ipv6 mld interface** *interface-type interface-number*	Display the MLD interface configurations.
Ruijie# **show ipv6 mld interface**	Display the configurations of all MLD interfaces.

Displaying the On/Off State of MLD Debug Switch

To display the on/off state of MLD debug switch, run the following command in the privilege mode:

Command	Function
Ruijie# **show debugging**	Display the on/off state of MLD debug switch.

Turning on MLD Debug Information Switch and Observing MLD Behaviors

To turn on MLD debug information switch and observe MLD behaviors, run the following command in the privilege mode:

Command	Function
Ruijie# **debug ipv6 mld all**	Turn on all MLD debug information switches
Ruijie# **debug ipv6 mld decode**	Turn on MLD debug message decoding switch.
Ruijie# **debug ipv6 mld encode**	Turn on MLD debug message encoding switch.
Ruijie# **debug ipv6 mld events**	Turn on MLD debug event information switch.
Ruijie# **debug ipv6 mld fsm**	Turn on MLD debug state switch.
Ruijie# **debug ipv6 mld tib**	Turn on MLD debug member tree structure information switch.
Ruijie# **debug ipv6 mld warnning**	Turn on MLD debug warning switch.

Configuring PIM-DM

PIM-DM Overview

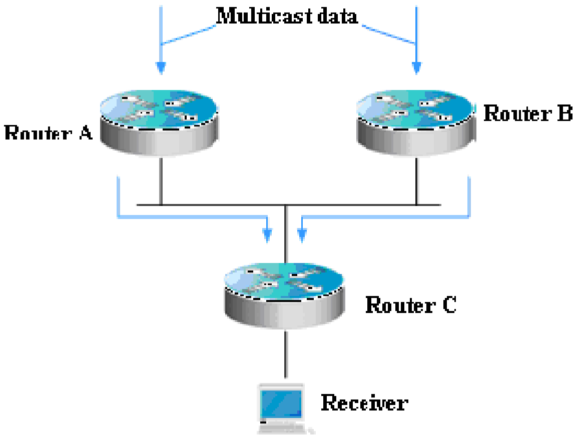
Protocol Independent Multicast-Dense Mode (PIM-DM) is a dense-mode multicast routing protocol, which is suitable for small-sized networks with densely distributed multicast members. As PIM-DM does not rely on any specific unicast routing protocol, it is called protocol independent multicast routing protocol. PIM-DM is defined in RFC 3973.

PIM-DM devices discover neighbors through Hello messages. After startup, a PIM-DM device sends a Hello message to each PIM-DM enabled interface periodically. The Hello message has a field of **Hello Hold Time**, which defines the maximum duration that a neighbor waits for the next message. If the neighbor does not receive another Hello message from the sender within this duration, this device will be removed from the adjacency list.

PIM-DM builds a shortest path tree (SPT) through flood and prune. PIM-DM assumes that when a multicast source begins to send a multicast packet, all the systems in the network need to receive this packet. As a result, this packet is forwarded to every system. The reverse path forwarding (RPF) check is performed for the packets received from the upstream interface. Those packets that fail to pass the check will be discarded. For the packets passing the check, the outgoing interface is computed based on the (S, G) pair of the packets, that is, source address and group address. If the outgoing interface is not null, an outgoing interface entry is created from the (S, G) pair and the multicast packet is forwarded through this outgoing interface. If the computed outgoing interface is null, a prune message is sent to the RPF neighbor, informing the upstream neighbor not to forward the multicast packets from the (S, G) pair to this interface. After the prune message is received on the upstream interface, the device marks the sending interface as pruned state and sets a pruned state timer. In this way, an SPT is created with the multicast source as its root.

PIM-DM uses the Assert mechanism to eliminate redundant routes.

Figure 11 Assert mechanism of PIM-DM



As shown in Figure-1, the multicast data arrives at Routers A and B at the same time, which forward the data to Router C. In this case, Router C receives duplicated data, which is not allowed. So there must be a mechanism to select Router A or B to forward the multicast data to Router C. This is the Assert mechanism of PIM-DM.

PIM-DM uses the state refresh message to update network state. The device directly connected to the multicast source sends the state refresh message to the downstream devices periodically to advertise the network topology changes. The devices receiving the message add their topology state to the state refresh message by modifying some fields, and then send it to the downstream devices. When the refresh message arrives at the leaf devices, the entire network state is updated.

PIM-DM uses the Graft mechanism to reestablish the connection with upstream devices. If the network topology of a downstream device in pruned state changes and the device needs to receive multicast data from a (S, G) pair, it sends the graft message to the upstream device. Upon receiving the graft message, the upstream device responds with a Graft-Ack message and forwards the multicast data to the downstream device again.

PIM-DM Configuration Tasks

The PIM-DM configuration tasks include the following items. However, only the first and second one are mandatory, and others are optional.

Enabling Multicast Routing

PIM-DM can forward multicast packets only after the multicast routing function is enabled.

Use the following command to enable or disable the multicast routing function in global configuration mode.

Command	Function
Ruijie (config) **# ip multicast-routing**	Enables multicast routing globally.
Ruijie (config) **# no ip multicast-routing**	Disables multicast routing globally.

Enabling PIM-DM

PIM-DM must be enabled on each interface. A device can exchange PIM-DM control messages with other devices, maintain and update the multicast routing table and forward multicast messages only after PIM-DM is enabled on the interface of the device.

Use the following commands to enable PIM-DM in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip pim dense-mode**	Enables the PIM-DM protocol on the interface.
Ruijie(config-if)**# no ip pim dense-mode**	Disables the PIM-DM protocol on the interface.

Caution

Enabling PIM-DM will take effect on an interface only after the multicast routing is enabled in global configuration mode.

When this command is configured, if the system displays "Failed to enable PIM-DM on <*interface name*>, resource temporarily unavailable, please try again", configure this command again.

When this command is configured, if the system displays "PIM-DM Configure failed! VIF limit exceeded in NSM!!!", the number of configured multicast interfaces reaches the threshold. If you still need to enable PIM-DM on the interface, remove some unnecessary PIM-DM, PIM-SM or DVMRP interfaces.

It is not recommended that different IPv4 multicast routing protocols be configured on different interfaces of a switch or router.

If the interface is of tunnel-type, only 4Over4 configuration tunnel, 4Over4 GRE tunnel, 4Over6 configuration tunnel and 4Over6 GRE tunnel support the IPv4 multicasting. The multicasting function can also be enabled on other tunnel interfaces that do not support IPv4 multicasting, but no error message will be displayed and no multicast packets will be received or sent.

Multicast tunnels can be created on Ethernet interfaces only. Nested tunnel and multicast data QoS/ACL are not supported.

Setting the Interval of Sending the Hello Message

After PIM-DM is enabled on an interface, the interface sends the Hello message to the interfaces of adjacent devices periodically. You can modify the interval according to the network situation.

Use the following command to configure the interval of sending the Hello message in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip pimquery-interval** *interval-seconds*	Sets the interval of sending the Hello message on the interface. *interval-seconds*: in the range of 1 to 65535 seconds
Ruijie(config-if)# **no ip pimquery-interval**	Restores the setting to the default value.

By default, the interval of sending the Hello message on the interface is 30 seconds.

Caution

When the interval of sending the Hello message is updated, Hello hold time will be updated as 3.5 times of the Hello sending interval automatically. If the interval of sending Hello message multiplying 3.5 is larger than 65535, Hello hold time is updated to 65535.

Configuring Propagation Delay of Hello Message

Options can be added to Hello messages. The default value of **propagation-delay** in **LAN Prune Delay Option** is 500 milliseconds.

Use the following command to configure the propagation delay of Hello messages in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip pim propagation-delay** *interval-milliseconds*	Sets the propagation delay in the range of 1 to 32767 milliseconds.
Ruijie(config-if)# **no ip pim propagation-delay**	Restores the setting to the default value.

Configuring Override Interval of Hello Message

Options can be added to Hello messages. The default value of **override-interval** in **LAN Prune Delay Option** is 2500 milliseconds.

Use the following command to configure the override interval in interface configuration mode.

Command	Function
Ruijie(config-if)# **ip pim override-interval** *interval-milliseconds*	Sets the override interval in the range of 1 to 65535 milliseconds.
Ruijie(config-if)# **no ip pim override-interval**	Restores the setting to the default value.

Configuring PIM-DM Neighbor Filtering

The neighbor filtering function can be configured on the interface to enhance network security. With neighbor filtering enabled, PIM-DM does not establish adjacency with the neighbor or deletes the established adjacency with the neighbor as long as a neighbor is denied by the access list.

Use the following command to configure the PIM neighbor filtering function in interface configuration mode.

Command	Function
Ruijie(config-if)#**ip pim neighbor-filter** *access-list*	Enables the PIM neighbor filtering function on the current interface.
Ruijie(config-if)#**no ip pim neighbor-filter** *access-list*	Disables the PIM neighbor filtering function on the current interface.

The PIM neighbor filtering function is disabled by default on an interface.

Note

ip pim neighbor-filter command description:

Only neighbor addresses permitted by the ACL can be the PIM neighbors of the current interface.

Configuring PIM-DM State Refresh

After PIM-DM is enabled on a device, if the RPF interface is directly connects to the multicast source (that is, the PIM interface is in the same network segment as the multicast source), the device periodically sends state refresh messages to downstream devices to update the entire network state. You can disable processing or forwarding of PIM state refresh messages in global configuration mode.

Use the following command to configure PIM-DM state refresh in global configuration mode.

Command	Function
Ruijie(config-if)#**no ip pim state-refresh disable**	Enables processing or forwarding PIM-DM state refresh messages.
Ruijie(config-if)# **ip pim state-refresh disable**	Disables processing or forwarding PIM-DM state refresh message.

The PIM-DM state refresh function is enabled by default.

Caution

Disabling the state refresh messages may cause the re-convergence of the converged PIM-DM multicast forward tree, resulting in unnecessary bandwidth waste and routing table flapping. Therefore, it is better not to disable the state refresh function in normal cases.

Configuring the Interval of Sending PIM-DM State Refresh Message

After PIM-DM is enabled on a device, if an interface is directly connected to the multicast source, the device periodically sends state refresh messages to downstream devices to update the entire network state. You can modify the interval of sending PIM state refresh message on an interface according to the network situation.

Use the following command to configure the interval of sending PIM state messages on the interface in interface configuration mode.

Command	Function
Ruijie(config-if)#**ip pim state-refresh origination-interval** *seconds*	Configures the interval of sending PIM state refresh messages on the current interface, in the range of 1 to 100 seconds.
Ruijie(config-if)#**no ip pim state-refresh origination-interval**	Restores the setting to the default value.

By default, the interval of sending PIM state refresh messages on the interface is 60 seconds.

Note

Only the devices directly connected to multicast source can periodically send the PIM state refresh message to the downstream interfaces. Therefore, if the devices are not directly connected to the multicast source, the interval of sending PIM state refresh messages configured on the downstream interface is invalid.

Monitoring and Maintaining PIM-DM

PIM-DM provides the following commands to monitor and maintain PIM-DM.

Displaying PIM-DM State

Command	Function
show ip pim dense-mode interface [*interface-type interface-number*] [**detail**]	Shows the PIM-DM information on the interface.
show ip pim dense-mode neighbor [*interface-type interface-number*]	Shows the PIM-DM neighbor information.
show ip pim dense-mode nexthop	Shows the next hop information of PIM-DM.
show ip pim dense-mode mroute [*group-or-source-address [group-or-source-address*]] [**summary**]	Shows the PIM-DM routing table.
show ip pim dense-mode track	Shows the number of PIM packets sent and received since the statistic beginning time.

For details about the preceding commands, see *PIM-DM Command References*.

Here are some examples of the commands:

show ip pim dense-mode interface detail command:

```
Ruijie# show ip pim dense-mode interface detail
FastEthernet 0/1 (vif-id: 3):
Address 10.10.10.10
Hello period 30 seconds, Next Hello in 15 seconds
Over-ride interval 2500 milli-seconds
Propagation-delay 500 milli-seconds
Neighbors:
10.10.10.1
FastEthernet 0/2 (vif-id: 2):
Address 50.50.50.50
Hello period 30 seconds, Next Hello in 2 seconds
Over-ride interval 2500 milli-seconds
Propagation-delay 500 milli-seconds
Neighbors:
50.50.50.1
```

In the preceding example, the IP address of FastEthernet 0/1 is 10.10.10.10, the Hello message sending interval is 30 seconds, the next Hello message is to be sent in 15 seconds, and the neighbor address is 10.10.10.1. The information about FastEthernet 0/2 is similar to that of FastEthernet 0/1.

show ip pim dense-mode neighbor command:

```
Ruijie# show ip pim dense-mode neighbor
Neighbor-Address Interface           Uptime/Expires    Ver
10.10.10.1      FastEthernet 0/1      00:19:29/00:01:21  v2
50.50.50.1      FastEthernet 0/2      00:22:09/00:01:39  v2
```

In the preceding example, the device has two neighbors. Neighbor 10.10.10.1 connects to FastEthernet 0/1 and has been alive for 19 minutes and 29 seconds, with the TTL to expire in one minute and 21 seconds. Neighbor 50.50.50.1 is similar.

show ip pim dense-mode nexthop command:

```
Ruijie# show ip pim dense-mode nexthop
Destination  Nexthop   Nexthop      Nexthop            Metric Pref
              Num      Addr        Interface
1.1.1.111      1      50.50.50.1    FastEthernet 0/2    0      1
```

In the preceding example, the next hop neighbor address to multicast source 1.1.1.111 is 50.50.50.1 and the egress is FastEthernet 0/2.

show ip pim dense-mode mroute command:

```
Ruijie# show ip pim dense-mode mroute
PIM-DM Multicast Routing Table
(1.1.1.111, 229.1.1.1)
MRT lifetime expires in 205 seconds
RPF Neighbor: 50.50.50.1, Nexthop: 50.50.50.1, FastEthernet 0/2
Upstream IF: FastEthernet 0/2
Upstream State: Pruned, PLT:200
Assert State: NoInfo
Downstream IF List:
FastEthernet 0/1:
```

```
Downstream State: NoInfo
Assert State: Loser, AT:170
```

The preceding example shows two entries: 1.1.1.111 and 229.1.1.1. The MRG aging time is 205 seconds, RPF neighbor is 50.50.50.1, the next hop is 50.50.50.1, and the egress to the next hop is FastEthernet 0/2. The upstream interface of these entries is FastEthernet 0/2 in Pruned state, indicating that there is no downstream forwarding egress. The downstream interface is FastEthernet 0/1 in NoInfo state. The Assert state of the interface is Loser. FastEthernet 0/1 is not a forwarding egress.

show ip pim dense-mode track command:

```
Ruijie# show ip pim dense-mode track
PIM packet counters
Elapsed time since counters cleared: 00:04:03

                           received    sent
Valid PIMDM packets:            1           8
Hello:                          1           8
Join/Prune:                 0           0
Graft:                          0            0
Graft-Ack:                      0            0
Assert:                     0            0
State-Refresh:              0            0
PIM-SM-Register:            0            0
PIM-SM-Register-Stop:           0            0
PIM-SM-BSM:                     0            0
PIM-SM-C-RP-ADV:                0            0
Unknown Type:                   0

Errors:
Malformed packets:          0
Bad checksums:              0
Unknown PIM version:            0
Send errors:                    0
```

Deleting PIM-DM State Information

Use the following command to delete the PIM-DM state information:

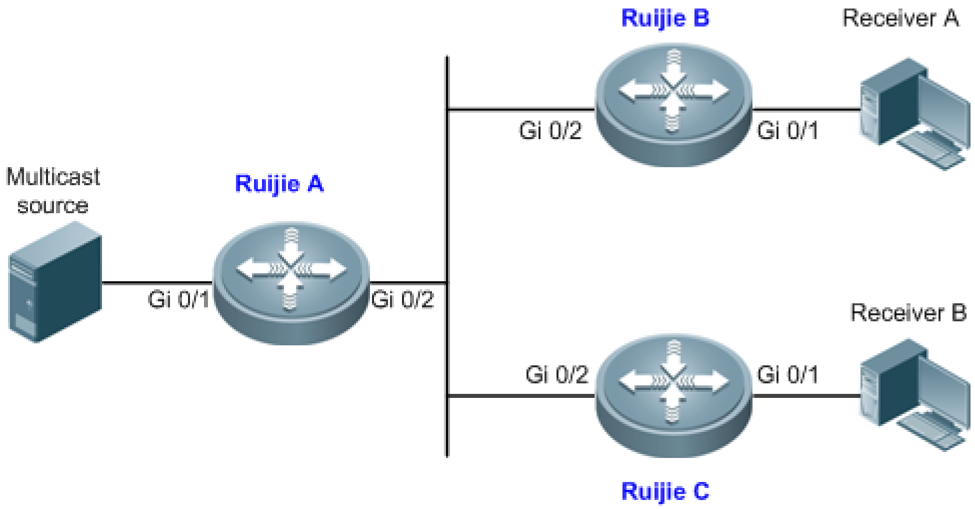
Command	Function
Ruijie# **clear ip pim dense-mode track**	Resets the start time of packet statistics and clears PIM packet counter.

PIM-DM Configuration Example

Configuration Requirements

Figure 12 shows the network topology. Ruijie A and the multicast source are in the same network, Ruijie B and receiver A are in the same network, and Ruijie C and receiver B are in the same network. Assume that the devices are properly connected to the hosts, and the IP addresses and unicast routes are configured.

Figure 12 Networking topology for PIM-DM configuration



Device Configuration

The following example shows how to configure PIM-DM on Ruijie A. The configurations on Ruijie B and Ruijie C are similar to those on Ruijie A.

- Step 1: Enable multicast routing.

```
Ruijie# configure terminal
Ruijie(config)# ip multicast-routing
```

- Step 2: Enable PIM-DM on the interface Gi 0/1.

```
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if)# ip pim dense-mode
Ruijie(config-if)# exit
```

- Step 3: Enable PIM-DM on the interface Gi 0/2 and return to the privileged EXEC mode.

```
Ruijie(config)# interface GigabitEthernet 0/2
Ruijie(config-if)# ip pim dense-mode
Ruijie(config-if)# end
```

The configuration on Ruijie B and Ruijie C is similar to Ruijie A, that is, enable multicast routing and enable PIM-DM on each interface.

Note

Enabling PIM-DM will automatically enable IGMP on each interface.

This example applies to both layer-3 switches and routers. However, if you need to configure the switch port as a layer-3 port, you must run the **no switchport** command (not needed for routers).

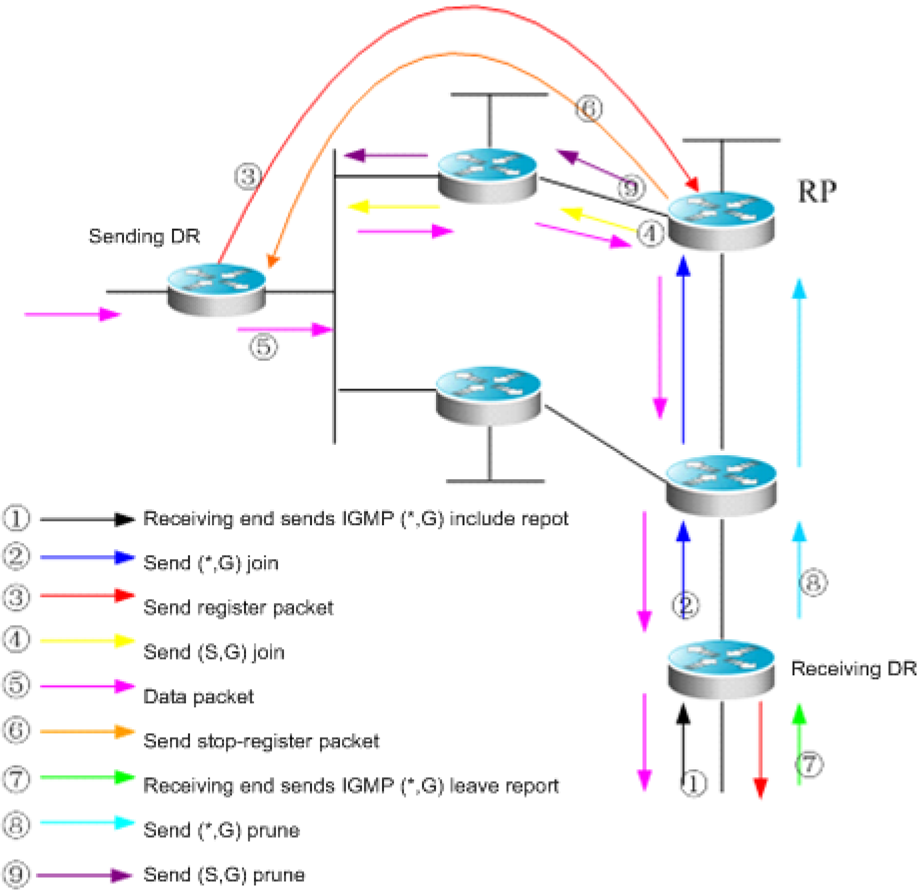
Configuring PIM-SM

PIM-SM Overview

The Protocol Independent Multicast (PIM) is designed by the Inter-Domain Multicast Routing (idmr) working group. As its name implied, PIM does not rely on any specific unicast routing protocol. It can use a unicast routing table established by any unicast routing protocol to perform the RPF check function, instead of maintaining separate multicast routing tables to implement multicast forwarding. As PIM is not required to receive or distribute route updates, compared to other multicast routing protocols, it costs much less. PIM is designed to support shortest path trees (SPTs) and rendezvous point trees (RPTs) simultanenously and enable flexible conversion between them, so that their advantages can be used to improve multicast efficiency. There are two PIM modes: dense mode and sparse mode.

The Protocol Independent Multicast – Sparse Mode (PIM-SM) is a multicast routing protocol of sparse mode. In a PIM-SM domain, the PIM-SM-enabled device periodically sends Hello messages to discover adjacent PIM-SM devices and selects a designated router (DR) in a multi-access network. The DR is responsible for sending Join/Prune messages towards the root of themulticast distribution tree from its directly connected group member, or itsdirectly connected multicast source.

Figure 13 Explicit Join/Prune mechanism of PIM-SM



PIM-SM forwards multicast data packets by establishing a multicast distribution tree. The multicast distribution tree is divided into two types: Shared Tree that takes the RP of the group G as the root and Shortest Path Tree that takes the multicast source as the root. PIM-SM establishes and maintains the multicast distribution tree by use of the explicit join/prune mechanism. As shown in Figure-1,

The DR at the receiving end receives an IGMP (*,G)include report packet from the receiving end.
If the DR at the receiving end is not the RP of this group G, it will send a (*.G)join packet towards the RP. The upstream router receiving this (*.G)join packet will send it towards the RP. In this way, the (*.G)join packet is sent hop by hop until the RP of the group G receives the (*.G)join packet. It is indicated that the DR has joined the shared tree.
When the source host sends multicast data to the group, the source data is encapsulated into a register message and unicasted by the DR at the data source to the RP. Then the RP will forward the decapsulated data packets to group members along the shared tree.
The RP will send a (S, G)join packet to the DR in the direction of the source to join the shortest path tree of this source. In this way, the source's packets are sent to the RP without encapsulation along its shortest path tree after the SPT from the RP to the DR at the source is established.
When the first multicast data reaches along the SPT, the RP will send the register - stop message to the DR at the source, notifying the DR of stopping register encapsulation. When the DR at the source received the register - stop message, it will not encapsulate register packets, but send them to the RP along its shortest path tree, which will forward them to group members along the shared tree.
When a receiving end needs no multicast data, it will send an IGMP leave message.
The DR at the receiving end multicasts the prune message to the group G's RP hop by hop to prune the shared tree. This prune message will finally arrive at the RP or a router with other (*G) receivers on the way to the RP. Therefore, the data packets will not be sent toward that receiving end.
If there is no downstream receiver on the RP, the RP will send the (S,G) prune packet toward the data source. As the (S, G) prune packets are sent to the DR at the source end one by one, the DR at the source end will prune the interface receiving the (S,G) prune packet. As a result, the data packets are filtered at the DR at the source end.

PIM-SM also offers a mechanism of selecting the root point (RP). One or more Candidate-BSRs are configured in a PIM-SM domain. PIM-SM selects a BSR by following a certain rule. There are also Candidate-RPs in a PIM-SM domain that unicast the packets including their IP addresses and available multicast groups to the BSR. The BSR will periodically generate a BSR message which includes a series ofcandidate RPs and corresponding multicast group addresses. The BSR messages are sent hop-by-hop within the entire domain. The device receives and saves these BSR messages. If the DR receives a report on the member relationship of a multicast group from its directly connected host but has no route entries of the multicast group, the DR will use a Hash algorithm to map the multicast group address to a candidate RP that can serve this group. Then, the DR multicasts the Join/Prune message to the RP hop-by-hop. If the DR receives multicast data packets from its directly connected host but has no route entries of the multicast group, the DR will usea Hash algorithm to map the multicast group address to a candidate RP that can serve this group. Then the DR encapsulates multicast data packets into a register message and unicasts it to the RP.

The main difference between PIM-SM and the flood/prune model-based PIM-DM is that PIM-SM is based on the explicit join model. In other words, the receiver sends the join message to the RP, while the router only forwards the packets of that multicast group on the outgoing interface that has joined a multicast group. PIM-SM uses the shared tree to forward multicast packets. Each group has a Rendezvous Point (RP). The multicast source sends data to the RP along the shortest path, and then the RP sends the data to the receivers along the shortest path. This is similar to CBT, but PIM-SM does not use the concept of core. One of the major advantages of PIM-SM is that it not only receives multicast messages through the shared tree but also provides a shared tree-to-SPT conversion mechanism. Such conversion reduces network delay and possible congestion on the RP, but it consumes enormous router resources. So it is suitable for the case where there are only a few multicast data sources and network groups.

PIM-SM uses the shared tree and SPT to distribute multicast frames. At this time, it is assumed that other devices don't want to receive these multicasts unless otherwise stated definitely. When a host joins a group, the equipment connected to the host must notify the root (or the RP) by using the PIM join message. This join message is transferred one after another through the routers to create a shared tree structure. Therefore, the RP records the transfer path and also the register message from the first hop router (DR) of the multicast source, and improves the shared tree upon these two messages. The branch/leaf messages are updated by periodically querying messages. With the shared tree, the multicast source first sends multicast packets to the RP, guaranteeing that all the receivers can receive them. The notation (*.G) represents a tree. The asterisk (*) represents all sources and G represents a specific multicast address. The prune message is also used in the shared tree. That is, the branch/leaf will send prune messages once it is not expecting to receive multicast frames.

PIMv2 BSR is a method of distributing group-to-RP messages to all devices without the need of setting an RP for them. BSR distributes mapping information by propagating BSR messages hop by hop. At first, BSR is selected among routers in the same process as selecting a root bridge based on priority level among layer 2 bridges. Each BSR checks the BSR messages and only forwards those having a priority higher than or equal to its own (higher IP address). The selected BSR sends its BSR message to the all-PIM-routers multicast group (224.0.0.13), where TTL is 1. After the adjacent PIMv2 router receives the message, it multicasts it while setting the TTL to 1. In this way, the BSR message is received by all devices hop by hop. Since the message contains the IP address of the BSR, the candidate BSR can know which router is the current BSR based on this message. The candidate RPs send candidate RP advertisements to announce in which address ranges they can become an RP. The BSR stores them in its local candidate RP cache. The BSP notifies all PIM routers of its local candidate RPs periodically. These messages reach various devices hop by hop in the same way.

☑ The VRF parameters only apply to RSR20, RSR30, RSR50 and RSR50E

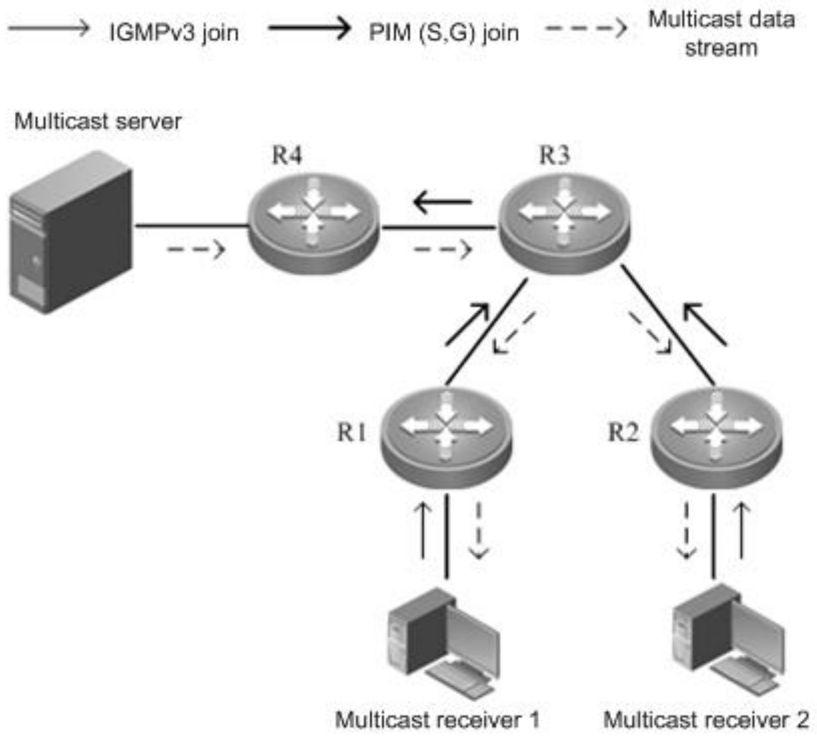
SSM Model

PIM-SM allows two multicast models,: Any-Source Multicast (ASM) and Source-Specific Multicast (SSM). In the ASM model, multicast receivers only specify a multicast group G to join but not a multicast source S. In the SSM model, multicast receivers can specify both a multicast source S and multicast group G.

The PIM-based SSM model provides implementation solutions for specified source multicast. It requires IGMPv3 to manage the membership between hosts and routers and PIM-SM to connect routers.

In the SSM model, multicast receivers have known the multicast source information (S, G) by some means such as accessing the server and accepting advertisements. Then, when a multicast receiver requests a multicast service, it can send IGMP(S, G) join directly to the last hop router. As shown in Figure 2, multicast receiver 1 sends the IGMP(S, G) join report to request the multicast service (S, G). The last hop router sends PIM (S, G) join to the multicast source hop by hop after receiving the IGMP (S, G) join from the multicast receiver. As shown in Figure 2, R1 sends the PIM(S, G) join to R3 after receiving the IGMP(S, G) join report from multicast receiver 1, and then R3 sends the PIM(S, G) join to R4. In this way, a shortest path tree from the multicast receiver to the multicast source is created.

Figure 14 SSM Model



Implementation of an SSM model requires that,

- The multicast receiver obtains the information about the multicast source (S, G) in advance through some channel; the multicast receiver initiates IGMP(S, G) join for the desired multicast services.
- IGMPv3 must be enabled on the interface of the last hop router connected to the multicast receiver. IGMPv1/IGMPv2 does not support the SSM.
- It is recommended that PIM-SSM be enabled on the routers on the way from the multicast receiver to the multicast source. AS PIM-SSM is compatible with PIM-SM, it is feasible to enable only PIM-SM.

Note With SSM enabled, the default group range of SSM is 232/8. The group range of SSM can be modified through commands or SSM can be disabled. For details, see the "Configuring SSM" section.

The SSM has the following features:

- In the SSM model, multicast receivers can obtain the information about the multicast source in advance through some channels, for example, advertisements or access to the specified server.
- The SSM model is a specific subset of PIM-SM. It only processes the PIM(S,G) join and PIM(S,G) prune messages and drops the RPT-related messages within the range of SSM, e.g. PIM(*,G) join/prune messages. It will respond immediately with the register - stop packet to the register packets within the range of SSM.
- In the SSM model, no PR or the election and distribution of RP messages is required. In the SSM, all the multicast distribution trees created are the shortest path trees (SPT).

Preparation before Configuring PIM-SM

Before configuring PIM-SM, enable a routing protocol such as OSPF to automatically discover routes.

PIM-SM Configuration Tasks

The PIM-SM configuration tasks cover the following items. However, only the first and second one are mandatory, and others are optional.

Enabling Multicast Routing

PIM-SM can forward multicast packets only after the multicast routing function is enabled.

Use the following command to enable the multicast routing function in global configuration mode.

Command	Function
ip multicast-routing [**vrf** *vrf-name*]	Enables multicast routing. If VRF is carried, multicast routing is enabled based on the VRF; if VRF is not carried, multicast routing is enabled globally.
no ip multicast-routing [**vrf** *vrf-name*]	Disables multicast routing.

Enabling PIM-SM

PIM-SM must be enabled on each interface. A device can exchange PIM-SM control messages with other devices, maintain and update multicast routing table, and forward multicast packets only after PIM-SM is enabled on its interface.

Use the following command to enable PIM-SM on the interface in interface configuration mode.

Command	Function
ip pim sparse-mode	Enables PIM-SM on the interface.
no ip pim sparse-mode	Disables PIM-SM on the interface.

Note

PIM-SM can be enabled on an interface only after multicast routing is enabled in global configuration mode.

Note

If the system prompts "Failed to enable PIM-SM on <*interface name*>, resource temporarily unavailable, please try again", run this command again.

Note

If the system prompts "PIM-SM Configure failed! VIF limit exceeded in NSM!!!", the number of configured interfaces exceeds the upper limit of the multicast interfaces. Remove some unnecessary PIM-DM, PIM-SM or DVMRP interfaces.

Note

It is not recommended that different IPv4 multicast protocols be configured on different interfaces of a switch or router.

Note

If the interface is of tunnel-type, only 4Over4 configuration tunnel, 4Over4 GRE tunnel, 4Over6 configuration tunnel and 4Over6 GRE tunnel support the IPv4 multicasting. Multicast can be also enabled on other tunnel interfaces that do not support the multicasting, but no error message will be displayed and no multicast packets will be received or sent.

Note

The multicast tunnel can be created on the Ethernet interface only. Nested tunnel and multicast data QoS/ACL are not supported.

Configuring the Interval of Sending Hello Messages

After PIM-SM is enabled on the interface, the device periodically sends Hello messages to the interfaces of neighbors. You can set the interval of sending Hello messages according to the actual network situation.

Use the following command to configure the interval of sending the Hello message in interface configuration mode.

Command	Function
ip pim query-interval *interval-seconds*	Sets the interval of sending Hello messages, in seconds. *interval-seconds*: in the range of 1 to 65535 seconds
no ip pim query-interval	Restores the setting to the default value.

By default, the interval of sending Hello messages on the interface is 30 seconds.

Note

When the interval of sending Hello messages is updated, Hello hold time will automatically be updated to 3.5 times of the interval of sending Hello messages. If the result is greater than 65535, Hello hold time is updated to 65535.

Configuring Propagation-Delay in Hello Message Option

Options can be added to Hello messages. The default value of propagation-delay in LAN Prune Delay Option is 500 milliseconds.

Use the following command to configure the propagation delay of Hello messages in interface configuration mode.

Command	Function
ip pim propagation-delay *interval-milliseconds*	Sets the propagation delay in the range of 1 to 32767 milliseconds.
no ip pim propagation-delay	Restores the setting to the default value.

Note

Modifying propagation delay or prune deny delay will affect J/P-override-interval. As specified in the protocol, J/P-override-interval is less than the hold time of Join-Prune message; otherwise streams may be interrupted temporarily. This can be ensured by network administrators.

Configuring Override-Interval in Hello Message Option

Options can be added to Hello messages. The default value of override-interval in LAN Prune Delay Option **i**s 2500 milliseconds.

Use the following command to configure the override interval in interface configuration mode.

Command	**Function**
ip pim override-interval *interval-milliseconds*	Sets the override interval in the range of 1 to 65535 milliseconds.
no ip pim override-interval	Restores the setting to the default value, namely, 2500 milliseconds.

Note

Modifying propagation delay or prune deny delay will affect J/P-override-interval. As specified in the protocol, J/P-override-interval must be less than the hold time of Join-Prune message; otherwise streams may be interrupted temporarily. This can be ensured by network administrators.

Configuring Neighbor-Tracking in Hello Message Option

The T bit of the LAN Prune Delay Option of the Hello message indicates whether to enable join restriction on the interface. When join restriction is enabled on the interface, the Join message to be sent from the interface to the upstream neighbor will be restricted, upon receipt of the Join message from its neighbor to the upstream neighbor. If this function is disabled, the Join message to be sent from the interface to the upstream neighbor will still be sent. Moreover, if join restriction is enabled on all downstream receivers, the upstream router can trace these receivers by received Join messages. By default, join restriction is enabled on the interface.

Use the following command to disable join restriction on the interface in interface mode.

Command	**Function**
ip pim neighbor-tracking	Disables join restriction on the interface.
no ip pim neighbor-tracking	Enables join restriction on the interface.

Configuring Triggered Hello Delay of Hello Messages

When a router starts or detects new neighbor, the device will send Hello messages after a random period of time to prevent congestion of Hello packets. This random interval can be calculated based on triggered hello delay, which is 5 seconds by default.

Use the following command to configure the triggered Hello delay in interface configuration mode.

Command	**Function**
ip pim triggered-hello-delay *interval-seconds*	Sets the triggered hello delay, in seconds. *interval-seconds*: in the range of 1 to 5 seconds
no ip pim triggered-hello-delay	Restores the setting to the default value.

Configuring PIM-SM Neighbor Filtering

You can filter neighbors on an interface to enhance network security. With this function enabled, when a neighbor is denied by an ACL, the PIM-SM will not establish the adjacency relationship with that neighbor or remove the currently established adjacency relationship with that neighbor.

Use the following command to configure PIM-SM neighbor filtering in interface configuration mode:

Command	Function
ip pim neighbor-filter *access-list*	Enables the PIM-SM neighbor filtering function on the interface.
no ip pim neighbor-filter *access-list*	Disables the PIM-SM neighbor filtering function on the interface.

By default, the PIM-SM neighbor filtering function is disabled on an interface.

Note

ip pim neighbor-filter command description:
When the associated ACL rule is permit, only the neighbor address in the ACL list can be used as the PIM neighbor of the current interface; when the associated ACL rule is deny, the neighbor address in the ACL list cannot be used as the PIM neighbor of the current interface.

Configuring the Priority of DR

This command is used to configure the priority of the designated router (DR). Higher weight means higher priority.

Use the following command to configure the DR priority in interface configuration mode.

Command	Function
ip pim dr-priority *priority-value*	Sets the DR priority. *priority-value*: in the range of 0 to 4294967294
no ip pim dr-priority	Restores the setting to the default value, namely 1.

Configuring Static RP

In a small network, you can configure static RP to use PIM-SM. All the devices in the PIM-SM domain have the same static RP configuration, ensuring no ambiguity of the PIM-SM multicast routes.

Use the following command to configure static RP in global configuration mode.

Command	Function
ip pim [**vrf** *vrf-name*] **rp-address** *rp-address* [*access-list*]	Configures the static RP address. *access-list*: supports the numerical ACL in the range of 1 to 99 and 1300 to 1999; also supports the named ACL. All multicast groups are permitted by default.
no ip pim [**vrf** *vrf-name*] **rp-address** *rp-address* [*access-list*]	Removes the static RP configuration.

Note

If the static RP and the dynamic RP take effect at the same time, the dynamic RP takes precedence. .

Note

The static RP address can be configured for multiple multicast groups (by ACL) or all multicast groups (not by ACL). However, a static RP address cannot be configured for several times.

Note

If more than one static RP are configured for a multicast group, the one with the highest IP address takes effect.

Note

Only the permitted addresses defined in the ACL are invalid multicast groups. By default, 0.0.0.0/0 refers to filtering all multicast groups (224/4).

Note

After configuration, the static RP source address is inserted into the tree of group-based static RP group. Each static multicast group maintains the link table structure of a static RP group. The link tables are ordered in descending sequence by IP addresses. When a RP is selected for a group, the first element, namely, the RP with the highest IP address is firstly selected.

Note

Deleting a static RP address deletes the address from all groups that has this address, and one address is selected from the existing tree structure as the RP address.

Configuring Candidate BSR

A globally unique BSR is elected from candidate BSRs configured on an interface in a PIM-SM domain. This BSR will collect and distribute RPs in the domain to ensure the uniqueness of RP mapping in the domain.

Use the following command to configure the candidate BSR in global configuration mode.

Command	Function
ip pim [**vrf** *vrf-name*] **bsr-candidate** *interface-type interface-number* [*hash-mask-length* [*priority-value*]]	Specifies an interface as a candidate BSR. The global BSR is elected through BSM message learning and competition. *hash-mask-length* ranges from 0 to 32, 10 by default. *priority-value* ranges from 0 to 255, 64 by default.
no ip pim [**vrf** *vrf-name*] **bsr-candidate** *interface-type interface-number*	Removes the configuration of a candidate BSR.

Configuring BSR Border

To restrict BSM flooding, you can set the BSR border on the interface so that BSM will be dropped immediately rather than being forwarded.

Use the following command to configure the BSR border in interface configuration mode.

Command	Function
ip pim bsr-border	Configures the BSR border on an interface.
no ip pim bsr-border	Removes the BSR border on an interface.

Ignoring RP Priorities in RP-SET

When an RP is selected for a multicast address, if several RPs can serve this multicast address, you can use this command to ignore the RP priority when comparing two RPs. If this command is not configured, the RP priority will be taken into account during comparison.

Command	Function
ip pim [**vrf** *vrf-name*] **ignore-rp-set-priority**	Ignores the RP priority in RP-Set.
no ip pim [**vrf** *vrf-name*] **ignore-rp-set-priority**	Considers the RP priority in RP-Set.

Configuring Candidate RP

Candidate RP advertisement is sent to the BSR at intervals and then propagated to all the PIM-SM devices in the domain, thus ensuring the uniqueness of RP mapping.

Use the following command to configure the candidate RP in global configuration mode.

Command	Function
ip pim rp-candidate *interface-type interface-number* [**priority** *priority-value*] [**interval** *interval-seconds*] [**group-list** *access-list*]	Configures the device as the candidate RP. When **priority** is default, *priority-value* ranges from 0 to 255, 192 by default. When **interval** is default, *interval-seconds* ranges from 1 to 16383, 60 seconds by default. When **group-list** is default, *access-list* permits all multicast groups by default, namely 224/4.
no ip pim rp-candidate *interface-type interface-number*	Removes the candidate RP configuration.

Note

You can use the ACL to specify an interface as the candidate RP of a specific group. It should be noted that the group calculation is based on the permit ACE, not the deny ACE. The source range of the ACE is matched as a specific group range.

Checking Reachability of Register Messages

You can use this command to check whether an RP is reachable. With this command configured, the DR checks whether RP is reachable before sending a register packet, that is whether there is a route to the RP by checking the unicast and static multicast routing tables. If there is no such a route, no register packet will be sent.

Use the following command to check the RP reachability in global configuration mode.

Command	Function
ip pim [**vrf** *vrf-name*] **register-rp-reachability**	Checks whether a register packet can reach the destination device. No check is conducted by default.
no ip pim [**vrf** *vrf-name*] **register-rp-reachability**	Disables this function.

Note

If there is a static multicast route to the RP and the next hop of the route is reachable in the unicast routing table, PIM-SM considers that a route to the RP exists even if the RP is not reachable in the unicast routing table.

Configuring Address-based Filtering for Register Packets

You can use this command to filter the register packets that have arrived at an RP by the source address and group address contained in the packets. Otherwise, every reached register packet is permitted. With this command configured, only the register packets with the source addresses and group addresses permitted by the ACL can be processed.

Use the following command to configure address-based filtering for register packets in global configuration mode.

Command	Function
ip pim [**vrf** *vrf-name*] **accept-register list** *access-list*	Enables filter of register packets by source addresses and group addresses. *access-list* ranges from 100 to 199 and 2000 to 2699; also supports named ACL.
no ip pim [**vrf** *vrf-name*] **accept-register**	Disables filter of register packets by source addresses and group addresses.

Configuring Rate Limit on Sending Register Packets

Use this command to configure the rate of sending register packets by DR. Use the **no** form of this command to cancel the rate limit. This command configures the rate of sending register packets for each (S, G) state, not the register packets in the whole system.

Use the following command to configure the rate limit on sending RPs in global configuration mode.

Command	Function
ip pim [**vrf** *vrf-name*] **register-rate-limit** *rate*	Sets the maximum number of register packets sent per second. *rate*: in the range of 1-65535
no ip pim [**vrf** *vrf-name*] **register-rate-limit**	Removes the rate limit.

Configuring the Whole-Packet Method for Calculating the Register Packet Checksum

Use this command to calculate the whole PIM packet including the multicast data packet encapsulated when calculating the register packet checksum. Otherwise, the checksum of register packets is calculated using the default method specified by the protocol.

Use the following command to configure the whole-packet method for calculating the register packet checksum in global configuration mode.

Command	Function
ip pim [**vrf** *vrf-name*] **register-checksum-wholepkt** [**group-list** *access-list*]	Configures the whole-packet method for calculating the register packet checksum. group-list *access-list*: Apply this configuration to all multicast addresses by default.
no ip pim [**vrf** *vrf-name*] **register-checksum-wholepkt** [**group-list** *access-list*]	Removes the whole-packet method for calculating the register packet checksum. group-list *access-list*: By default, this configuration is removed for all the multicast addresses.

Note

Some devices from other vendors make checksum calculation of register packets based on the overall packets. This function is introduced in Ruijie's devices to be compatible with those devices.
If a device from those vendors serves as the RP and Ruijie's device serves as the source DR, you can use this command on the source DR; if the device from other vendors serves as the source DR and Ruijie's device serves as the RP, you can use this command on the RP.

Configuring the RP to Forward Multicast Packets to Downstream Interfaces after Decapsulating Register Packets

Use this command to decapsulate a register packet and forward its multicast packets. Without this command, the multicast packets in the register packet are not de-capsulated or forwarded.

Use the following command in global configuration mode.

Command	Function
ip pim [**vrf** *vrf-name*] **register-decapsulate-forward**	Decapsulates the register packet and forwards its multicast packets
no ip pim [**vrf** *vrf-name*] **register-decapsulate-forward**	Removes the configuration.

Note

Since the register packet is decapsulated and its multicast packets are forwarded through software, in case of decapsulation and forwarding of many register packets, this function incurs additional workload to CPU. So it is not recommended.

Limiting the Range of Legal BSRs

Use this command to limit the range of legal BSRs. Without this function, PIM-SM-enabled routers will receive all external BSM messages.

Use the following command in global configuration mode.

Command	Function
ip pim [**vrf** *vrf-name*] **accept-bsr list** *accept-bsr list*	Filters the BSM packet of BSR. The range is from 1 to 99, 1300 to 1999, or can be characters.
no ip pim [**vrf** *vrf-name*] **accept-bsr**	Removes the filtering of the BSM packet of BSR.

Note

This command filters the BSR address field of the BSM message. If this address is denied by ACL, the BSM message is filtered.

Configuring the Electing BSR to Limit the Legal CRP Address Range and the Multicast Group Range It Serves

Use this command to configure the electing BSR to limit the legal CRP address range and the multicast group range it serves. Without this function, the electing BSR will receive all external advertisement messages of candidate RPs.

In this command, the *source* parameter of ACL rule specifies the C-RP address and the *destination* parameter specifies the multicast group range the C-RP serves. If both addresses are denied by ACL, the group of the C-RP will be filtered.

Use the following command in global configuration mode.

Command	Function
ip pim [**vrf** *vrf-name*] **accept-crp list** *accpet-crp list*	Enables the electing BSR to filter the candidate RP advertisement. The range is from 100 to 199, 2000 to 2699 or can be characters.
no ip pim [**vrf** *vrf-name*] **accept-crp**	Disables the electing BSR to filter the candidate RP advertisement.

Configuring the Electing BSR to Receive the C-RP-ADV Message Whose Prefix-count Is 0

Use this command to configure the electing BSR to receive the C-RP-ADV message whose prefix-count is 0. Without this command, the electing BSR will not process the C-RP-ADV packet whose prefix-count is 0.

With this function, the electing BSR considers that the C-RP supports all groups after receiving the C-RP-ADV message whose prefix-count is 0.

Use the following command in global configuration mode.

Command	Function

Command	Function
ip pim [**vrf** *vrf-name*] **accept-crp-with-null-group**	Configures the electing BSR to receive the C-RP-ADV message whose prefix-count is 0.
no ip pim [**vrf** *vrf-name*] **accept-crp-with-null-group**	Removes the configuration.

Configuring the Source IP Address of Register Packets

This command sets the source IP address of register packets sent from DR. With this command not configured or the **no** form of this command, the DR interface address connected to the multicast source is used as the source address of the register packet. If the address parameter of this command is used, the configured address must be reachable for unicast routes. If the interface parameter of this command is used, it is generally a loopback interface, but can also be other types. This interface address must have been advertised by the unicast route.

Use the following command in global configuration mode.

Command	Function
ip pim register-source { *local_address* | *Interface-type interface-number* }	Configures the source IP address used in RPs.
no ip pim register-source	Sets the RPF interface address as the source IP address of register packets.

Configuring Register Suppression Time

This command configures the registersuppression time. It will modify the register suppression time defined on the DR. If the **ip pim rp-register-kat command** is not configured, defining the register suppression time in the RP will change RP keepalive period.

Use the following command to configure the register suppression time in global configuration mode.

Command	Function
ip pim [**vrf** *vrf-name*] **register-suppression** *seconds*	Configures the register suppression time. *seconds* ranges from 1 to 65535 seconds.
no ip pim [**vrf** *vrf-name*] **register-suppression**	Sets the suppression time to 60 seconds.

Configuring the Probe Interval of Null Register Packet

The source DR can send Null-Register packet to the RP in a period of time before the registersuppression time expires. This period is called probe interval, 5 seconds by default.

Use the following command to configure the probe time of null register packets in global configuration mode.

Command	Function
ip pim [**vrf** *vrf-name*] **probe-interval** *interval-seconds*	Configures the probe time of null register packets. *interval-seconds*: in the range of 1 to 65535 seconds

Command	Function
no ip pim [**vrf** *vrf-name*] **probe-interval**	Restores the probe time to 5s.

Note

The probe time should be less than half of register suppression time. Moreover, the register suppression time times three and plus the probe time should not be greater than 65535 seconds; otherwise, the system displays a warning message.

Configuring the RP KAT Timer

Use this command to configure the keepalive time of the (S, G) state created by register packets on the RP in global configuration mode.

Command	Function
ip pim [**vrf** *vrf-name*] **rp-register-kat** *seconds*	Configures KAT timer. *seconds*: in the range of 1 to 65535 seconds
no ip pim [**vrf** *vrf-name*] **rp-register-kat**	Uses the default KAT value, namely, register suppression time times three and plus register probe time.

Note

The value of the timer should be greater than register suppression time of source DR times three and plus register probe time. Otherwise, the RP may timeout the (S, G) state before the source DR sends the register packet again, causing temporary interruption of the multicast stream.

Configuring the Interval of Sending the Join/Prune Message

By default, the Join/Prune message is sent at the interval of 60 seconds by default. Use this command to modify this interval. With this command not configured, the default sending interval of join/prune packets is 60 seconds.

Use the following command in global configuration mode.

Command	Function
ip pim [**vrf** *vrf-name*] **jp-timer** *seconds*	Sets the interval of sending the Join/Prune message. *interval-seconds*: in the range of 1 to 65535 seconds.
no ip pim [**vrf** *vrf-name*] **jp-timer** [*interval-seconds*]	Restores the setting to the default value, namely 60s.

Note

When the sending interval of the join/prune packets is configured, if the interval times3.5 is more than 65535, a warning message is displayed and the interval is changed to 65535/3.5 seconds.

Allowing the Last Hop Device to Switch from the Shared Tree to the Shortest Path Tree

With this command configured, when the first (S, G) packet is received, a PIM join message is triggered and a source tree is created. If the keyword **group-list** is defined, all the groups specified will switch to the source tree. Use the **no** form of this command to enable the device to switch back to the shared tree and send a prune message.

Use the following command in global configuration mode.

Command	Function
ip pim [**vrf** *vrf-name*] **spt-threshold** [**group-list** *access-list*]	If **group-list** is defined, allows the last hop device of a specific group to switch from the shared tree to the shortest path tree. If **group-list** is not defined, allows all multicast groups.
no ip pim [**vrf** *vrf-name*] **spt-threshold** [**group-list** *access-list*]	Disables this function.

Configuring MIB in Dense Mode

Use this command to configure MIB in dense mode; With this command not configured, MIB is in sparse mode.

Use the following command in global configuration mode.

Command	Function
ip pim mib dense-mode	Uses MIB in dense mode.
no ip pim mib dense-mode	Uses MIB in sparse mode,

Enabling SSM

In the SSM mode, multicast packets can be directly received from the multicast source instead of through the RP tree.

Use the following command in global configuration mode.

Command	Function
ip pim [**vrf** *vrf-name*] **ssm** { **default** | **range** *access-list* }	Enables SSM.
no ip pim [**vrf** *vrf-name*] **ssm**	Disables SSM.

Monitoring and Maintaining PIM-SM

PIM-SM provides the following commands to monitor and maintain PIM-SM.

Displaying PIM-SM Information

Use the following commands to show information about PIM-SM on the local device.

Command	Function
show debugging	Shows the status of the debugging switch.
show ip pim sparse-mode [**vrf** *vrf-name*] **bsr-router**	Shows BSR details.
show ip pim sparse-mode [**vrf** *vrf-name*] **interface** [*interface-type interface-number*] [**detail**]	Shows the PIM-SM information of the interface.
show ip pim sparse-mode [**vrf** *vrf-name*] **local-members** [*interface-type interface-number*]	Shows local IGMP information about a PIM-SM interface.
show ip pim sparse-mode [**vrf** *vrf-name*] **mroute** [*group-or-source-address* [*group-or-source-address*]] [**proxy**]	Shows information about a PIM-SM multicast routing table. With the parameter **proxy**, this command shows the RPF Vector information about PIM-SM entries.
show ip pim sparse-mode [**vrf** *vrf-name*] **neighbor** [**detail**]	Shows information about the PIM-SM neighbors.
show ip pim sparse-mode [**vrf** *vrf-name*] **nexthop**	Shows the next hop of PIM-SM from NSM.
show ip pim sparse-mode [**vrf** *vrf-name*] rp-**hash** *group-address*	Shows a specified group address. *group-address* corresponds to RP information.
show ip pim sparse-mode [**vrf** *vrf-name*] **rp mapping**	Shows information about all current RPs and the groups they serve.
show ip pim sparse-mode [**vrf** *vrf-name*] **track**	Shows the number of PIM packets sent and received from the start time of statistics till now

☑ The parameter **proxy** in the command **show ip pim sparse-mode mroute** is only supported by RSR20, RSR30, RSR50 and RSR50E.

Deleting Internal Information About PIM-SM

Use the following commands to delete internal information about PIM-SM on the local device.

Command	Function
clear ip mroute [**vrf** *vrf-name*] { * | *group_address* [*source_address*] }	Deletes a multicast routing table entry.
clear ip mroute [**vrf** *vrf-name*] **statistics** { * | *group_address* [*source_address*] }	Deletes the statistics of a multicast routing table entry.
clear ip pim sparse-mode [**vrf** *vrf-name*] **bsr rp-set** *	Deletes RP-SET.
clear ip pim sparse-mode [**vrf** *vrf-name*] **track**	Resets the start time of statistics and clears the PIM packet counter

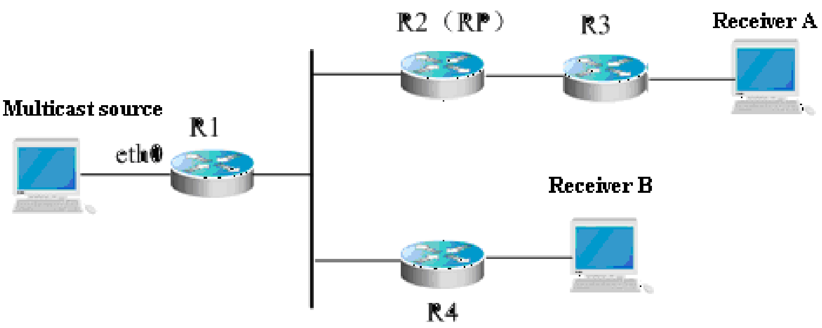
For details about the preceding commands, see *PIM-SM Commands*.

PIM-SM Configuration Example

Configuration Requirements

Figure 3 shows the network topology. R1 and the multicast source are in the same network. R2 will be set as an RP. R3 and receiver A are in the same network, and R4 and receiver B are in the same network. Assume that the devices connect to the host properly, IP addresses are configured on each interface, and IP unicast is enabled on each device.

Figure 15 Network topology for PIM-SM configuration



Device Configuration

Step 1: Enable multicast routing.

R1 is used as an example to show how to enable IP multicast routing. The configurations on R2, R3 and R4 are similar to R1.

```
Ruijie# configure terminal
Ruijie(config)# ip multicast-routing
```

Step 2: Enable PIM-SM on the interface.

The following shows how to enable PIM-SM on Gi 0/1 of R1. The configurations on interfaces of R1, R2, R3 and R4 are similar.

```
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if)# ip pim sparse-mode
Ruijie(config-if)# end
```

Step 3: Configure the candidate BSR and the candidate RP.

Configure loopback 1 of R2 as C-BSR and C-RP.

```
Ruijie(config)# interface loopback 1
Ruijie(config-if)# ip address 100.1.1.1 255.255.255.0
Ruijie(config-if)# ip pim sparse-mode
Ruijie(config-if)# exit
Ruijie(config)# ip pim bsr-candidate loopback 1
Ruijie(config)# ip pim rp-candidate loopback 1
Ruijie(config-if)# end
```

After the receivers join the group and the multicast source sends multicast streams, you can use the **show** command provided by PIM-SM to monitor the running status.

Note Enabling PIM-DM will automatically enable IGMP on each interface.

Note This example applies to both layer-3 switches and routers. However, if you need to configure the switch port as a layer-3 port, you must run the **no switchport** command (not needed for routers).

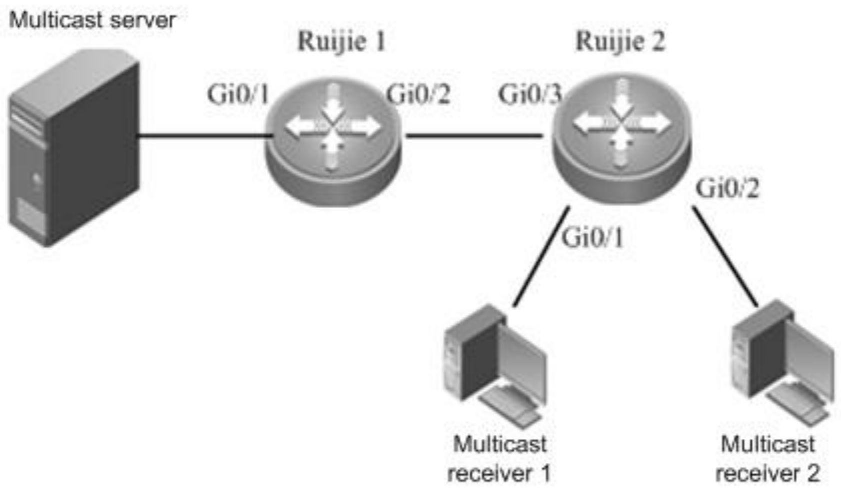
Enabling SSM based on PIM-SM

Networking Requirements

- The network must be interconnected on layer 3, for example, based on OSPF.
- The multicast receivers can obtain the information about the multicast source through some channels, depending on application software of hosts and deployment of network administrators.
- The PIM-SM protocol is applied within the network.

Networking Topology

Figure 16 Network topology for SSM configuration



Device name	Interface	IP address
Ruijie 1	Gi 0/1	2.2.2.1/24
	Gi 0/2	3.3.3.1/24
Ruijie 2	Gi 0/3	3.3.3.2/24
	Gi 0/1	4.4.4.1/24
	Gi 0/2	5.5.5.1/24

Configuration Steps

- Perform basic configuration on interfaces of Ruijie 1 and Ruijie 2.

Perform configurations on interfaces of Ruijie 1 and Ruijie 2 based on the IP addresses specified in the networking topology.

- Enable interworking on layer 3.

Enable OSPF on all interfaces of Ruijie 1 and Ruijie 2, implementing interworking on layer 3.

- Configure multicast on Ruijie 1 and Ruijie 2.

Firstly, enable the multicast routing on Ruijie 1 and Ruijie 2; secondly, enable PIM-SM on the interfaces of Ruijie 1 and Ruijie 2; at last, enable IGMPv3 on the interfaces where Ruijie 2 connects to the multicast receivers. Ruijie 2 is used as an example below.

# Enable the multicast routing on Ruijie 2.

```
Ruijie(conf)#ip multicast-routing
```

# Enable PIM-SM on all the interfaces of Ruijie 2. Interface Gi 0/1 is used as an example below:

```
Ruijie(conf-GigabitEthernet0/1)#ip pim sparse-mode
```

# Enable IGMPv3 on the interfaces where Ruijie 2 connects to the multicast receivers. Interface Gi 0/1 is used as an example below:

```
Ruijie(conf-GigabitEthernet0/1)#ip igmp version 3
```

The configuration procedure for Ruijie 1 is similar to that for Ruijie 2.

- Enable the SSM function on Ruijie 1 and Ruijie 2.

# Enable SSM on Ruijie 2. The default group range of SSM is used, namely 232/8.

```
Ruijie(conf)#ip pim ssm default
```

# Enable SSM on Ruijie 1. The default group range of SSM is used, namely 232/8.

```
Ruijie(conf)#ip pim ssm default
```

Verification

- Multicast receivers 1 and 2 request the multicast service (2.2.2.2, 232.0.0.1) by sending IGMP (2.2.2.2, 232.0.0.1) join.

Protocol entry (2.2.2.2, 232.0.0.1) will be created on Ruijie 2. Use the **show ip pim sparse-mode mroute** command to view it.

```
Ruijie#show ip pim sparse-mode mroute
IP Multicast Routing Table

```

As shown in the preceding information, the protocol entry (2.2.2.2, 232.0.0.1) has been created on Ruijie 2 and there are two multicast receivers.

- The multicast server sends data stream (2.2.2.2, 232.0.0.1).

Multicast forwarding table (2.2.2.2, 232.0.0.1) will be created on Ruijie 2. Use the **show ip mroute** command to view it.

```
Ruijie#show ip mroute

IP Multicast Routing Table
Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT
Timers: Uptime/Stat Expiry
Interface State: Interface (TTL)

(2.2.2.2, 232.0.0.1), uptime 00:19:31, stat expires 00:02:53
Owner PIMSM, Flags: TFSs
  Incoming interface: GigabitEthernet 0/3
  Outgoing interface list:
     GigabitEthernet 0/1(1)
     GigabitEthernet 0/2(1)
```

As shown in the preceding information, the multicast forwarding table (2.2.2.2, 232.0.0.1) has been created on Ruijie 2. Multicast egresses Gi 0/1 and Gi 0/2 are connected to multicast receivers 1 and 2 respectively. The forwarding table has been marked with the flag “s", which indicates that the table is in the SSM model.

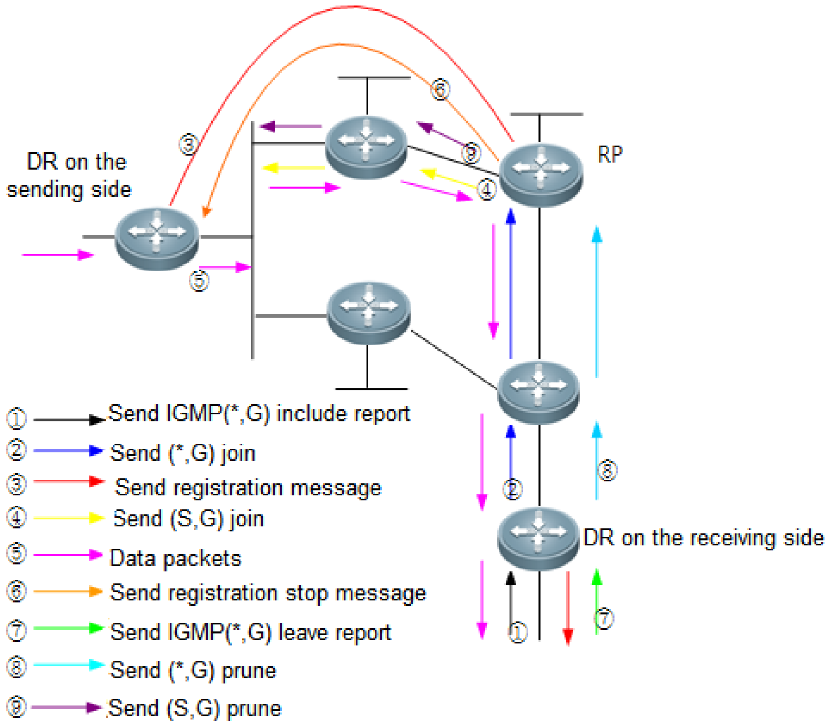
Configuring PIM-SMv6

PIM-SM Overview

PIM (Protocol Independent Multicast) is designed by IDMR (Inter-domain Multicast Routing) working group. As its name implied, PIM does not depend on a specific unicast routing protocol. It utilizes the unicast routing table established by various unicast routing protocols to enable the RPF check function instead of maintaining a separate multicast routing table for forwarding multicast packets. Compared with other multicast protocols, PIM overhead falls down at large extent for PIM does not need to receive and send multicast route update. The concept behind PIM design is that support and flexible transformation between SPT and the shared tree is enabled for higher multicast efficiency. There are two kinds of PIM modes-dense mode and sparse mode.

PIM-SM (Protocol Independent Multicast Sparse Mode) is a multicast routing protocol in sparse mode. In the PIM-SM domain, the device running PIM-SM sends the Hello message at a specific interval to discover adjacent devices running PIM-SM and be in charge of DR election. Here DR sends the “join/prune” message to its direct group members in the direction of the root node of the multicast distribution tree or sends the data from the direct multicast source to the multicast distribution tree.

Figure 17 PIM-SM explicit join/prune mechanism



PIM-SM forwards multicast data packets by setting up a multicast distribution tree. There are two kinds of multicast distribution tree: the shared tree using G’s RP as root and the shortest path tree using the multicast source as root. With the explicit join/prune mechanism, PIM-SM sets up and maintains the multicast distribution tree.

As illustrated in the above figure:

1. The DR on the receiving side receives the MLD (*,G) report message from a host on the same side.

2. If the DR on the receiving side is not the RP of G, it will send a (*.G) Join message to the RP. Upon receiving this message, the upstream router will send the (*.G) Join message to the RP without the forwarding entry of the corresponding group. In this way, the (*,G) Join message is transmitted hop to hop until G's RP receives the (*,G) Join message, indicating that the DR joins the shared tree.
3. When the source host sends multicast data to a group, the data is encapsulated in the registration message and sent by the DR on the source side to the RP in unicast form. Then, the RP decapsulates the registration message, extracts the data and forwards the data to every member of the group along the shared tree.
4. The RP sends the (S,G) Join message to the DR on the source side to join its shortest path tree.
5. After the shortest path tree from the RP to the DR on the source side is established, data packets are sent to the RP along this STP without encapsulation.
6. When the first multicast data arrives along the SPT, the RP sends the registration stop message to the DR on the source side, notifying the DR of stopping registration and encapsulation. Upon receiving the registration stop message, the DR no longer registers and encapsulates data packets. Instead, it sends data packets to the RP along the shortest path tree, which then forwards data packets to every group member along the shared tree.
7. When a receiving end does not need multicast packets, it sends the MLD leave message.
8. The DR on the receiving side sends the prune message in multicast form hop by hop to G's RP, the prune message arrives at the RP or the router along the way to the RP which has other (*,G) receiver so that data packets are not sent to this receiving side any more.
9. If the RP has no downstream receiver at present, it sends (S,G) prune message to the DR of the data source hop by hop. Consequently, the DR on the source side prunes the interface receiving this (S,G) prune message. In this way, data packets are filtered on the DR of the data source.

RP election is also involved in PIM-SM. when there is one or more candidate BSRs configured in the PIM-SM domain, some rule is applied to elect BSR. Candidate RPs are also configured in the PIM-SM domain, which send the packets containing their addresses and serviceable multicast groups to BSRs in unicast form. BSRs generate bootstrap messages with a series of candidate RPs and the addresses of corresponding multicast groups periodically. These bootstrap messages are transmitted in the overall domain hop by hop. Devices will receive and save these bootstrap messages. Upon receiving the member relation report of a multicast group from the directly connected device, the DR will use a hash algorithm and map the multicast group address to a candidate RP who can serve this group if it has not the routing entry of this group. Then the DR will send the join/prune message in multicast form hop by hop along the way to the RP. On the other hand, upon receiving multicast packets from the directly connected device, the DR will use a hash algorithm and map the multicast group address to a candidate RP who can serve this group, and then encapsulate these multicast packets in the registration message and send it to the PR in unicast form.

The essential difference between PIM-SM and PIM-DM is that PIM-SM is based on explicit join mode and PIM-DM is based on flood/prune mode. For PIM-SM, the receiver sends a join message to the PR, but the device forwards the packets of a multicast group only on the interface joining this multicast group. PIM-SM forwards multicast packets through the shared tree. Each multicast group has a rendezvous point. The multicast source sends packets to the RP along the shortest path, and then the RP sends the packets to every receiver along the shortest path. This process is similar to CBT. However, the core concept is not used in PIM-SMv6. One of the main advantages of PIM-SMv6 is that it not only receives multicast packets through the shared tree but also offers the shared tree-to-SPT transformation mechanism. This transformation consumes a lot number of resources, even though it reduces network delay and possible block on the RP. It is suitable for the environment where there are many pairs of multicast sources yet fewer networks.

PIM-SM distributes multicast packets through the shared tree and SPT. Assume that other devices do not need to receive these multicast packets, unless otherwise specified. When a host joins a multicast group, the devices connecting to the host notify the root (or RP) through the PIM join message. This message is transferred among these devices in order to set up the structure of a shared tree. So, the RP records this transmission path and the registration message from the first hop device (DR) of the sending multicast source, and perfects the shared tree based on these two messages. Update of leaf messages is enabled on periodic query message. For the shared tree, the multicast source sends multicast packets to the RP so that all receivers can receive these multicast packets. *.G indicates a tree, in which * indicates all sources and G indicates the specific multicast address. The prune message is also used in the shared tree when leafs do not need to receive multicast packets.

PIMv2 BSR distributes the group-to-RP message to all devices without the necessity for configuring RP for every device. The BSR distributes the mapping message through the hop-by-hop flooding BSR message. First of all, the BSR is elected among devices. This election procedure is similar to electing the root bridge in STP by priority. Every BSR device checks the BSR message, and only forwards the BSR messages with higher or equivalent priority (or higher IP address). The elected BSR sends the BSR message to the all-PIM-routers multicast group (ff02::d) with TTL 1. Upon receiving the BSR message, the adjacent PIMv2 device sends it out in multicast form and then reset TTL to 1. In this way, the BSR message is sent to all devices hop by hop. Since the BSR message includes the IP addresses of BSR devices, the candidate BSR can determine which device is the current BSR device. The candidate RP sends the candidate RP advertisement and alleges in which address ranges it can become RP. The BSR stores the advertisement message in its local candidate RP cache, and notifies all PIM devices of local candidate RPs periodically. Also in this way, the message is sent to all devices hop by hop.

Embedded RP is a new feature introduced in IPv6 multicast. It provides a new type of mapping from IPv6 multicast group to RP to replace the RP configured statically or the one calculated by BSR mechanism dynamically.

Some special IPv6 multicast addresses are called that of the embedded RP, the range of which is FF70::/12. You can obtain IPv6 unicast addresses by calculating the special IPv6 multicast group addresses, which means a RP address is embedded in each IPv6 multicast group address.

If the multicast group address extracted from MLD packets, PIM packets and multicast data packets by routers is the IPv6 multicast address of embedded RP, the router can calculate the RP address from this multicast group address directly. The embedded-RP multicast groups have the following advantages:

1) Since an IPv6 multicast group address is bound with a RP address. You can calculate the RP address directly rather than learning and updating the group RP mapping.

2) It can be deployed not only for intra-domain multicast, but also for inter-domain multicast. For IPv6 multicast group addresses of the same embedded RP, the same RP address is calculation no matter where the router is located.

SSM Model for PIM

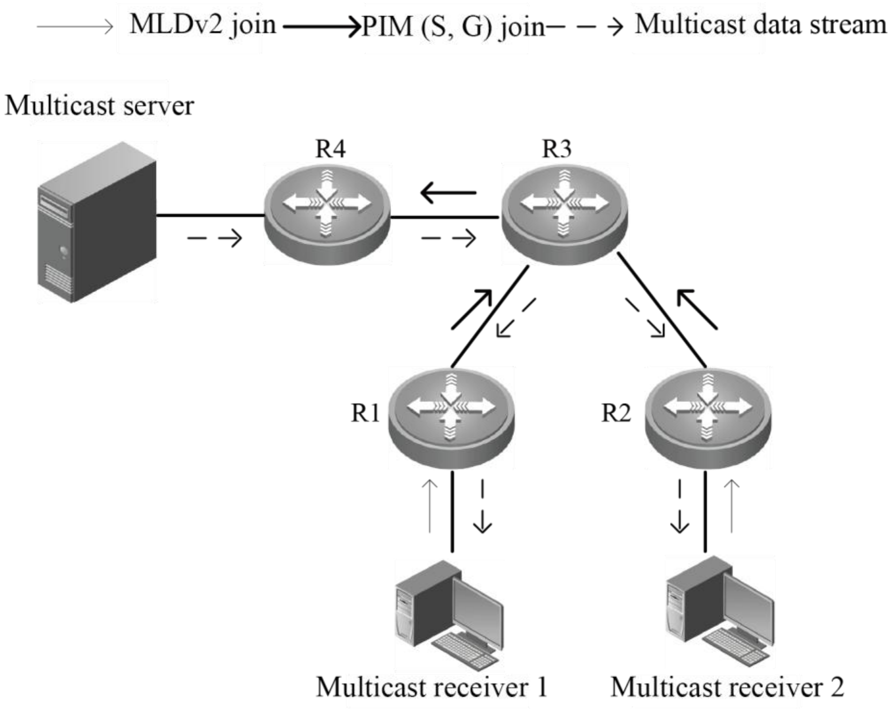
The traditional PIM-SM mode and PIM-DM mode are Any-Source Multicast (ASM) models, in which multicast data receivers specify only a specific multicast group G.

Source-Specific Multicast (SSM) and ASM are two independent models. The SSM model can be implemented by the PIM-SM technology, in which multicast data receivers specify both the multicast source S and multicast group G.

The PIM-based SSM model provides a solution for specifying the source multicast. It requires MLDv2 to manage the membership between hosts and routers and uses PIM-SM to connect hosts and routers.

In the SSM model, multicast receivers learn information about the multicast source (S,G) through a channel, such as accessing servers or accepting advertisements. Therefore, when the multicast receiver requests a multicast service, it can send the MLD (S, G) Join message directly to the last-hop router, as shown in Figure 2, and the multicast receiver 1 sends the MLD (S, G) Join message to request the multicast service (S, G). After receiving the MLD (S, G) Join message from the multicast receiver, the last-hop router sends PIM (S ,G) to the multicast source hop by hop, as shown in Figure 2. After receiving the MLD (S, G) Join message from multicast receiver 1, R1 sends PIM (S ,G) Join message to R3, and then R3 sends PIM (S ,G) Join message to R4. As a result, a shortest path tree from multicast receivers to the multicast source is established, as shown in Figure 2.

Figure 18 SSM working model



Requirements for SSM models:

1) The multicast receiver learns information about the multicast source (S, G) through a channel and initiates an MLD (S, G) Join message to the multicast service.

2) The last-hop router connects to the interface of multicast receivers and must be enabled with MLDv2 but not MLDv1. MLDv1 cannot processing the MLD Join message of the specified source.

3) It is recommended to enable PIM-SSM on path routers from multicast receivers to the multicast source. Since PIM-SSM is compatible with PIM-SM, you can enable only PIM-SM without enabling PIM-SSM.

By default, the multicast group range reserved for SSM is FF3x::/32. However, you can expand or shrink the multicast group range of SSM, or even disable the SSM function at the CLI. For more information, see the commands described in Configuring the Specific Source Multicast.

Compared to PIM-SM, PIM-SM-based SSM has the following features:

1) In the SSM model, multicast receivers can obtain information about the multicast source in advance through a channel, such as advertisements or accessing specified servers.

2) As a specific subset of PIM-SM, the SSM model processes only PIM (S, G) Join message and PIM (S, G) prune messages and discards RPT-associated messages that fall in the range of SSM, such as PIM (*, G) Join message and prune messages. For register messages fall into the range of SSM, the model will respond to the register-stop message immediately.

3) In the SSM model, RP information selection and distribution are unnecessary. The established multicast distribution tree in SSM are shortest path tree (SPT).

PIM-SMv6 Configuration Preparation

Enable a unicast routing protocol, for instance OSPFv3, to automatically discover routes.

PIM-SMv6 Configuration Task List

PIM-SMv6 configuration includes the following tasks, but only the first and the second tasks are mandatory, and you can determine whether to configure the other tasks based on actual networks.

Enabling multicase routing

Enabling PIM-SMv6

Configuring Hello message transmission interval

Configuring the propagation delay of the Hello message

Configuring the override interval of the Hello message

Configuring the neignbor tracking of the Hello message

Configuring the triggered Hello delay of the Hello message

Configuring PIM-SMv6 neighbor filtering

Configuring DR priority

Configuring static RP

Configure candidate BSR

Configure BSR border

Ignoring the RP priority of RP-SET

Configuring candidate RP

Checking the reachability of RP registration message

Filtering the addresses of registration packets on RP

Limiting the rate to send registration packets

Configuring the calculation method of checksum of registration packets

Limiting the range of legal BSRs

Configuring elected BSR to limit the address range of legal candidate RP and the multicast group range it serves

Enabling elected BSR to receive the candidate RP advertisement whose prefix-count is 0

Please configure this command to make elected BSR receive C-RP-ADV whose prefix-count is 0. If this command is not configured, the elected BSR cannot deal with C-RP-ADV whose prefix-count is 0.

Please run the following command in the global configuration mode.

Command	Function
ipv6 pim accept-crp-with-null-group	Elected BSR can receive C-RP-ADV whose prefix-count is 0.
no ipv6 pim accept-crp-with-null-group	Elected BSR cannot receive C-RP-ADV whose prefix-count is 0.

Enabling Multicast Routing

Multicast packets can be forwarded and enabling PIM-SMv6 makes sense only after multicast routing is enabled.

To enable or disable multicast routing, run the following command in the global configuration mode.

Command	Function
Ruijie(config)# **ipv6 multicast-routing**	Enable multicast routing globally.
Ruijie(config)# **no ipv6 multicast-routing**	Disable multicast routing globally.

Enabling PIM-SMv6

In order for one device to interact with other devices on PIM-SMv6 control messages, maintain and update the multicast routing table and forward multicast packets, PIM-SMv6 must be enabled on every interface.

To enable PIM-SMv6 on the interface, run the following commands in the interface configuration mode.

Command	Function
Ruijie(config-if)# **ipv6 pim sparse-mode**	Enable PIM-SMv6 on the interface.
Ruijie(config-if)# **no ipv6 pim sparse-mode**	Disable PIM-SMv6 on the interface.

⚠ Caution Enabling PIM-SMv6 brings into effect only after multicast routing is enabled globally.

Caution

If an interface is the tunnel interface, only IPv6 over IPv4 tunnel, IPv6 over IPv4 GRE tunnel, IPv6 over IPv6 tunnel and IPv6 over IPv6 GRE tunnel support IPv6 multicast. You can also enable multicast on tunnel interfaces not supporting multicast. However, the system neither prompts error messages nor receives or sends multicast packets.

Caution

Multicast tunnels can be set up only on Ethernet interfaces. They do not support embedded tunnels or QoS/ACL of multicast data.

Configuring the Hello Message Transmission Interval

After enabling PIM-SMv6, the interface sends the Hello message to the ones of adjacent devices at an interval. This transmission interval can be set as required.

To configure the Hello message transmission interval, run the following command in the interface configuration mode.

Command	Function
Ruijie(config-if)# **ipv6 pim query-interval** *interval-seconds*	Set the Hello message transmission interval. *interval-seconds*: in the range 1 to 65535 seconds
Ruijie(config-if)# **no ipv6 pim query-interval**	Restore the setting to the default value.

By default, the Hello message transmission interval is 30 seconds on the interface.

Note

When the Hello message transmission interval is updated every time, the Hello message hold time is updated 3.5 times of the Hello message transmission interval. If the Hello message transmission interval multiplying 3.5 is larger than 65535, the Hello message hold time is updated to 65535.

Configuring the Propagation Delay of the Hello Message

After the interface sends the Hello message, you can set the options of the Hello message. For LAN prune delay, the Propagation_Delay field is 500 ms by default.

To configure the propagation delay, run the following command in the interface configuration mode.

Command	Function
Ruijie(config-if)# **ipv6 pim propagation-delay** *interval-milliseconds*	Set the propagation delay. *interval-milliseconds:* in the range of 1-32767 ms.
Ruijie(config-if)# **no ipv6 pim propagation-delay**	Restore the propagation delay setting to the default value, namely 500 ms.

Note

Change of propagation delay or prune delay will influence the override interval of Join/prune message. As specified in the protocol, the override interval of Join/prune message must be less than its hold time or otherwise this will cause temporary interruption.

Configuring the Override Interval of the Hello Message

After the interface sends the Hello message, you can set the options of the Hello message. For LAN prune delay, the override-interval field is defaulted to 2500ms.

To configure the override-interval field, run the following command in the interface configuration mode.

Command	Function
Ruijie(config-if)# **ipv6 pim override-interval** *interval-milliseconds*	Set the override-interval. *interval-milliseconds:* In the range of 1 to 65535 seconds.
Ruijie(config-if)# **no ipv6 pim override-interval**	Restore the setting to the default value.

Note

Change of propagation delay or prune delay will influence the override interval of Join/prune message. As specified in the protocol, the override interval of Join/prune message must be less than its hold time or otherwise this will cause temporary interruption.

Configuring the Neighbor Tracking of the Hello Message

After an interface sends the Hello message, the LAN Prune Delay option of the Hello message has a T bit, indicating whether join constraint is enabled on the interface. With join constraint enabled, the interface is constrained not to send its Join message to the upstream neighbor when it receives the Join message that its neighbor sends to the upstream neighbor. On the other hand, with join constrain disabled, the interface will send its Join message to the upstream neighbor when it receives the Join message that its neighbor sends to the upstream neighbor. This function allows upstream routers to track how many receivers in downstream in accord with all received Join messages. Join constraint is enabled on the interface by default.

To disable join constraint on the interface, run the following command in the interface configuration mode.

Command	Function
Ruijie(config-if)# **ipv6 pim neighbor-tracking**	Disable join constraint on the interface.
Ruijie(config-if)# **no ipv6 pim neighbor-tracking**	Enable join constraint on the interface

Configuring the Triggered Hello Delay of the Hello Message

When the router starts or detects a new neighbor starts, it sends the Hello message. To avoid congestion, the router will send the Hello message at random. This random time is calculated by triggered hello delay, which is 5s by default.

To configure triggered hello delay, run the command in the interface configuration mode.

Command	Function
Ruijie(config-if)# **ipv6 pim triggered-hello-delay** *interval-seconds*	Configure triggered hello delay. *interval-seconds*: In the range of 1 to 5 seconds
Ruijie(config-if)# **no ipv6 pim triggered-hello-delay**	Restore the setting to the default value.

Configuring PIM-SMv6 Neighbor Filtering

Neighbor filtering can be enabled on the interface for security. PIM-SMv6 will not establish adjacency relation with a neighbor device and delete the established adjacency relation as long as the neighbor device is denied by the filtering access list.

To configure neighbor filtering, run the following command in the interface configuration mode.

Command	Function
Ruijie(config-if)# **ipv6 pim neighbor-filter** *ipv6_access-list*	Enable neighbor filtering on the interface.
Ruijie(config-if)# **no ipv6 pim neighbor-filter** *ipv6_access-list*	Disable neighbor filtering on the interface.

By default, neighbor filtering is disabled on the interface.

Note

Only the neighbors whose IP address matches ACL filtering can serve as the PIM neighbors of the interface. The neighbor addresses filtered by ACL cannot function as the PIM neighbors of the interface.

Configuring DR Priority

Use this command to set the priority of a device. The higher the value, the higher the priority.

Run the following commands in the interface mode:

Command	Function
Ruijie(config-if)# **ipv6 pim dr-priority** *priority-value*	Configure DR priority in the range of 0 to 4294967294.
Ruijie(config-if)# **no ipv6 pim dr-priority** *priority-value*	Restore DR priority to the default value, namely 1.

Configuring Static RP

In a smaller network, you can use PIM-SMv6 by configuring static RP. All devices in the PIM-SMv6 domain should be configured with similar static RP for consistent PIM-SMv6 multicast routes.

To configure static RP, run the following command in the global configuration mode.

Command	Function
Ruijie(config)# **ipv6 pim rp-address** *ipv6_rp-address* [*ipv6_access-list*]	Configure static RP.
Ruijie(config)# **no ipv6 pim rp-address** *ipv6_rp-address* [*ipv6_access-list*]	Remove the configuration.

Note that:

- When BSR and static RP take effect simultaneously, static RP is preferred.
- Static RP can be configured for many multicast groups (by using ACL) or all multicast groups. However, one static RP can be configured only once.
- If more than one IPv6 address is configured to be RP, the highest IPv6 address is adapted first.
- Only the IPv6 addresses defined and permitted by ACL are valid multicast groups. By default, all multicast groups are permitted.
- After configuration, the source address of static RP is inserted in the tree structure of the group range-based static RP group. Each group range-based static RP group maintains a chain structure that lists static RP groups in the descending order of IPv6 addresses. When a group range selects a RP, the first element, or the highest IPv6 address is selected.
- Deleting a static RP will delete it from all multicast groups and a new one is selected from the static RP tree structure as static RP.

Configuring Candidate BSR

Configuration of candidate BSR produces globally unique BSR in the PIM-SMv6 domain, which collects and distributes the RPs in the domain for the uniqueness of RP mapping.

To configure candidate BSR, run the following command in the global configuration mode.

Command	Function
Ruijie(config)# **ipv6 pim bsr-candidate** *interface-type interface-number* [*hash-mask-length*] [*priority-value*]	Set the device as the candidate BSR. *hash-mask-length:* In the range 0 to 128, 126 by default. *priority-value:* In the range 0 to 255, 64 by default.
Ruijie(config)# **no ipv6 pim bsr-candidate**	Remove the configuration.

Note

To set an interface as the candidate BSR, it must be configured with a global unicast address used for unicast routes or a local address. The first global unicast address or local address is elected as the candidate BSR.

Configuring BSR Border

To restrain BSM flooding, configure BSR border on the interface so that the interface drops BSM messages upon receiving them.

To configure BSR border, run the following command in the interface configuration mode.

Command	Function
Ruijie(config-if)# **ipv6 pim bsr-border**	Set the interface to be BSR border.
Ruijie(config-if)# **no ipv6 pim bsr-border**	Remove the configuration.

Ignoring the RP Priority of RP-Set

When you select a RP for a multicast address, ignore their priorities in comparison if there are more than one RP. If this command is not configured, the priority is used to compare two RPs.

To ignore RP priority, run the following command in the global configuration mode.

Command	Function
Ruijie(config)# **ipv6 pim ignore-rp-set-priority**	Ignore RP priority of RP-SET.
Ruijie(config)# **no ipv6 pim ignore-rp-set-priority**	Compare the RP priority of RP-SET.

Configuring Candidate RP

Configure candidate RP to periodically send candidate RP advertisement to the BSR so that the candidate RP advertisement is propagated to all PIM-SMv6 devices in the domain and guarantee the uniqueness of RP mapping.

To configure candidate RP, run the following command in the global configuration mode.

Command	Function
Ruijie(config)# **ipv6 pim rp-candidate** *interface-type interface-number* [**priority** *priority-value*] [**interval** *interval-seconds*] [**group-list** *ipv6_access-list*]	Configure candidate RP. *priority-value*: In the range 0 to 255, 192 by default *interval-seconds*: In the range 1 to 16383s, 60s by default *ipv6_access-list*: All multicast groups are allowed by default.
Ruijie(config)# **no ipv6 pim rp-candidate**	Remove the configuration.

Note

To set an interface as the candidate RP of the specific group range, use this command with ACL option. Note that the calculation of group range is only based on the ACE with permit rule, not deny rule.

Checking the Reachability of RP Registration Message

This command can be used to check whether the RP is reachable before the DR sends the registration message to the RP. In other words, the DR queries the unicast routing and static multicast routing tables to learn whether a route to the RP exists. If not, DR does not send the register packet.

To check the reachability of RP, run the following command in the global configuration mode.

Command	Function
Ruijie(config)# **ipv6 pim register-rp-reachability**	Check the reachability of the RP.
Ruijie(config)# **no ipv6 pim register-rp-reachability**	Remove the configuration.

Caution

If there is a static multicast route to the RP and the next hop of this static multicast route is reachable in the unicast routing table, PIM-SMv6 considers that the RP is reachable, even though the RP is not reachable in the unicast routing table.

Filtering the Addresses of Registration Packets on RP

This command filters the source addresses and group addresses of the registration packets arrived on RP. If this command is not configured, each register packet is allowed to reach the RP. Only the registration packets whose source addresses and group addresses are permitted by ACL or the route map are processed. Other registration packets are filtered and the Register-stop message is sent back.

Run the following command in global configuration mode.

Command	Function
Ruijie(config)# **ipv6 pim accept-register** {**list** *ipv6_access-list* | **route-map** *map-name* }	Filter the source addresses and group addresses of registration packets.
Ruijie(config)# **no ipv6 pim accept-register**	Remove the configuration.

Limiting the Rate to Send Registration Packets

This command applies to the registration packets in (S, G) state, not the overall system.

To limit the rate to send registration packets, run the following commands in the global configuration mode.

Command	Function
Ruijie(config)# **ipv6 pim register-rate-limit** *rate*	Set the maximum number of registration packets sent per second, in the range of 1 to 65535.
Ruijie(config)# **no ipv6 pim register-rate-limit**	Remove the configuration.

Configuring the Calculation Method of Checksum of Registration Packets

This command calculates the checksum of all the packets of PIM protocol, including encapsulated multicast packets.

Without this command, the checksum of registration packets is calculated by default methods of PIM protocol.

To configure the calculation method of checksum of registration packets, run the following command in the global configuration mode.

Command	Function
Ruijie(config)# **ipv6 pim register-checksum-wholepkt** [**group-list** *ipv6_access-list*]	Calculate the checksum for registering packets based on the overall packets. When the **group-list** *ipv6 access-list* value is the default value, apply the configuration to all multicast addresses.
Ruijie(config)# **no ipv6 pim register-checksum-wholepkt** [**group-list** *ipv6_access-list*]	Remove the checksum calculation for registering packets. When the **group-list** *ipv6 access-list* value is the default value, apply the configuration to all multicast addresses.

Note

Some vendors calculate checksum based on the overall registration packets. Ruijie Networks introduces this function for the compatibility with these vendors.

If the device of other vendors serves as the RP and the Ruijie device serves as the source DR, you can use this command on the source DR. If the device of other vendors serves as the source DR and the Ruijie device serves as the RP, you can use this command on the RP.

Limiting the Range of Legal BSRs

This command limits the range of legal BSRs. Without this command the PIM-SMv6 enabled router receives all external BSM packets.

To limit the range of legal BSRs, run the following command in the global configuration mode.

Command	Function
Ruijie(config)# **ipv6 pim accept-bsr list** *WORD*	Filter the BSM packets of BSRs.
Ruijie(config)# **no ipv6 pim accept-bsr list**	Remove the configuration.

Note

This command filters the BSR address field of BSM packets. If the address of a BSM packet is denied by ACL, the BSM packet is filtered.

Configuring Elected BSR to Limit the Address Range of Legal Candidate RP and the Multicast Group Range it Serves

This command configures elected BSR to limit the address range of legal candidate RP and the multicast group range it serves. Without this command, the elected BSR receives all external advertisements of candidate RPs.

For the ACL rule of this command, source specifies the address of candidate RP, and destination specifies the multicast group range that the candidate RP serves. If the ACL denies both addresses, the multicast group range of the candidate RP is filtered.

To configure elected BSR to limit the address range of legal candidate RP and the multicast group range it serves, run the following command in the global configuration mode.

Command	Function
Ruijie(config)# **ipv6 pim accept-crp list** *WORD*	Elected BSR filters the advertisement of candidate RP.
Ruijie(config)# **no ipv6 pim accept-crp**	Remove the configuration.

Enabling Elected BSR to Receive the Candidate RP Advertisement whose Prefix-count is 0

This command enables the elected BSR to receive the candidate RP advertisement whose prefix-count is 0. Without this command, the elected BSR will not process this kind of packets.

Once configured, the elected BSR considers that the candidate RP supports all multicast groups upon receiving the candidate RP advertisement whose prefix-count is 0.

To enable the elected BSR to receive the candidate RP advertisement whose prefix-count is 0, run this command in the global configuration mode.

Command	Function
ipv6 pim accept-crp-with-null-group	The elected BSR can receive the C-RP-ADV packet whose prefix-count is 0.
no ipv6 pim accept-crp-with-null-group	The elected BSR cannot receive the C-RP-ADV packet whose prefix-count is 0.

Configuring the Source Address of Registration Packets

This command configures the source address of registration packets. Without this command or with the no form of this command, the interface address of DR connecting to the multicast source is used. For address parameter of this command, the address to be set must be reachable to unicast routes. For interface parameter of this command, the interface to be set must be loopback interface or other type of interface whose address is advertised by unicast routes, in which the first non-local link address of the interface serves as the source address of registration packets.

To configure the source address of registration packets, run the following command in the global configuration mode.

Command	Function
Ruijie(config)# **ipv6 pim register-source** {*ipv6_local_address* | *interface-type interface-number*}	Configure the source address of registration packets.
Ruijie(config)# **no ipv6 pim register-source**	Use the RPF's interface address as the source address of registration packets.

Configuring the Suppression Time of Registration Packets

When the receiver does not receive the data packets destined to a multicast group from RP (namely RP does not serve this multicast group) or RP begins to receive multicast packets from the multicast source, RP sends the registration stop message to the DR on the multicast source side. Upon receiving this message, DR stops sending the registration packets encapsulated with multicast packets and transfers into the register suppression state.

During registration suppression, DR sends null registration packets, namely registration packets not encapsulated with multicast packets), to DR, indicating that the multicast source is still active. Probe time refers to the period that DR is allowed to send null registration packets before the registration suppression state is timed out. When registration suppression is timed out, DR starts to send registration packets. The smaller registration suppression timeout means the higher frequency that RP receives multicast packets; the larger timeout means the higher delay for a receiver to join a multicast group.

Running this command on DR will change the registration packet suppression time defined on DR.

To configure the registration packet suppression time, run this command in the global configuration mode.

Command	Function
Ruijie(config)# **ipv6 pim register-suppression** *seconds*	Configure registration packet suppression time. *Seconds*: in the range *1 to 65535*s
Ruijie(config)# **no ipv6 pim register-suppression**	Configure the suppression time to 60s.

Configuring the Probe Time of Null Registration Packet

The DR can send the null registration message to the RP in a period before the registration suppression time expires. This period is call probe time, 5 seconds by default

To configure the probe time of null registration packet, run the following command in the global configuration mode.

Command	Function
Ruijie(config)# **ipv6 pim probe-interval** *interval-seconds*	Configure the probe time of null registration packet. *interval-seconds*: in the range 1 to 65535 seconds
Ruijie(config)# **no ipv6 pim probe-interval**	Restore the probe time to 5s.

Note

The probe time must be less than half of registration suppression time. Furthermore, 3* registration suppression time plus registration probe time should be no more than 65535s or otherwise the system triggers an alarm.

Configuring RP KAT Timer

This command configures the hold time of (S, G) state that registration packets set up on RP.

To configure RP KAT timer, run this command in the global configuration mode.

Command	Function
Ruijie(config)# **ipv6 pim rp-register-kat** *seconds*	Configure the KAT timer, which ranges from 1 to 65535 seconds.
Ruijie(config)# **no ipv6 pim rp-register-kat**	Restore the setting to the default value, namely 3* registration suppression time plus registration probe time.

Caution

The timer should be larger than 3* registration suppression time plus registration probe time on the source DR, or otherwise the RP may time out the (S, G) state before the source DR sends the registration packet and thus leading to temporary interruption of multicast packets.

Configuring the Join/Prune Message Sending Interval

By default, the Join/Prune message is sent at the interval of 60s. You can use this command to change the sending interval.

To configure the Join/Prune message sending interval, run the following command in the global configuration mode.

Command	Function
Ruijie(config)# **ipv6 pim jp-timer** *interval-seconds*	Configure the Join/Prune message sending interval. *interval-seconds*: in the range 1 to 65535s

Ruijie(config)# **no ipv6 pim jp-timer**	Restore the setting to the default value, namely 60s.

Note

When you configure the Join/Prune message sending interval, if the sending interval * 3.5 is larger than 65535s, the system triggers an alarm and the sending interval is changed to be 65535/3.5 seconds.

Enabling the Last Hop Device to Transfer from the Shared Tree to the Shortest Path Tree

With this command, a PIM join message is triggered and a source tree is constructed upon the receipt of the first (S, G) message. The keyword **group-list** means all the groups in the list transfer to the source tree. After you use the **no** form of this command without the keyword **group-list**, to disable switching from the shared tree to the SPT, the device re-directs to the shared tree and sends a prune message to the source. If you use the previous command with a configured ACL, the association between the ACL and the **group-list** is removed, and all groups can switch from the shared tree to the SPT.

To enable the last hop device to transfer from the shared tree to the shortest path tee, run the following command in the global configuration mode.

Command	Function
Ruijie(config)# **ipv6 pim spt-threshold** [**group-list** *ipv6_access-list*]	If group-list is configured, the last hop device of this multicast group is enabled to transfer from the shared tree to the shortest path tree. Without group-list, all multicast groups are permitted.
Ruijie(config)# **no ipv6 pim spt-threshold** [**group-lis**t *ipv6_access-list*]	If the group-list is defined and the carried ACL is configured, the association between the ACL and the group-list is removed, and all multicast groups can switch from the shared tree to the shortest path tree. If group-list is not defined, the function of switching from the shared tree to the SPT is disabled.

Configuring the Specific Source Multicast

This command enables the device to directly receive multicast packets from the specific multicast source rather than the PR tree.

To configure the specific source multicast, run the following command in the global configuration mode..

Command	Function
Ruijie(config)# **ipv6 pim ssm** {**default** |**range** *ipv6_access-list*]}	Configure the specific source multicast, FF3x::/32 by default. x is an any valid range. If the ACL is specified, SSM is applied only to multicast groups that fall into this ACL.
Ruijie(config)# **no ipv6 pim ssm**	Remove the configuration.

Note

Interfaces on the last-hop switch or router connected to multicast receivers must enable MLDv2. Otherwise, the last-hop switch or router cannot process the MLD (S, G) Join message, and the specified source multicast will fail.

Configuring Static RP Preference

To configure the static RP's priority higher than the one elected through BSR mechanism, run the following command in the global configuration mode.

Command	Function
Ruijie(config)# **ipv6 pim static-rp-preferred**	Configure the static RP's priority higher than the one elected through BSR mechanism.
Ruijie(config)# **no ipv6 pim static-rp-preferred**	Configure the RP priority elected through BSR mechanism higher than the one of static RP.

Enabling Embedded RP

Embedded RP is the special RP discovery mechanism for IPv6 PIM that uses its IPv6 multicast address, from which the multicast router can directly resolve RP's address.

By default, embedded RP is enabled for the IPv6 multicast addresses of all embedded RP addresses. To enable embedded RP for the IPv6 multicast address of some embedded RP address, run this command in the global configuration mode.

Command	Function
Ruijie(config)# **ipv6 pim rp embedded** [**group-list** *ipv6_acl_name*]	Without *ipv6_acl_name,* enable embedded RP for the IPv6 multicast addresses of all embedded RP addresses. With *ipv6_acl_name,* enable embedded RP for the IPv6 multicast address of some embedded RP address.
Ruijie(config)# **no ipv6 pim rp embedded**	Disable embedded RP for the IPv6 multicast addresses of all embedded RP addresses. After embedded RP is disabled, the group address of the embedded RP is considered as an ordinary one, which means the RP mapping to the group address is no longer the embedded RP. It must calculate the embedded RP based on the learned RP mapping or the one configured statically.

Note

In addition to enabling embedded RP on the device, which is enabled by default, you also need to configure static RP on devices acting as embedded RP, or otherwise the device cannot serve as RP, even though its interface has the same address as embedded RP.

PIM-SMv6 Monitoring and Maintenance

PIM-SMv6 offers show commands to show the information on PIM-SMv6 interface, multicast group and multicast routing table.

Showing PIM-SMv6 Status

Use the following commands to show PIM-SMv6 status.

Command	Function
Ruijie# **show debugging**	Show debugging switches.
Ruijie# **show ipv6 pim sparse-mode bsr-router**	Show BSR details.
Ruijie# **show ipv6 pim sparse-mode interface** [i*nterface-type interface-number* [**detail**]]	Show PIM-SMv6 interface information.
Ruijie# **show ipv6 pim sparse-mode local-members** [*interface-type interface-number*]	Show local MLD information of PIM-SMv6 interface.
Ruijie# **show ipv6 pim sparse-mode mroute** {*ipv6_group_address* | *ipv6_source_address* | }	Show PIM-SMv6 multicast routing information.
Ruijie# **show ipv6 pim sparse-mode neighbor** [**detail**]	Show PIM-SMv6 neighbors.
Ruijie# **show ipv6 pim sparse-mode nexthop**	Show PIM-SMv6 next hop information from NSM.
Ruijie# **show ipv6 pim sparse-mode rp-hash** *ipv6_group-address*	Show the RP information of the specific multicast group address.
Ruijie# **show ipv6 pim sparse-mode rp mapping**	Show all RPs and the groups they serve.
Ruijie# **show ipv6 pim sparse-mode track**	Show the number of received and sent PIMv6 packets.

Deleting Internal PIM-SMv6 Messages

The following commands delete internal PIM-SMv6 messages.

Command	Function
Ruijie# **clear ipv6 mroute** {* | *group_address* [*source_address*] }	Clear multicast routing entries.
Ruijie# **clear ipv6 mroute statistics** {* | *group_address* [*source_address*] }	Clear multicast routing entry statistics.
Ruijie# **clear ipv6 pim sparse-mode bsr rp-set ***	Clear RP-SET.
Ruijie# **clear ipv6 pim sparse-mode track**	Reset the beginning time of statistics and reset PIMv6 packet counter.

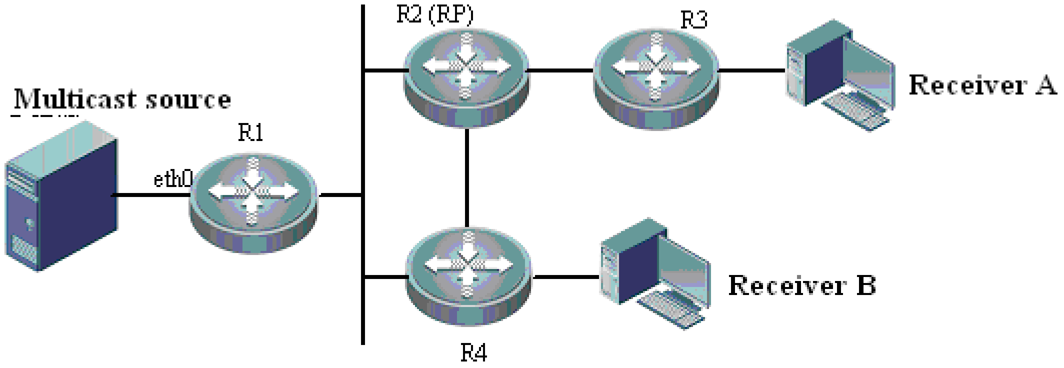
For details, refer to *PIM-SMv6 Command Reference*.

PIM-SMv6 Configuration Example

Configuration Requirements

Figure 3 illustrates network topology. R1 and the multicast source are located in one network. R2 is set to be RP. R3 and receiver A are located in the same network. R4 and receiver B are in the same network. Assume that devices are connected properly, IPv6 is enabled on each interface and IPv6 unicast is enabled on every device.

Figure 19 PIM-SMv6 topology



Configuration steps

Step1: Enable multicast routing

Enable IPv6 multicast routing on R1. The configuration is similar on R2, R3 and R4.

```
Ruijie# configure terminal
Ruijie(config)# ipv6 multicast-routing
```

Step 2: Enable PIM-SMv6 on the interface

Enable PIM-SMv6 on R1’s eth0. This configuration is similar on the interfaces of R1, R2, R3 and R4.

```
Ruijie(config)# interface eth 0
Ruijie(config-if)# ipv6 pim sparse-mode
Ruijie(config-if)# end
```

Step 3: Configure candidate BSR and candidate RP.

Set R2’s loopback1 to be C-BSR and C-RP

```
Ruijie(config)# interface loopback 1
Ruijie(config-if)# ipv6 address 2008:1::1/64
Ruijie(config-if)# ipv6 pim sparse-mode
Ruijie(config-if)# exit
Ruijie(config)# ipv6 pim bsr-candidate loopback 1
Ruijie(config)# ipv6 pim rp-candidate loopback 1
```

After the receiver joins the multicast group and the multicast source sends multicast packets, you can use show commands to monitor operation status.

Note MLD is automatically enabled on each interface while PIM-SMv6 is enabled.

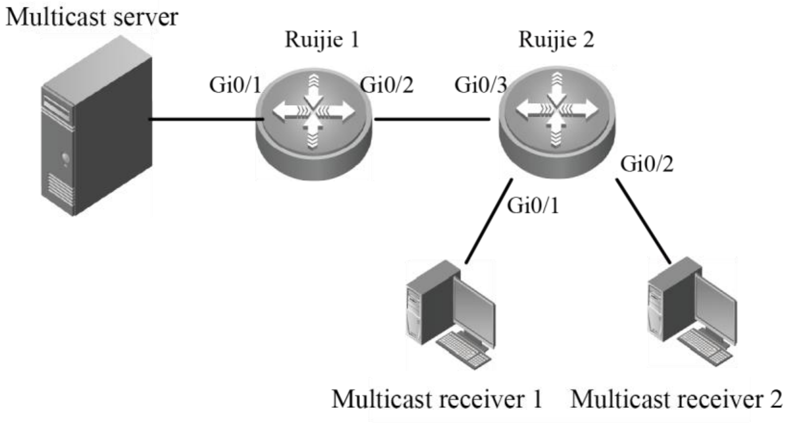
Configuration Examples of SSM Based on PIM

Networking Requirements

1. Network communication must be available at Layer 3. For example, run OSPFv3.
2. Multicast receivers obtain information about the multicast source through a channel depending on application software and deployment of network administrators on hosts.
3. Run PIM-SMv6 on the network.

Networking Topology

Figure 20 SSM configuration example



Basic configuration of devices and interfaces in Figure 4:

Device name	Interface	Basic configuration
Multicast server		Provides multicast data (2222::2, FF33::1111)
Ruijie 1	Gi 0/1	IPv6 address is 2222::1/64
Ruijie 1	Gi 0/2	IPv6 address is 3333::1/64
Ruijie 2	Gi 0/3	IPv6 address is 3333::2/64
Ruijie 2	Gi 0/1	IPv6 address is 4444::1/64
Ruijie 2	Gi 0/2	IPv6 address is 5555::1/64

Configuration Procedure

1. Basic configuration of interfaces on Ruijie 1 and Ruijie 2:

Configure interfaces on Ruijie 1 and Ruijie 2 according to the IPv6 addresses specified in the topology. The procedure is omitted.

2. Enable network interconnection on Layer 3:

Enable OSPFv3 on all interfaces of Ruijie 1 and Ruijie 2 and ensure devices are interconnected at Layer 3. The procedure is omitted.

3. Configure multicast on Ruijie 1 and Ruijie 2:

Enable the multicast routing on Ruijie 1 and Ruijie 2. Then, enable PIM-SMv6 on interfaces of Ruijie 1 and Ruijie 2. Lastly, enable MLDv2 on the interface connecting to multicast receivers of Ruijie 2. The following description uses Ruijie 2 as an example.

# Enable multicast routing on Ruijie 2:

```
Ruijie(conf)#ipv6 multicast-routing
```

# Enable PIM-SMv6 on all interfaces of Ruijie 2, such as interface Gi 0/1:

```
Ruijie(conf-GigabitEthernet0/1)#ipv6 pim sparse-mode
```

# Enable MLDv2 on the interface connected to the multicast receiver of Ruijie 2, such as interface Gi 0/1:

```
Ruijie(conf-GigabitEthernet0/1)#ipv6 mld version 2
```

The configuration steps of Ruijie 1 are similar to that of Ruijie 2. The procedure for configuring Ruijie 1 is omitted.

4. Enable SSM on Ruijie 1 and Ruijie 2:

# Enable SSM on Ruijie 2 and use the default SSM group range: FF3x::/32

```
Ruijie(conf)#ipv6 pim ssm default
```

# Enable SSM on Ruijie 1 and use the default SSM group range: FF3x::/32

```
Ruijie(conf)#ipv6 pim ssm default
```

Verifying the Configuration

1. Multicast receivers 1 and 2 request the multicast service (2222::2, FF33::1111) by sending MLD (2222::2, FF33::1111) join.

The protocol table of (2222::2, FF33::1111) will be created on Ruijie 2. You can view the protocol table by running the **show ipv6 pim sparse-mode mroute** command.

Ruijie#show ipv6 pim sparse-mode mroute

```
IPv6 Multicast Routing Table
(*,*,RP) Entries: 0
(*,G) Entries: 0
(S,G) Entries: 1
(S,G,rpt) Entries: 1
FCR Entries: 0
REG Entries: 0

(2222::2, FF33::1111)
RPF nbr: 3333::1
RPF idx: GigabitEthernet0/3
SPT bit: 0
Upstream State: JOINED
kat expires in 175 seconds
   00 01 02 03 04 05 06 07 08 09 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31
Local

1  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .
Asserted
0  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .
1  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .
Outgoing
0.o o  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .
1  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .
```

The output shows that the entry of (2222::2, FF33::1111) is created on Ruijie 2 and two multicast receivers exist.

The multicast server sends the data flow (2222::2, FF33::1111):

The multicast forwarding table of (2222::2, FF33::1111) will be created on Ruijie 2. You can view the multicast forwarding table with the **show ipv6 mroute** command.

```
Ruijie#show ipv6 mroute

IPv6 Multicast Routing Table

Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT

Timers: Uptime/Stat Expiry

Interface State: Interface (TTL)

(2222::2, FF33::1111), uptime 00:19:31, stat expires 00:02:53

Owner PIMSMV6, Flags: TFSs

  Incoming interface: GigabitEthernet 0/3

  Outgoing interface list:

      GigabitEthernet 0/1(1)

      GigabitEthernet 0/2(1)
```

The output indicates that the multicast forwarding table of (2222::2, FF33::1111) is established on Ruijie 2 and the multicast egresses are Gi 0/1 and Gi 0/2, which are connected with multicast receiver 1 and multicast receiver 2 respectively. In addition, the Flags of this forwarding table is tagged with ‘s’, indicating that this forwarding table uses the SSM model.

Configuration Examples of Embedded RP

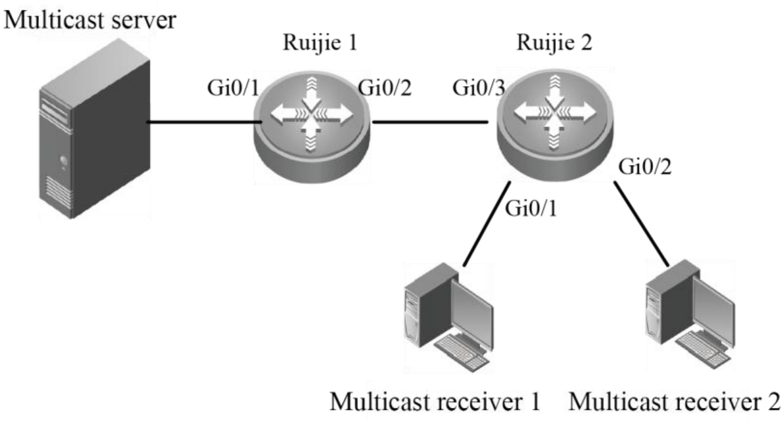
Networking Requirements

1. Network communication must be available at Layer 3. For example, run OSPFv3.

2. Run PIM-SMv6 on the network.

Networking Topology

Figure 21 Configuring embedded RP



Basic configuration of devices and interfaces in Figure 5:

Device name	Interface	Basic configuration
Multicast server		Provides multicast source (2222::2, FF7E:0540:6666::1)
Ruijie 1	Gi0/1	IPv6 address is 2222::1/64
Ruijie 1	Gi0/2	IPv6 address is 3333::1/64
Ruijie 2	Gi0/3	IPv6 address is 3333::2/64
Ruijie 2	Gi0/1	IPv6 address is 4444::1/64
Ruijie 2	Gi0/2	IPv6 address is 5555::1/64
Ruijie 2	Loopback0	IPv6 address is 6666::5/64

Configuration Procedure

1. Basic configuration of interfaces on Ruijie 1 and Ruijie 2:

Configure interfaces on Ruijie 1 and Ruijie 2 according to the IPv6 addresses specified in the topology. The procedure is omitted.

2. Configure the networks to interoperate on layer 3:

Enable OSPFv3 on all interfaces of Ruijie 1 and Ruijie 2 and ensure that networks are interoperable on layer 3. The procedure is omitted.

3. Configure the multicast on Ruijie 1 and Ruijie 2:

Enable multicast routing on Ruijie 1 and Ruijie 2, and then enable PIM-SMv6 on all interfaces on Ruijie 1 and Ruijie 2, and configure the static RP on Ruijie 2 to enable it acting as the embedded RP.

# Enable multicast routing on Ruijie 2:

```
Ruijie(conf)# ipv6 multicast-routing
```

# Enable PIM-SMv6 on all interfaces of Ruijie 2, with Gi 0/1 as an example:

```
Ruijie(conf-GigabitEthernet0/1)# ipv6 pim sparse-mode
```

# Configure static RP 6666::5 on Ruijie 2:

```
Ruijie(conf)# ipv6 pim rp-address 6666::5
```

The configuration steps of Ruijie 1 are similar with that of Ruijie 2; therefore, the procedure for configuring Ruijie 1 is omitted.

4. Enable embedded RP on Ruijie 1 and Ruijie 2:

By default, embedded RP is enabled. Enable it if it is disabled.

# Enable embedded RP on Ruijie 2:

```
Ruijie(conf)# ipv6 pim rp embedded
```

# Enable embedded RP on Ruijie 1:

```
Ruijie(conf)# ipv6 pim rp embedded
```

Verifying the Configuration

1. Multicast receivers 1 and 2 send MLD (*,FF7E:0540:6666::1) join:

The protocol table of (*,FF7E:0540:6666::1) is created on Ruijie 2. You can view the protocol table by running the show ipv6 pim sparse-mode mroute command. Meanwhile, the group RP mapping corresponding to the IPv6 multicast address FF7E:0540:6666::1 of the embedded RP will be saved on Ruijie 2. You can will the group RP mapping by running the show ipv6 pim sparse-mode rp mapping command.

```
Ruijie#sh ipv6 pim sparse-mode rp mapping

PIM Group-to-RP Mappings

Group(s): ff7e:540:6666::/96

  RP: 6666::5

    Info source: Embedded RP

      Uptime: 00:00:12, expires: 00:00:48
```

The preceding output indicates that on Ruijie 2, the group RP mapping of the IPv6 multicast address FF7E:0540:6666::/96 of the embedded RP is created automatically and the RP address is 6666::5.

```
Ruijie#show ipv pim sparse-mode mroute

IPv6 Multicast Routing Table

Configuring RMEF

RMEF Overview

IP multicast realizes efficient point-to-multipoint data transmission over IP networks. Since IP multicast can effectively save network bandwidth and reduce network load, it is widely applied in real-time data transmission, multimedia conferencing, data copying, gaming and simulation.

Ruijie Multicast Express Forward (RMEF) maintains a mirror image of control-plane multicast routing table at the express forwarding data plane, so that forwarding of multicast packets can be done at the express forwarding data plane, thus improving the performance and efficiency of multicast forwarding.

Configuring REMF

Enabling/Disabling Multicast Express Forwarding On the Interface

Use the following commands to enable/disable multicast express forwarding on the interface in interface configuration mode.

Command	**Function**
Ruijie(config-if)# **ip ref**	Enables multicast express forwarding on the interface.
Ruijie(config-if)# **no ip ref**	Disables multicast express forwarding on the interface.

By default, multicast express forwarding is enabled on the interface.

Displaying RMEF Configuration and Status

Use the following commands to show RMEF configurations and statistics.

Command	**Function**
show ip ref mcast route [*ip address ip address*]	Shows the multicast express forwarding table. When no parameters are set, this command shows all table entries. When parameters are set (the first parameter is the IP address of the multicast source and the second one is the IP address of the multicast group), this command shows the table entries that match the two IP addresses.
show ip ref mcast info	Shows RMEF information, including the RMEF status, whether RMEF is enabled, number of express forwarding tables, and data packet uploading rate of RMEF in the case of no forwarding table or in data packet uploading process.
show ip ref mcast statistics **interface** *interface-type interface-number*	Shows statistics on the packets forwarded on the multicast express forwarding interface.

Command	Function
show ip ref mcast statistics mfc	Shows statistics on data packets forwarded on all multicast express forwarding entries.

Configuration Examples

The following examples show typical configurations on a router:

```
RSR20-04# config
```

! Enable multicast forwarding.

```
RSR20-04(config)# ip multicast-routing
```

! Enter the related interface and enable the multicast protocol.

```
RSR20-04(config)# interface fastEthernet 0/0
RSR20-04(config-if)# ip pim dense-mode
```

! Enable express forwarding on the interface.

```
RSR20-04(config-if)# ip ref
```

The following example shows how to debug multicast express forwarding:

! Display all multicast express forwarding tables.

```
Ruijie (config-if)# show ip ref mcast route
IP Multicast EF Routing Table
Interface State: Interface (Interface Index)
(30.1.1.2, 224.1.1.2)
 In_interface: GigabitEthernet 0/1.100(8)
 Hit: Yes
 To_cpu: No
 Oif_list: GigabitEthernet 0/2.100 (12)
```

! Display multicast express forwarding information.

```
Ruijie (config-if)# show ip ref mcast info
---------------------------------
IP RMEF is open
total RMEF MFC NUM = 1
to_cpu ratelimit PPS in one second = 10
no_mfc ratelimit PPS in one second = 10
---------------------------------
```

! Display multicast express forwarding statistics.

```
Ruijie (config-if)# show ip ref mcast statistics mfc
(30.1.1.2, 224.1.1.2)
 In_interface: GigabitEthernet 0/1.100(8)
 Match_PKTNUM: 17058555
```

```
Match_PKTBYTES: 1091747520
WRONG_IN_IF_PKTNUM: 0
TO_CPU_RESERVE_PACKET: 0
TO_CPU_DROP_PACKET: 0
Oif_list: GigabitEthernet 0/2.100(12)
```

Configuring MSDP

Overview

In PIM-SM network, network domains with same group-RP mapping information form a special multicast network domain, which is called PIM-SM domain.

1) The need for cross-domain multicasting

In the basic PIM-SM mode, a multicast source registers only with the RP in the local PIM-SM domain, and the multicast source information of a PIM-SM domain is isolated from that of another PIM-SM domain. As a result, the RP is aware of the source information only within the local domain and a multicast distribution tree is built only within the local domain; since RP is not aware of the multicast source information of other PIM-SM domains, it cannot join the multicast sources in other domains and build the multicast distribution tree. Therefore, cross-domain multicast application becomes impossible.

Given the feature of PIM-SM domain and the aforementioned problem, a mechanism is needed to allow RPs of different PIM-SM domains to share their multicast source information, so that the RP can learn the multicast source information of other PIM-SM domains. In this way, the local RP will be able to join multicast sources in other domains and the cross-domain multicast distribution tree can be built to carry out cross-domain multicast applications.

2) The need for Anycast-RP deployment

In a single PIM-SM domain, RP is the root node of share tree. RP is a critical device in PIM-SM domain, and it may fail due to excessive loads. Therefore, a RP load sharing mechanism will be needed to ease the burden of a single RP, and this mechanism is called Anycast-RP. In practice, we configure the same IP address for multiple RPs in a single PIM-SM domain; the multicast receiver joins the nearest RP according to the route, while the multicast source will register the multicast source information with the nearest RP according to the route, namely each RP will share certain PIM-SM activities.

During the deployment of Anycast-RP, we can encounter one problem: since the multicast source only registers the multicast source information with the nearest RP according to the route, other RPs acting as Anycast-RP will be unaware of the multicast source information and thus will not join the multicast source, leading to the failure of Anycast-RP deployment.

Given the aforementioned problem, a mechanism is needed to allow RPs acting as Anycast-RP to share their multicast source information, so that each RP acting as Anycast-RP can learn the multicast source information of the local domain. In this way, each RP will be able to join multicast sources and build the multicast distribution tree, allowing successful Anycast-RP deployment.

3) MSDP

Given the needs for cross-domain multicasting and Anycast-RP deployment, MSDP (Multicast Source Discovery Protocol) is introduced. With MSDP peer relationships established between different RPs, the RPs are interconnected with one another. If different RPs are distributed in different PIM-SM domains, then RP can discover the multicast source information in other PIM-SM domains, allowing cross-domain multicasting; if different RPs are distributed in the same PIM-SM domain, then RPs can share the multicast source information in the domain, allowing Anycast-RP deployment.

Basic Concepts

MSDP Peer

By establishing a special MSDP relationship between two layer-3 devices running MSDP protocol, these two layer-3 devices can share the multicast source information with each other. Such a special MSDP relationship is called MSDP peer relationship. Two layer-3 devices with MSDP peer relationship are called a pair of MSDP peers.

MSDP peer relationship is based on TCP connection and utilizes TCP 639 port. As long as the layer-3 route can reach, the MSDP peer relationship can be established between any two layer-3 devices.

Note The layer-3 device as mentioned herein refers to the generic router or layer-3 switch.

Peer-RPF Check of SA messages

MSDP device acting as RP will encapsulate the multicast source information registered with RP in SA messages, and forward SA messages to MSDP peers, which will then be able to learn the multicast source information.

Since the MSDP peers of the local MSDP device may form a loop. To avoid looping, MSDP protocol has introduced Peer-RPF check of SA messages.

The basic principle of Peer-RPF check of SA messages: According to the source address of SA messages, MSDP device will select the only MSDP peer for each SA message, and this MSDP peer is called Peer-RPF neighbor. When the local MSDP device receives SA message from Peer-RPF neighbor, it will accept this SA message and forward to other MSDP peers. Otherwise, it will drop this SA message.

Peer-RPF Forwarding of SA Messages

Once a MSDP device receives a SA message from the Peer-RPF neighbor, it will need to forward this SA message to other MSDP peers. This kind of behavior is called: Peer-RPF forwarding.

Mesh Group

An MSDP mesh group refers to a group of MSDP peers that have MSDP peering relationships among one another, namely any two layer-3 devices form a pair of MSDP peers.

When a SA messages is accepted by a MSDP peers in the mesh group, this SA message will not be forwarded to other MSDP peers in the same mesh group. This has reduced the flooding of SA messages and simplified Peer-RPF forwarding of SA messages.

Working Principle

1. MSDP peer

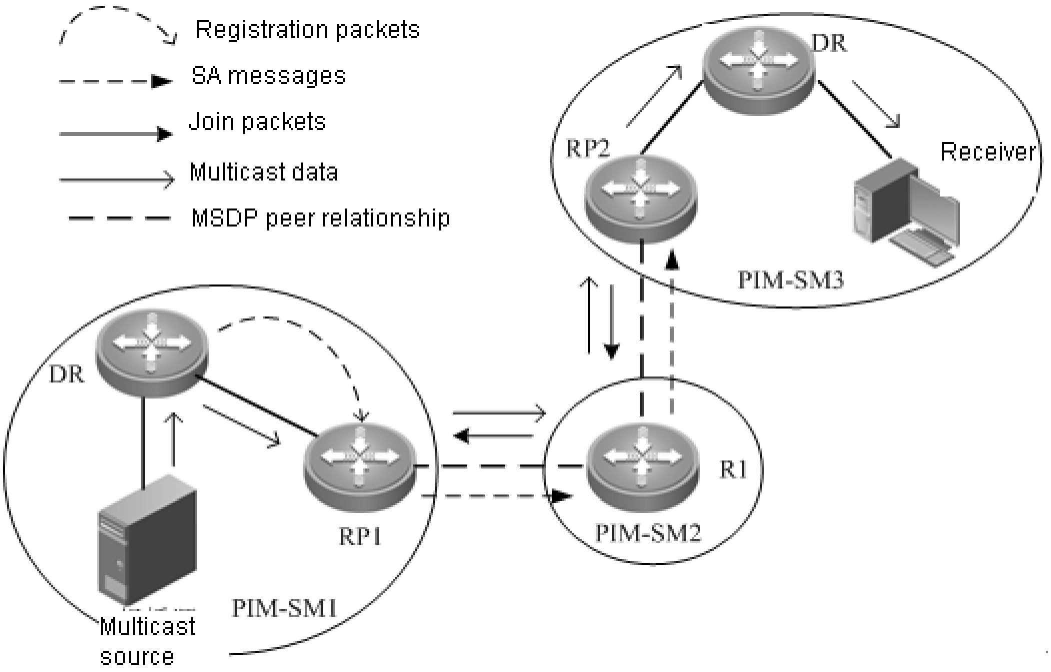
By configuring one or more pairs of MSDP peers in the multicast network, different RPs will be interconnected and send the multicast source information learned to MSDP peers, so as to advertise the multicast source information to other RPs.

If the aforementioned RPs are in different PIM-SM domains, then these PIM-SM domains can be interconnected. If the aforementioned RPs are in the same PIM-SM domain, then the multicast source information of the same PIM-SM domain will be shared among RPs.

2. Create MSDP peer

You can create MSDP peer on any layer-3 device. Devices that assume different multicast roles function differently. These peers can be classified into MSDP peers created on RP and MSDP peers created on non-RP.

Fig 1 MSDP Peers



(1) Creating MSDP peers on RPs

Source-side MSDP peer

According to PIM-SM protocol, the multicast source information is resisted with RP via registration message, indicating that the RP nearest to the multicast source (source-side RP) is aware of the multicast source information. The source-side RP creates SA messages according to the multicast source information registered and sends the messages to other RPs. Therefore, the MSDP peer must be created on the source-side RP; otherwise it will not be able to advertise the multicast source information.

As shown in Figure 1, the multicast source is in PIM-SM1, while RP1 is the RP nearest to the multicast source. The multicast source information is registered with RP1. Therefore, the peer must be created on RP1, so that RP1 can advertise the multicast source information. For example, the MSDP peer relationship is created between RP1 and R1 in PIM-SM2, so that the multicast source information can be sent to R1.

Receiver-side MSDP peer

If the receiver-side RP is unable to learn the multicast source information, it will not be able to join the multicast source and build the multicast distribution tree. Therefore, the MSDP peer must be created on the RP nearest to the receiver and being unaware of the multicast source information.

As shown in Figure 1, the receiver is in PIM-SM3, while RP2 is the nearest RP. Therefore, the peer must be created on RP2 in order to learn multicast source information from other PIM-SM domains. For example: MSDP peer relationship is established between RP2 and R1 in PIM-SM2; R1 sends the multicast source information learned from RP1 to RP2, so that RP2 can learn the same multicast source information. Then, RP2 joins the multicast source and build the multicast distribution tree from PIM-SM1 to PIM-SM3.

Intermediate MSDP Peer

The RP which is neither nearest to the multicast source nor nearest to the multicast receiver, functioning as a relay of multicast source information.

(2) MSDP created on non-RP: It will only forward the SA messages. As indicated in Figure 1, R1 in PIM-SM2 only forwards the SA messages to other MSDP peers. For example: R1 forwards SA messages to RP2.

Protocol Specification

Please refer to RFC3618.

Default Configurations

The following table describes the default configurations of MSDP.

Function	Default setting
Create MSDP peer	No MSDP peer is created.
Specify the default MSDP peer	No default MSDP peer is specified.
Configure MSDP peer description	No MSDP peer description is configured.
Configure SA request filtering	SA request messages are not filtered.
Configure mesh group	No MSDP peer will join the mesh group.
Change the originator address of SA messages	The originator address of SA messages is the address of RP.
Configure MD5 key for MSDP peer	MD5 encryption is not applied on the TCP connections between MSDP peers.
Configure redistribution filtering	All multicast source information registered with RP will be propagated to the MSDP peers.
Configure SA filtering	All SA messages from MSDP peers will be accepted; Each SA message received will be forwarded to the MSDP peer.
Configure the upper threshold of SA learning	No upper threshold for the SA information learned from MSDP peers.
Deactivate MSDP peer	MSDP peer is not deactivated.

Configure TTL upper threshold	TTL upper threshold is not configured. If the SA messages received carry the multicast data, then the SA messages forwarded to other MSDP peers will still carry the multicast data.

Configuring MSDP Peer

(Required) Creating MSDP peer

(Optional) Configuring MSDP peer description

(Optional) Configuring MD5 encryption for MSDP peer

Creating MSDP Peer

To enable MSDP, you need to configure MSDP peer. Execute the following command in the global configuration mode.

Command	Function
Ruijie(config)# **ip msdp peer** *peer-address* **connect-source** *interface-type interface-number*	Create MSDP peer The main address of the interface specified by the key word of "connect-source" will be used as the source address of MSDP TCP connection.

Configuring MSDP Peer Description

Each MSDP peer is an IP address with poor readability. In order to better distinguish different MSDP peers, you can configure text descriptions for MSDP peers.

To configure MSDP peer description, execute the following command in the global configuration mode:

Command	Function
Ruijie(config)# **ip msdp description** *peer-address text*	Configure text description for MSDP peer.

Configuring MD5 Encryption for MSDP Peer

The connection between MSDP peers is based on TCP connection. By default, the TCP connection will not use MD5 encryption, which is to say, TCP connection will not be subject to identity authentication. Under circumstances with high security needs, the identity authentication of TCP connections will be needed. To enable the identity authentication of TCP connections, execute the following commands in the configuration mode.

Command	Function
Ruijie(config)# **ip msdp password peer** *peer-address [encryption-type] string*	Enable MD5 encryption of the TCP connections between MSDP peers.

Controlling the Propagation of Multicast Source Information

(Optional) Redistribution filtering

(Optional) Filtering SA request messages

Redistribution Filtering

When the multicast source registers with RP, RP will learn the multicast source information and generate SA messages. By default, all registered multicast source information will be distributed by RP.

To control which registered sources can be distributed, execute the following commands in the global configuration mode.

Command	Function
Ruijie(config)# **ip msdp redistribute** [**list** *access-list-name*] [**route-map** *route-map-name*]	Only multicast source information passing the filtering rule will be propagated to the MSDP peers. 1) If the "list" or "route-map" is not specified, then no multicast source information (S, G) will be propagated. 2) If the "list" or "route-map" is specified, then only the multicast source information (S, G) meeting the access list or route map rule will be propagated to MSDP peers. 3) If the "list" and "route-map" is specified at the same time, then only the multicast source information (S, G) meeting both the access list and route map rule will be propagated to MSDP peers.

Filtering SA Request Messages

MSDP peer will request the multicast source information about a certain multicast group from local MSDP device by sending SA request messages. If the local device has the multicast source information about a certain multicast group, then the local MSDP device will need to send SA reply message to this MSDP peer, so as to inform the MSDP peer of the relevant multicast source information.

By default, the MSDP device will accept all SA request messages from the MSDP peer and give replies. However, you can configure to ignore all SA request messages, or only accept the SA request messages from certain multicast groups and ignore those from other multicast groups through the standard ACL.

To filter SA request messages, execute the following command in the global configuration mode:

Command	Function

Ruijie(config)# **ip msdp filter-sa-request** *peer-address* [**list** *access-list-name*]	Filter SA request messages from the specified MSDP peer, and only rely to SA request messages passing the filtering rule. 1) If the "list" is not specified, then all SA request messages from this MSDP peer will be rejected. 2) If the "list" is specified, then only SA request messages meeting ACL will be accepted.

Controlling the Forwarding of Multicast Source Information

(Optional) Using MSDP filter

(Optional) Using TTL to limit the multicast data carried in SA messages

Using MSDP Filter

After accepting a SA message, the MSDP device will need to forward the SA message to other MSDP peers. By default, MSDP device will forward the received SA messages to other MSDP peers without any change. However, in certain deployment environment, we need to limit the multicast source information that can be learned by other MSDP peers. In such a case, we will need to control which multicast source information can be forwarded to other MSDP peers.

To control which multicast source information that can be forwarded to MSDP peers, execute the following commands in the global configuration mode:

Mode	Function
Ruijie(config)# **ip msdp sa-filter out** *peer-address* [**list** *access-list-name*] [**route-map** *map-name*] [**rp-list** *rp-access-list-name*] [**rp-route-map** *rp-route-map-name*]	Configure SA message filtering rule for the specified MSDP peer. Only the multicast source information passing the filtering rule will be forwarded to MSDP peers. 1) If no key word is specified, SA messages will not be sent to the specified MSDP peer. 2) If one or more key words are specified, only multicast source information (S,G) meeting all rules corresponding to these key words will be forwarded the MSDP peer.

Using TTL to Limit the Multicast Data Carried in SA Messages

The SA messages can carry multicast data. In certain deployment environment, for efficiency related considerations, the TTL value of multicast data may be required to reach a certain threshold. If the TTL value of multicast data is less than the threshold, then the multicast data will be separated from SA messages and discarded. For example: By limiting the TTL value of multicast data packets to 8, the TTL of multicast data packets sent to MSDP peers shall be greater than or equal to 8.

To configure TTL threshold, execute the following commands in the global configuration mode.

Command	Function
Ruijie(config)# **ip msdp ttl-threshold** *peer-address ttl-value*	Limit the TTL value of multicast data carried in SA messages. When a SA message is received from one MSDP peer, if this SA message carries multicast data with TTL value less than the TTL threshold configured, then the multicast data will be separated from the SA message, and the SA message without multicast data will then be forwarded to other MSDP peers.

Controlling the Acceptance of Multicast Source Information

By default, MSDP device will accept all SA messages from the Peer-RPF neighbor. However, we can configure filtering rule to control which SA messages will be accepted by the local device.

There are several ways to control the multicast source information from MSDP peers:

- Filter all SA messages from a certain MSDP peer;
- Filter by using the specified access control list;
- Filter based on route map.

To control the multicast source information that can be accepted by the local device, apply the filter in the global configuration mode.

Command	Function
Ruijie(config)# **ip msdp sa-filter in** *peer-address* [**list** *access-list-name*] [**route-map** *route-map-name*] [**rp-list** *rp-access-list-name*] [**rp-route-map** *rp-route-map-name*]	Configure inbound SA message filtering rule for the specified MSDP peer. Only the multicast source information passing the filtering rule will be accepted. 1) If no key word is specified, SA messages from the specified MSDP peer will not rejected; 2) If one or more key words are specified, only multicast source information (S,G) meeting all rules corresponding to these key words will be accepted.

Configuring Default Peer

When the MSDP device receives an SA message, MSDP device will need to determine whether this SA message is from Peer-RPF neighbor; if not, the MSDP device will discard this SA message. To avoid the absence of Peer-RPF neighbor, you can configure the default peer, which is also a default Peer-RPF neighbor.

In the global configuration mode, execute the following command to specify the default MSDP peer:

Command	Function
Ruijie(config)# **ip msdp default-peer** *peer-address* [**prefix-list** *prefix-list-name*]	Specify the default MSDP peer. If "prefix-list" is not specified, then all SA messages from this default MSDP peer will be accepted; otherwise, only SA messages meeting prefix-list rule will be accepted.

Configuring MSDP Mesh Group

MSDP mesh group consists of a group of fully connected MSDP peers. The SA messages received by one MSDP peer in the mesh group will not be forwarded to other MSDP peers in the same mesh group. Therefore, it can reduce the flooding of SA messages and simplify Peer-RPF computation.

To create mesh group, execute the following command in the global configuration mode.

Command	Function
Ruijie(config)# **ip msdp mesh-group** *mesh-name peer-address*	Configure a MSDP mesh group and specify one MSDP peer to join this mesh group.

Deactivating MSDP Peer

If you don't want to activate a MSDP peer but deleting this MSDP peer will lose the relevant configurations, you can then deactivate this MSDP peer. After the MSDP peer is deactivated, only the TCP connection is terminated, and the configurations of this MSDP peer won't be deleted.

In the global configuration mode, execute the following command to deactivate the MSDP peer:

Command	Function
Ruijie(config)# **ip msdp shutdown** *peer-address*	Deactivate MSDP peer.

Configuring the Address of Originator other than RP

By default, the originator address of SA messages uses the address of RP in PIM-SM domain.

During the deployment of Anycast-RP, MSDP peer relationship will be established between RPs with the same IP address. When the multicast source registers with a RP nearest to the route, this RP will send SA messages to other RPs. By default, the originator address of such SA messages will be the address of RP. Upon receipt of such SA messages, other RPs will find out that the originator address is the local address, and the computation of Peer-RPF neighbor may fail. There are three solutions to the abovementioned problem:

- Configure mesh group
- Configure default MSDP peer
- Change the originator address of SA messages

To change the originator address of SA messages, execute the following command in the global configuration mode**.**

Command	Function

Ruijie(config)# **ip msdp originator-id** *interface-type interface-number*	Configure the originator address of SA messages to the main IP address of the specified interface.

Monitoring and Maintaining MSDP

Use the following commands to monitor MSDP.

Command	Function
Ruijie# **debug ip msdp peer** [*peer-address*]	Debug a specific peer or all peers, including: peer connection establishment/shutdown, MSDP protocol packets reception/forwarding, etc.
Ruijie# **show ip msdp count** [*as-number*]	Display the number of sources and groups indicated in the SA messages generated by each autonomous system.
Ruijie# **show ip msdp mesh-group**	Display the information of mesh group.
Ruijie# **show ip msdp peer** [*peer-address*]	Display the detailed information of a specific or all MSDP peers.
Ruijie# **show ip msdp rpf-peer** *ip-address*	Display the information of RPF-Peer with the specified address.
Ruijie# **show ip msdp sa-cache** [*group-address*|*source–address*] [*group-address*|*source–address*] [*as-number*]	Display the status of multicast source (S,G) learned from MSDP peer.
Ruijie**#** **show ip msdp sa-originated**	Display the SA originated multicast source (S, G).
Ruijie# **show ip msdp summary**	Display the brief information of MSDP peers.
Ruijie# **clear ip msdp peer** *peer-address*	Reset the TCP connection with a specific MSDP peer; reset all MSDP message counters.
Ruijie# **clear ip msdp statistics** [*peer-address*]	Clear the statistics of a specific or all MSDP peers.
Ruijie# **clear ip msdp sa-cache** [*group-address*]	Clear all SA cache entries or those of a specific group.

Typical MSDP Configuration Example

Cross-domain Multicasting

Networking Requirements

1) Three ISPs maintains autonomous system AS 100, AS 200 and AS 300 respectively. OSPF is adopted for the internal communication within each AS, while BGP is adopted for exchanging routing information between the autonomous systems.

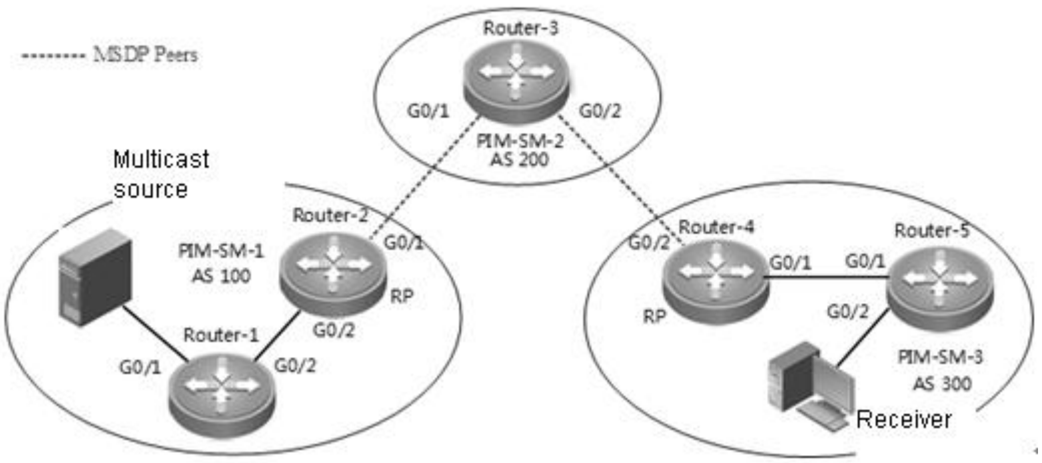
2) PIM-SM-1 belongs to AS 100, PIM-SM-2 belongs to AS 200, and PIM-SM-3 belongs to AS 300. Each PIM-SM domain has 0 or 1 multicast source and 0 or 1 receiver.

3) Configure the Loopback1 interface of Router-2 to C-BSR and C-RP of PIM-SM-1, and configure the Loopback1 interface of Router-4 to C-BSR and C-RP of PIM-SM-3.

4) Establish MSDP Peer relationship between Router-2 and Router-3 via EBGP, and establish MSDP Peer relationship between Router-3 and Router-4 via EBGP.

Network Topology

Fig 2 Cross-domain multicasting



Basic configurations of major interfaces in Figure 2.

```
Device      Interface       IP address
Router-1    G0/1            200.200.200.1/24
G0/2            100.100.100.1/24
Router-2    G0/2            100.100.100.2/24
G0/1            1.1.1.1/24
Loopback1       111.111.111.111/32
Loopback0       10.10.10.10/32
Router-3    G0/1            1.1.1.2/24
G0/2            2.2.2.1/24
Loopback0       30.30.30.30/32
Loopback1       40.40.40.40/32
Router-4    G0/2            2.2.2.2/24
G0/1            3.3.3.1/24
Loopback1       222.222.222.222/32
Loopback0       20.20.20.20/32
Router-5    G0/1            3.3.3.2/24
G0/2            4.4.4.1/24
```

Configuration Steps

(1) Configure the IP address and unicast routing protocol for the interfaces of respective devices

Configure the IP address and subnet mask of respective interfaces according to Figure 2. Configure OSPF protocol to connect the devices in each domain, and make sure the devices are interconnected at the network layer.

(2) Enable IP multicast routing, and enable PIM-SM on each interface.

# On Router-1, enable IP multicast routing, and enable PIM-SM on each interface.

```
Ruijie# conf t
Ruijie(config)# ip multicast-routing
Ruijie(config)# int g 0/1
Ruijie(config-if)# ip pim sparse-mode
```

Proceed with the similar configurations on other interfaces of the local device and on the interfaces of other devices.

(3) Configure BSR border

# Configure BSR border on G0/1 of Router-2.

```
Ruijie(config)# int g 0/1
Ruijie(config-if)# ip pim bsr-border
```

Configure BSR border on G0/1 and G0/2 of Router-3 and on G0/2 of Router-4.

(4) Configure C-BSR and C-RP

# Configure C-BSR and C-RP on Loopback1 of Router-2.

```
Ruijie# conf t
Ruijie(config)# int loopback 1
Ruijie(config-if)# ip pim sparse-mode
Ruijie(config-if)# ip address 111.111.111.111 255.255.255.255
Ruijie(config-if)# exit
Ruijie(config)# ip pim bsr-candidate loopback 1
Ruijie(config)# ip pim rp-candidate loopback 1
```

Configure Lookback1 of Router-4 to C-BSR and C-RP as shown above.

(5) Configure BGP routing protocol between the autonomous systems, and configure mutual route redistribution between BGP and OSPF

We need to configure EBGP Peer between Router-2 and Router-3 and between Router-3 and Router-4, and configure mutual route redistribution between BGP and OSPF. Please refer to BGP configuration guide for the detailed configuration process. You can execute BGP commands to display the route learning conditions between autonomous systems.

(6) Configure MSDP Peer

Configure Router-2 and Router-3 to MSDP peers.

# On Router-2, configure the main address of interface Loopback0 to the source address of TCP connection.

```
Ruijie(config)# ip msdp peer 30.30.30.30 connect-source loopback 0
```

# On Router-3, configure the main address of interface Loopback0 to the source address of TCP connection.

```
Ruijie(config)# ip msdp peer 10.10.10.10 connect-source loopback 0
```

Configure Router-3 and Router-4 to MSDP peers.

# On Router-4, configure the main address of interface Loopback0 to the source address of TCP connection.

```
Ruijie(config)# ip msdp peer 40.40.40.40 connect-source loopback 0
```

# On Router-3, configure the main address of interface Loopback1 to the source address of TCP connection.

```
Ruijie(config)# ip msdp peer 20.20.20.20 connect-source loopback 1
```

Verification

(1) Multicast source information

Multicast source sending multicast data (200.200.200.200, 225.1.1.1).

(2) Display MSDP peer status on Router-4

```
Ruijie#sh ip msdp summary
Msdp Peer Status Summary
Peer Address        As      State       Uptime/Downtime Reset-Count     SA-Count
    Peer-Name
40.40.40.40    200     Up          00:01:42           0                       1
    ?
```

(3) Display the multicast source information learned by Router-4

```
Ruijie#sh ip msdp sa-cache

MSDP Source-Active Cache: 1 entries
  (200.200.200.200,225.1.1.1),RP:111.111.111.111,MBGP/AS 100, 00:00:18/00:01:57, Peer

```

Deploying Anycast-RP

In Anycast-RP, two or more RPs with the same address are configured in the same PIM-SM domain, and MSDP peer relationship is established between these RPs, allowing load sharing and redundant backup between RPs in the domain.

The significance of Anycast-RP is shown below:

- RP with the shortest path: Multicast source registers with the nearest RP and build the SPT; the receiver joins the nearest RP and build the RPT.
- Load sharing between RPs: Each RP only maintains partial source/group information in the PIM-SM domain, allowing the load sharing between RPs.

- Redundant backup between RPs: When one RP fails, the multicast source registering with this RP or the receiver joining this RP will automatically select the nearest RP for registration or joining, allowing redundant backup between RPs.

Networking Requirements

In the PIM-SM domain, there are multiple multicast data senders and receivers; the OSPF protocol is running in the PIM-SM domain to allow intercommunication between devices at the network layer.

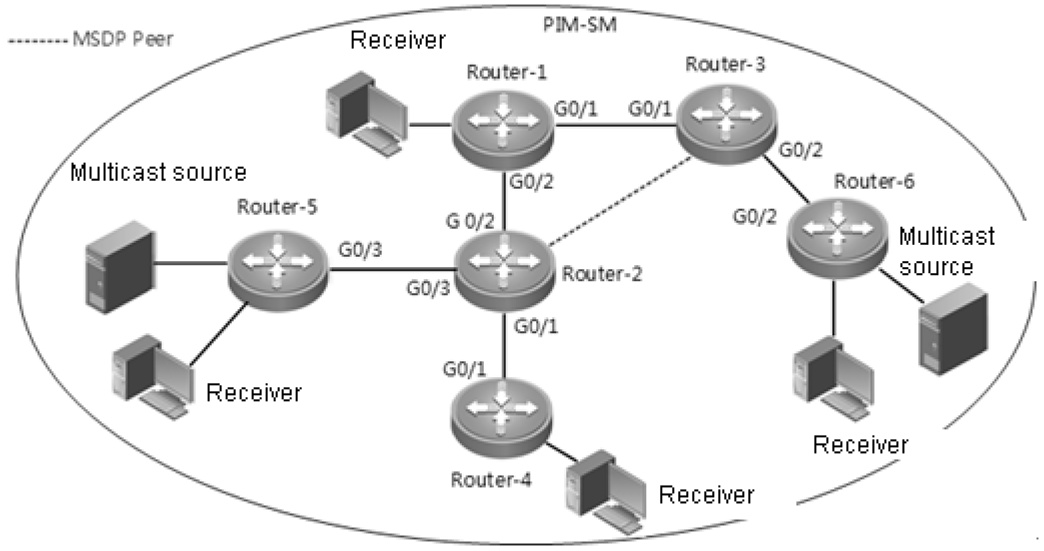
By configuring Anycast-RP in the PIM-SM domain, when a new member joins the multicast group, the receiver-side DR or router acting as DR can join the RP with the nearest unicast distance.

Establish MSDP Peer relationship between Router-2 and Router-3.

Configure C-BSR on Loopback0 of Router-1, and configure C-RP on Loopback1 of Router-2 and Router-3.

Network Topology

Fig 3 Anycast-RP deployment



Basic configurations of major interfaces in Figure 3.

Device	Interface	IP address
Router-1	G0/1	1.1.1.1/24
	G0/2	2.2.2.1/24
	Loopback0	100.100.100.100/32
Router-2	G0/1	3.3.3.1/24
	G0/2	2.2.2.2/24
	G0/3	4.4.4.1/24
	Loopback0	20.20.20.20/32
	Loopback1	10.10.10.10/32
Router-3	G0/1	1.1.1.2/24
	G0/2	5.5.5.1/24

	Loopback0	30.30.30.30/32
	Loopback1	10.10.10.10/32
Router-4	G0/1	3.3.3.2/24
Router-5	G0/3	4.4.4.2/24
Router-6	G0/2	5.5.5.2/24

Configuration Steps

(1) Configure the IP address and unicast routing protocol for the interfaces of respective routers

Configure the IP address and subnet mask of respective interfaces according to Figure 3. Configure to interconnect the routers via OSPF protocol.

(2) Enable IP multicast routing, and enable PIM-SM on each interface.

# On Router-1, enable IP multicast routing, and enable PIM-SM on each interface.

```
Ruijie# conf t
Ruijie(config)# ip multicast-routing
Ruijie(config)# int g 0/1
Ruijie(config-if)# ip pim sparse-mode
```

Proceed with the similar configurations on other interfaces of the local device and on the interfaces of other devices.

(3) Configure C-BSR and C-RP

# Configure C-BSR on Router-1

```
Ruijie(config)# int loopback 0
Ruijie(config-if)# ip pim sparse-mode
Ruijie(config-if)# ip address 100.100.100.100 255.255.255.255
Ruijie(config-if)# exit
Ruijie(config)# ip pim bsr-candidate loopback 0
```

# Configure Loopback1 of Router-2 and Loopback1 of Router-3 to the same address, and configure both interfaces to C-RP;

```
Ruijie# conf t
Ruijie(config)# int loopback 1
Ruijie(config-if)# ip pim sparse-mode
Ruijie(config-if)# ip address 10.10.10.10 255.255.255.255
Ruijie(config-if)# exit
Ruijie(config)# ip pim rp-candidate loopback 1
```

(4) Configure MSDP Peer

Configure Router-2 and Router-3 to MSDP peers.

# On Router-2, configure the main address of interface Loopback0 to the source address of connection.

```
Ruijie(config)#ip msdp peer 30.30.30.30 connect-source loopback 0
```

# On Router-3, configure the main address of interface Loopback0 to the source address of connection.

```
Ruijie(config)# ip msdp peer 20.20.20.20 connect-source loopback 0
```

Verification

(1) Multicast source information

There are two multicast source in Figure 2: (6.6.6.6, 225.1.1.1) and (7.7.7.7, 225.1.1.1). (6.6.6.6, 225.1.1.1) is registered with Router-2, while (7.7.7.7, 225.1.1.1) is registered with Router-3.

(2) Display MSDP peer status on Router-2

```
Ruijie#sh ip msdp summary
Msdp Peer Status Summary
Peer Address        As      State       Uptime/Downtime Reset-Count     SA-Count
    Peer-Name
30.30.30.30    ?       Up          00:01:42           0                       1
    ?
```

(3) Display the multicast source information learned by Router-2

The following messages show that Router-2 has learned the multicast source information (7.7.7.7, 225.1.1.1) registered with Router-3.

```
Ruijie#sh ip msdp sa-cache

MSDP Source-Active Cache: 1 entries
  (7.7.7.7,225.1.1.1),RP:10.10.10.10,MBGP/AS ?, 00:00:18/00:01:57, Peer 30.30.30.30
   Learned from peer 30.30.30.30, RPF peer 30.30.30.30,
SAs received: 1, Encapsulated data received: 1
```

Configuring Multicast VPN

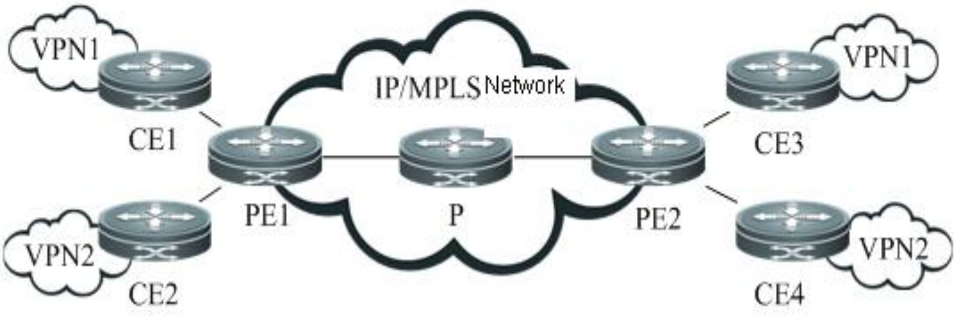
Introduction to multicast VPN

Overview

IP multicast is being widely applied, and it is being used as the solution to many applications in many sectors. Meanwhile, the application of VPN technology is getting more and more popular in the enterprise networks. BGP/MPLS L3VPN based architecture can be widely found in E-government network, electric power data network and other enterprise networks. By setting different departments into different VPNs, the data of different departments can be well isolated. Meanwhile, the intra-department video conferencing, data sharing and other multicast services will also involve VPN-based data isolation, leading to the increasingly pressing needs for multicast VPN.

Multicast VPN is a BGP/MPLS L3VPN network based technology to transmit multicast data within the VPN network, with network structure similar to that of BGP/MPLS L3VPN, as shown below:

Figure 22 Basic structure of multicast VPN



- CE

CE (Customer Edge Router) is an edge device of customer network, and is logically a customer VPN, with certain interface directly connected to the ISP device. CE can be a host, router or switch, such as CE1, CE2, CE3 and CE4 shown above.

- PE

PE (Provider Edge Router) is an edge device of SP backbone network (it can be a router, ATM switch, frame relay switch and etc), such as PE1 and PE2 as shown in the figure. Logically belonging to the service provider, PE is directly connected with CE, and one PE can be connected with multiple CEs.

- P

P (Provider Router) is the core device within the SP backbone network, such as P1, P2 and P3 as shown in the figure. P is not connected with CE, and is responsible for routing and fast forwarding on the public network.

As shown above, the multicast protocol is run on customer VPN to establish inter-VPN multicast routes and forward multicast traffic for the private network. When PE1 receives the multicast traffic from CE1 and CE2, it will convert the traffic into multicast data format that can be transmitted over the public network, and forward the traffic to PE2 of other VPN sites. PE2 will then de-encapsulate the traffic and forward to the corresponding VPN site.

Multicast Domain

MD (Multicast-Domain) is a scheme to realize multicast VPN, and is achieved by maintaining a multicast domain for each VPN in the service provider network. MD scheme will create a MDT (Multicast Distribution Tree) for reach VPN in the public network to transmit private network multicast protocol packets and data packets, which will be converted into public network multicast data packets on PE and be forwarded via MDT. There are two types of MDTs in the MD scheme:

➢ Default-MDT

Each multicast domain will create a Default-MDT to connect all PEs in the domain. Through this Default-MDT, the customer network can treat the multicast domain as a LAN, which is to say the CE multicast data transmitted to the ingress PE will be forwarded over the public network to all egress PEs in this multicast domain, while such multicast data are transmitted on Default-MDT in the form of multicast. The egress PE will determine whether or not to forward these multicast data by verifying whether there is multicast receiver in the VPN sites connected. If no receiver exists in the sites, the multicast data will be discarded.

➢ Data-MDT

Data-MDT is an optional optimized means to transmit multicast traffic. It will only forward to multicast traffic to the egress PE in need of such multicast traffic. When the ingress PE intends to create a Data-MDT, it will first send a MDT-join packet through Default-MDT, and such packets carries such information as C-S (source address of customer multicast traffic), C-G (group address of customer multicast traffic) and P-G (group address for transmission over public network), indicating that C-S and C-G identified multicast traffic will be transmitted along P-G identified Data-MDT. Upon receipt of MDT-Join packets, the egress PE will only join the Data-MDT when it is in need of such multicast traffic. Therefore, the multicast traffic will arrive at the egress PE in need of the multicast traffic along Data-MDT, thus saving the resources of irrelevant egress PEs and the bandwidth of public network. Hence, if the private network contains certain high-rate multicast traffic, we can forward such multicast traffic by configuring Data-MDT, so as to avoid bandwidth wasting caused by the use of Default-MDT.

Single-AS Multicast VPN

In the single-AS multicast VPN, we can use PIM-SM/SSM to create Default-MDT in order to interconnect different PEs.

➢ Use PIM-SM to create Default-MDT

In this scheme, by running PIM-SM on the public network, each PE uses the same group address (group address of Default-MDT) to join the RP on the public network, thus forming a shared tree (RPT) connecting RP and each PE. Then, each PE will register with RP, so that RP creates the SPT reaching each PE. In this way, the multicast packets sent by each PE can be transmitted through such SPT and RPT, and eventually reach other PEs. The Default-MDT is hence successfully created.

➢ Use PIM-SSM to create Default-MDT

In this scheme, by running PIM-SSM on the public network, each PE uses the MDT address-family routes of BGP to inform other PEs of its NLRI information (including PE address and Default-MDT group address). When one PE receives the MDT address-family route of BGP, it will use the PE address and Default-MDT group address contained therein to join SPT with the PE providing this route. A SPT is eventually formed with PE initiating the MDT address-family routes being the root and PEs receiving such MDT address-family routes being the leaves. Since each PE will initiate the MDT address-family route, multiple SPTs will be formed eventually. In this way, the multicast packets sent by each PE can be transmitted to other PEs via these SPTs, and Default-MDT is created accordingly.

Multi-AS Multicast VPN

When VPN needs to cross multiple ASes, there are three unicast solutions to address the PE communication problem between ASes. There are also different multicast VPN options based on these three unicast solutions.

- OptionA: VRF-to-VRF

VRF is configured for each VPN on the ASBR, which act as PE, and ASBRs are interconnected through their respective VPN instance and regard each other as a CE device. In this approach, ASBR acts as PE and the MDT is established within each AS. The multicast data is transmitted over the public network through MDTs of multiple ASes.

- OptionB: Single-hop EBGP

PE uses to IBGP to advertise the VPN route to the ASBR of local AS, and then ASBRs of different ASes will advertise the VPN route of other ASes to the local ASes through EBGP. In this way, ASBR no long acts as PE, and the MDT of multicast VPN must cross each AS in order to connect PEs of respective ASes.

- OptionC: Multi-hop EBGP

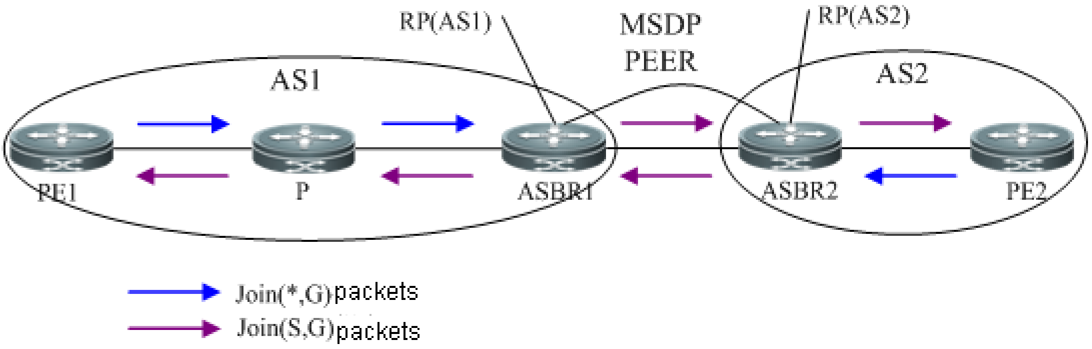
In this way, PEs of different ASes are interconnected via Multihop-EBGP, and ASBR will neither participate in the reception and advertisement of VPN route nor act as PE. In this approach, the MDT of multicast VPN must cross each AS in order to connect PEs of respective ASes.

In OptionA, since MDT is established within AS, the process is similar to that of single-AS multicast VPN. In OptionB and OptionC, when MDT is created using PIM-SM and PIM-SSM, there will be two different scenarios:

- Use PIM-SM to create multi-AS MDT

In order to interconnect different PEs in respective ASes via the same MDT, we can use MSDP to share multicast source information between RPs of two ASes. The process is shown below:

Figure 23 Use PIM-SM to create multi-AS MDT

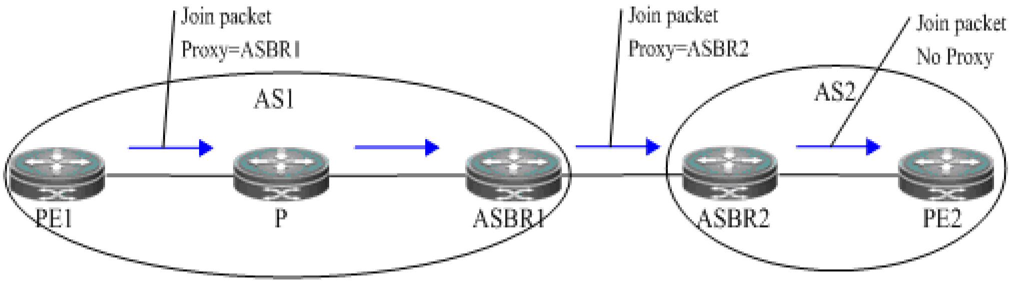


In this scenario, the ASBR of each AS is configured to MSDP peer, which is used to learn the multicast source information of other ASes, so as to initiate the grafting of SPT to other ASes. As shown above, PE1 and PE2 first initiate shared tree grafting to local RPs in order to create Default-MDT. When RP (ASBR1) in AS1 learns the multicast source information (PE2) of AS2 via MSDP, it will send Join (S,G) packets and eventually create a SPT with ASBR1 as the leave and PE2 as the root. Likewise, when ASBR2 learns the multicast source information (PE1) of AS1, a SPT with ASBR2 as the leave and PE1 as the root will also be created. In this way, the multicast packets sent by PE1 can be forwarded to ASBR2 along SPT, while ASBR2 will forward such packets to PE2 along the shared tree. Therefore, through the shared tree and SPT tree, PEs in different ASes can then be interconnected.

➢ Use PIM-SSM to create multi-AS MDT

In the process of using PIM-SSM to create multi-AS SPT, the P router in one AS may not have the route to the PE in another AS, and this will lead to the failure in SPT creation. To address this problem, PIM-SSM extends the attribute of Join packet so that it carries proxy information, while P router will use such proxy information to create SPT, as shown below:

Figure 24 Create multi-AS SPT



In the above figure, when PE1 initiates to create SPT, it will select ASBR1 as the proxy and include its IP address in the Join packet. When P receives this Join packet, it will use proxy as the destination address to discover RPF neighbors and initiate SPT grating to neighbor ASBR1 that leads to the proxy. After ASBR1 receives the Join packet, it will find out that the proxy address is its own IP address, and it will reselect a new proxy (ASBR2) and initiate SPT grafting. In this way, a SPT is formed through proxy grafting, so that PEs in respective ASes can be interconnected.

Note

When using PIM-SM to create multi-AS MDT, all routers along the path from RPs in respective ASes to the multicast source (namely PEs in other ASes) must have the unicast route to the multicast source. Therefore, this scenario requires advertising the route of each PE to the IGP of each AS.

Note

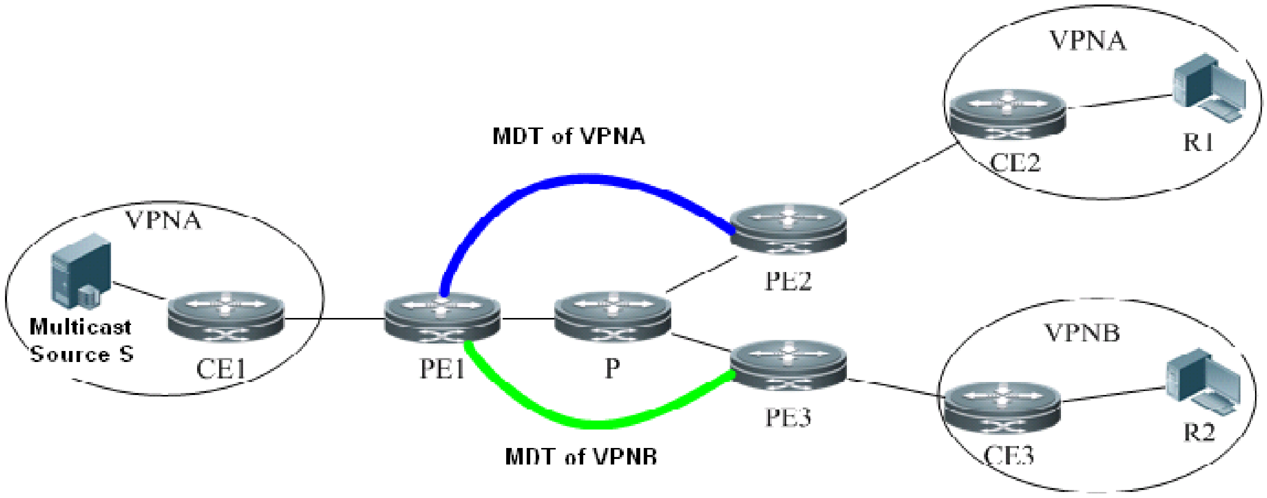
When using PIM-SSM to create multi-AS MDT, the P router is not required to have the route to PEs in other ASes. This scenario boasts higher flexibility, but will require PEs on the public network and P router to support proxy-based SPT creation.

Extranet Application of Multicast VPN

Extranet multicast VPN (Extranet-MVPN) enables the multicast source of a multicast VPN to send multicast streams to other multicast VPN sites. On the Extranet-MVPN, a cross-VPN sender is called an "Extranet-Source". The VRF where the sender is located is called the source MVRF. The PE connected to the source MVRF is called the ingress PE. A cross-VPN receiver is called an Extranet-Receiver. The VRF where the receiver is located is called a receiver MVRF. The PE connected to the receiver MVRF is called an egress PE. See the following figure. The multicast source on VPN A can forward the multicast stream to VPN B, so that the receiver on VPN B can receive the multicast stream. In this scenario, the VRF (on PE1) connected to the VPNA can be referred to as the source MVRF. Multicast source S can be referred to as the Extranet-Source. The VRF (on PE3) connected to VPN B can be referred to as the receiver MVRF. The receiver R2 can be referred to as the Extranet-Receiver.

On the Extranet-MVPN, a PE establishes a cross-VRF multicast distribution tree for introducing multicast streams of other VPN sites to the PE. Meanwhile, the PE uses the cross-VRF multicast stream forwarding function to forward streams from one VPN to another. The following figure shows the detailed process.

Figure 25 Work process of the Extranet-MVPN



As shown in the preceding figure, VPN A works as the sharing VPN; VPN B works as the receiver VPN; The VPNA unicast route is imported for VPN B on PE1 and PE3, so that CE3 can locate the route leading to the multicast source S. The corresponding VRF is configured for every VPN on all PEs and the MD function is enabled. They form the Extranet-MVPN for R2 between the multicast source S and VPN B.

➢ Establishment Process of MDTs on a Public Network

As shown in the preceding figure, the corresponding VRF is configured for every VPN on all PEs and the MD function is enabled (the VRFs corresponding to VPN A and VPN B are both configured on PE1). In this case, an MDT is created to connect PE1 VPN A to PE2 VPN A for transmitting multicast streams of VPN A on the public network; another MDT is created to connect PE1 VPN B to PE2 VPN B for transmitting multicast streams of VPN B on the public network.

➢ Process of Creating MDTs

The processes of creating MDTs are similar for PIM-SM and PIM-SSM. The only difference lies in that a multicast router initiates the graft process in the RP direction for PIM-SM, while a multicast router initiates the graft process in the multicast source direction for PIM-SSM. The process of creating an MDT for PIM-SSM is set out as follows as an example.

1) During the transmission from R1 to S, CE2 sends a Join packet to PE2 to create a MDT, and then PE2 uses the MDT of VPN A to send the Join packet to PE1. Upon receiving the Join packet, PE1 initiates the graft process to CE1, and eventually an MDT from CE1 to CE2 is created on VPN A.

2) During the transmission from R2 to S, CE3 sends a Join packet to PE3 to create an MDT, and then PE3 uses the MDT of VPN B to send the Join packet to PE1. Upon receiving the Join packet, PE1 performs the RPF check and finds that the RPF interface belongs to VRF A. PE1 notifies the PIM instance on VRF A of the receiving request. Then, the PIM instance on VRF A takes over the initiating of the MDT creation process. The PIM instance on VRF A sends the Join packet to CE1 for grafting. Finally, an MDT from CE1 (on VPN A) to CE3 (on VPN B) is created.

- Multicast Stream Forwarding Process

1) After a multicast stream of the multicast source S is forwarded through CE1 to PE1, PE1 forwards the multicast stream to PE2 and eventually to R1 through the MDT of VPN A.

2) After a multicast stream of the multicast source S is forwarded through CE1 to PE1, PE1 can detect VRF B's request on the multicast stream because the PIM instance of VRF B has notified the PIM instance of VRF A of the multicast-receving request when the MDT is created previously. In this case, PE 1 forwards the multicast stream to VRF B, transmits the multicast stream on the public network through the MDT on VPN B first to PE3 and eventually to R2.

Note

If a private network runs PIM-SM, the multicast source and RP must be on a same VPN. Otherwise, the source DR fails to register with RP and an MDT fails to be created.

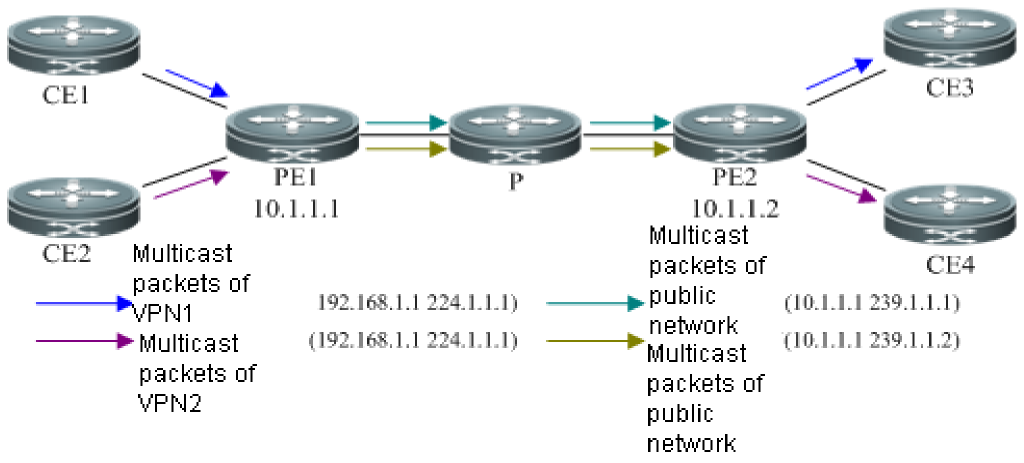
Multicast VRF

One PE may be connected with multiple CEs of different VPN sites. In order to differentiate the multicast traffic from different VPN sites on PE, the MD scheme also uses multiple VRFs to forward the multicast traffic from multiple VPN sites, and these VRFs are called MVRF (Multicast VPN Routing and Forwarding). The connection between PE and the CE of each VPN site needs to be associated with one VRF. When PE receives the multicast packets from CE, it will look up the multicast forwarding table under corresponding MVRF and forward packets as per such forwarding table. In this way, MVRF addresses the problem of local multicast route conflict on PE and isolate the multicast traffic in each VPN site.

The creation and maintenance process of MVRF is similar to that of VRF, yet multicast route must be initiated for each MVRF so that it can generate relevant multicast forwarding table. In the MD scheme, an MVRF is created on PE for each VPN to forward the corresponding multicast traffic. Meanwhile, each MVRF contains one Multicast Tunnel Interface (MTI), which is a GRE Tunnel interface converting private network multicast traffic into public network multicast traffic, which will then be transmitted over the public network through the public network multicast forwarding table.

Through the forwarding of private network multicast traffic by MVRF and the conversion of multicast traffic by MTI interface, the multicast data packets will eventually be forwarded from one VPN site to another VPN site over the public network. The packet forwarding process is shown below:

Figure 26 Forwarding process of multicast data packets



CE1
CE3
PE1
10.1.1.1
P
PE2
10.1.1.2
CE2
CE4
Multicast packets of VPN1
Multicast packets of VPN2
192.168.1.1 224.1.1.1)
(192.168.1.1 224.1.1.1)
Multicast packets of public network
Multicast packets of public network
(10.1.1.1 239.1.1.1)
(10.1.1.1 239.1.1.2)

As shown above, the forwarding process of multicast data packets is shown below:

1) CE1 and CE2 forward the multicast data packets in respective VPNs to PE1. The source address and destination address carried by data packets of two VPNs could be identical (as shown above, they are both 192.168.1.1, 224.1.1.1).

2) After PE1 receives the data packets transmitted from CE1 and CE2, it will select different MVRFs to forward these two multicast traffic according to the VPN. When each multicast traffic is forwarded to the MTI of respective MVRF, the multicast traffic will be encapsulated into the corresponding public network multicast traffic. As shown above, the multicast traffic of VPN1 is encapsulated into (10.1.1.1, 239.1.1.1), and that of VPN2 is encapsulated into (10.1.1.1, 239.1.1.2). These two multicast traffic will be transmitted to PE2 through public network multicast routing and forwarding.

3) PE2 will de-encapsulate these two public network multicast traffic and restore to the private network multicast traffic, which will then be forwarded by the MVRFs corresponding to their own VPNs and reach CE3 and CE4 respectively. Such traffic will eventually reach the multicast receivers in respective VPNs.

Caution To enhance the efficiency of packet processing, no GRE checksum will be calculated or configured during packet encapsulation on the MTI interface of ingress PE.

Caution Before packet encapsulation, the MTI interface of ingress PE cannot proceed with fragmentation first according to IP MTU of MTI interface.

Configuring multicast VPN

Configuring Single-AS Multicast VPN

Before configuring single-AS multicast VPN, the following network configurations must be completed first:

- Configure a unicast routing protocol to enable routes in AS
- Configure BGP/MPLS L3VPN

The configuration of single-AS multicast VPN mainly involves the following:

- Configure Default-MDT (Required)
- Configure Data-MDT (Optional)
- Configure multicast routing on VRF (Required)
- Configure PIM-SSM (Optional)
- Configure BGP MDT address family (optional)

Configuring Default-MDT

Steps of Default-MDT configuration are shown below:

Command	Function
Ruijie# **configure terminal**	Enter global configuration mode.
Ruijie(config)# **ip vrf** *vrf_name*	Create a VRF and enter VRF configuration mode.
Ruijie(config-vrf)# **rd** *route_distinguisher*	Configure a RD for VRF; RD information will be need when BGP distributes VPN routes and MDT-SAFI routes.
Ruijie(config-vrf)# **route-target** {**both | export | import}** *rt-value*	Configure RT value.
Ruijie(config-vrf)# **mdt default** *group_address*	Configure Default-MDT: specify the group address and enable MD.

Note

After executing "**mdt default**" command, a MTI interface will be generated automatically. This MTI interface can only be dynamically generated by MD control plane instead of user configuration.

Note

Execute "**neighbor** *ip-address* **activate**" command under vpnv4 address family; after establishing the connection between device and neighbor, MTI interface will take the interface automatically acquired to establish connection with neighbor as the source interface, and take the source address to establish connection with neighbor as its IP address.

Note

After configuration, the group address of Default-MDT cannot be changed by running the command. To change the group address, you can only delete the existing one and configure a new one. If you run the **no mdt default** command to delete Default-MDT, the MTI interface and the configuration command of Data-MDT corresponding to the VRF will also be deleted.

# Configure Default-MDT

```
Ruijie# configure terminal
Ruijie(config)# ip vrf vpn1
Ruijie(config-vrf)# rd 1: 100
Ruijie(config-vrf)# route-target both 1: 100
Ruijie(config-vrf)# mdt default 239.1.1.1
```

Configuring Data-MDT

To configure Data-MDT forwarding for some high-rate private network multicast traffic, you need to configure Data-MDT under VRF mode, as shown below:

Command	Function
Ruijie# **configure terminal**	Enter global configuration mode.
Ruijie(config)# **ip vrf** *vrf_name*	Create a VRF and enter VRF configuration mode.

Ruijie(config-vrf)# **mdt data** group_address wildcard_bits [**list** access-list]	Configure Data-MDT.

Note

After executing "mdt data" command, all private network multicast traffic meeting ACL filtering conditions will reach PE, which will create a Data-MDT. Each PE can only create a limited number of Data-MDT. Therefore, it is suggested that Data-MDT can only be configured for certain high-rate private network multicast traffic.

Note

Data-MDT cannot be reused, i.e., one Data-MDT can only be used to forward one private network multicast traffic.

# Configure Data-MDT, so that the private network multicast traffic specified by ACL will be forwarded with Data-MDT.

```
Ruijie(config)# ip vrf vpn1
Ruijie(config-vrf)# mdt data 238.1.1.0 0.0.0.255 list vpn1-datamdt
Ruijie(config-vrf)# exit
Ruijie(config-vrf)# ip access-list standard vpn1-datamdt
Ruijie(config-std-nacl)# permit 224.1.1.0 0.0.0.255
```

Configuring Multicast Routing on VRF

Configuration of multicast routing on VRF will need to enable multicast routing on VRF and configure the PIM-SM instance on this VRF. When vrf parameter is not specified, the following commands shall mean the configuration of public network multicast routing. The following table describes the procedure.

Command	Function
Ruijie# **configure terminal**	Enter global configuration mode.
Ruijie(config)# **ip multicast-routing vrf** *vrf_name*	Enable multicast routing of certain VRF.
Ruijie(config)# **ip pim** [**vrf** *vrf-name*] **rp-address** *rp-address* [*access_list*]	Configure static RP on certain VRF.
Ruijie(config)**#** **interface** *type ID*	Configure interface.
Ruijie(config-if-*type ID*)# **ip vrf forwarding** *vrf_name*	Bind the interface with certain VRF.
Ruijie(config-if-*type ID*)# **ip address** *ip-address mask*	Configure IP address on interface.
Ruijie(config-if-*type ID*)# **ip pim sparse-mode**	Enable PIM-SM on interface.

# Configure multicast routing

```
Ruijie# configure terminal
Ruijie(config)# ip multicast-routing
Ruijie(config)# ip pim rp-address 10.1.1.2
Ruijie(config)# interface loopback 0
Ruijie(config-Loopback 0)# ip address 10.1.1.1 255.255.255.255
Ruijie(config-Loopback 0)# ip pim sparse-mode
Ruijie(config-Loopback 0)# exit
Ruijie(config)# ip multicast-routing vrf vpn1
Ruijie(config)# ip pim vrf vpn1 rp-address 1.1.1.1
Ruijie(config)# interface gigabitethernet 0/1
```

# "no switchport" command is used to switch the port mode to "Routed Port" mode on switch products, and is not applicable to the router. Therefore, you don't need to execute this command on router products.

```
Ruijie(config-GigabitEthernet 0/1)# no switchport
Ruijie(config-GigabitEthernet 0/1)# ip vrf forwarding vpn1
Ruijie(config-GigabitEthernet 0/1)# ip address 1.1.1.1 255.255.255.0
Ruijie(config-GigabitEthernet 0/1)# ip pim sparse-mode
```

Configuring PIM-SSM

This step intends to create Default-MDT in order to use PIM-SSM, as shown below:

Command	Function
Ruijie# **configure terminal**	Enter global configuration mode.
Ruijie(config)# **ip pim ssm** { **default** | **range** *access_list*}	Configure the scope of PIM-SSM. After configuring PIM-SSM, the group address in "mdt default" command must fall within the scope of SSM. Only in this way we can use PIM-SSM to create Default-MDT.

# Configure the scope of SSM

```
Ruijie# configure terminal
Ruijie(config)# ip pim ssm default
```

Configuring BGP MDT Address Family

When using PIM-SSM to create Default-MDT, you will need to configure BGP MDT address family. Through the routing of MDT address family, PE can discover other PE addresses and initiate the grating of SPT to other PEs. The configuration steps of MDT address family are shown below:

Command	Function
Ruijie# **configure terminal**	Enter global configuration mode.
Ruijie(config)# **router bgp** *asn-num*	Create BGP and enter BGP configuration mode.
Ruijie(config-router)# **neighbor** *ip-address* **remote-as** *asn-number*	Configure BGP session.
Ruijie(config-router)# **neighbor** *ip-address* **update-source** *interface-name*	Configure to use interface address as the source address when MP-IBGP session is established; usually, the Loopback interface address is used as the source address.
Ruijie(config-router)# **address-family ipv4 mdt**	Enter MDT address family.
Ruijie(config-router-af)# **neighbor** *ip-address* **activate**	Activate the route to exchange MDT address family on BGP session.
Ruijie(config-router-af)# **neighbor** *ip-address* **next-hop-self**	Change the next-hop route to self; this command can be executed on ASBR in OptionB.

# Configure MDT address family

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 10.1.1.3 remote-as 2
Ruijie(config-router)# neighbor 10.1.1.3 update-source loopback 0
Ruijie(config-router)# address-family ipv4 mdt
Ruijie(config-router-af)# neighobr 10.1.1.3 activate
```

Configuring Multi-AS Multicast VPN

The configuration of multi-AS multicast VPN could be different according to different unicast schemes. In OptionA, the configuration of multicast VPN is similar to that of single AS, and is hence not introduced herein. We will mainly introduce the configurations of OptionB and OptionC. Before configuring multi-AS multicast VPN, the following network configurations must have been completed:

- Configure multi-AS BGP/MPLS L3VPN
- Configure Default-MDT

The configuration of multi-AS multicast VPN mainly involves the following:

- Multicast VPN configuration when using PIM-SM
- Multicast VPN configuration in OptionB when using PIM-SSM
- Multicast VPN configuration in OptionC when using PIM-SSM

Multicast VPN Configuration when Using PIM-SM

When configuring MSDP-based multi-AS multicast VPN, the multicast configuration on PE shall be the same as the configuration to create Default-MDT with PIM-SM. MSDP must be configured on ASBR, as shown below:

Command	Function
Ruijie# **configure terminal**	Enter global configuration mode.
Ruijie(config)# **ip msdp peer** *peer-address* **connect-source** *interface-type interface-number*	Configure MSDP peer.

# Configure MSDP peer

```
Ruijie# configure terminal
Ruijie(config)# ip msdp peer 10.0.5.9 connect-source gi 0/1
```

Multicast VPN Configuration in OptionB when Using PIM-SSM

Configure multicast VPN in OptionB, so that it can use PIM-SSM to create Default-MDT, as shown below:

Command	Function
Ruijie# **configure terminal**	Enter global configuration mode.
Ruijie(config)# **router bgp** *asn-num*	Create BGP and enter BGP configuration mode.
Ruijie(config-router)# **neighbor** *ip-address* **remote-as** *asn-number*	Configure BGP session.
Ruijie(config-router)# **neighbor** *ip-address* **update-source** *interface-name*	Configure to use interface address as the source address when BGP session is established; usually, the Loopback interface address is used as the source address.
Ruijie(config-router)# **address-family ipv4 mdt**	Enter MDT address family.

Ruijie(config-router-af)# **neighbor** *ip-address* **activate**	Activate the route to exchange MDT-SAFI on BGP session.
Ruijie(config-router-af)# **exit**	Exit the address family.
Ruijie(config-router)# **exit**	Exit BGP mode.
Ruijie(config)# **ip multicast** [**vrf** *vrf-name*] **rpf proxy rd vector**	Configure whether to enable RPF Vector on certain VRF. In OptionB, the rd parameter of this command must be configured to carry RD information in Join attribute. This is because in OptionB, the next-hop of route will change when MDT-SAFI route passes the ASBR. Therefore, the next hop may be different for route entries with same destination address but different group addresses. By this time, we will need to use RD+ destination address as the index for discovering routes.
Ruijie(config)**# ip pim ssm default**	Configure PIM-SSM.

# Configure multicast VPN in OptionB

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 10.1.1.3 remote-as 1
Ruijie(config-router)# neighbor 10.1.1.3 update-source loopback 0
Ruijie(config-router)# address-family ipv4 mdt
Ruijie(config-router-af)# neighbor 10.1.1.3 activate
Ruijie(config-router-af)# neighbor 10.1.1.3 next-hop-self
Ruijie(config-router-af)# exit
Ruijie(config-router)# exit
Ruijie(config)# ip multicast vrf vpn1 rpf proxy rd vector
Ruijie(config)# ip pim ssm default
```

Multicast VPN Configuration in OptionC when Using PIM-SSM

Configure multicast VPN in OptionC, so that it can use PIM-SSM to create Default-MDT, as shown below:

Command	Function
Ruijie# **configure terminal**	Enter global configuration mode.
Ruijie (config)# **router bgp** *asn-num*	Create BGP and enter BGP configuration mode.
Ruijie (config-router)# **neighbor** *ip-address* **remote-as** *asn-number*	Configure BGP session.
Ruijie(config-router)# **neighbor** *ip-address* **update-source** *interface-name*	Configure to use interface address as the source address when BGP session is established; usually, the Loopback interface address is used as the source address.

Ruijie(config-router)# **neighbor** *ebgp-peer-address* **ebgp-multihop**	Configure multi-hop attribute.
Ruijie (config-router)# **address-family ipv4 mdt**	Enter MDT address family.
Ruijie (config-router-af)# **neighbor** *ip-address* **activate**	Activate the route to exchange MDT-SAFI on BGP session.
Ruijie (config-router-af)# **exit**	Exit the address family.
Ruijie (config-router)# **exit**	Exit BGP mode.
Ruijie (config)# **ip multicast rpf proxy vector**	Enable RPF Vector.
Ruijie (config)# **ip pim ssm default**	Configure PIM-SSM.

# Configure multicast VPN in OptionC.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 10.1.1.5 remote-as 2
Ruijie(config-router)# neighbor 10.1.1.5 update-source loopback 0
Ruijie(config-router)# address-family ipv4 mdt
Ruijie(config-router-af)# neighbor 10.1.1.5 activate
Ruijie(config-router-af)# exit
Ruijie(config-router)# exit
Ruijie(config)# ip multicast rpf proxy vector
Ruijie(config)# ip pim ssm default
```

Extranet-MVPNConfiguring Extranet-MVPN

Ensure that the following network configurations are completed before configuring Extranet-MPVN:

- Configuration of single-AS or cross-AS multicast VPN

To ensure that the multicast stream can be transmitted from the ingress PE to the egress PE on the public network, the following two ways to configure Extranet-MVPN:

- Configuring the receiver MVRF on the ingress PE.
- Configuring the source MVRF on the egress PE.

Configuring the Receiver MVRF on the Ingress PE

After this method is used, the ingress PE is added to the Mobile Data Terminal (MDT) of the receiver MVRF. In this case, the ingress PE can send the multicast stream to the public network MDT of the egress PE, and eventually to the egress PE. The following table describes the procedure.

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **ip vrf** *vrf_name*	Create a VRF and enter the VRF configuration mode.
Ruijie(config-vrf)# **rd** *route_distinguisher*	Configure an RD, BGP distribution VPN routing, and RD information used during MDT-SAFI routing for the VRF.
Ruijie(config-vrf)# **route-target import** *rt-value*	Configure the RT value to be imported. Ensure that the receiver MVRF of the ingress PE imports the VPN route where the multicast source resides, so that the PE can create the cross-VRF multicast distribution tree.
Ruijie(config-vrf)# **mdt default** *group_address*	Configure Default-MDT. The command specifies the group address and enables the MD. The group address must be the same as that of the MVRF of the egress PE.

If multiple receiver VPNs exist, you need to configure multiple receiver MVRFs on the ingress PE. When forwarding the multicast stream, the ingress PE makes a copy of the multicast steam and broadcasts it on the public network for the MDT of each receiver MVRF. If the traffic of the multicast steam is high, making copies of the multicast stream will cause heave waste of the public network's bandwidth. In this case, you can configure the source MVRF on the egress PE. The method saves the trouble of configuring the source MVRF on all egress PEs. However, it may waste bandwidth. Therefore, it should only be used when the traffic of the multicast stream is low.

# Configure the receiver MVRF.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf vpn2
Ruijie(config-vrf)# rd 2: 200
Ruijie(config-vrf)# route-target import 1: 100
Ruijie(config-vrf)# mdt default 239.2.2.2
```

Configuring the Source MVRF on the Egress PE

This method is to configure the MVRF consistent with the ingress PE on the egress PE, so that the egress PE can join the public-network MDT of the source MVRF and receive the multicast stream sent by the ingress PE on the public network.

The following table describes the procedure.

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **ip vrf** *vrf_name*	Create a VRF and enter the VRF configuration mode.
Ruijie(config-vrf)# **rd** *route_distinguisher*	Configure an RD, BGP distribution VPN routing, and RD information used during MDT-SAFI routing for the VRF.

Ruijie(config-vrf)# **mdt default** *group_address*	Configure Default-MDT. This command specifies the group address and enables the MD. The group address must be the same as that of the MVRF of the ingress PE.
Ruijie(config-vrf)# **ip mroute** [**vrf** *vrf-name*] *source-address mask* **fallback-lookup** { **global** | **vrf** *vrf-name* } [*distance*]	Configure a static multicast route and specify the VRF to be selected during the RPF check. Ensure that the VRF is consistent with the source MVRF.

This method is recommended for saving public-network bandwidth when the traffic of the multicast stream send by the multicast source is high. Pay attention to the following points when using this method:

- You must configure the source MVRF on all egress PEs. The configuration is more complicated than configuring the receiver PE on the ingress PE.
- When querying the multicast RPF on the VRF (connected to the receiver VPN) of the egress PE, you need to locate the source MVRF and use the MDT of the source MVRF to send the multicast receiving request to the ingress PE through the public network.

# Configure the source MVRF.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf vpn1
Ruijie(config-vrf)# rd 1: 100
Ruijie(config-vrf)# route-target import 1: 100
Ruijie(config-vrf)# mdt default 239.1.1.1
Ruijie(config-vrf)# ip mroute vrf vpn2 192.168.0.0 255.255.255.0 fallback-lookup vrf vpn1
```

Configuring the VRF to Be Selected by the Static Multicast Route

The unicast route is used in the RPF check by default. Therefore, the same VRF is used in the multicast RPF check and unicast routing. You can configure the static multicast route to change default RPF configuration for distinguishing the topology of the multicast route from the topology of the unicast route and enabling the unicast and multicast routes to use different VRFs.

Specifically, you need to specify a VRF (not used by the unicast route) to be used by the static multicast route for the multicast RPF check on the network segment. The VRF must be different from that used by the unicast route.

This configuration method allows the multicast stream of a VPN site to be released on the public network. BGP cannot deliver a VPN route to the routing table on the public network. As a result, the RPF check on the public network cannot locate the next-hop leading to the multicast source of the VPN site. The configuration of the static multicast route, however, allows specifying a VRF used in the RPF check. Thereafter, the next-hop leading to the multicast source of the VPN site can be located.

The following table describes the procedure.

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.

Ruijie(config)# **ip mroute** [**vrf** *vrf-name*] *source-address mask* **fallback-lookup** {**global | vrf** *source-vrf-name*} [*distance*]	Specify a VRF in the static multicast route. Set vrf *vrf-name* to the VRF where this command functions for the RPF check. Set *source-address mask* to the route prefix and mask for specifying the route range where the command functions for the RPF check. Use the keyword global to indicate that the RPF check is performed on the public network. Set vrf *source-vrf-name* to the VRF used in the RPF check. Set *distance* to the distance value of the route.
Ruijie(config)# **end**	Exit the configuration mode.
Ruijie# **show ip mroute** [**vrf** *vrf-name*] static	Show the configuration result of static multicast route.

# Specify the VRF to be selected by the static multicast route.

```
Ruijie# configure terminal
Ruijie(config)# ip mroute vrf vpn1 1.1.1.0 255.255.255.0 fallback-lookup vrf vpn2
Ruijie(config)# end
```

Verifying the Operating Status of Multicast VPN

This section will introduce how to verify the configurations of multicast VPN and routing information. Enter privilege mode and execute the following commands:

Command	Function
Ruijie# **show ip pim mdt** [**bgp**]	Display MDT information.
Ruijie# **show ip pim vrf** *vrf-name* **mdt send**	Display the sending status of MDT-Join message.
Ruijie# **show ip pim vrf** *vrf-name* **mdt receive**	Display the reception status of MDT-Join message.
Ruijie# **show ip pim sparse-mode** [**vrf** *vrf-name*] **neighbor [detail]**	Display the establishment status of PIM-SM neighbor.
Ruijie# **show ip pim sparse-mode mroute proxy**	Display the RPF Vector information of PIM-SM.

# Display MDT information

```
Ruijie# show ip pim mdt
* implies group is the MDT default group
  MDT Group      Interface   Source                 VRF
* 239.1.1.1      Tunnel0     Loopback0               vpn1
```

# Display the sending and reception information of MDT-Join packets.

```
Ruijie# show ip pim vrf vpn1 mdt send
MDT-data send list for VRF: vpn1
  (source, group)                   MDT-data group
  (192.168.1.107, 224.1.1.1)          239.1.2.0

Ruijie# show ip pim vrf vpn1 mdt receive
```

```
Joined MDT-data [group : source]  uptime/expires for VRF: vpn1
 [239.1.2.0 : 0.0.0.0]  00:00:28/00:02:35
```

# Display PIM-SM neighbor

```
Ruijie# show ip pim sparse-mode vrf vpn1 neighbor
Neighbor    Interface          Uptime/Expires     Ver   DR
Address                                                Priority/Mode
1.1.1.20    FastEthernet 0/1   00:02:25/00:01:20   v2   1 / P
```

# Display PIM-SM RPF Vector

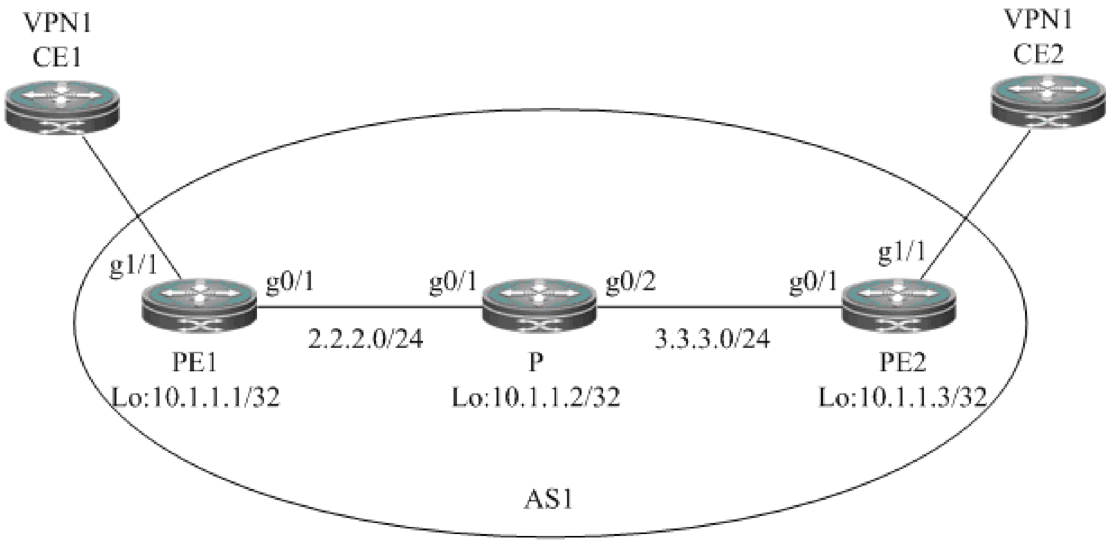
```
Ruijie# show ip pim sparse-mode mroute proxy
(20.1.1.1, 232.1.1.1)
  Proxy                    Assigner        Origin   Uptime/Expire
  1:100/10.1.1.3           0.0.0.0         BGP MDT   00:09:25/stopped
```

Multicast VPN Configuration Example

Example of Single-AS Multicast VPN Configuration

Requirement: The unicast routing has been configured for VPN and public network, and MPLS has also been configured for the public network, with topology shown below:

Figure 27 Topology of single-AS multicast VPN



Configuration steps:

- CE1:

# Configure multicast routing

```
Ruijie# configure terminal
Ruijie(config)# ip multicast-routing
Ruijie(config)# ip pim rp-address 192.168.0.1
Ruijie(config)# interface gigabitethernet 0/1
Ruijie(config-GigabitEthernet 0/1)# ip address 192.168.0.1 255.255.255.0
Ruijie(config-GigabitEthernet 0/1)# ip pim sparse-mode
```

- PE1:

# Configure VRF

Create a VRF of "vpn1", define RD value and RT value and configure Default-MDT.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf vpn1
Ruijie(config-vrf)# rd 1:100
Ruijie(config-vrf)# route-target both 1:100
Ruijie(config-vrf)# mdt default 239.1.1.1
Ruijie(config-vrf)# end
```

# Configure private network multicast routing

```
Ruijie# configure terminal
Ruijie(config)# ip multicast-routing vrf vpn1
Ruijie(config)# ip pim vrf vpn1 rp-address 192.168.0.1
Ruijie(config)# interface gigabitethernet 1/1
```

# "no switchport" command is used to switch the port mode to "Routed Port" mode on switch products, and is not applicable to the router. Therefore, you don't need to execute this command on router products.

```
Ruijie(config-GigabitEthernet 1/1)# no switchport
Ruijie(config-GigabitEthernet 1/1)# ip vrf forwarding vpn1
Ruijie(config-GigabitEthernet 1/1)# ip address 192.168.0.2 255.255.255.0
Ruijie(config-GigabitEthernet 1/1)# ip pim sparse-mode
Ruijie(config-GigabitEthernet 1/1)# end
```

# Configure public network multicast routing

```
Ruijie# configure terminal
Ruijie(config)# ip multicast-routing
Ruijie(config)# ip pim rp-address 10.1.1.2
Ruijie(config)# interface gigabitethernet 0/1
```

# "no switchport" command is used to switch the port mode to "Routed Port" mode on switch products, and is not applicable to the router. Therefore, you don't need to execute this command on router products.

```
Ruijie(config-GigabitEthernet 0/1)# no switchport
Ruijie(config-GigabitEthernet 0/1)# ip address 2.2.2.1 255.255.255.0
Ruijie(config-GigabitEthernet 0/1)# ip pim sparse-mode
Ruijie(config-GigabitEthernet 0/1)# exit
Ruijie(config)# interface loopback 0
Ruijie(config-Loopback 0)# ip address 10.1.1.1 255.255.255.255
Ruijie(config-Loopback 0)# ip pim sparse-mode
Ruijie(config-Loopback 0)# end
```

# Configure BGP protocol to establish IBGP session with PE2 and configure VPNv4 address family

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 10.1.1.3 remote-as 1
Ruijie(config-router)# neighbor 10.1.1.3 update-source loopback 0
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 10.1.1.3 activate
Ruijie(config-router-af)# neighbor 10.1.1.3 send-community extended
Ruijie(config-router-af)# end
```

- P:

# Configure public network multicast routing

```
Ruijie# configure terminal
Ruijie(config)# ip multicast-routing
Ruijie(config)# ip pim rp-address 10.1.1.2
Ruijie(config)# interface gigabitethernet 0/1
```

# "no switchport" command is used to switch the port mode to "Routed Port" mode on switch products, and is not applicable to the router. Therefore, you don't need to execute this command on router products.

```
Ruijie(config-GigabitEthernet 0/1)# no switchport
Ruijie(config-GigabitEthernet 0/1)# ip address 2.2.2.2 255.255.255.0
Ruijie(config-GigabitEthernet 0/1)# ip pim sparse-mode
Ruijie(config-GigabitEthernet 0/1)# exit
Ruijie(config)# interface gigabitethernet 0/2
```

# "no switchport" command is used to switch the port mode to "Routed Port" mode on switch products, and is not applicable to the router. Therefore, you don't need to execute this command on router products.

```
Ruijie(config-GigabitEthernet 0/2)# no switchport
Ruijie(config-GigabitEthernet 0/2)# ip address 3.3.3.1 255.255.255.0
Ruijie(config-GigabitEthernet 0/2)# ip pim sparse-mode
Ruijie(config-GigabitEthernet 0/2)# exit
Ruijie(config)# interface loopback 0
Ruijie(config-Loopback 0)# ip address 10.1.1.2 255.255.255.255
Ruijie(config-Loopback 0)# ip pim sparse-mode
```

- PE3:

The configuration steps are similar to that of PE1.

- CE2:

The configuration steps are similar to that of CE1.

- Verify configurations:

# Execute "**show ip pim mdt**" command on PE1 to display MDT established.

```
Ruijie# show ip pim mdt
```

```
* implies group is the MDT default group
  MDT Group       Interface   Source                VRF
* 239.1.1.1       Tunnel0     Loopback0             vpn1
```

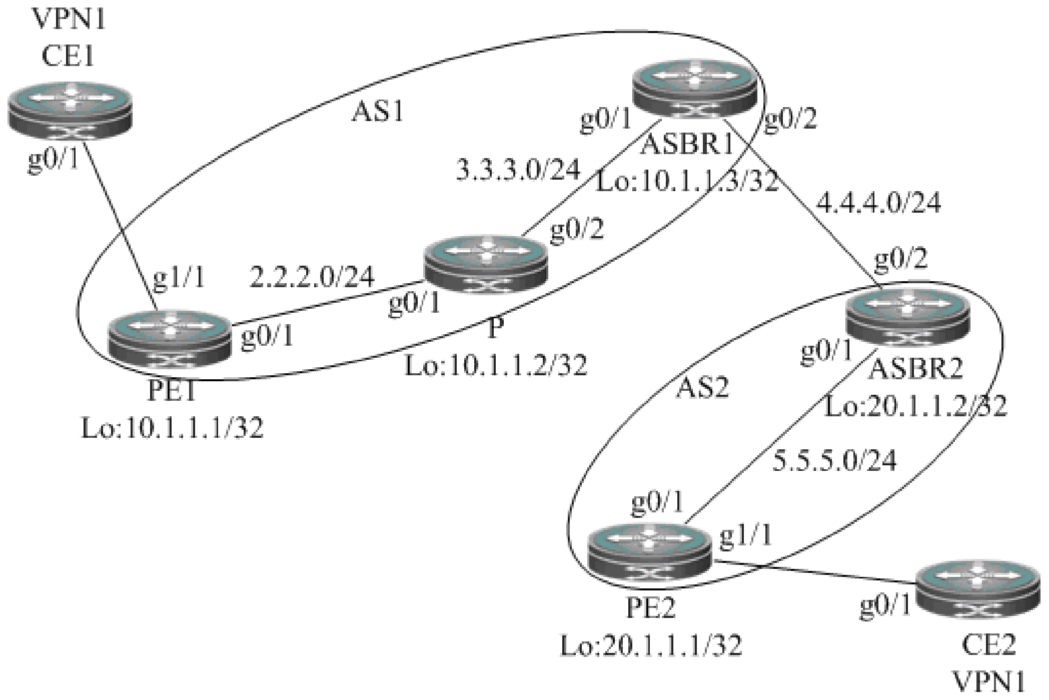
# Execute "**show ip pim sparse-mode neighbor**" command on PE1 to display the neighbors established under VRF.

```
Ruijie# show ip pim sparse-mode vrf vpn1 neighbor
Neighbor    Interface           Uptime/Expires     Ver   DR
Address                                                 Priority/Mode
192.168.0.1 Gigabitethernet 0/1 00:00:01/00:01:44  v2    1 / P
10.1.1.3     Tunnel0             00:02:25/00:01:20  v2    1 / P
```

Example of Multicast VPN Configuration in OptionC when Using PIM-SM

Requirement: BGP/MPLS L3VPN has been configured according to the scheme of OptionC, and PE route has been distributed to respective ASes through BGP.

Figure 28 Topology of multi-AS multicast VPN



Configuration steps:

- CE1:

The configuration steps are similar to that of CE1 in the scheme of single-AS multicast VPN.

- CE2:

The configuration steps are similar to that of CE2 in the scheme of single-AS multicast VPN.

- PE1:

# Configure VRF

Create a VRF of "vpn1", define RD value and RT value and configure Default-MDT.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf vpn1
Ruijie(config-vrf)# rd 1:100
Ruijie(config-vrf)# route-target both 1:100
Ruijie(config-vrf)# mdt default 239.1.1.1
Ruijie(config-vrf)# end
```

# Configure private network multicast routing

```
Ruijie# configure terminal
Ruijie(config)# ip multicast-routing vrf vpn1
Ruijie(config)# ip pim vrf vpn1 rp-address 192.168.0.1
Ruijie(config)# interface gigabitethernet 1/1
```

# "no switchport" command is used to switch the port mode to "Routed Port" mode on switch products, and is not applicable to the router. Therefore, you don't need to execute this command on router products.

```
Ruijie(config-GigabitEthernet 1/1)# no switchport
Ruijie(config-GigabitEthernet 1/1)# ip vrf forwarding vpn1
Ruijie(config-GigabitEthernet 1/1)# ip address 192.168.0.2 255.255.255.0
Ruijie(config-GigabitEthernet 1/1)# ip pim sparse-mode
Ruijie(config-GigabitEthernet 1/1)# end
```

# Configure public network multicast routing

```
Ruijie# configure terminal
Ruijie(config)# ip multicast-routing
Ruijie(config)# interface gigabitethernet 0/1
```

# "no switchport" command is used to switch the port mode to "Routed Port" mode on switch products, and is not applicable to the router. Therefore, you don't need to execute this command on router products.

```
Ruijie(config-GigabitEthernet 0/1)# no switchport
Ruijie(config-GigabitEthernet 0/1)# ip address 2.2.2.1 255.255.255.0
Ruijie(config-GigabitEthernet 0/1)# ip pim sparse-mode
Ruijie(config-GigabitEthernet 0/1)# exit
Ruijie(config)# interface loopback 0
Ruijie(config-Loopback 0)# ip address 10.1.1.1 255.255.255.255
Ruijie(config-Loopback 0)# ip pim sparse-mode
Ruijie(config-Loopback 0)# end
```

- P:

The configuration steps are similar to that of P in the scheme of single-AS multicast VPN.

- ASBR1:

# Configure public network multicast routing

```
Ruijie# configure terminal
Ruijie(config)# ip multicast-routing
Ruijie(config)# interface gigabitethernet 0/1
```

# "no switchport" command is used to switch the port mode to "Routed Port" mode on switch products, and is not applicable to the router. Therefore, you don't need to execute this command on router products.

```
Ruijie(config-GigabitEthernet 0/1)# no switchport
Ruijie(config-GigabitEthernet 0/1)# ip address 3.3.3.2 255.255.255.0

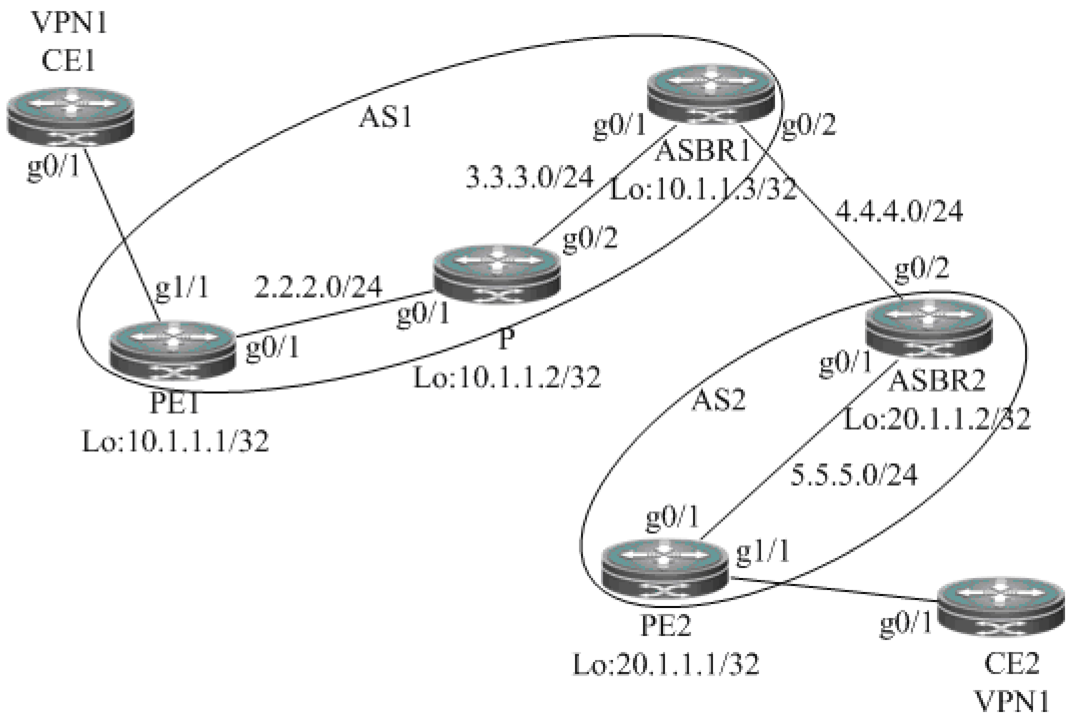
Example of Multicast VPN Configuration in OptionB when Using PIM-SSM

Requirement: BGP/MPLS L3VPN has been configured according to the scheme of OptionB.

Figure 29 Topology of multi-AS multicast VPN (OptionB)



Configuration steps:

- CE1:

The configuration steps are similar to that of CE1 in the scheme of single-AS multicast VPN.

- CE2:

The configuration steps are similar to that of CE2 in the scheme of single-AS multicast VPN.

- PE1:

# Configure VRF

Create a VRF of "vpn1", define RD value and RT value and configure Default-MDT. The group address of Default-MDT must fall within the scope of PIM-SSM.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf vpn1
Ruijie(config-vrf)# rd 1:100
Ruijie(config-vrf)# route-target both 1:100
Ruijie(config-vrf)# mdt default 232.1.1.1
Ruijie(config-vrf)# end
```

# Configure private network multicast routing

```
Ruijie# configure terminal
Ruijie(config)# ip multicast-routing vrf vpn1
Ruijie(config)# ip pim vrf vpn1 rp-address 192.168.0.1
Ruijie(config)# interface gigabitethernet 1/1
```

# "no switchport" command is used to switch the port mode to "Routed Port" mode on switch products, and is not applicable to the router. Therefore, you don't need to execute this command on router products.

```
Ruijie(config-GigabitEthernet 1/1)# no switchport
Ruijie(config-GigabitEthernet 1/1)# ip vrf forwarding vpn1
Ruijie(config-GigabitEthernet 1/1)# ip address 192.168.0.2 255.255.255.0
Ruijie(config-GigabitEthernet 1/1)# ip pim sparse-mode
Ruijie(config-GigabitEthernet 1/1)# end
```

# Configure public network multicast routing, and configure to use RPF Vector that carries RD information.

```
Ruijie# configure terminal
Ruijie(config)# ip multicast-routing
Ruijie(config)# ip multicast vrf vpn1 rpf proxy rd vector
Ruijie(config)# ip pim ssm default
Ruijie(config)# interface gigabitethernet 0/1
```

# "no switchport" command is used to switch the port mode to "Routed Port" mode on switch products, and is not applicable to the router. Therefore, you don't need to execute this command on router products.

```
Ruijie(config-GigabitEthernet 0/1)# no switchport
Ruijie(config-GigabitEthernet 0/1)# ip address 2.2.2.1 255.255.255.0
Ruijie(config-GigabitEthernet 0/1)# ip pim sparse-mode
Ruijie(config-GigabitEthernet 0/1)# exit
Ruijie(config)# interface loopback 0
Ruijie(config-Loopback 0)# ip address 10.1.1.1 255.255.255.255
Ruijie(config-Loopback 0)# ip pim sparse-mode
Ruijie(config-Loopback 0)# end
```

# Configure BGP protocol to establish IBGP session with ASBR1 and configure MDT address family

```

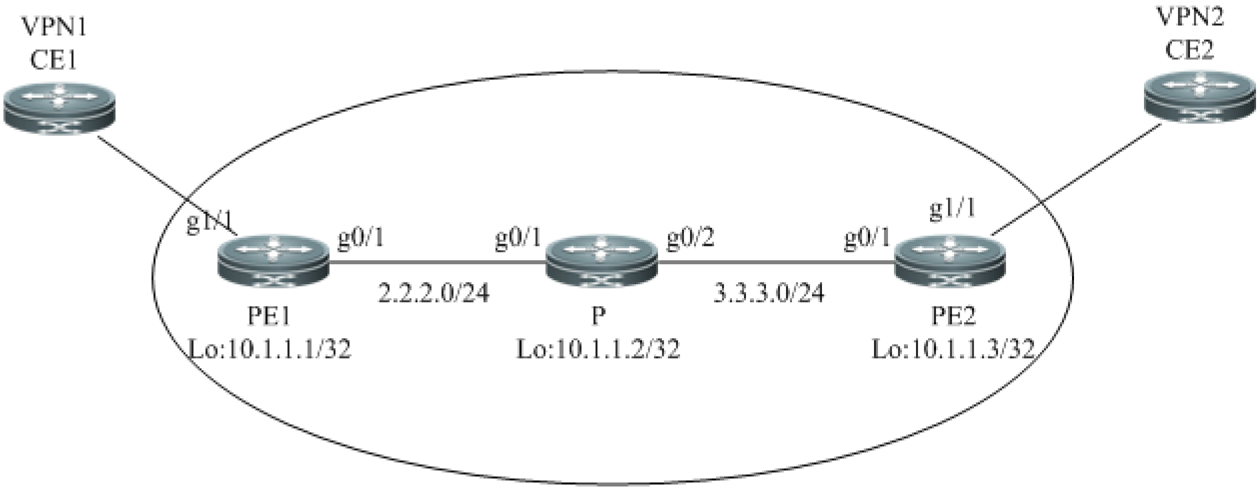
Extranet-MVPN Configuration Instance of Configuring the Receiver MVRF on the Ingress PE

Prerequisite: Multicast VPN has been configured in single AS mode. Extranet-MVPN configuration in the cross-AS topology is the same as that in the single AS topology.

Figure 31 Topology of configuring the receiver MVRF on the ingress PE



Procedure:

- CE1:

# Configure the multicast route.

```
Ruijie# configure terminal
Ruijie(config)# ip multicast-routing
Ruijie(config)# ip pim rp-address 192.168.0.1
Ruijie(config)# interface gigabitethernet 0/1
Ruijie(config-GigabitEthernet 0/1)# ip address 192.168.0.1 255.255.255.0
Ruijie(config-GigabitEthernet 0/1)# ip pim sparse-mode
```

- PE1:

# Configure the VRF.

Configure an MVRF (vpn1), define the RD value and the RT value, and configure Default-MDT.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf vpn1
Ruijie(config-vrf)# rd 1:100
Ruijie(config-vrf)# route-target both 1:100
Ruijie(config-vrf)# mdt default 239.1.1.1
Ruijie(config-vrf)# end
```

Configure a receiver MVRF (vpn2), import the vpn1 route, and configure Default-MDT.

```
Ruijie# configure terminal
```

```
Ruijie(config)# ip vrf vpn2
Ruijie(config-vrf)# rd 2:200
Ruijie(config-vrf)# route-target import 1:100
Ruijie(config-vrf)# mdt default 239.2.2.2
Ruijie(config-vrf)# end
```

# Configure the multicast route on a private network.

```
Ruijie# configure terminal
Ruijie(config)# ip multicast-routing vrf vpn1
Ruijie(config)# ip multicast-routing vrf vpn2
Ruijie(config)# ip pim vrf vpn1 rp-address 192.168.0.1
Ruijie(config)# ip pim vrf vpn2 rp-address 192.168.0.1
Ruijie(config)# interface gigabitethernet 1/1
```

# The **no switchport** command is used to switch the port mode to **Routed Port** on a switch and is inapplicable to a router. Therefore, it does not need to be run on a router.

```
Ruijie(config-GigabitEthernet 1/1)# no switchport
Ruijie(config-GigabitEthernet 1/1)# ip vrf forwarding vpn1
Ruijie(config-GigabitEthernet 1/1)# ip address 192.168.0.2 255.255.255.0
Ruijie(config-GigabitEthernet 1/1)# ip pim sparse-mode
Ruijie(config-GigabitEthernet 1/1)# end
```

# Configure the multicast route on a public network.

```
Ruijie# configure terminal
Ruijie(config)# ip multicast-routing
Ruijie(config)# ip pim rp-address 10.1.1.2
Ruijie(config)# interface gigabitethernet 0/1
```

# The no switchport command is used to switch the port mode to Routed Port and is inapplicable to a router. Therefore, it does not need to be run on a router.

```
Ruijie(config-GigabitEthernet 0/1)# no switchport
Ruijie(config-GigabitEthernet 0/1)# ip address 2.2.2.1 255.255.255.0
Ruijie(config-GigabitEthernet 0/1)# ip pim sparse-mode
Ruijie(config-GigabitEthernet 0/1)# exit
Ruijie(config)# interface loopback 0
Ruijie(config-Loopback 0)# ip address 10.1.1.1 255.255.255.255
Ruijie(config-Loopback 0)# ip pim sparse-mode
Ruijie(config-Loopback 0)# end
```

# Configure BGP, establish the IBGP session with PE2, and configure the VPNv4 address family.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 10.1.1.3 remote-as 1
Ruijie(config-router)# neighbor 10.1.1.3 update-source loopback 0
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 10.1.1.3 activate
Ruijie(config-router-af)# neighbor 10.1.1.3 send-community extended
Ruijie(config-router-af)# exit
Ruijie(config-router)# address-family ipv4 mdt
Ruijie(config-router-af)# neighbor 10.1.1.3 activate
Ruijie(config-router-af)# neighbor 10.1.1.3 send-community extended
Ruijie(config-router-af)# end
```

- P:

The procedure is similar to the procedure for configuring P on the single-AS multicast VPN.

- PE2:

# Configure the VRF.

Configure an MVRF (vpn1), define the RD value and the RT value, import the vpn1 route, and configure Default-MDT.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf vpn2
Ruijie(config-vrf)# rd 2:200
Ruijie(config-vrf)# route-target both 2:200
Ruijie(config-vrf)# route-target import 1:100
Ruijie(config-vrf)# mdt default 239.2.2.2
Ruijie(config-vrf)# end
```

# Configure the multicast route on a private network.

```
Ruijie# configure terminal
Ruijie(config)# ip multicast-routing vrf vpn2
Ruijie(config)# ip pim vrf vpn2 rp-address 192.168.0.1
Ruijie(config)# interface gigabitethernet 1/1
```

# The **no switchport** command is used to switch the port mode to **Routed Port** on a switch and is inapplicable to a router. Therefore, it does not need to be run on a router.

```
Ruijie(config-GigabitEthernet 1/1)# no switchport
Ruijie(config-GigabitEthernet 1/1)# ip vrf forwarding vpn2
Ruijie(config-GigabitEthernet 1/1)# ip address 192.168.1.2 255.255.255.0
Ruijie(config-GigabitEthernet 1/1)# ip pim sparse-mode
Ruijie(config-GigabitEthernet 1/1)# end
```

# Configure the multicast route on a public network.

```
Ruijie# configure terminal
Ruijie(config)# ip multicast-routing
Ruijie(config)# ip pim rp-address 10.1.1.2
Ruijie(config)# interface gigabitethernet 0/1
```

# The **no switchport** command is used to switch the port mode to **Routed Port** and is inapplicable to a router. Therefore, it does not need to be run on a router.

```

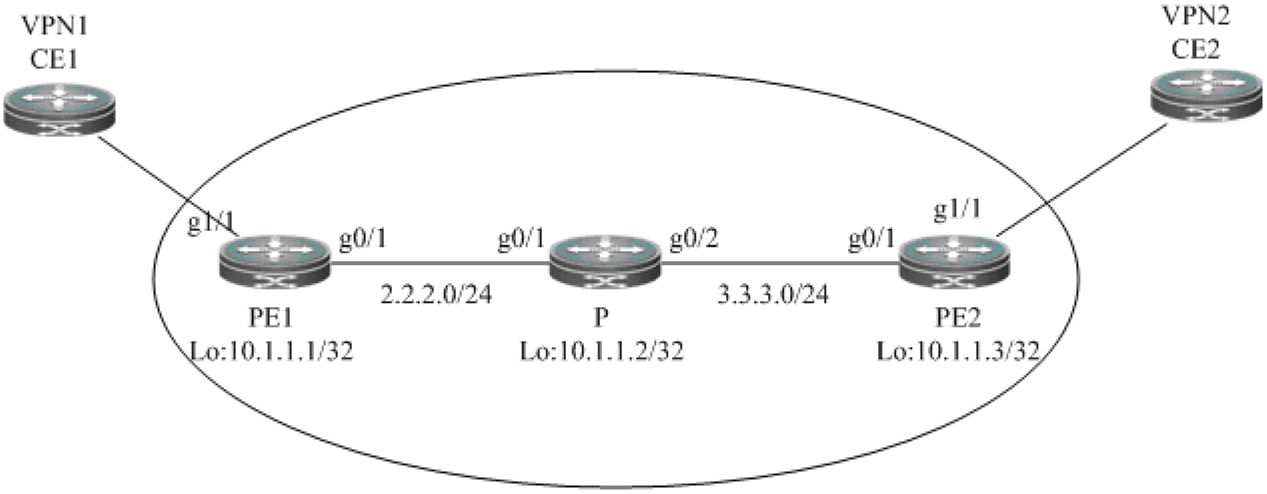
Extranet-MVPN Configuration Instance of Configuring the Source MVRF on the Egress PE

Prerequisite: Multicast VPN has been configured in single AS mode. Extranet-MVPN configuration in the cross-AS topology is the same as that in the single AS topology.

Figure 32 Topology of configuring the receiver MVRF on the ingress PE



Procedure:

- CE1:

# Configure the multicast route.

```
Ruijie# configure terminal
Ruijie(config)# ip multicast-routing
Ruijie(config)# ip pim rp-address 192.168.0.1
Ruijie(config)# interface gigabitethernet 0/1
Ruijie(config-GigabitEthernet 0/1)# ip address 192.168.0.1 255.255.255.0
Ruijie(config-GigabitEthernet 0/1)# ip pim sparse-mode
```

- PE1:

# Configure the VRF.

Configure an MVRF (vpn1), define the RD value and the RT value, and configure Default-MDT.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf vpn1
Ruijie(config-vrf)# rd 1:100
Ruijie(config-vrf)# route-target both 1:100
Ruijie(config-vrf)# mdt default 239.1.1.1
Ruijie(config-vrf)# end
```

# Configure the multicast route on a private network.

```
Ruijie# configure terminal
Ruijie(config)# ip multicast-routing vrf vpn1
Ruijie(config)# ip pim vrf vpn1 rp-address 192.168.0.1
Ruijie(config)# interface gigabitethernet 1/1
```

# The **no switchport** command is used to switch the port mode to **Routed Port** on a switch and is inapplicable to a router. Therefore, it does not need to be run on a router.

```
Ruijie(config-GigabitEthernet 1/1)# no switchport
Ruijie(config-GigabitEthernet 1/1)# ip vrf forwarding vpn1
Ruijie(config-GigabitEthernet 1/1)# ip address 192.168.0.2 255.255.255.0
Ruijie(config-GigabitEthernet 1/1)# ip pim sparse-mode
Ruijie(config-GigabitEthernet 1/1)# end
```

# Configure the multicast route on a public network.

```
Ruijie# configure terminal
Ruijie(config)# ip multicast-routing
Ruijie(config)# ip pim rp-address 10.1.1.2
Ruijie(config)# interface gigabitethernet 0/1
```

# The no switchport command is used to switch the port mode to Routed Port on a switch and is inapplicable to a router. Therefore, it does not need to be run on a router.

```
Ruijie(config-GigabitEthernet 0/1)# no switchport
Ruijie(config-GigabitEthernet 0/1)# ip address 2.2.2.1 255.255.255.0
Ruijie(config-GigabitEthernet 0/1)# ip pim sparse-mode
Ruijie(config-GigabitEthernet 0/1)# exit
Ruijie(config)# interface loopback 0
Ruijie(config-Loopback 0)# ip address 10.1.1.1 255.255.255.255
Ruijie(config-Loopback 0)# ip pim sparse-mode
Ruijie(config-Loopback 0)# end
```

# Configure BGP, establish the IBGP session with PE2, and configure the VPNv4 address family.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1

MPLS Configuration

Configuring MPLS

Note The term “router” and router icons in this chapter refer to routers in a generic sense and layer-3 switches running routing protocols.

Understanding MPLS

Multiprotocol Label Switching (MPLS) supports multiple network-layer protocols such as IP, IPv6, and IPX and is compatible with multiple link-layer technologies including ATM, frame relay, Ethernet, and PPP. MPLS forwards packets based on labels attached to them. It works at both the connectionless control plane and the connection-oriented data plane, thereby introducing connection-oriented attributes to connectionless IP networks. The MPLS technology was first introduced to enhance the forwarding rate of routing devices. However, with the development of hardware technologies and network processors, this competitive edge gradually loses its appeal. Because MPLS combines Layer 2 switching with Layer 3 routing technologies, it has unprecedented edges over other technologies in terms of addressing issues of virtual private networks (VPNs) and traffic engineering (TE). MPLS VPN is increasingly favored by carriers to address interconnection problems between companies and to provide various new services. It has already become an important means for carriers to provide value-added services over IP networks. At the same time, the MPLS TE technology also turns into a major method to reduce congestion and guarantee quality of service (QoS) on IP networks by managing network traffic. Therefore, the MPLS technology receives more and more attention and the MPLS applications gradually shift to MPLS VPN and TE applications.

- Basic Concept
- Different from incoming label map (ILM), FEC-to-NHLFE (FTN) maps each forwarding equivalence class (FEC) to a series of next hop label forwarding entries (NHLFEs) which indicates there are multiple paths. An FTN table is used when a label edge router (LER) encapsulates a label in an unlabeled packet before forwarding the packet.
- Label
- Label Distribution Protocol
- MPLS Network
- An MPLS network comprises two basic components: Label Switching Routers (LSRs) and LERs. An LSR is located at the core of the MPLS network and runs the LDP signaling protocol to forward labeled packets. An LER classifies and labels incoming packets into FECs and encapsulates the labeled packets as MPLS packets for forwarding. The LER also removes the labels from outgoing MPLS packets and restores these packets to the original packets. On the MPLS network, packets with labels are forwarded along the label switched path (LSP) set up through LDP.

The MPLS architecture is divided into two parts: the forwarding unit (data plane) and control unit (control plane). The former forwards a packet by searching the label forwarding information base (LFIB) based on the label carried by the packet whereas the latter is responsible for creating and maintaining the LFIB between the connected MPLS nodes. Each MPLS node must run one or more routing protocols (including static routes) to exchange routing information with other MPLS nodes on the MPLS network. Therefore, in effect, each MPLS node is an IP router on the control plane. Similar to a conventional IP router, an MPLS node also uses unicast routing protocols (including static routes) to create and maintain a routing table. The difference is that the traditional router uses the routing table to create a forwarding table and the

MPLS node uses the routing table to exchange label binding information between each destination subnet and neighboring MPLS nodes. The protocol responsible for exchanging label binding information is LDP.

- MPLS Forwarding Behaviors
- The MPLS forwarding process is as follows (IP routing for example):

1) All LSRs (including LERs) run routing protocols such as Open Shortest Path First (OSPF) and Intermediate System to Intermediate System (IS-IS) to establish IP routing tables on LSRs and LERs.
2) LDP creates an LSP based on the IP routing tables.
3) The ingress LER receives an IP packet, analyzes the IP header, associates it with an FEC, labels the IP header with L1, and sends the labeled packet to the next-hop LSR along the LSP.
4) After receiving the packet, the next-hop LSR searches the next LSP based on the label on the stack top, replaces the label with a new label, and sends the packet to the next LSR of the LSP.
5) The subsequent LSRs repeat as step 4.
6) When the last but one LSR receives the labeled packet and looks up the LFIB, if the egress label is found to be an implicit label, it pops the label and forwards the pure IP packet to the last hop LSR; and if the egress label is an explicit null one, the LSR pops the label and forwards the packet by looking up the IP forwarding table based on the IP header..
7) If the last but one LSR pops the label, the egress LER receives the original IP packet and forwards the packet according to the IP routing table.

- LSP Establishment and Loop Detection
- MPLS Applications

Basic Concepts

- MPLS Node

MPLS-enabled nodes can identify MPLS signaling protocols (control protocols), support one or more Layer 3 routing protocols (including static routes), and forward packets based on MPLS labels. Generally, an MPLS node can forward original Layer 3 packets (such as IP packets).

- FEC

An FEC refers to a set of data packets that are forwarded in the same way, such as data packets that have the same prefix in their destination addresses. The FEC supports different classification methods for different applications. For example, the FEC classifies IP unicast routes based on the address prefixes. That is, one route corresponds to one FEC. All the packets in the same FEC are equally handled on the MPLS network.

- LSR

As a core device on an MPLS network, the LSR provides label switching and distribution functions. As specified in RFC 3031 for MPLS system, an LSR is also an MPLS node which is capable of forwarding original Layer 3 packets (such as IPv4 andIPv6 packets). Since MPLS can forward normal IP packets, LSRs also have this capability.

- LER

Located on the edge of an MPLS network, an LER classifies incoming traffic into different FECs, requests labels for these FECs, and restores outgoing traffic to the original packets by popping labels. The LER thus provides traffic classification, label mapping, and label removal functions.

- LSP

An FEC data stream is assigned with specific labels on different nodes and transmitted along the nodes according to the switching of assigned labels. The path where the data stream travels is an LSP. It is a collection of multiple LSRs. Therefore, an LSP can be considered as a tunnel that traverses the MPLS core network.

- NHLFE

An NHLFE table is used to store the next-hop information about MPLS packets. Typically, a next hop label forwarding entry contains the following information:

1) Next hop of data packets
2) Link layer encapsulation to use when forwarding data packets
3) Coding scheme for the label stack when forwarding data packets
4) Operations on the label stack of data packets, including:
    a) Replacing the label at the top of the label stack with a new label
    b) Popping the label off the stack top
    c) Pushing one or more labels
    d) Replacing the label at the top of the label stack with a new label and pushing one or more new labels on the label stack

- ILM

An ILM table is a label forwarding table where each incoming label is mapped to a series of NHLFEs (multiple NHLFEs indicate multiple paths). The ILM is used when an LSR receives and forwards MPLS packets with labels.

- FTN

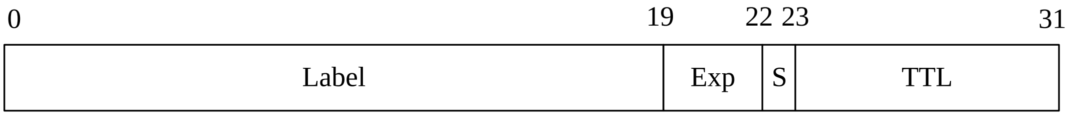
Different from ILM, FTN maps each FEC to a series of NHLFEs (multiple NHLFEs indicate multiple paths). An FTN table is used when an LER encapsulates labels to an unlabeled packet before forwarding the packet.

Label

A label is a short identifier with fixed length and of local significance. The label is distributed and transmitted only between two adjacent LSRs. As a result, it is valid only between the two LSRs. One label identifies one FEC. When arriving at the MPLS ingress, packets are classified into different FECs according to certain rules. Based on the FECs, the packets are encapsulated with different labels and then forwarded on the MPLS network based on the labels.

Label Format

Figure 1 MPLS label format



As shown in Figure-1, a label consists of four fields, which is described as follows:

- Label field

The label field is a 20-bit label value. The label value is an index for the label forwarding table. The Internal Engineering Task Force (IETF) classifies 0 to 15 as reserved labels and predefines their meanings:

Reserved Label	**Description**

0	IPv4 explicit null label. As specified in RFC 3032, label 0 must be placed at the bottom of the label stack, which means that the label must be popped before packets are forwarded according to destination IP addresses. RFC 4182 modifies the description of label 0 in RFC 3032. In RFC 4182, label 0 is popped directly upon receipt of a label 0 packet. The subsequent forwarding behavior is determined by the content behind the label 0. If another label follows, the packet is forwarded according to the label; if the packet is an IPv4 packet, it is forwarded based on the destination IP address.
1	Router alert label. This label is not allowed to be placed at the bottom of the label stack. When a receiving packet carries a router alert label, it must be sent to the local software module for processing. The actual forwarding of the packet must be based on the label behind the router alert label. Before the packet is forwarded, however, the router alert label must be pushed to the label stack again. This option is similar to the Router Alert Option of IP packets. You can use this option to configure each LSR to check MPLS packets.
2	IPv6 explicit null label. As specified in RFC 3032, label 2 must be placed at the bottom of the label stack. This means that the label must be popped before the packet is forwarded according to the destination IP address. RFC 4182 modifies the description of label 2 in RFC 3032. In RFC 4182, label 2 is popped directly upon receipt of a label 2 packet. The subsequent forwarding behavior is based on the content behind the label2. If another label follows, the packet is forwarded according to the label; if it is an IPv6 packet, it is forwarded according to the destination IP address.
3	Implicit null label. This label can be distributed by LDP but can never be transmitted in the label stacks of MPLS packets. When an LSR exchanges MPLS packets, if the label on the top of the label stack has a value of 3, it can be popped but should not be replaced with another label. The implicit null label is used in the Penultimate Hop Popping (PHP) function.
4 to 15	Reserved by the IETF for future use.

- Exp field

The Exp field is currently used to store the QoS information about MPLS. This field contains 3 bits.

- S mark

The S mark field indicates the stack bottom. It contains one bit. If multiple labels exist, the S bit of the label at the stack bottom is set to **1** and the S bits of other labels are **0**. If only one label exists, the S bit is set to 1.

- TTL

Time to Live. This field contains 8 bits. It is similar to the TTL value in an IP packet header. When a label is first added to an IP packet, the TTL value can be copied from the TTL field (or Hop Limit of IPv6) of the IP packet header. The TTL value of the outer (stack top) label then decreases by one at every label switching. When MPLS runs on ATM links, the label encoding methods are different and no TTL field exists. For methods and solutions, refer to RFC 3032.

Label Stack

An MPLS packet can contain several labels to form a label stack. The label after the link layer header is the top label and the label before the IP header is the bottom label. An LSR exchanges labels based on the top label. When multiple labels exist, each label must be complete and contain 32 bits. A label stack supports multiple layers of labels to be carried in an MPLS packet. The purpose is to enable the MPLS technology to support hierarchical network systems and LSP tunnels.

Operation Methods of Labels

The following lists basic label operations on MPLS nodes:

- Push

Insert a label between the link layer header and the network layer header on an ingress LER or add a new label to the stack top of an MPLS packet on an intermediate LSR.

- Pop

Remove labels off packets on the egress LER to restore the IP packets or remove the top label on an intermediate LSR to reduce layers of a label stack.

- Swap

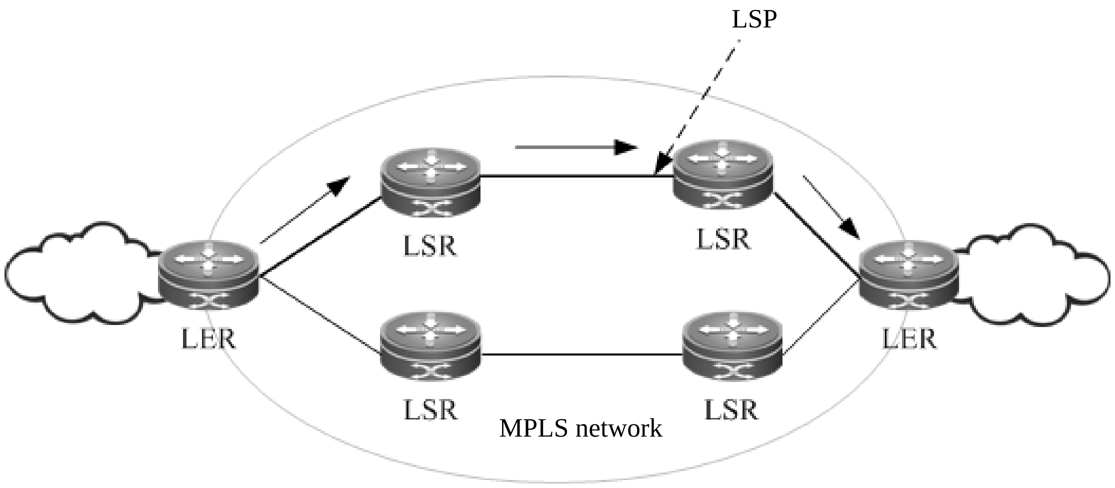
Replace the top label in the label stack of a packet based on the ILM during forwarding of the packet.

LDP

As an emerging network system, MPLS also has its own signaling protocols or "routing protocols". One of the basic concepts in the MPLS system is that two LSRs must reach consensus on the meaning of labels used for traffic transmission. This consensus is realized through a series of processes, that is, LDP. Through LDP, one LSR can notify the other LSR of the label binding. The MPLS system architecture does not assume that there is only a single LDP. Some MPLS systems use independent distribution protocols, such as LDP defined in RFC 3036 by the IETF; other MPLS systems support the distribution of labels by extending existing protocols in piggybacking mode, such as MP-BGP and RSVP. You can choose different LDPs for MPLS networks based on different application scenarios.

MPLS Network

Figure 2

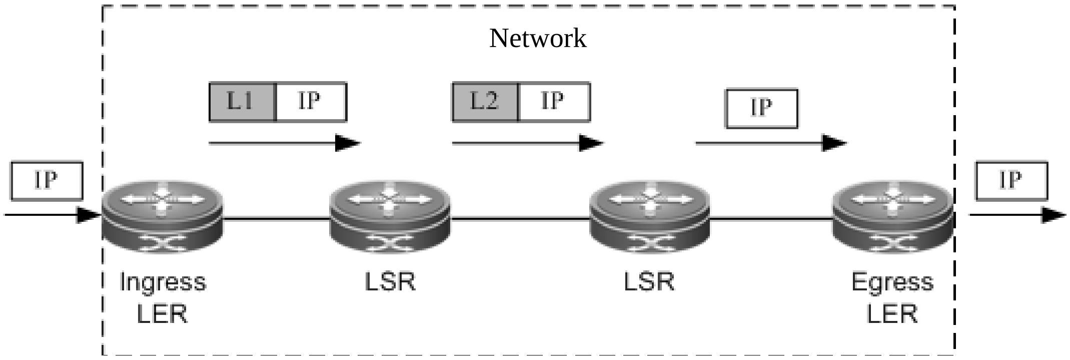


An MPLS network comprises two basic components: Label Switching Routers (LSRs) and LERs. An LSR is located at the core of the MPLS network and runs the LDP signaling protocol to forward labeled packets. An LER classifies and labels incoming packets into FECs and encapsulates the labeled packets as MPLS packets for forwarding. The LER also removes the labels from outgoing MPLS packets and restores these packets to the original packets. On the MPLS network, packets with labels are forwarded along the label switched path (LSP) set up through LDP.

The MPLS architecture is divided into two parts: the forwarding unit (data plane) and control unit (control plane). The former forwards a packet by searching the label forwarding information base (LFIB) based on the label carried by the packet whereas the latter is responsible for creating and maintaining the LFIB between the connected MPLS nodes. Each MPLS node must run one or more routing protocols (including static routes) to exchange routing information with other MPLS nodes on the MPLS network. Therefore, in effect, each MPLS node is an IP router on the control plane. Similar to a conventional IP router, an MPLS node also uses unicast routing protocols (including static routes) to create and maintain a routing table. The difference is that the traditional router uses the routing table to create a forwarding table and the MPLS node uses the routing table to exchange label binding information between each destination subnet and neighboring MPLS nodes. The protocol responsible for exchanging label binding information is LDP.

MPLS Forwarding Behaviors

Figure 3 Forwarding process of MPLS packets that support PHP



The following takes traditional IP routing services as an example to show the MPLS forwarding process:

- Enable traditional routing protocols (OSPF or IS-IS) on all LSRs (including LERs) and create IP routing tables on the LSRs and LERs.
- Set up an LDP LSP based on the IP routing table.
- Upon receipt of an IP packet, the ingress LER analyzes the IP packet header and maps it to an FEC. The ingress LER then adds the label L1 to the packet and sends the labeled packet to the next hop LSR along the LSP.
- The next-hop LSR receives the labeled packet, searches the LSP based on the label on the stack top, and then forwards the packet to the next-hop LSR along the LSP after replacing the label with a new one.
- The intermediate LSRs perform the same actions as step 4.
- Upon receipt of the labeled packet, the PHP LSR searches the label forwarding table and pops the label after learning that the outgoing label is the implicit null label 3. The PHP LSR then forwards the original IP packet to the last-hop LSR. If the outgoing label is the explicit null label, the PHP LSR pops the label and directly sends the original packet based on the routes of the IP header in the IP forwarding table.
- If the label is popped on the PHP LSR, the last-hop egress LER receives the original IP packet and forwards it according to the IP routing table.

LSP Establishment and Loop Detection

A virtual MPLS connection is an LSP. One FEC data stream is assigned with different labels on different MPLS nodes and forwarded according to the labels. The path that the data stream travels is an LSP that consists of a series of LSRs. Data streams of the same FEC pass through the same LSP.

- LSP Establishment
- LSP Loop Control

LSP Establishment

The LSP establishment is the process of binding an FEC to a label and notifying adjacent LSRs of the binding. This process is completed by LDP. RFC 3036 stipulates the protocol specifications of LDP, the interactive process of LSRs, and the message formats.

LDP detects adjacent LSRs by sending Hello messages periodically. The LDP Hello messages are encapsulated using the User Datagram Protocol (UDP) and use the well-known port 646 as the destination port. The destination address of these packets is 224.0.0.2, the multicast address of all routers in the subnet. The discovery of an adjacent LSR triggers the creation of LDP sessions. An LDP session is created in the following two steps:

- Establish a transmission connection. The connection is established after the completion of TCP three-way handshakes that do not require any interaction of LDP messages.
- Initialize the session. Both parties exchange their initialization information to negotiate and determine the LDP session parameters such as the label distribution mode, Keepalive duration, and the maximum length of Protocol Data Unit (PDU).

After the LDP session is created and both parties enter the operational state, the two parties can exchange label messages to distribute and manage labels, and create an LSP for each FEC.

During the process of LSP establishment, two label distribution modes are used: Downstream on Demand (DOD) and Downstream Unsolicited (DU). In DOD mode, an LSR responds to a label binding message only after it receives a label request from an adjacent LSR. In DU mode, the LSR voluntarily sends label binding messages to its adjacent LSRs without receiving any request.

During the LSP establishment, two label control methods are used: independent and ordered control. In independent control mode, each LSR announces to its adjacent devices the binding of labels and FECs at any required time. In independent DOD mode, one LSR can immediately answer an upstream label mapping request without waiting for the label mapping from the next hop device. In independent DU mode, one LSR can announce the label mapping of an FEC at any time deemed as proper for swapping the label of the FEC.

In ordered control mode, one LSR binds an FEC to a label and sends the binding upstream only when the FEC has the next-hop label mapping or the LSR is the egress of the FEC. Otherwise, the LSR does not bind the FEC to a label, or send the binding to an upstream LSR until receiving the label mapping of the FEC from a downstream LSR. In ordered control and DU mode, one LSR announces the label to an upstream LSR only when the LSR is the egress of the FEC or the LSR receives the label distributed by a downstream LSR. If the label distribution mode of the downstream LSR is DOD, the LSR, either in DOD or DU mode, passes on the label request from an upstream LSR to downstream devices.

LSP Loop Control

During the LSP setup process, the loop detection mechanism must be provided to ensure timely detection of any loops formed by the LSP. The maximum number of hops and path vector can be used to avoid LSP loops.

When the maximum number of hops is used, the message that transmits label binding information records the number of bypassing LSRs. The number increases by one after passing an LSR. If the number exceeds the specified maximum value, the system considers that a loop occurs and terminates the LSP.

When the path vector is used, the message that transmits label binding information records IDs of bypassing LSRs. The ID of an LSR is recorded to the vector table of the message after each LSR. Upon receipt of a label binding message, an LSR checks whether its ID is included in the vector table. If not, the LSR adds its ID to the record when distributing the message; if yes, the LSR considers that a loop occurs and terminates the LSP.

MPLS Applications

Thanks to the combination of Layer 2 switching and Layer 3 routing technologies, the MPLS technology improves the forwarding rate of packets. With the development of the Application-Specific Integrated Circuit (ASIC) technologies, the forwarding rate is no longer a bottleneck in network development. As a result, the edges of MPLS in enhancing forwarding rates are not remarkable. Due to the innate advantage of combining Layer 2 switching and Layer 3 routing technologies, however, MPLS still has unprecedented edges over other technologies in terms of VPNs and TE. In this context, MPLS receives more and more attention. The MPLS applications also gradually shift to the application areas of MPLS VPN and MPLS TE.

Configuring MPLS

Caution

1. LDP is a topology-driven protocol. To ensure normal operation of LDP, enable IPv4 routing protocols and ensure their normal operations.
2. To enable the router MPLS express forwarding function and improve the forwarding performance of routers, use the **ip ref** command in interface configuration mode.

Enabling MPLS Forwarding Globally

Use the **mpls ip** command to enable a device to support MPLS forwarding in configuration mode. By default, MPLS forwarding is disabled on a device. After MPLS forwarding is enabled, the device first forwards packets according to their labels. When the label forwarding fails, the device attempts to forward packets based on their IP addresses.

Use the **no mpls ip** command to disable MPLS forwarding.

Command	Function
Ruijie(config)# **mpls ip**	Enables MPLS forwarding globally.
Ruijie(config)# **no mpls ip**	Disables MPLS forwarding globally.

Caution

This command is not applicable to controlling switch chip forwarding.

Enabling LDP Globally

Use the **mpls router ldp** [*vrf-name*] command to enable LDP for a VRF instance in global configuration mode and enter LDP configuration mode.

Use the **no mpls router ldp** [*vrf-name*] command to disable LDP for a VRF instance.

Command	Function
Ruijie(config)# **mpls router ldp** [*vrf-name*]	Enables LDP for a VRF instance and enters LDP configuration mode.
Ruijie(config-mpls-router)# **ldp router-id interface loopback** *id* [**force**]	Configures the LDP router ID. The loopback address is generally used as the router ID.
Ruijie(config)# **no mpls router ldp** [*vrf-name*]	Disables LDP for a VRF instance.

Caution

1. After LDP is enabled globally, use the **mpls ip** command to enable LDP for an interface in interface configuration mode.
2. If *vrf-name* is not specified, LDP is globally enabled for all VRF instances.
3. You are required to specify the router ID for an LDP when enabling LDP.

Enabling Label Switching on an Interface

By default, interfaces do not forward MPLS packets. To enable MPLS forwarding on a device, use the **mpls ip** command in global configuration mode. To explicitly enable MPLS forwarding on a specified interface, use the **label-switching** command. When enabling the label forwarding function of an interface, adjust the maximum transmission unit (MTU) of the interface based on service types to facilitate the transmission of large packets.

Command	Function
Ruijie(config-if-*type ID*)# **label-switching**	Enables MPLS forwarding on an interface.
Ruijie(config-if-*type ID*)# **no label-switching**	Disables MPLS forwarding on an interface.

☑ To enable the MPLS express forwarding function of a router and to improve the forwarding performance, use the **ip ref** command in interface configuration mode

☑ If label forwarding is enabled on a switch on a VLAN, there must be only one member port. Otherwise, packets cannot be flooded on the VLAN.

☑ When unknown unicast packets or broadcast packets enter the switch through a port, these packets (including packets of VLANs with label forwarding disabled) cannot be forwarded if label forwarding is enabled on a VLAN where the port belongs to. You are advised to enable label forwarding on routing ports.

Note

After the MPLS packet forwarding is disabled on a public network interface, packet forwarding from the AC to the PW is not affected.

Enabling LDP on an Interface

After LDP is enabled globally, use the **mpls ip** command to enable LDP on an interface in interface configuration mode.

Command	Function
Ruijie(config-if-*type ID*)# **mpls ip**	Enables LDP on an interface.
Ruijie(config-if-*type ID*)# **no mpls ip**	Disables LDP on an interface.

Caution

After LDP is enabled in interface configuration mode, LDP does not take effect on an interface if the **mpls router ldp** command is not used in global configuration mode. To enable LDP on the interface, you must also use the **label-switching** command to enable MPLS forwarding on the interface.

Configuring MPLS MTU on an Interface (Optional)

By default, values of the MPLS MTU and the MTU are the same for an interface. The MPLS MTU determines whether MPLS packets must be fragmented during forwarding. The MPLS MTU indicates the overall length of MPLS encapsulation and encapsulated (such as IP) layers.

Use the **no mpls mtu** command to restore the default value of the MPLS MTU on an interface.

Command	Function
Ruijie(config-if-*type ID*)# **mpls mtu** *bytes*	Configures the MPLS MTU on an interface.
Ruijie(config-if-*type ID*)# **no mpls mtu**	Restores the default value of the MPLS MTU on an interface.

Caution

The MPLS MTU on an interface cannot exceed the actual size of packets transmitted on the interface. For switches that forward packets based on ASIC, this configuration is invalid. These switches forward packets based on the MTU configured on interfaces and directly discard packets that exceed the MTU rather than performing fragmentation. To adjust the MTU of an interface, use the **mtu** command in interface configuration mode. Fragmentation is supported by only process forwarding and router forwarding. In actual applications, you must adjust the MTU value to avoid performance degradation caused by fragmentation.

Fragmenting MPLS Packets (Optional)

By default, MPLS packets that exceed the MPLS MTU on an interface are fragmented as IP fragmentations. The fragmented IP packets are still encapsulated with the original labels and transmitted along the original LSP.

Use the **no mpls ip fragment** command to directly discard packets that must be fragmented.

Command	Function
Ruijie(config)# **no mpls ip fragment**	Directly discards MPLS packets that exceed the MPLS MTU on an interface.
Ruijie(config)# **mpls ip fragment**	Restores the default value to fragment packets that exceed the MPLS MTU on an interface.

Caution

This command is valid only for the encapsulated IP packets.

Handling ICMP Error Messages (Optional)

ICMP error messages (such as typical MPLS TTL timeout messages) generated during the forwarding of MPLS packets are forwarded along the LSP of the label stack by default. To provide different processing methods for MPLS packets with different numbers of labels, use the **mpls ip icmp-error pop** *labels* command. For ICMP error messages with the forwarding label stack not greater than the specified number of labels, they are forwarded through routes on the IP routing table where the FEC of the stack top label is stored. For ICMP error messages with the forwarding label stack greater than the specified number of labels, they are forwarded along the LSP of the original label stack.

Command	Function

Ruijie(config)# **mpls ip icmp-error pop** *labels*	Controls the handling of ICMP error messages generated by labeled MPLS packets.
Ruijie(config)# **no mpls ip icmp-error pop**	Restores the default value.

Configuring the MPLS TTL Replication Function (Optional)

There are two modes for handling the TTL of encapsulated and de-encapsulated IP (or MPLS) packets on an MPLS network:

- TTL replication mode: This is the default working mode. The procedure is as follows: When a label is pushed, the label TTL copies the TTL of the existing IP or MPLS header to the TTL field of the label. When a label is popped out, the TTL is copied back from the outer label to the inner IP packet or MPLS packet.
- TTL non-replication mode: In this mode, the TTL is not copied. The procedure is as follows: When a label is pushed, the TTL value of the label is directly set to 255. When a label is popped out, the original TTL value of the inner IP packet or MPLS packet is exposed and retained.

Use the **mpls ip ttl propagate** { **public** | **VPN** } command to configure the TTL replication function for packets sent and forwarded by a device.

Command	**Function**
Ruijie(config)# [**no**] **mpls ip ttl propagate public**	Enables or disables the TTL replication function for MPLS packets sent by the device.
Ruijie(config)# [**no**] **mpls ip ttl propagate VPN**	Enables or disables the TTL replication function for MPLS service packets forwarded by the device.

After the TTL replication function is enabled on an MPLS network, you can use the Tracert tool on a CE to track all the LSRs that the packets pass through in the MPLS domain. If the TTL non-replication mode is configured on PEs, the entire LSP of the packets is considered as only one hop.

Caution

After TTL replication is enabled, the TTL of the inner header is not copied but retained if it is smaller than the TTL of the outer header.

Verifying the MPLS Information

To view MPLS information and verify the configuration results, use the **show** commands in privileged mode.

- Displaying MPLS information

Display the utilization information about the label space and the interfaces enabled with MPLS. You can verify whether the configurations are accurate based on the information.

Command	**Function**
Ruijie# **show mpls summary**	Displays basic MPLS information.

- Displaying the MPLS forwarding table

Display contents of MPLS forwarding entries and MPLS forwarding entries added to an MPLS application protocol (such as LDP and MP-BGP).

Command	**Function**

Ruijie# **show mpls forwarding-table** [**summary** | [[*ip-address/mask* | **label** *label* | **interface** *interface-name* | **next-hop i***p-address*] | [**ftn** [**ip** | **vc**] | **ilm** [**ip** | **vc**]] | { **vrf** *vrf-name* | **global** } [**ftn** | **ilm**]] [**frr**] [**detail**]]	Displays the information about the MPLS forwarding table.

- Displaying the utilization of the label pool

Command	Function
Ruijie# **show mpls label-pool**	Displays information about the utilization of the MPLS label pool.

- Check the LSP connectivity.

Command	Function
Ruijie# **ping mpls ipv4** *ip-address/mask* [**repeat** *repeat*] [**ttl** *time-to-live*] [**timeout** *timeout*] [**size** *size*] [**interval** *mseconds*] [**source** *ip-address*] [**destination** *ip-address*] [**force-explicit-null**] [**pad** *pattern*] [**reply mode** { **ipv4** | **router-alert** }] [**dsmap**] [**flags fec**] [**verbose**]	Checks the LSP connectivity.
Ruijie# **traceroute mpls ipv4** *ip-address/mask* [**timeout** *timeout*] [**ttl** *ttl*] [**source** *ip-address*] [**destination** *ip-address*] [**force-explicit-null**] [**reply mode** { **ipv4 |** **router-alert** }] [**flags fec**] [**verbose**]	Checks the LSR nodes that the LSP passes through.

Configuring Optional LDP Parameters (Optional)

You can modify the default LDP parameter settings as required. To modify LDP parameters, use the commands in LDP configuration or interface configuration mode.

Configuring Parameters for an LDP Session

Configuring the LDP Router ID

The LDP router ID, expressed in the format of IP addresses, uniquely identifies one LSR in a domain. By default, the system router ID is used as the LDP router ID, that is, the LSR ID. The value of an LDP router ID must be globally unique. In addition, the LDP router ID must be reachable to other LSRs because LDP uses the LDP router ID as the transport address by default. To modify the LSR ID, use the **ldp router-id** command.

Command	Function
Ruijie(config-mpls-router)# **ldp router-id interface** *interface-name* [**force**]	Specifies the address of an interface as the LDP router ID of the LSR. **force** indicates that the current configurations immediately take effect.
Ruijie(config-mpls-router)# **no ldp router-id**	Restores the default value. The system router ID is used as the LDP router ID.

Configuring transport-address

By default, the LSR ID is used as the global transport address. As an option, you can choose the main address of an interface or specify an IP address as the transport address to set up an LDP session on the interface. The following shows two configuration methods.

Use the following commands to configure the transport address of an interface.

Command	Function
Ruijie(config-if-*type ID*)# **mpls ldp transport-address** { **interface** | *ip-address*}	Configures the transport address for LDP sessions on an interface.
Ruijie(config-if-*type ID*)# **no mpls ldp transport-address**	Deletes the configuration on the interface. By default, the global transport address is used. If no global transport address is configured, the LSR ID is used as the transport address.

Use the following commands to globally configure a transport address for all LDP sessions in LDP configuration mode.

Command	Function
Ruijie(config-mpls-router)# **transport-address** { **interface** | *ip-address* | *interface-name* }	Configures a global transport address for LDP sessions.
Ruijie(config-mpls-router)# **no transport-address**	Removes the global setting and restores the LSR ID as the transport address.

Caution

1. When you specify an IP address as the transport address, ensure that the address is reachable to other directly connected LSRs; otherwise, the LDP session cannot be set up.
2. If transport addresses are configured on an interface and globally, the basic LDP session set up on the interface prefers the transport address configured for the interface.
3. The configured transport address is valid only for the basic LDP session. The LDP session set up through extended mechanisms use the LSR ID as the transport address.

Configuring the Time Interval for Hello Packets

LDP periodically sends Hello packets to detect LDP peers. By default, the interval for sending Hello packets in the basic LDP discovery mechanism is 5 seconds. You can freely set the interval that ranges from 1 to 65535 seconds in interface mode.

Command	Function
Ruijie(config-if-type ID)# mpls ldp hello-interval seconds	Sets the interval for sending Hello packets in the basic LDP discovery mechanism.
Ruijie(config-if-type ID)# no mpls ldp hello–interval	Restores the default interval for sending Hello packets in the basic LDP discovery mechanism.

The default interval for sending Hello packets in the extended LDP discovery mechanism is 10 seconds. To modify the interval, use the **discovery target-hello** *interval* command.

Command	Function
Ruijie(config-mpls-router)# **discovery target-hello interval** *seconds*	Sets the interval for sending Hello packets in the extended LDP discovery mechanism.
Ruijie(config-mpls-router)# **no discovery target-hello interval**	Restores the default interval for sending Hello packets in the extended LDP discovery mechanism.

Configuring the Hold Time of Hello Packets

After an LDP peer is detected by periodically sent Hello packets, the local LDP device retains the peer for a period of time although no Hello packet is received from the peer, and considers that the peer expires after this period. This period of time is called the hold time of Hello packets. The default hold time of Hello packets is 15 seconds. You can freely set the interval that ranges from 1 to 65535 seconds in interface mode. The value 65535 indicates an indefinite hold time.

Command	**Function**
Ruijie(config-if-*type ID*)# **mpls ldp hello-holdtime** *seconds*	Sets the hold time of Hello packets.
Ruijie(config-if-*type ID*)# **no mpls ldp hello-holdtime**	Restores the default hold time of Hello packets.

The default hold time of Hello packets in the extended LDP discovery mechanism is 45 seconds. To modify this value, use the **discovery target-hello** *holdtime* command.

Command	**Function**
Ruijie(config-mpls-router)# **discovery target-hello holdtime** *seconds*	Sets the hold time of Hello packets in the extended LDP discovery mechanism.
Ruijie(config-mpls-router)# **no discovery target-hello holdtime**	Restores the default hold time of Hello packets in the extended LDP discovery mechanism.

Configuring the Hold Time of Keepalive Packets

After an LDP peer is detected by periodically sent Hello packets and an LDP session is set up in TCP mode, the local LDP device retains the peer for a period of time although no Keepalive packet is received from the peer. The local LDP device considers that the peer expires and voluntarily terminates the LDP session after this period. This period of time is called the hold time of Keepalive packets. The default hold time of Keepalive packets for the session set up in the basic discovery mechanism is 45 seconds and that for the session set up in the extended discovery mechanism is 180 seconds. You can freely set the value at the range of 15 to 65535. The interval for sending Keepalive packets is one third of the hold time of Keepalive packets.

Command	Function
Ruijie(config-if-*type ID*)# **mpls ldp keepalive–holdtime** *seconds*	In interface mode, sets the hold time of Keepalive packets for the session set up in the basic discovery mechanism.
Ruijie(config-if-*type ID*)# **no mpls ldp keepalive–holdtime**	Restores the default hold time of Keepalive packets for the session set up in the basic discovery mechanism.
Ruijie(config-mpls-router)# **targeted-session holdtime** *seconds*	In LDP mode, sets the hold time of Keepalive packets for the session set up in the extended discovery mechanism.
Ruijie(config-mpls-router)# **no targeted-session holdtime**	Restores the default hold time of Keepalive packets for the session set up in the extended discovery mechanism.

Configuring the Maximum Number of Repeated Label Requests

When an LDP device requests labels, it waits for a period of time to start another attempt if no label is detected due to various reasons. The default number of repeated requests is indefinite. You can freely set the value that ranges from 0 to 255 in interface mode.

Command	**Function**
Ruijie(config-mpls-router)# **mpls ldp max-label-requests** *times*	Sets the maximum number of repeated LDP label requests.

Ruijie(config-mpls-router)# **no mpls ldp max-label-requests**	Restores the default number of repeated LDP label requests.

Configuring the Maximum PDU

The messages exchanged between LDP devices are all contained in PDUs. You can freely set the value of the PDU that ranges from 256 to 4096 in interface mode. The default PDU value is 4096.

Command	Function
Ruijie(config-mpls-router)# **mpls ldp max-pdu** *max-pdu*	Sets the maximum PDU.
Ruijie(config-mpls-router)# **no mpls ldp max-pdu**	Restores the default PDU (4096).

Configuring the Extended LDP Discovery Mechanism

The basic discovery mechanism is used to detect the local LDP peers. That is, set up a local LDP session with the directly connected LSR. The extended discovery mechanism is used to detect the remote LDP peers. That is, set up a remote LDP session with the non-directly connected LSR.

Command	Function
Ruijie(config-mpls-router)# **neighbor** *ip-address*	Creates an extended LDP peer.
Ruijie(config-mpls-router)# **no neighbor** *ip-address*	Deletes an extended LDP peer.

Configuring LDP Loop Detection

Configuring the Loop Detection Mode

LDP provides two methods to detect loops: maximum number of hops and path vector. By default, loop detection is disabled for LDP.

In the loop detection based on the maximum number of hops, a packet carries both label information and the number of hops. The number increases by one every time the packet passes an LSR. When the number exceeds a preconfigured maximum value, the device considers that a loop occurs on the LSP.

In the loop detection based on the path vector, the packet carries the LSR ID apart from the label information. At each hop, an LSR first checks whether the number of LSRs in the path vector list exceeds the preset maximum number in the path vector list. If yes, a loop occurs. If no, the LSR continues to check whether its LSR ID exists in the path vector list of the LDP message. If yes, a loop occurs; if no, the LSR adds its own LSR ID to the path vector list.

Command	Function
Ruijie(config-mpls-router)# **loop-detection**	Enables loop detection.
Ruijie(config-mpls-router)# **no loop-detection**	Disables loop detection.

Configuring the Maximum Number of Hops

In interface mode, you can set the maximum number of hops allowed in loop detection mode. By default, the number is 254. You can set the value at the range of 1 to 255. If loop detection is enabled and the number of hops in an LDP message is detected to exceed the preset value, the LSR considers that a loop occurs.

Command	Function
Ruijie(config-if-*type ID*)# **mpls ldp max-hop-count** *number*	Sets the maximum number of hops in loop detection.

Ruijie(config-if-*type ID*)# **no mpls ldp max-hop-count**	Restores the default value of the maximum number of hops in loop detection.

Configuring the Maximum Number in the Path Vector List

In interface mode, you can set the maximum number of LSRs included in the path list of the loop detection based on path vector. By default, the number is 254. You can set the number at the range of 0 to 254. The number means the maximum number of LSRs that can be carried in the path vector list. After loop detection is enabled, an LSR considers that a loop occurs if the LSR detects its own LSR ID in the path vector list or the number of LSR IDs in the path vector list exceeds the preset value.

Command	Function
Ruijie(config-mpls-router)# **mpls ldp max-path-vector** *number*	Sets the maximum number in the path vector list of loop detection.
Ruijie(config-mpls-router)# **no mpls ldp max-path-vector**	Restores the default value of the maximum number in the path vector list of loop detection.

Configuring the LDP Working Mode

Configuring the LDP Label Distribution Control Mode

The LDP label distribution control mode specifies when an LSR notifies its neighbors of the binding between labels and FECs. There are two control modes: independent control and ordered control.

In independent control mode, the LSR can announce the binding of labels and FECs to its neighbors at any required time. In ordered control mode, an LSR binds an FEC to a label and sends the binding upstream only when the FEC has the next-hop label mapping or the LSR is the egress LSR of the FEC.

By default, LDP uses the independent control mode. To configure the LDP control mode, use the **lsp-control-mode** command.

Command	**Function**
Ruijie(config-mpls-router)# **lsp-control-mode** { **independent** | **orderd** }	Configures the label distribution control mode.
Ruijie(config-mpls-router)# **no lsp-control-mode**	Restores the default label distribution control mode.

Configuring the LDP Label Distribution Mode

The LDP label distribution mode specifies how an LSR notifies its neighbors of the binding between labels and FECs. There are two modes: DOD and DU.

In DOD mode, a downstream LSR responds to a label binding message only after receiving a label request from an upstream LSR. In DU mode, one LSR voluntarily sends label binding messages to its upstream LSRs according to certain triggering policies. If the upstream and downstream LSRs use different label distribution modes, the DU mode is used if the LSRs are connected to each other through Ethernet.

By default, LDP works in DU mode. You can use the **mpls ldp distribution-mode** command in interface mode to set the label distribution mode on an interface.

Command	**Function**
Ruijie(config-if-*type ID*)# **mpls ldp distribution-mode { du | dod }**	Configures the label distribution mode.

Ruijie(config-if-*type ID*)# **no mpls ldp distribution-mode**	Restores the default label distribution mode (DU).

Configuring the LDP Label Retention Mode

The label retention mode specifies whether an LSR should retain the label binding learnt from a label mapping message if the message is not sent from the next hop of the corresponding FEC or the message does not match any existing IP route. There are two label retention modes: conservative and liberal modes.

When the preceding situations occur, the liberal mode retains the binding of the FEC and label from the neighbor whereas the conservative mode does not retain the binding information.

The conservative label retention mode uses and maintains a small number of labels. The LSR should re-obtain the label values in case of route changes, prolonging responses. The liberal label retention mode, however, responds rapidly to route changes but unnecessary label mappings are also distributed and maintained.

By default, LDP uses the liberal label retention mode.

Use the **label-retention-mode** command to configure the label retention mode.

Command	Function
Ruijie(config-mpls-router)# **label-retention-mode** { **liberal | conservation** }	Configures the label retention mode.
Ruijie(config-mpls-router)# **no label-retention-mode**	Restores the default label retention mode.

Configuring Label Merging

If an LSR binds several incoming labels for a FEC but uses the same outgoing label for all packets in the FEC, it indicates that the LSR is capable of label merging. You can enable or disable label merging through LDP configurations.

By default, label merging is enabled for LDP.

Use the **label-merge** command to enable or disable label merging.

Command	Function
Ruijie(config-mpls-router)# **label-merge**	Enables label merging.
Ruijie(config-mpls-router)# **no label-merge**	Disables label merging.

Configuring the Transmission Mode of Label Release Messages

When an FEC becomes invalid, LDP sends label release messages to downstream devices to cancel the label bound to the FEC. Each LDP device on the LSR determines whether to transmit the messages to downstream devices based on the transmission mode of label release messages.

By default, an LDP device does not send label release messages received from an upstream device to downstream devices.

Use the **propagate-release** command to configure the transmission mode of label release messages.

Command	Function
Ruijie(config-mpls-router)# **propagate-release**	Configures a device to send label release messages to downstream devices.
Ruijie(config-mpls-router)# **no propagate-release**	Configures a device not to send label release messages to downstream devices.

Configuring Label Control Policies

Configuring Label Distribution Policies

By default, LDP assigns labels to all valid IGP routes (excluding BGP routes). In some special situations, you may only want to assign labels to some routes or to certain LDP peers to reduce the number of labels and the number of LSPs to lessen device and network burdens.

Command	Function
Ruijie(config-mpls-router)# **advertise-labels for host-routes**	Configures the device to assign labels to only host routes that satisfy the mask length of 32 bits in the route forwarding table. By default, the mask length of routes is not restricted.
Ruijie(config-mpls-router)# **advertise-labels for bgp-routes** [**acl** *acl-name*]	Configures the device to assign labels to BGP routes. By default, LDP does not assign labels to BGP routes.
Ruijie(config-mpls-router)# **advertise-labels for default-route**	Configures the device to assign labels to default routes. By default, LDP assigns implicit null label 3 to default routes.
Ruijie(config-mpls-router)# **advertise-labels for acl** *prefix-access-list* [**to** *peer-access-list*]	Configures the device to assign labels to FECs that match ACL rules and specify the device to assign labels only to LDP peers that match the rules.

Caution

1. By default, LDP assigns labels to only IGP routes. To assign labels to BGP routes, use the **advertise-labels for bgp-routes** command.
2. By default, LDP does not set up an LSP for default routes.

Configuring Label Reception Policies

By default, LDP can receive all label binding information sent from all neighbors. In certain situations, you may need to control the device to receive only some binding information about FECs and labels from certain neighbors. In this case, use the **neighbor** *ip-address* **labels accept** command.

Command	Function
Ruijie(config-mpls-router)# **neighbor** *ip-address* **labels accept** *acl-name*	Configures a label reception policy.

Configuring Policies for Distributing Explicit Null Labels

By default, LDP assigns implicit null labels to the FEC (such as direct routes) with the local device as the egress. You can use the **explicit-null** command to assign explicit null labels to all direct routes or routes that match certain ACL rules. To restore the default setting, use the **no explicit-null** command.

Command	Function
Ruijie(config-mpls-router)# **explicit-null** [**for** *prefix_acl* **| to** *peer_acl*]	Configures a device to assign explicit null labels to all direct routes or routes that match certain ACL rules.
Ruijie(config-mpls-router)# **no explicit-null**	Restores the default setting.

Caution

1. For an FEC with the local device as the egress, the device cannot assign explicit null labels to the FEC if the corresponding LSP is a tunnel that carries L2VPN or L3VPN services.
2. Configure this function only for the global LDP instance. This function is not supported by the VRF instance.

Configuring the LDP MD5 Authentication

To enhance the reliability of LDP sessions, you can configure the MD5 authentication for the TCP connections used by the LDP sessions. To configure the MD5 authentication for TCP connections between a device and its peer, use the **neighbor** *ip-address* **password** [**0 | 7**] *pwd-string* command. To restore the default setting, use the **no neighbor** *ip-address* **password** [**0 | 7**] *pwd-string* command.

Command	Function
Ruijie(config-mpls-router)# **neighbor** *ip-address* **password** [**0 | 7**] *pwd-string*	Configures a device to adopt the MD5 authentication for the TCP connections with its peer.
Ruijie(config-mpls-router)# **no neighbor** *ip-address* **password**	Restores the default setting.

Verifying the LDP Information

- Displaying LDP attributes

Use the **show mpls ldp parameters** [all **| vrf** *vrf-name*] command to view information about LDP attributes, including the LSR ID, transport address, loop detection mechanism, label distribution control mode, label retention mode, the interval and hold time of Hello packets with extended peers, and the interval and hold time of Keepalive packets with extended peers. You can verify the information to check whether the configurations are correct. By default, the LDP attributes of the default VRF are displayed. If **all** is chosen, the LDP attributes of all VRFs are displayed; if *vrf-name* is specified, the LDP attributes of a specified VRF are displayed.

Command	Function
Ruijie# **show mpls ldp parameters** [**all | vrf** *vrf-name*]	Displays information about LDP attributes.

- Displaying information about an interface enabled with LDP

Use the **show mpls ldp interface** [**all** | **vrf** *vrf-name* | *interface-name*] command to display the LDP status of interfaces in all or a specified VRF. You can also query the LDP status of specific interfaces. By default, the interface LDP status of interfaces in the default VRF is displayed. If **all** is chosen, the LDP status of interfaces in all VRFs is displayed; if *vrf-name* is specified, the LDP status of interfaces in a specified VRF is displayed; if *interface-name* is specified, the LDP status of the specified interface is displayed.

Command	Function
Ruijie# **show mpls ldp interface** [**all | vrf** *vrf-name* **|** *interface-name*]	Displays information about the interface enabled with LDP.

- Displaying the binding between FECs and labels

Use the **show mpls ldp bindings** [**all** |**vrf** *vrf-name*] | [*ip-address*/*mask* | **label** *label*] | [**remote** | **local**] command to display the binding information between FECs and labels. You can also use this command to view the LDP working status, to check whether an FEC is properly bound to a label, or query the specific label value bound to an FEC. When using this command, you can filter the display information based on the VRF, address prefix, label value, remote binding, or local binding.

Command	Function
Ruijie# **show mpls ldp bindings** [**all | vrf** *vrf-name*] | [*ip-address/mask* | **label** *label* **|** [**remote | local**]	Displays the binding between FECs and labels.

- Displaying LDP neighbors

Use the **show mpls ldp neighbor** [**all** \| **vrf** *vrf-name*] [*ip-address*] [**detail**] command to view the LDP neighbors of all or a specified VRF, including the TCP connection port, LDP status, statistics about packets received and transmitted, and the voluntary LDP discovery party of the local and remote LDP devices. If parameter **detail** is added, detailed information about LDP neighbors is displayed.

Command	Function
Ruijie# **show mpls ldp neighbor** [**all | vrf** *vrf-name*] | [**detail**]	Displays information about LDP neighbors.

- Displaying information about discovered LDP neighbors

Use the **show mpls ldp discovery** [**all** \| **vrf** *vrf-name*] \| [**detail**] command to display ports where LDP neighbors are discovered and information about the neighbors. If parameter **detail** is added, detailed information about LDP neighbors is displayed.

Command	Function
Ruijie# **show mpls ldp discovery** [**all | vrf** *vrf-name*] **|** [**detail**]	Displays information about discovered LDP neighbors.

- Resetting the LDP session

Use the **clear mpls ldp neighbor** command to reset an LDP session and set up a new session.

Command	Function
Ruijie# **clear mpls ldp neighbor** [**all** | **vrf** *vrf-name*] [*| *ip-address*]	Resets an LDP session and sets up a new session.

Configuring Static MPLS Forwarding

To support basic MPLS forwarding functions, you can also use static configurations other than LDP. To configure basic MPLS forwarding functions in static mode, perform the following configuration procedures:

- (Mandatory) Enable MPLS forwarding globally.
- (Mandatory) Enable MPLS forwarding on an interface.
- (Mandatory) Configure a static LSP.

Caution

LDP is not required when configuring a static LSP. As a result, IPv4 routes are also not required. If no IPv4 route exists on the network, the static LSP can still take effect as long as the physical network is reachable.

For configuration procedures to enable MPLS forwarding globally or on an interface, refer to the basic procedures for configuring MPLS forwarding.

Configuring a Static LSP

The configuration of an MPLS network in static mode centers around the static LSP. The other configurations are the same as those of LDP. To configure a static LSP, perform the following steps:

- Configure a static FTN on the ingress LSR.
- Configure a static ILM on the intermediate LSR.
- Configure a static ILM on the PHP LSR.

Note

Label values 16 to 1024 are reserved for static LSPs. You can select only from these label values when configuring static LSPs.

☑ On a router, use the **ip ref** command on the label forwarding interface to enable MPLS fast forwarding to improve forwarding performance of the router.

Configuring a Static FTN on the Ingress LSR

On the ingress LSP, set up an FTN entry for the FEC, that is, bind the FEC to a label.

Use the **mpls static ftn** command to configure a static FTN in global configuration mode. The syntax of the command is as follows:

Command	Function
Ruijie(config)# **mpls static ftn** *ip-address / mask* **out-label** *label* **nexthop** *interface nexthop-ip*	Adds a global FTN.
Ruijie(config)# **no mpls static ftn** *ip-address/mask*	Deletes a global FTN.

For example, to configure a global FTN that binds label 16 to FEC 192.168.1.0/24 and supports the next hop of the LSP as 192.168.10.10 and the outgoing interface as GigabitEthernet 2/1, run the following command:

```
Ruijie(config)# mpls static ftn 192.168.1.0/24 out-label 16 GigabitEthernet 2/1 192.168.10.10
```

To delete the TFN, run the following command. In this case, you are required to only enter the FEC. Other parameters are not required.

```
Ruijie(config)# no mpls static ftn 192.168.1.0/24
```

Configuring a Static ILM on the Intermediate LSR

An intermediate LSR forwards labels for incoming labeled packets. In this case, you are required to configure ILM forwarding entries to map incoming labels to outgoing ones. Use the **mpls static ilm in-label** command to configure a static ILM in global configuration mode. The syntax of the command is as follows:

Command	Function
Ruijie(config)# **mpls static ilm in-label** *in_label* **forward-action swap-label** *swap_label* **nexthop** *interface nexthop-ip* **fec** *ip-address/mask*	Adds a global ILM.
Ruijie(config)# **no mpls static ilm in-label** *in_label*	Deletes a global ILM.

For example, to configure a global ILM that maps the incoming label 16 to the outgoing label 17 and supports the next hop of the LSP as 192.168.11.11, the outgoing interface as GigabitEthernet 2/2, and the FEC of the LSP as 192.168.1.0/24, run the following command:

```
Ruijie(config)# mpls static ilm in-label 16 forward-action swap-label 17 nexthop
GigabitEthernet 2/2 192.168.11.11 fec 192.168.1.0/24
```

To delete the ILM, run the following command:

```
Ruijie(config)# no mpls static ilm in-label 16
```

Configuring a Static ILM on the PHP LSR

Because the second but last hop is required to perform PHP, its ILM entries must be different from those on other intermediate LSRs. That is, the outgoing label in the ILM of the PHP LSR on the LSP should be an implicit null label (3).

Note

For information about the PHP, refer to related materials.

For example, you are required to configure a global ILM on the PHP LSR of the LSP. The LSR is required to pop out the incoming label 17 and send the packets from GigabitEthernet 2/2. The next hop address is 192.168.12.12 and the corresponding FEC is 192.168.1.0/24. Run the following command:

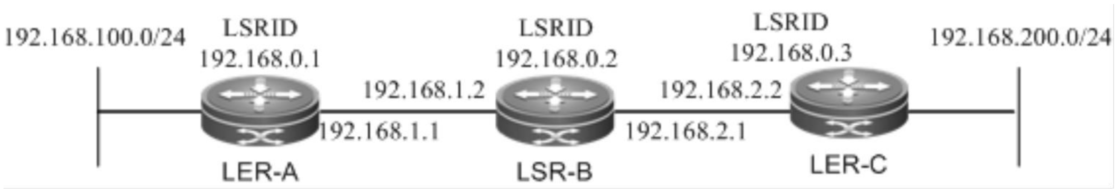
```
Ruijie(config)# mpls static ilm in-label 17 forward-action swap-label 3 nexthop GigabitEthernet
2/2 192.168.11.11 fec 192.168.1.0/24
```

To delete the ILM, run the following command:

```
Ruijie(config)# no mpls static ilm in-label 17
```

Example for Configuring Basic MPLS Functions

Figure 4



As shown in the preceding figure, three MPLS devices are deployed to construct an MPLS network. The following section introduces the setup of an LSP through LDP and the setup of a static LSP to show the MPLS configuration procedures.

Setting Up an LSP Through LDP

LDP works only with IPv4 routes. Here, OSPF is enabled to set up IPv4 routes. Before the following configuration, ensure that you have created a loopback interface (Loopback 0) and assigned an IP address, which also serves as the router ID, to the loopback interface on each device.

Configurations on LER_A:

Command	Function

Command	Function
Ruijie(config)# **mpls ip**	Enables MPLS forwarding globally. (Note: This command is not applicable to switch chip forwarding.)
Ruijie(config)# **mpls router ldp**	Enables LDP and enters LDP mode.
Ruijie(config-mpls-router)# **ldp router-id interface loopback** 0 **force**	Configures the LDP router ID. The loopback address is generally used as the router ID.
Ruijie (config-mpls-router)# **exit**	Exits LDP mode and enters global configuration mode.
Ruijie(config)# **interface gigabitEthernet** *2/2*	Enters interface mode of GigabitEthernet 2/2.
Ruijie(config-if-GigabitEthernet 2/2)# **mpls ip**	Enables LDP on the interface.
Ruijie(config-if-GigabitEthernet 2/2)# **label-switching**	Enables MPLS on the interface.
Ruijie(config-if-GigabitEthernet 2/2)# **ip ref**	Enables MPLS fast forwarding on the interface of a router.
Ruijie(config-if-GigabitEthernet 2/2)# **exit**	Exits interface mode and enters global configuration mode.
Ruijie (config)# **router ospf** *10*	Enables OSPF and enters OSPF mode.
Ruijie (config-router)# **network** *192.168.100.0 0.0.0.255* **area 0** Ruijie (config-router)# **network** *192.168.0.1 0.0.0.0* **area 0** Ruijie (config-router)# **network** *192.168.1.0 0.0.0.255* **area 0**	Adds routing information to OSPF.
Ruijie(config-router)# **end**	Ends the configuration.

Configurations on LER_B:

Command	Function
Ruijie (config)# **mpls ip**	Enables MPLS forwarding globally. (Note: This command is not applicable to switch chip forwarding.)
Ruijie (config)# **mpls router ldp**	Enables LDP and enters LDP mode.
Ruijie(config-mpls-router)# **ldp router-id interface loopback** *0* **force**	Configures the LDP router ID. The loopback address is generally used as the router ID.
Ruijie (config-mpls-router)# **exit**	Exits LDP mode and enters global configuration mode.
Ruijie (config)# **interface gigabitEthernet** *2/1*	Enters interface mode of GigabitEthernet 2/1.
Ruijie(config-if-GigabitEthernet 2/1)# **mpls ip**	Enables LDP on the interface.
Ruijie(config-if-GigabitEthernet 2/1)# **label-switching**	Enables MPLS on the interface at the public network side.
Ruijie(config-if-GigabitEthernet 2/2)# **ip ref**	Enables MPLS fast forwarding on the interface of a router.
Ruijie(config-if-GigabitEthernet 2/1)# **exit**	Exits interface mode and enters global configuration mode.
Ruijie (config)# **router ospf** *10*	Enables OSPF and enters OSPF mode.
Ruijie (config-router)# **network** *192.168.1.0 0.0.0.255* **area** *0* Ruijie (config-router)# **network** *192.168.2 .0 0.0.0.255* **area** *0* Ruijie (config-router)# **network** *192.168.0.2 0.0.0.0.0* **area** *0*	Adds routing information to OSPF.
Ruijie (config-router)# **end**	Ends the configuration.

Configurations on LER_C:

Command	Function
Ruijie (config)# **mpls ip**	Enables MPLS forwarding globally. (Note: This command is not applicable to switch chip forwarding.)
Ruijie (config)# **mpls router ldp**	Enables LDP and enters LDP mode.
Ruijie(config-mpls-router)# **ldp router-id interface loopback** *0* **force**	Configures the LDP router ID. The loopback address is generally used as the router ID.
Ruijie (config-mpls-router)# **exit**	Exits LDP mode and enters global configuration mode.
Ruijie (config)# **interface gigabitEthernet** *2/1*	Enters interface mode of GigabitEthernet 2/1.
Ruijie(config-if-GigabitEthernet 2/1)# **mpls ip**	Enables LDP on the interface.
Ruijie(config-if-GigabitEthernet 2/1)# **label-switching**	Enables MPLS on the interface at the public network side.
Ruijie(config-if-GigabitEthernet 2/2)# **ip ref**	Enables MPLS fast forwarding on the interface of a router.
Ruijie(config-if-GigabitEthernet 2/1)# **exit**	Exits interface mode and enters global configuration mode.
Ruijie (config)# **router ospf** *10*	Enables OSPF and enters OSPF mode.
Ruijie (config-router)# **network** *192.168.200.0 0.0.0.255* area *0* Ruijie (config-router)**#** **network** *192.168.0.3 0.0.0.0* **area** *0* Ruijie (config-router)# **network** *192.168.2.0 0.0.0.255* **area** *0*	Adds routing information to OSPF.
Ruijie (config-router)# **end**	Ends the configuration.

Configuring a Static LSP

You can configure a static LSP without IPv4 routes.

For example, set up two LSPs between interface 1 at the 192.168.100.0/24 network segment on LER_A and interface 2 at the 192.168.200.0/24 network segment on LER_C to connect the two network segments. You need to configure one LSP from LER_A to LER_C and the other LSP from LER_C to LER_A. This is because the LSP is uni-directional.

☑ On a router, you must use the **ip ref** command on the label forwarding interface to enable MPLS fast forwarding to improve forwarding performance of the router.

Configurations on LER_A:

Command	Function
Ruijie (config)# **mpls ip**	Enables MPLS forwarding globally. (Note: This command is not applicable to switch chip forwarding.)
Ruijie (config)# **interface gigabitEthernet** *2/2*	Enters interface mode of GigabitEthernet 2/2.
Ruijie(config-if-GigabitEthernet 2/2)# **label-switching**	Enables MPLS on the interface at the public network side.
Ruijie(config-if-GigabitEthernet 2/2)# **ip ref**	Enables MPLS fast forwarding on the interface of a router.
Ruijie(config-if-GigabitEthernet 2/2)# **exit**	Exits interface mode and enters global configuration mode.

Command	Function
Ruijie (config)# **mpls static ftn** *192.168.200.0/24* **out-label** *16* **nexthop gigabitEthernet** *2/2 192.168.1.2*	Creates an FTN that binds 192.168.200.0/24 to label 16. Specifies the next hop of the FTN as 192.168.1.2 and the outgoing interface as GigabitEthernet 2/2.
Ruijie(config-router)# **end**	Ends the configuration.

Configurations on LER_B:

Command	Function
Ruijie (config)# **mpls ip**	Enables MPLS forwarding globally. (Note: This command is not applicable to switch chip forwarding.)
Ruijie (config)# **interface gigabitEthernet** *2/1*	Enters interface mode of GigabitEthernet 2/1.
Ruijie(config-if-GigabitEthernet 2/1)# **label-switching**	Enables MPLS on the interface at the public network side.
Ruijie(config-if-GigabitEthernet 2/1)**# ip ref**	Enables MPLS fast forwarding on the interface of a router.
Ruijie(config-if-GigabitEthernet 2/1)# **exit**	Exits interface mode and enters global configuration mode.
Ruijie (config)# **interface gigabitEthernet** *2/2*	Enters interface mode of GigabitEthernet 2/2.
Ruijie(config-if-GigabitEthernet 2/2)# **label-switching**	Enables MPLS on the interface at the public network side.
Ruijie(config-if-GigabitEthernet 2/1)**# ip ref**	Enables MPLS fast forwarding on the interface of a router.
Ruijie(config-if-GigabitEthernet 2/2)# **exit**	Exits interface mode and enters global configuration mode.
Ruijie (config)# **mpls static ilm in-label** *16* **forward-action swap-label** *3* **nexthop gigabitEthernet** *2/2 192.168.2.2* **fec** *192.168.200.0/24*	Creates an ILM that maps the incoming label 16 to the outgoing label 3 (implicit null label) on GigabitEthernet 2/2. Specifies the next hop address as 192.168.2.2 and the FEC as 192.168.200.0/24.
Ruijie (config)# **mpls static ilm in-label** *17* **forward-action swap-label** *3* **nexthop gigabitEthernet** *2/1 192.168.1.1* **fec** *192.168.100.0/24*	Creates an ILM that maps the incoming label 17 to the outgoing label 3 (implicit null label) on GigabitEthernet 2/1. Specifies the next hop address as 192.168.1.1 and the FEC as 192.168.100.0/24.
Ruijie (config-router)# **end**	Ends the configuration.

Because LER_B is the PHP LSR for the FEC 192.168.100.0/24, the incoming label 17 is mapped to the outgoing label 3 (implicit null label). The outgoing interface is GigabitEthernet 2/1.

Similarly, because LER_B is the PHP LSR for the FEC 192.168.200.0/24, the incoming label 16 is also mapped to the outgoing label 3 (implicit null label). The outgoing interface is GigabitEthernet 2/2.

Configurations on LER_C:

Command	Function
Ruijie (config)# **interface gigabitEthernet** *2/1*	Enters interface mode of GigabitEthernet 2/1.
Ruijie(config-if-GigabitEthernet 2/1)# **label-switching**	Enables MPLS on the interface at the public network side.
Ruijie(config-if-GigabitEthernet 2/1)# **ip ref**	Enables MPLS fast forwarding on the interface of a router.
Ruijie(config-if-GigabitEthernet 2/1)# **exit**	Exits interface mode and enters global configuration mode.
Ruijie (config)# **mpls static ftn** *192.168.100.0/24* **out-label** *17* **nexthop gigabitEthernet** *2/1 192.168.2.1*	Creates an FTN that binds 192.168.200.0/24 to label 17. Specifies the next hop of the FTN as 192.168.2.1 and the outgoing interface as GigabitEthernet 2/1.
Ruijie (config-router)# **end**	Ends the configuration.

After the preceding configurations, packets destined for the 192.168.200.0/24 network segment on LER_A are sent out through GigabitEthernet 2/2 on LER_A and pushed with label 16. After arriving at the GigabitEthernet 2/1 interface on LER_B, these packets with label 16 are then transformed to IP packets and sent out through GigabitEthernet 2/2 on LER_B. After these IP packets destined for the 192.168.200.0/24 network segment arrives at LER_C, LER_C selects routes based on the destination IP address and sends out the packets from GigabitEthernet 2/1.

Configuring **BGP/MPLS IP VPN**

Understanding the BGP/MPLS IP VPN

Overview

In traditional VPNs, private network data streams are generally transmitted over public networks through Generic Routing Encapsulation (GRE), Layer 2 Tunneling Protocol (L2TP), and Point-to-Point Tunneling Protocol (PPTE). As another implementation of a VPN, a BGP/MPLS IP VPN can be considered as a VPN between Layer 2 and Layer 3. A label switched path (LSP) is a tunnel that is set up through MPLS LDP on the public network. In an MPLS VPN, the different branches of private networks at different locations are connected to form one network through LSPs. The MPLS VPN also supports interworking between different VPNs. The implementation of the VPN through MPLS has natural advantages. For VPN users, the workload is largely reduced because no special VPN devices are required to construct the VPN. Instead, the VPN users can directly use traditional routers. For carriers, the MPLS VPN can be easily expanded.

As a highly effective technical platform for IP backbone networks, MPLS provides VPNs with flexible and scalable technical foundations.

The L3VPN based on BGP/MPLS IP VPN has the following features:

- The VPN tunnels are set up on the provider edge (PE) devices of network service providers rather than the customer edge (CE) devices. The VPN routes are also transmitted between PEs. In this manner, users are not required to maintain VPN information.
- Existing routing protocols are directly utilized. The setup of VPN tunnels and route advertising are dynamically implemented, facilitating the expansion of VPNs.
- Address overlapping is supported. Different VPN users can use the same address space.
- On the network of service providers, VPN services are exchanged by label switching rather than traditional route distribution.
- The L3VPN is as secure as user dedicated lines.

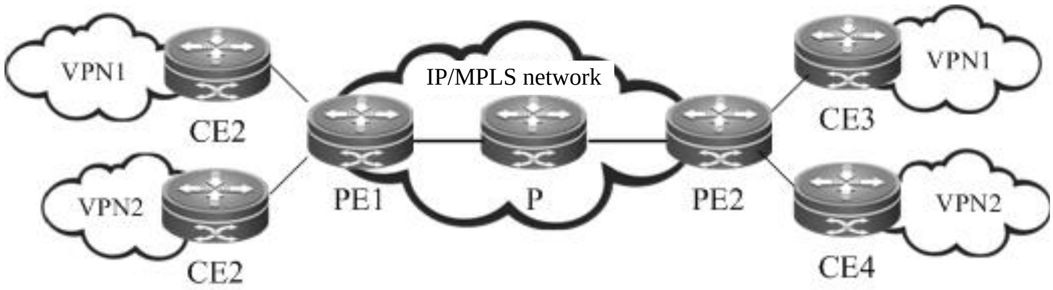
The BGP/MPLS IP VPN provides the following functions:

- Adopts the LDP to set up LSPs on the backbone network. This process is generally performed on the provider's network and completed when the topology becomes stable.
- Forwards data packets based on the pushed labels and the local mapping table.
- Supports MP-BGP and extended BGP attributes to transmit VPN routes and carry VPN attributes and labels.
- Manages VPN routes to set up multiple routing tables and maintain VPN routes.

Components of the BGP/MPLS IP VPN

A BGP/MPLS IP VPN model consists of three components, as shown in the following figure.

Figure 5 Basic components of the VPN



- CE

Located at a customer edge, a CE logically belongs to a user VPN. One interface on the CE is directly connected to a PE device. The CE can be a host, router or switch that may not support MPLS. As shown in the figure, CE1, CE2, CE3, and CE4 are CE devices.

- PE

A PE is an edge device on the SP backbone network. It can be a router, an ATM switch, or an FR switch, as shown by PE1 and PE2 in the figure. A PE logically belongs to the service provider and is directly connected to a CE. You can connect one PE to multiple CEs. The PE is mainly responsible for receiving the VPN information from CEs and transmitting the information to other PEs, or receiving the VPN information from other PEs and distributing it to the CEs. The PEs should support MPLS.

- P

The provider router (P) is a core device on the SP backbone network, as shown by P1, P2, and P3 in the figure. The P is not connected to CEs. It is responsible for routing and rapid forwarding. As a device on the core MPLS backbone network, the P should support MPLS. The P knows the routes to any destination on the backbone network but does not know the routes to a VPN.

VRF

- VRF

The VPN routing and forwarding table (VRF) is used to solve the conflicts of local routes. Each connection between a PE and a CE is associated with a VRF. One PE can have several VRFs to exchange route information with CEs. You can consider a VRF as a virtual router. Each virtual router should be connected to a CE to receive route information from the CE or advertise the VPN route information to the CE. The VRF solves the conflicts of local routes due to the adoption of the same address space by different VPNs. One VRF includes:

5) An independent routing table

6) A group of interfaces that belong to the VRF

7) A group of routing protocols that are used in the VRF

The VRF has two important attributes: route distinguisher (RD) and route-target (RT) attributes.

- RD

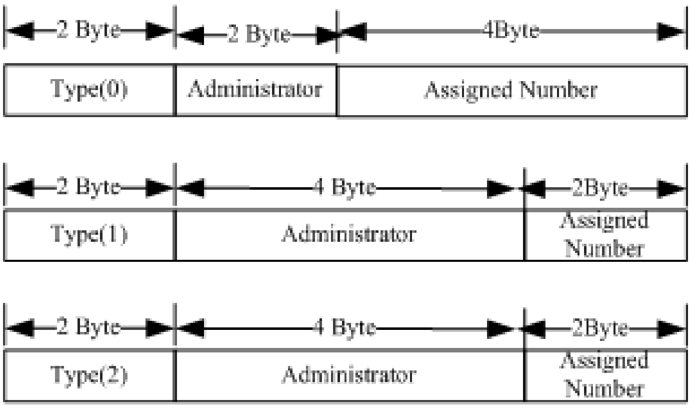
The RD is introduced to solve the conflict of routes during the transmission.

You can consider the RD as a distinguisher. If different VPNs use the same network address and advertise their route information on the backbone network through BGP, BGP chooses and advertises only the best route from the overlapped addresses. As a result, some VPNs cannot obtain their route information. If the RD values are added to the overlapped addresses, BGP identifies the same network addresses based on the different RDs carried in the VPN information. In this manner, each VPN can obtain its own route information. The RD only serves as a distinguisher to distinguish the same network addresses. If address overlapping does not exist for different VPNs, you can configure no RD values.

Generally, a unique RD value is specified for one VPN. In this manner, different VPNs have different RDs, facilitating the transmission of route information on the backbone network. The RD value is generally defined as xx: xx, such as RD 1: 100, where 1 stands for the AS number of the backbone network and 100 is a number specified by the user. One VPN route can carry only one RD value.

The RD consists of three fields: type, administrator, and assigned number. Based on the value of the type field, the encoding formats are classified into the following three types:

Figure 6 RD structure.



8) When Type = 0, the administrator field has two bytes and is marked by the AS number that must be a public AS number. The assigned number has four bytes and is managed by the service provider.

9) When Type = 1, the administrator field has four bytes and uses an IPv4 address that must be a global IP address. The assigned number has two bytes and is managed by the service provider.

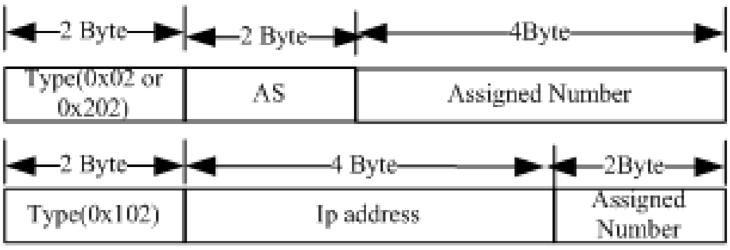
10) When Type = 2, the administrator field has four bytes and is marked by the four-byte AS number. The assigned number has two bytes and is managed by the service provider.

- Route-Target

The introduction of the RT attribute is to let the VRF choose its route selection mode. The RT attributes are classified into route-target export and route-target import. A PE receives routes from a CE and adds route-target export to the VPN routes and then advertises the VPN routes to other PEs. The PE determines whether to import the routes received from other PEs to the VRF based on the route-target import. One principle is that when a PE receives a VPN route, the PE imports the route to the VRF only when at least one RT attribute carried in the route is the same as the import RT in the VRF of the PE. In this manner, you can flexibly control the distribution of VPN routes. One VPN route can carry multiple RT values.

The BGP extended community attribute defines the RT encoding structure, as shown in the following figure.

Figure 7 RT structure



The definition of RT is similar to that of RD. For 0x02 and 0x202, the AS number must be a public one. For 0x102, the IPv4 address must be a global one rather than a private address.

MP-BGP

The VPN route information is transmitted on the backbone network through BGP. The export RT attribute is carried in the BGP extended community attribute. The traditional BGP4, however, transmits only IPv4 routes and cannot carry the VPN route that includes RDs. Therefore, the BGP is extended to introduce new attributes. One of the biggest advantages of BGP is its scalability. The Multi-Protocol (MP-BGP) is a new attribute introduced to the original BGP to support multiple protocols. The MP-BGP can carry VPN information. In this manner, the VPN route takes up the form of RD + IP address prefix. By adding RDs to VPN routes exchanged between PEs, the MP-BGP allows VPN users to change the IPv4 routes to VPN-IPv4 routes and transmit the routes on the backbone network.

Protocol Specification

- IETF RFC 4364: BGP/MPLS IP Virtual Private Networks (VPNs)

Configuring the BGP/MPLS IP VPN

☑ On a router, you must use the **ip ref** command on the interface to enable MPLS fast forwarding to improve forwarding performance of the router.

Default Configuration

BGP/MPLS L3 VPN is disabled by default.

Function	Default Setting
Basic BGP/MPLS L3 VPN functions	Disabled
VPN label distribution mode	Distributing labels to each VRF
Inter-AS VPN	Disabled
CSC VPN	Disabled
MPLS VPN over GRE	Disabled

Configuring the Basic BGP/MPLS IP VPN

To configure basic BGP/MPLS IP VPN functions, perform the following configurations:

- Configuring an MPLS Network (Mandatory)

- Configuring a VPN Routing Instance (Mandatory)
- Configuring PEs to Transmit VPN Routes (Mandatory)
- Configuring Route Exchange Between PEs and CEs (Mandatory)
- Configuring VPN Label Distribution Mode (Optional)
- Configuring Import and Export Policies for VPN Routes (Optional)
- No import VPN route-target community //Import extended community attribute list (not configured)
-

Configuring an MPLS Network

To use MPLS on the backbone network, you must configure the MPLS LDP on the P and PE to set up public tunnels. This means that you must configure LDP on MPLS devices and enable MPLS on each interface.

Use the following commands to configure an MPLS network.

Command	**Function**
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **mpls ip**	Enables MPLS globally. ⚠ Caution This command is not available on a switch chip.
Ruijie(config)# **mpls router ldp**	Enables LDP and enters LDP configuration mode.
Ruijie(config-mpls-router)# **ldp router-id interface loopback** *id* [**force**]	Configures the LDP router ID. The IP address of the loopback interface is generally used as the router ID.
Ruijie(config-mpls-router)# **exit**	Exits LDP configuration mode.
Ruiije(config)# **interface** *type ID*	Enters interface configuration mode.
Ruijie(config-if-*type ID*)# **ip address** *ip-address mask*	Assigns an IP address to the interface.
Ruijie(config-if-*type ID*)# **label-switching**	Enables MPLS on the interface at the public network side.
Ruijie(config-if-*type ID*)# **ip ref**	☑ In case of a router, enables MPLS fast forwarding on the interface.
Ruijie(config-if-*type ID*)# **mpls ip**	Enables LDP on the interface.
Ruijie(config-if-*type ID*)# **show running-config**	Displays existing configuration information.

# Configure an MPLS network.

```
Ruijie# configure terminal
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)#interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-gigabitethernet 1/1)# no switchport
Ruijie(config-if-gigabitethernet 1/1)# ip address 192.168.10.1 255.255.255.0
Ruijie(config-if-gigabitethernet 1/1)# label-switching
Ruijie(config-if-gigabitethernet 1/1)# mpls ip
```

Configuring a VPN Routing Instance

A VPN routing instance is the VRF that is configured on PEs. The CE and P devices do not have VRFs.

The configuration of a VRF includes defining the VRF, assigning RD and RT values to the VRF, and associating the VRF with an interface.

Use the following commands to configure a VPN routing instance.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **ip vrf** *vrf-name*	Creates a VRF and enters VRF configuration mode.
Ruijie(config-vrf)# **rd** *rd-value*	Sets the RD value.
Ruiije(config-vrf)# **route-target {both | export | import**} *rt-value*	Sets the RT value.
Ruijie(config-vrf)# **exit**	Exits VRF configuration mode.
Ruijie(config)# **interface type** *ID*	Enters interface configuration mode.
Ruijie(config-if-*type ID*)# **ip vrf forwarding** *vrf-name*	Associates the interface with the VRF.
Ruijie(config-if-*type ID*)# **ip address** *address mask*	Assigns an IP address to the interface.
Ruijie(config-if-*type ID*)# **ip ref**	☑ In case of a router, enables MPLS fast forwarding on the interface.
Ruijie(config-if-*type ID*)# **show running-config**	Displays existing configuration information.

# Configure a VRF and bind it to interface Gigabitethernet 1/1.

```
Ruijie(config)# ip vrf vpn1
Ruijie(config-vrf)# rd 100: 1
Ruijie(config-vrf)# route-target both 100: 1
Ruijie(config-vrf)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-gigabitethernet 1/1)# no switchport
Ruijie(config-if-gigabitethernet 1/1)# ip vrf forwarding vpn1
Ruijie(config-if-gigabitethernet 1/1)# ip address 192.168.10.1
255.255.255.0
```

Caution

If an RD value is specified for the VRF on a PE or the BGP VRF function is enabled on the PE, the RD value cannot be modified or deleted. In this case, you can only delete the VRF and create the VRF again to set the RD value.

Two different VRFs on the same PE cannot be assigned the same RD.

If you enter the **ip vrf forwarding** *vrf-name* command, the IP address assigned to the interface earlier is deleted. In this case, you need to redefine the IP address in interface configuration mode.

Configuring PEs to Transmit VPN Routes

PEs transmit route information to each other through BGP. Because a PE needs to transmit VPN route information rather than common IPv4 route information to another PE, you need to enter VPN address family configuration mode to configure the PE to transmit VPN routes to the peer PE.

Use the following commands to configure the PE to transmit VPN routes to another PE.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *asn-num*	Creates a BGP domain and enters BGP configuration mode.
Ruijie(config-router)# **neighbor** *ip-address* **remote-as** *asn-number*	Configures a BGP session.
Ruiije(config-router)# **neighbor** *ip-address* **update-source** *interface-name*	Sets the interface address used to set up the MP-IBGP session as the source address. The address of the loopback interface is generally used as the source address.
Ruiije(config-router)# **address-family vpnv4**	Enters the VPN address family.
Ruijie(config-router-af)# **neighbor** *ip-address* **activate**	Activates the BGP session to exchange VPN routes.
Ruijie(config-router-af)# **show running-config**	Displays existing configuration information.

# Set up an MP-BGP session with the neighboring PE at 1.1.1.1.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 1.1.1.1 remote-as 1
Ruijie(config-router)# neighbor 1.1.1.1 update-source loopback 0
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 1.1.1.1 activate
```

Configuring Route Exchange Between PEs and CEs

Running BGP Between PEs and CEs to Transmit Route Information

To configure a BGP session with a CE, you need to enter VRF address family configuration mode on the PE and then configure the routing protocol with the CE.

Use the following commands on the PE to configure BGP.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *pe-asn-num*	Creates a BGP domain and enters BGP configuration mode.
Ruijie(config-router)# **address-family ipv4 vrf** *vrf-name*	Configures and enters BGP VRF address family configuration mode.
Ruiije(config-router-af)# **neighbor** *ip-address* **remote-as** *ce-asn-num*	Sets up an EBGP session with a CE.
Ruijie(config-router-af)# **show running-config**	Displays existing configuration information.

# Set up an EBGP session with the neighboring CE at 192.168.10.2.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# address-family ipv4 vrf vrf1
Ruijie(config-router)# neighbor 192.168.10.2 remote-as 2
```

Caution

If no RD is specified for the VRF, you will be reminded that no RD value is configured when you use the **address-family ipv4 vrf vrf-name** command to enter the specified VRF address family. As a result, you cannot enter the address family.

Use the following commands on the CE to configure a PE peer.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *ce-asn-num*	Creates a BGP domain and enters BGP configuration mode.
Ruiije(config-router)# **neighbor** *ip-address pe-asn*	Sets up an EBGP session with a PE.
Ruijie(config-router)# **show running-config**	Displays existing configuration information.

# Set up an EBGP session with the PE at 192.168.10.1.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 2
Ruijie(config-router)# neighbor 192.168.10.1 remote-as 1
```

Configuring OSPF Between PEs and CEs to Transmit Route Information

To run OSPF between a PE and a CE, you must configure an OSPF instance for the VRF on the PE. The VRF then uses the OSPF instance to exchange route information between the PE and the CE. By redistributing BGP routes, OSPF sends the VPN routes received from other PEs to the CE. At the same time, by redistributing OSPF routes, BGP sends the VPN route information that is distributed to the PE by the CE to other PE peers.

Use the following commands on the PE to configure OSPF.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router ospf** *ospf-id* **vrf** *vrf-name*	Creates an OSPF instance and enters OSPF configuration mode.
Ruijie(config-router)# **network** *prefix mask* **area** *area-id*	Configures an OSPF link.
Ruiije(config-router)# **redistribute bgp subnets**	Configures OSPF to redistribute BGP routes.
Ruiije(config-router)# **exit**	Exits OSPF configuration mode.
Ruijie(config)# **router bgp** *asn*	Enables BGP and enters BGP configuration mode.
Ruijie(config-router)# **address-family ipv4 vrf** *vrf-name*	Enters BGP VRF configuration mode.
Ruijie(config-router-af)# **redistribute ospf** *ospf-id*	Redistributes OSPF routes.
Ruijie(config-router-af)# **show running-config**	Displays existing configuration information.

# Run OSPF between a PE and a CE to distribute VPN routes.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10 vrf vrf1
Ruijie(config-router)# network 192.168.10.0 255.255.255.0 area 0
Ruijie(config-router)# redistribute bgp subnets
Ruijie(config-router)# exit
Ruijie(config)# router bgp 1
Ruijie(config-router)# address-family ipv4 vrf vrf1
Ruijie(config-router-af)# redistribute ospf 10
```

Configuring RIP Between PEs and CEs to Transmit Route Information

The PE and CE run RIP. The VRF on the PE can exchange route information between the PE and the CE. RIP redistributes BGP routes and transmits VPN routes from other PEs to the CE. Meanwhile, BGP redistributes RIP routes and transmits VPN routes distributed by the CE to the PE to other PE peers.

Use the following commands on the PE to configure RIP.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router rip**	Creates a RIP instance and enters RIP configuration mode.
Ruiije(config-router)# **address-family ipv4 vrf** *vrf-name*	Enters RIP VRF address family configuration mode.
Ruijie(config-router)# **version 2**	Configures the version of RIP.
Ruiije(config-router-af)# **network** *network-number* [*wildcard*]	Configures RIP on the PE and CE.
Ruiije(config-router-af)# **redistribute bgp**	Configures RIP to redistribute BGP routes.
Ruiije(config-router-af)# **exit**	Exits address family configuration mode.
Ruijie(config)# **router bgp** *asn*	Configures BGP and enters BGP configuration mode.
Ruijie(config-router)# **address-family ipv4 vrf** *vrf-name*	Enters BGP VRF configuration mode.

Command	Function
Ruijie(config-router-af)# **redistribute rip**	Redistributes OSPF routes.
Ruijie(config-router)# **show running-config**	Displays existing configuration information.

# Run RIP between a PE and a CE to distribute VPN routes.

```
Ruijie# configure terminal
Ruijie(config)# router rip
Ruijie(config-router)# address-family ipv4 vrf vrf1
Ruijie(config-router-af)# version 2
Ruijie(config-router-af)# network 192.168.10.0
Ruijie(config-router-af)# redistribute bgp
Ruijie(config-router-af)# exit-address-family
Ruijie(config)# router bgp 1
Ruijie(config-router)# address-family ipv4 vrf vrf1
Ruijie(config-router-af)# redistribute rip
```

Transmitting Route Information Between a PE and a CE Through Static Configurations

In simple network environments, you can generally configure static routes. Use the following commands to configure a static route.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **ip route vrf** vrf-name prefix mask interface-name nexthop	Configures a static route.
Ruijie(config)# **router bgp** *asn*	Enters BGP configuration mode.
Ruijie(config-router)# **address-family ipv4 vrf** *vrf-name*	Enters BGP VRF address family configuration mode.
Ruijie(config-router-af)# **redistribute static**	Redistributes static routes.
Ruijie(config-router)# **show running-config**	Displays existing configuration information.

# Configure a static route on the PE to distribute VPN routes.

```
Ruijie# configure terminal
Ruijie(config)# ip router vrf vrf1 192.168.20.0 255.255.255.0 gigabitEthernet 2/3 192.168.10.2
Ruijie(config)# router bgp 1
Ruijie(config-router)# address-family ipv4 vrf vrf1
Ruijie(config-router-af)# redistribute static
```

Configuring VPN Label Distribution Mode (Optional)

RFC 4364 describes two label distribution modes for L3VPN applications: route-based label distribution and VRF-based label distribution. The advantage of the former is rapid forwarding that allows a device to forward packets to the next hop by searching the ILM table. The disadvantage, however, is the large capacity of the ILM table. The advantage of the latter is the reduced capacity of the ILM table. This is because one label is assigned to each VRF and all routes in the VRF thus share the label. The disadvantage is the lower forwarding efficiency because it requires two times of table searching. The device should first locate the VRF of the packets based on the ILM table and then forward the packets by searching routes in the VRF based on the destination IP address.

An L3VPN adopts VRF-based label distribution mode by default. You can run the **alloc-label** command in VRF configuration mode to change default label distribution mode. You can also choose different distribution modes for different VRFs.

To configure label distribution mode, enter privileged EXEC mode and use the following commands.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **ip vrf** *vrf-name*	Creates a VRF and enters VRF configuration mode.
Ruijie(config-vrf)# alloc-label per-vrf	Assigns one label to all routes in the VRF. When distributing VPN routes, MP-BGP uses the same label for all routes.
Ruijie(config-vrf)# **alloc-label per-route**	Assigns one label to each route in the VRF. When distributing VPNv4 routes, MP-BGP uses a different label for each route.
Ruijie(config-vrf)# **show running-config**	Displays existing configuration information.

Caution

When you change label distribution mode, MP-BGP cancels all routes advertised in the VPN and advertises the routes again.

VRF-based label distribution mode is adopted by default. In this case, a PE first pops out the received packets with labels and then chooses routes to forward the packets based on the IP routing table.

Configuring Import and Export Policies for VPN Routes (Optional)

In most situations, you can define the route-target import attribute in VRF configuration mode to determine the routes to be imported into the VRF and define the route-target export attribute to determine the RTs to be carried in the routes. These configurations are effective for all routes. In certain application scenarios that require accurate policy-based control on the import and export of VPN routes, however, you need to adopt policies.

Enter privileged EXEC mode and use the following commands to configure import and export policies.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **ip vrf** *vrf-name*	Creates a VRF and enters VRF configuration mode.

Ruijie(config-vrf)# **import map** *routemap-name*	Sets the policy to import VPNv4 routes from the remote end to the local VPN routes based on the rules defined in the route map.
Ruijie(config-vrf)# **export map** *routemap-name*	Sets the extended community attribute to export VPNv4 routes from the local end to the remote end based on the rules defined in the route map.
Ruijie(config-vrf)# **show running-config**	Displays existing configuration information.

Caution

The rules defined by using the **import map** command take effect after the import extended community attribute defined in the VRF. That is, VPN routes received from the remote end can be further filtered by using the rules defined with the **import map** command only after the routes match the extended community attribute defined by the **route-target import** command in the VRF.

# Configure a route map for importing VPN routes with the RT of 100:1 to vrf1.

```
Ruijie# configure terminal
Ruijie(config)# ip extcommunity-list 1 permit rt 100: 1
Ruijie(config)# route-map IN-RT-FILTER
Ruijie(config-route-map)# match extcommunity 1
Ruijie(config-route-map)# exit
Ruijie(config)# ip vrf vrf1
Ruijie(config-vrf)# rd 100: 2
Ruijie(config-vrf)# route-target export 100: 30
Ruijie(config-vrf)# import map IN-RT-FILTER
Ruijie(config-route-map)# end
Ruijie# show ip vrf detail vrf1
VRF vrf1: default RD : 100: 2
Interfaces:
Vlan 1 //Interface bound to the VRF
Export VPN route-target communities: //Export extended community attribute list
RT : 100: 30
No import VPN route-target community //Import extended community attribute list (not
configured)
import-map: IN-RT-FILTER//Import policy
```

Configuring a Static L3VPN FTN and ILM (Optional)

In most situations, MP-BGP assigns labels to private routes and a public LSP is generated by running LDP on a public network. You can also configure a static LSP to assign labels to private routes and set up private LSPs.

To configure an FTN for the L3VPN on the PE, enter privileged EXEC mode and use the following commands.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.

Ruijie(config)# **mpls static l3vpn-ftn** *vrf-name ip-address/mask* **out-label** *out-label* **remote-pe** *ip-address*	Configures a static private FTN that specifies the egress of the FEC as another PE. In this case, you must specify the private label and the egress PE. The address of the egress PE is then used to configure the public LSP.
Ruijie(config)# **mpls static l3vpn-ftn** *vrf-name fec-prefix/fec-mask* **local-forward nexthop** *interface-name nexthop-ip*	Configures a static private FTN that specifies the egress of the FEC as the local PE. In this case, you must specify the outgoing interface on the local PE and the next-hop address (the outgoing interface and the next hop are generally in another VRF). You can use this command when the local PE has several VRFs that belong to the same VPN.
Ruijie# **show running-config**	Displays existing configuration information.

To configure an ILM for the L3VPN on the PE, enter privileged EXEC mode and use the following commands.

Command	**Function**
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **mpls static ilm in-label** *in-label* **forward-action pop-l3vpn-nexthop** *vrf-name* **nexthop** *interface-name nexthop-ip-address* **fec** *ip-address/mask*	Configures an ILM entry for the L3VPN on the PE. You need to specify the incoming label, the outgoing interface, and the next-hop address.
Ruijie# **show running-config**	Displays existing configuration information.

Caution

The configured static private FTN and ILM take effect only after the corresponding public LSP is set up. To set up the public LSP, see the "Configuring an MPLS Network" section. You can set up a public LSP through LDP or static configurations.

Configuring an Inter-AS VPN

On an actual network, different sites of VPN users may be located on different ASs and mutual communication is required between these sites. In this case, the VPN routes should be exchanged between different ASs. This technology is called the inter-AS VPN.

RFC 4364 introduces three inter-AS VPN schemes:

- OptionA: VRF-to-VRF mode
- OptionB: single-hop MP-EBGP mode
- OptionC: multi-hop MP-EBGP mode

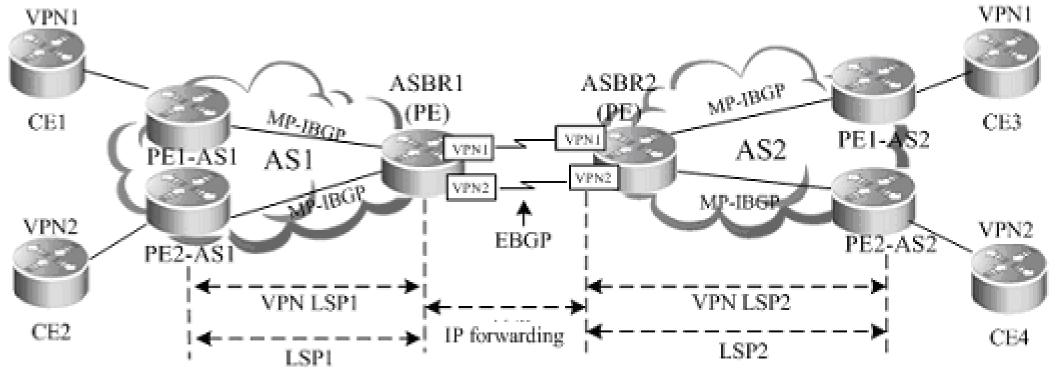
OptionA: VRF-to-VRF Mode

Also referred to as VRF back-to-back, VRF-to-VRF mode is easy to implement. The autonomous system boundary router (ASBR) of an AS sets up a VRF for each inter-AS VPN to bind an interface to the VRF. The VRFs on ASBRs then exchange VPN routes through the interface.

The purpose of creating a VRF and binding an interface to it is as follows:

- To receive VPN routes from the local AS
- To set up an EBGP connection between the VRF and the VRF of another AS to exchange IPv4 routes

Figure 8 VRF-to-VRF inter-AS VPN



As shown in the preceding figure, the VRFs between the ASBRs set up common EBGP sessions to exchange IPv4 routes and the ASBRs and PEs set up MP-IBGP sessions to exchange VPN routes. For the VRF on an ASBR, the other VRF, with which the EBGP session is set up, is equivalent to a CE. This configuration scheme is similar to the common intra-domain configuration scheme. The ASBRs and PEs set up MP-IBGP sessions to exchange VPN routes. The VRFs of ASBRs set up EBGP sessions in BGP VRF address family configuration mode to exchange IPv4 routes.

- Characteristics and limitations

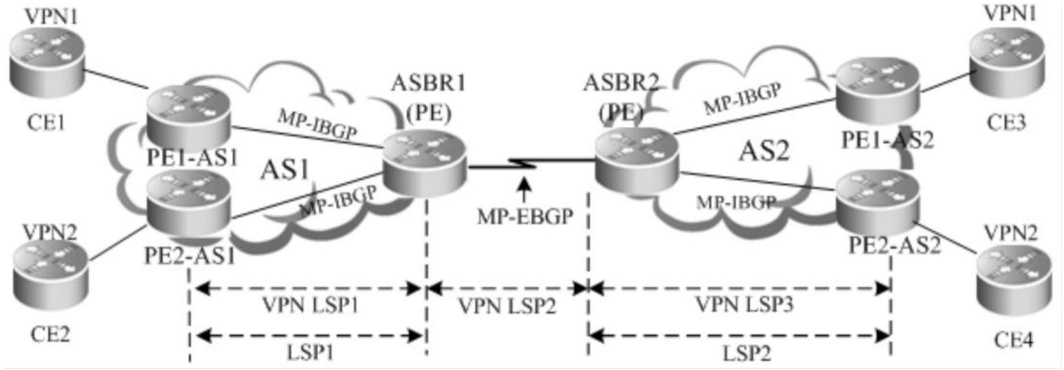
VRF-to-VRF mode is easy to implement by directly using MP-IBGP. The service deployment is also simple. This scheme, however, requires an interface (generally a logical sub-interface) for each inter-AS VPN on an ASBR. The number of bound interfaces at least should be equal to the number of inter-AS VPNs. You should configure an interface for each VPN on the ASBR, complicating network expansion. In addition, the separate creation of sub-interfaces for each VPN imposes high requirements on ASBRs. As a result, this scheme is generally applicable to networks with a small number of inter-AS VPNs.

The configuration of OptionA is similar to that of a BGP/MPLS IP VPN and is not described here.

OptionB: Single-Hop MP-EBGP Mode

In the OptionA scheme, you need to configure a VRF for each VPN on an ASBR and bind an interface to the VRF. This is because VPN routes cannot be directly transmitted between EBGP peers and can only be carried through MP-IBGP. If the VPN routes can be directly transmitted between EBGP peers, you are not required to configure VRFs on the ASBR. This is clearly a better implementation mode. In this case, the OptionB scheme extends MP-IBGP and allows the direct distribution of VPN routes between ASBRs. This is called single-hop EBGP, as shown in the following topology.

Figure 9 OptionB inter-AS VPN



- Characteristics and limitations

The advantage of this MP-EBGP scheme is that you are not required to configure a sub-interface for each site of VPN users on an ASBR. You are also not required to set up an inter-AS LSP. The VPN routes are directly transmitted between single-hop MP-EBGP neighbors. The VPN route information, however, is maintained and spread by the ASBRs between ASs. If a large number of VPN routes exist, the ASBRs are faced with heavy pressure. Because the ASBRs also generally assume tasks of forwarding IP packets on the public network, high requirements are imposed on these devices. In addition, the ASBRs cancel the RT filtering function for received VPN routes. The VPN routes on PEs may be spread to the ASBRs in another AS. This may lead to the leakage of VPN routes. As a result, the SPs, who exchange VPN routes, must reach trust agreements on route exchange. The ASBRs should trust each other and implement corresponding route filtering policies. The OptionB scheme is applicable to networks with lots of inter-AS VPN services.

OptionB has two schemes:

- The ASBR does not change the next hop of a VPN route.
- The ASBR changes the next hop of a VPN route.

The following describes the configuration procedures of the two schemes.

Scheme 1: Next Hop Unchanged

When an ASBR receives VPN routes sent from the ASBR in another AS and sends the routes to the MP-IBGP neighbors in the local AS, the next hop of the routes is not changed. This mode is called the "OptionB Next Hop Unchanged Scheme". In this mode, the PEs and ASBRs in an AS still set up MP-IBGP sessions to exchange VPN routes and the two ASBRs set up MP-EBGP sessions to directly exchange VPN routes. When sending routes to an MP-IBGP neighbor, the ASBR does not change the next hop of the VPN routes received from the MP-EBGP neighbor. This requires that the PE in the AS should have a route to the next hop address (that is, the ASBR in another AS). For this purpose, you can configure the local ASBR to redistribute routes destined for the other ASBR to the IGP protocol in the local AS. In this manner, the address of the ASBR in another AS becomes reachable and you can set up an LSP through LDP.

The configuration procedure is as follows:

11) Configuring route exchange between PEs and CEs

12) Configuring an IGP and MPLS signaling protocol in an AS

13) Configuring an ASBR to cancel the default RT filtering function

14) Configuring PEs and ASBRs in the same AS to exchange VPN route information

15) Setting up an MP-EBGP session between ASBRs

16) Configuring route map rules to filter VPN routers (optional)

17) Configuring an IGP to redistribute ASBR routes of another AS

- Configuring route exchange between PEs and CEs

This procedure is similar to configuring route exchange between PEs and CEs and is not described here.

- Configuring an IGP and MPLS signaling protocol in an AS

This procedure is similar to configuring an MPLS network and is not described here.

- Configuring an ASBR to cancel the default RT filtering function

By default, a PE rejects a VPN route sent by another PE (or ASBR), if the route is not imported by any VRF on the PE. Therefore, you should disable the default filtering on an ASBR so that the ASBR can receive all VPN routes from others PEs (or ASBRs), no matter whether these routes are imported into the local VRF or not.

Enter privileged EXEC mode and use the following commands.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *asn-number*	Enables BGP and enters BGP configuration mode.
Ruijie(config-router)# **no bgp default route-target filter**	Disables RT filtering.
Ruijie(config-router)# **show running-config**	Displays existing configuration information.

# Disable RT filtering.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 2
Ruijie(config-router)# no bgp default route-target filter
```

- Configuring PEs and ASBRs in the same AS to exchange VPN route information

This procedure is similar to configuring PEs to transmit VPN routes and is not described here.

- Setting up an MP-EBGP session between ASBRs

Set up directly-connected single-hop MP-EBGP sessions between inter-AS ASBRs to distribute VPN routes.

Enter privileged EXEC mode and use the following commands.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *asn-number*	Enables BGP and enters BGP configuration mode.
Ruijie(config-router)# **neighbor** *asbr-address* **remote-as** *asbr-asn-number*	Configures an ASBR EBGP session.
Ruijie(config-router)# **address-family vpnv4**	Enters the BGP VPN address family.
Ruijie(config-router-af)# **neighbor** *asbr-address* **activate**	Enables the VPN route exchange with the peer.
Ruijie(config-router-af)# **show running-config**	Displays existing configuration information.

# Configure an EBGP neighbor at 20.20.20.2 and activate the VPN address family.

```
Ruijie# configure terminal
```

```
Ruijie(config)# router bgp 2
Ruijie(config-router)# neighbor 20.20.20.2 remote-as 1
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 20.20.20.2 activate
```

⚠ Caution

You must run the **label-switching** command on the interface that connects two ASBRs to enable MPLS on the interface so that the links between the ASBRs can forward MPLS packets.

☑ On a router, use the **ip ref** command on the interface to enable fast forwarding to improve forwarding performance.

⚠ Caution

If the ASBRs do not use directly connected addresses to set up an MP-EBGP session but use the loopback address with a 32-bit mask as the source address to set up an MP-EBGP session, you must use the **neighbor ebgp-multihop** command to enable multi-hop EBGP. At the same time, you must configure static routes on the ASBR to the loopback address on the peer, enable LDP or configure a static FTN (with an outgoing label as 3, indicating that the ASBR is the second to last hop).

- Configuring route map rules to filter VPN routes (optional)

In view of the AS security in actual applications, you can generally configure policies on ASBRs to send or receive only certain VPN routers. You can realize this purpose by filtering the RT extended community attributes of VPN routes. In addition, all VPN routes are saved because the default RT filtering function is disabled on the ASBR. In this case, you can configure VPN routing policies to receive only inter-AS VPN routes sent from the local AS, lessening the capacity pressure of the ASBR.

To configure a filtering policy, enter privileged EXEC mode and use the following commands.

Command	**Function**
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **ip extcommunity-list standard** *extcommunity-name* | *extcommunity-number* {**permit|deny**} **rt** *rt-value*	Creates a rule for the extended community attribute list.
Ruijie(config)# **show ip extcommunity-list** [*list-number*|*list-name*]	Verifies the configured rule for the extended community attribute list.
Ruijie(config)# **route-map** *route-map-name* **permit** [*number*]	Creates a route map rule and enters route map configuration mode.
Ruijie(config-route-map)# **match extcommunity** *extcommunity-name*|*extcommunity-number*	Sets the RT matching rule for a route map.
Ruijie(config-route-map)# **show route-map** route-map-name	Displays the route map rule.
Ruijie(config-route-map)# **exit**	Exits route map configuration mode.
Ruijie(config)# **router bgp** *as-num*	Enables BGP and enters BGP configuration mode.
Ruijie(config-router)# **address-family vpnv4**	Enters the VPN address family.

Command	Function
Ruijie(config-router-af)# **neighbor** *peer-address* **route-map** *route-map-name* **in**	Filters the VPN routes received from the ASBR in another AS.
Ruijie(config-router-af)# **neighbor** *peer-address* **route-map** *route-map-name* **out**	Filters the VPN routes sent to the ASBR in another AS.
Ruijie(config-router-af)# **show running-config**	Displays existing configuration information.

# Configure an ASBR to receive VPN routes with an RT value of 100:1 from the MP-IBGP peer at 1.1.1.1.

```
Ruijie# configure terminal
Ruijie(config)# ip extcommunity-list standard RT permit rt 100:1
Ruijie(config)# show ip extcommuniy-list RT
Named extended community standard list RT
permit rt 100:1
Ruijie(config)# route-map RT-IN permit
Ruijie(config-route-map)# match extcommunity RT
Ruijie(config-route-map)# show route-map RT-IN
route-map map, permit, sequence 10
  Match clauses:

- Configuring an IGP to redistribute ASBR routes of another AS

Because the ASBR does not change the next hop of VPN routes sent to the IBGP peer, the next hop address of VPN routes learned by the PEs in the local AS is the ASBR address in another AS. Therefore, you must configure the PEs to learn the route to the next hop address. For the single-hop directly-connected MP-EBGP session where BGP is enabled to carry labels (through IPv4 routes or VPN routes), MP-BGP supports the automatic generation of a host route with a 32-bit mask and FTN entry (with the outgoing label 3) on the ASBR. In this manner, the tunnel egress is not terminated on the local ASBR. Therefore, as long as the ASBR redistributes the host route to the IGP in the local AS, the PEs can learn routes to the ASBR in the other AS.

Enter privileged EXEC mode and use the following commands.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router** *igp*	Enables an IGP that can be OSPF, RIP, or IS-IS.
Ruijie(config-router)# **redistribute connected subnets**	Redistributes directly connected subnet routes.

Ruijie(config-router)# **show running-config**	Displays existing configuration information.

# Configure OSPF on an ASBR to redistribute the directly connected subnet routes.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 1
Ruijie(config-router)# redistribute connected subnets
```

Scheme 2: Next Hop Changed

When an ASBR receives VPN routes sent from the ASBR in another AS and sends the routes to the PEs in the local AS, the next hop of the routes is changed. This mode is called the "OptionB Next Hop Changed Scheme". In this mode, the PEs and ASBRs in the same AS can set up MP-IBGP sessions to exchange VPN routes. Two ASBRs can set up MP-EBGP sessions to exchange VPN routes. Upon receipt of a VPN route from another ASBR neighbor, an ASBR changes the next hop to its own address when advertising the route to the MP-IBGP peer in the AS.

The configuration procedure is as follows:

18) Configuring route exchange between PEs and CEs
19) Configuring an IGP and MPLS signaling protocol in an AS
20) Configuring an ASBR to cancel the default RT filtering function
21) Setting up an MP-IBGP session between an ASBR and PE and changing the next hop address to its own address
22) Setting up an MP-EBGP session between ASBRs
23) Configuring route map rules to filter VPN routes (optional)

- Configuring route exchange between PEs and CEs

This procedure is similar to configuring route exchange between PEs and CEs and is not described here.

- Configuring an IGP and MPLS signaling protocol in an AS

This procedure is similar to configuring an MPLS network and is not described here.

- Configuring an ASBR to cancel the default RT filtering function

This procedure is similar to configuring an ASBR to cancel the default RT filtering function in Scheme 1 and is not described here.

- Setting up an MP-IBGP session between an ASBR and PE and changing the next hop address to its own address

By default, an ASBR does not change the next hop of the VPN route received from an MP-EBGP peer when the ASBR sends the route to the MP-IBGP peer. You can configure the ASBR to forcibly change the next hop of the VPN route to the ASBR address in the local AS. In this manner, the PEs in the local AS are not required to learn the address of the peer ASBR. This is the major difference with Scheme 1 (Next Hop Unchanged Scheme).

Enter privileged EXEC mode and use the following commands.

Command	**Function**
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *asn-num*	Enables BGP and enters BGP configuration mode.

Ruijie(config-router)# **neighbor** *pe-address* **remote-as** *asn-num*	Sets up an IBGP session with a PE.
Ruijie(config-router)# **neighbor** *pe-address* **update-source** *interface-name*	Specifies the local loopback interface as the source address to set up an IBGP session.
Ruijie(config-router)#**address-family vpnv4**	Enters BGP VPN address family configuration mode.
Ruijie(config-router-af)# **neighbor** *pe-address* **activate**	Enables the VPN route exchange with the peer.
Ruijie(config-router-af)# **neighbor** *pe-address* **next-hop-self**	Sets the ASBR to change the next hop to its own address when sending VPN routes to the IBGP neighbor.
Ruijie(config-router-af)# **show running-config**	Displays existing configuration information.

# Set up an MP-IBGP session, activate the VPN address family, and change the next hop address to the ASBR address.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 1.1.1.1 remote-as 1
Ruijie(config-router)# neighbor 1.1.1.1 update-source loopback 0
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 1.1.1.1 activate
Ruijie(config-router-af)# neighbor 1.1.1.1 next-hop-self
Ruijie(config-router-af)# end
```

- Setting up an MP-EBGP session between ASBRs

This procedure is similar to setting up an MP-EBGP session between ASBRs in Scheme 1 and is not described here.

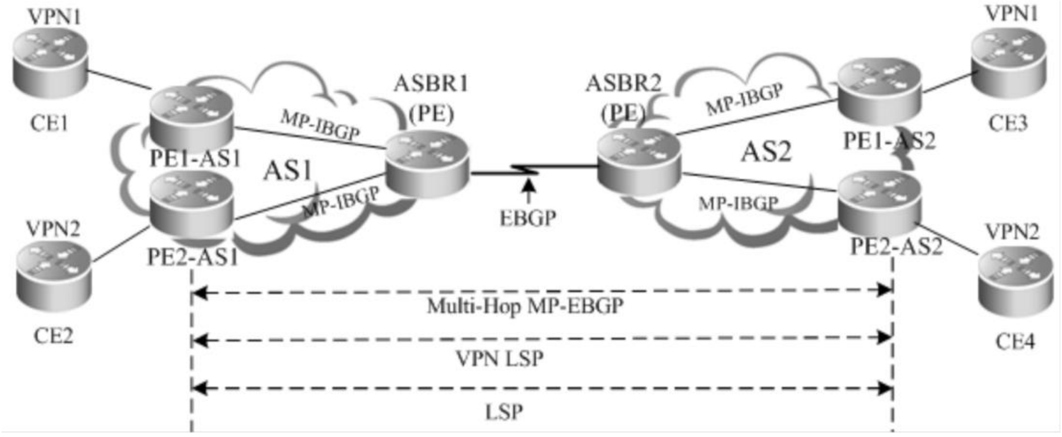
- Configuring route map rules to filter VPN routes (optional)

This procedure is similar to configuring route map rules to filter VPN routers (optional) in Scheme 1 and is not described here.

OptionC: Multi-Hop MP-EBGP Mode

Both OptionA and OptionB can meet the networking requirements of inter-AS VPNs. In these two schemes, ASBRs are required to maintain and advertise VPN routes. If a large number of inter-AS VPN routes should be advertised in each AS, the ASBRs may become the bottleneck of further network expansion. To solve this problem, a third scheme is developed, that is, the multi-hop MP-EBGP. In multi-hop MP-EBGP mode, the PEs in different ASs set up multi-hop MP-EBGP sessions to directly exchange VPN routes. As a result, the ASBRs are not required to maintain or advertise VPN routes.

Figure 10 Multi-hop MP-EBGP



- Characteristics and limitations

In multi-hop MP-EBGP mode, only PEs rather than ASBRs are required to store VPN information. This incurs complex configurations. This scheme is applicable to networks to be deployed with inter-AS VPN services on a large scale.

In terms of implementation principle, OptionC is further classified into two modes:

24) Enabling label distribution for IPv4 routes only between EBGP neighbors.

25) Enabling label distribution for IPv4 routes between EBGP and IBGP neighbors.

To facilitate expansion in OptionC, each AS is generally deployed with a route reflector (RR). The RRs of two ASs set up multi-hop MP-EBGP sessions to exchange VPN routes. Judged from deployment, OptionC can be referred to as the scheme of "Setting Up a Multi-Hop MP-EBGP Session Between RRs".

The following describes the configuration procedures of these schemes.

Scheme 1: Enabling Label Distribution for IPv4 Routes Only Between EBGP Neighbors

In this scheme, the IGP (such as OSPF or RIP) that runs on an ASBR is required to redistribute BGP routes so that each device in the AS can have routes to the PE in another AS. In the AS, you can use LDP to assign labels to the routes to the PE in another AS and set up an LSP. On the directly connected ASBRs of the two ASs, enable label distribution for IPv4 routes. In this manner, BGP serves as the MPLS signaling protocol to assign labels to the routes to the PE in another AS and set up an inter-AS LSP.

The configuration procedure is as follows:

26) Configuring route exchange between PEs and CEs in each AS

27) Configuring an IGP and MPLS signaling protocol in an AS

28) Setting up an EBGP session between ASBRs to distribute labels for IPv4 routes

29) Configuring an ASBR to redistribute inter-AS PE routes learned from EBGP to the IGP

30) Configuring a multi-hop MP-EBGP session

- Configuring route exchange between PEs and CEs

This procedure is similar to configuring route exchange between PEs and CEs and is not described here.

- Configuring an IGP and MPLS signaling protocol in an AS

This procedure is similar to configuring an MPLS network and is not described here.

- Setting up an EBGP session between ASBRs to enable label distribution for IPv4 routes

Set up an EBGP session between inter-AS ASBRs and enable label distribution of IPv4 routes. To import PE routes to BGP, you can use the **network** command in BGP IPv4 address family configuration mode or run commands to redistribute IGP routes. In view of the AS security in actual applications, you are generally required to configure IPv4 route distribution policies on ASBRs. By configuring route map rules, you can control the routes sent to neighbors and specify whether the routes carry labels. Similar control is available for receiving routes.

Enter privileged EXEC mode and use the following commands.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *asn-num*	Enables BGP and enters BGP configuration mode.
Ruijie(config-router)# **neighbor** *asbr-address* **remote-as** *asbr-asn-num*	Sets up an EBGP session with an ASBR.
Ruijie(config-router)#**address-family ipv4**	Enters BGP IPv4 address family configuration mode.
Ruijie(config-router-af)# **neighbor** asbr-address **send-label**	Configures the device to exchange labeled IPv4 routes with the ASBR peer in another AS.
Ruijie(config-router-af)# **network** *pe-address* **mask** *mask*	(Optional) Configures PE addresses to be imported into the BGP routing table in the local AS, that is, host routes of each PE in the AS.
Ruijie(config-router-af)# **neighbor** *asbr-address* **route-map** *routemap-name* **out**	(Optional) Configures a route distribution policy to control the routes sent to neighbors and specify whether the routes can carry labels, by defining a route map rule.
Ruijie(config-router-af)# **neighbor** *asbr-address* **route-map** *routemap-name* **in**	(Optional) Configures a route distribution policy to receive only labeled routes by defining a route map rule.
Ruijie(config-router-af)# **show running-config**	Displays existing configuration information.

⚠ Caution

You must run the **label-switching** command on the interface that connects two ASBRs to enable MPLS on the interface so that the links between the ASBRs can forward MPLS packets.

☑ On a router, use the **ip ref** command on the interface to enable fast forwarding to improve forwarding performance.

⚠ Caution

If the ASBRs do not use directly connected addresses to set up an MP-EBGP session but use the loopback address with a 32-bit mask as the source address to set up an MP-EBGP session, you must use the **neighbor ebgp-multihop** command to enable multi-hop EBGP. At the same time, you must configure static routes on the ASBR to the loopback address on the peer, enable LDP or configure a static FTN (with an outgoing label as 3, indicating that the ASBR is the second to last hop).

# Set up an EBGP session between ASBRs, enable label distribution for IPv4 routes, and run the **network** command to import PE routes to BGP.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 20.20.20.2 remote-as 2
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 20.20.20.2 send-label
Ruijie(config-router-af)# network 10.10.10.10 mask 255.255.255.255
Ruijie(config-router-af)# end
```

In actual applications, an ASBR is generally required to distribute labels for PE routes for only inter-AS VPN services. For this purpose, you can use the route map rules defined by the **set mpls-label** command.

The **set mpls-label** command sets labels for routes. You can create a route map rule to distribute only inter-AS PE routes to the peer ASBR and set labels for the routes. Set route map rules and then run the **neighbor** *peer-address* **route-map** *rmap_name* **out** command in BGP IPv4 address family configuration mode to associate the rules with the route map.

The following example creates a route map to assign an MPLS label to the route with a prefix as 1.1.1.1/32, to assign a common IPv4 route without a label to the route with a prefix as 1.1.1.2/32, and not to send neighbors routes that fail to match acl1 and acl2.

```
Router(config)# ip access-list standard acl1
Router(config-std-nacl)# permit host 1.1.1.1
Router(config-std-nacl)# exit
Router(config)# ip access-list standard acl2
Router(config-std-nacl)# permit host 1.1.1.2
Router(config-std-nacl)# exit
Router(config)# route-map out-as permit 10
Router(config-route-map)# match ip address acl1
Router(config-route-map)# set mpls-label
Router(config-std-nacl)# exit
Router(config)# route-map out-as permit 20
Router(config-route-map)# match ip address acl2
Router(config)# router bgp 100
Router(config-router)# neighbor 30.30.30.2 remote-as 100
Router(config-router)# neighbor 30.30.30.2 route-map out-as out
```

Similarly, to receive only labeled IPv4 routes, you can run the **match mpls-label** command in route map mode. Set route map rules and then run the **neighbor** *peer-address* **route-map** *rmap_name* **in** command to associate the rules with the route map.

The following example creates a route map to receive labeled IPv4 routes from only the BGP peer at 30.30.30.2 and reject other routes.

```
Router(config)# route-map match-mpls
Router(config-route-map)# match mpls-label
Router(config)# router bgp 100
Router(config-router)# neighbor 30.30.30.2 remote-as 100
Router(config-router)# neighbor 30.30.30.2 route-map match-mpls in
```

- Configuring an ASBR to redistribute inter-AS PE routes learned from EBGP to the IGP

When an ASBR learns a route to the PE in another AS from the peer ASBR, the ASBR should advertise the route to other PEs in the local AS. The ASBR should also set up an LSP to the PE in another AS. In this manner, the ASBR can redistribute routes learned from EBGP to the IGP and at the same time, enable LDP to distribute labels for BGP routes and then set up an LSP to the PE in another AS.

Enter privileged EXEC mode and use the following commands.

Command	**Function**
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router** *igp*	Enters IGP configuration mode.
Ruijie(config-router)# **redistribute bgp subnets [route-map** *routemap-name*]	Redistributes BGP routes. Route filtering by using route map rules is optional.
Ruijie(config-router)# **exit**	Exits IGP configuration mode.
Ruijie(config)# **mpls router ldp**	Enters LDP configuration mode.
Ruijie(config-mpls-router)# **ldp router-id interface loopback** *0* force	Configures the LDP router ID. The loopback address is generally used as the router ID.
Ruijie(config-mpls-router)# **advertise-labels for bgp-routes [acl** *acl-name*]	Distributes labels for BGP routes. Filtering based on ACL rules is optional.
Ruijie(config-mpls-router)# **show running-config**	Displays existing configuration information.

Caution

By default, LDP distributes labels for only IGP routes and does not distribute labels for BGP routes. To distribute labels for BGP routes, you can run the **advertise-labels for bgp-routes** command.

# Configure an IGP and MPLS signaling protocol in an AS.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 1
Ruijie(config-router)# redistribute bgp subnets
Ruijie(config-router)# exit
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# advertise-labels for bgp-routes
Ruijie(config-mpls-router)# end
```

When an IGP redistributes the learned BGP routes in the OptionC scheme, you can run the **redistribute bgp subnets route-map** *routemap-name* command in IGP configuration mode to control the BGP routes to be redistributed to the IGP. In LDP configuration mode, you can run the **advertise-labels for bgp-routes acl** *acl-name* command to control the labels distributed for BGP routes.

# Configure ACL rules and route map routes so that:

- The IGP redistributes only routes 1.1.1.1 and 2.2.2.2.
- The LDP assigns labels to only routes 1.1.1.1 and 2.2.2.2.

The configuration procedure is as follows:

```
Router(config)# ip access-list extended 101
Router(config-ext-nacl)# permit ip host 1.1.1.1 any
Router(config-ext-nacl)# permit ip host 2.2.2.2 any
Router(config-ext-nacl)# exit
Router(config)# route-map pe-routes
Router(config-route-map)# match ip address 101
Router(config-route-map)# exit
Router(config)# router ospf 1
Router(config-router)# redistribute bgp subnets route-map pe-routes
Router(config-route-map)# exit
Router(config)# mpls router ldp
Router(config-mpls-router)# advertise-labels for bgp-routes acl 101
```

■ Configuring a multi-hop MP-EBGP session

In the earlier steps, the inter-AS LSP is already set up. At this time, you can directly set up a multi-hop MP-EBGP session on the PE to be deployed with inter-AS VPN services with the PE in another AS. The session can then exchange VPN routes.

To configure a multi-hop MP-EBGP session, enter privileged EXEC mode and use the following commands.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *asn-num*	Enables BGP and enters BGP configuration mode.
Ruijie(config-router)# **neighbor** *ebgp-peer-address* **remote-as** *ebgp-asn-num*	Sets up a multi-hop EBGP session with the PE in another AS.
Ruijie(config-router)# **neighbor** *ebgp-peer-address* **update-source** *interface-name*	Configures the device to use the loopback address to set up a neighbor relation with the EBGP peer.
Ruijie(config-router)# **neighbor** *ebgp-peer-address* **ebgp-multihop**	Configures multi-hop attributes.
Ruijie(config-router)#**address-family vpnv4**	Enters BGP VPN address family configuration mode.
Ruijie(config-router-af)# **neighbor** *ebgp-peer-address* **activate**	Enables the VPN route exchange with the peer.
Ruijie(config-router-af)# **exit**	Exits the BGP VPN address family.
Ruijie(config-router)# **address-family ipv4**	Enters BGP IPv4 address family configuration mode.
Ruijie(config-router-af)# **no neighbor** *ebgp-peer-address* **activate**	Disables the IPv4 route exchange.
Ruijie(config-router)# **show running-config**	Displays existing configuration information.

Caution

The exchange of IPv4 routes is not required in a multi-hop MP-EBGP session. At least the routes of the two addresses used to set up the BGP session should be avoided. Otherwise, a PE has two routes to the PE in another AS. One route is advertised by the ASBR in the local AS and the other is advertised by the multi-hop EBGP session. According to the BGP specification, the EBGP route has a higher priority over the IBGP route by default. As a result, BGP chooses the route advertised by the multi-hop BGP, resulting in continuous flapping of routes on the PE to the PE in another AS. The VPN routes are thus not reachable.

# Set up a multi-hop EBGP session.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 1.1.1.1 remote-as 2
Ruijie(config-router)# neighbor 1.1.1.1 update-source loopback 0
Ruijie(config-router)# neighbor 1.1.1.1 ebgp-multihop
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 1.1.1.1 activate
Ruijie(config-router-af)# exit
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# no neighbor 1.1.1.1 activate
Ruijie(config-router-af)# end
```

Scheme 2: Enabling Label Distribution for IPv4 Routes Between EBGP and IBGP Neighbors

In Scheme 1 (Enabling Label Distribution for IPv4 Routes Only Between EBGP Neighbors), the IGP and LDP in one AS are required to maintain the PE routes from another AS. That is, inter-AS PE routes should be advertised to each device in the AS. In view of the AS security in actual applications, the PE routes of another AS are generally not advertised to each device in the local AS. Instead, these routes should be owned by the BGP protocol so that the routes can be transparent to the IGP and LDP in the local AS. You can enable label distribution for IPv4 routes between EBGP and IBGP neighbors.

This scheme differs from Scheme 1 in that the IGP on an ASBR is not required to redistribute BGP routes and that the LDP is not required to assign labels to BGP routes, though the LDP is still responsible for the setup of an LSP in the local AS. The setup of an inter-AS LSP, however, requires label distribution for IPv4 routes between both IBGP and EBGP neighbors. The PEs are also required to push three consecutive layers of labels.

The configuration procedure is as follows:

31) Configuring route exchange between PEs and CEs in each AS

32) Configuring an IGP and MPLS signaling protocol in an AS

33) Setting up an IBGP session between a PE and an ASBR to distribute labels for IPv4 routes

34) Setting up an EBGP session between ASBRs to distribute labels for IPv4 routes

35) Configuring a multi-hop MP-EBGP session

■ Configuring route exchange between PEs and CEs

This procedure is similar to configuring route exchange between PEs and CEs and is not described here.

■ Configuring an IGP and MPLS signaling protocol in an AS

This procedure is similar to configuring an MPLS network and is not described here.

■ Setting up an IBGP session between a PE and an ASBR to distribute labels for IPv4 routes

This scheme differs from Scheme 1 mainly in this configuration procedure. In this scheme, the PE routes that are learned by EBGP from another AS are not redistributed to the IGP in the local AS. Instead, the IBGP session between an ASBR and a PE is used to transmit the PE routes of another AS and BGP is used to assign labels to the PE routes.

Enter privileged EXEC mode and use the following commands.

Command	**Function**
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *asn-number*	Enables BGP and enters BGP configuration mode.
Ruijie(config-router)# **neighbor** *peer-address* **remote-as** *asn-number*	Sets up an IBGP session with an ASBR (PE).
Ruijie(config-router)# **neighbor** *peer-address* **update-source** *interface-name*	Configures the device to use the loopback address as the source address to set up the BGP session with an ASBR (PE) peer.
Ruijie(config-router)# **address-family ipv4**	Enters the IPv4 address family.
Ruijie(config-router-af)# **neighbor** *peer-address* **send-label**	Configures the device to exchange labeled IPv4 routes with an ASBR (PE) peer.
Ruijie(config-router-af)# **show running-config**	Displays existing configuration information.

Caution

Before you enable label distribution for IPv4 routes for an IBGP session with an IBGP peer, run the **neighbor update-source** command to specify the source address of the IBGP session. This source address must be the address of the loopback interface; otherwise, the inter-AS LSP cannot be set up.

# Configure a PE to set up an MP-IBGP session with the ASBR at 10.10.10.2.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 10.10.10.2 remote-as 1
Ruijie(config-router)# neighbor 10.10.10.2  update-source loopback 0
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 10.10.10.2 activate
Ruijie(config-router-af)# neighbor 10.10.10.2 send-label
Ruijie(config-router-af)# exit
```

# Configure an ASBR to set up an MP-IBGP session with the PE at 10.10.10.1 in the local AS.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 10.10.10.1 remote-as 1
Ruijie(config-router)# neighbor 10.10.10.1 update-source loopback 0
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 10.10.10.1 send-label
Ruijie(config-router-af)# end
```

- Setting up an EBGP session between ASBRs to enable label distribution for IPv4 routes

This procedure is similar to the corresponding procedure in Scheme 1 and is not described here.

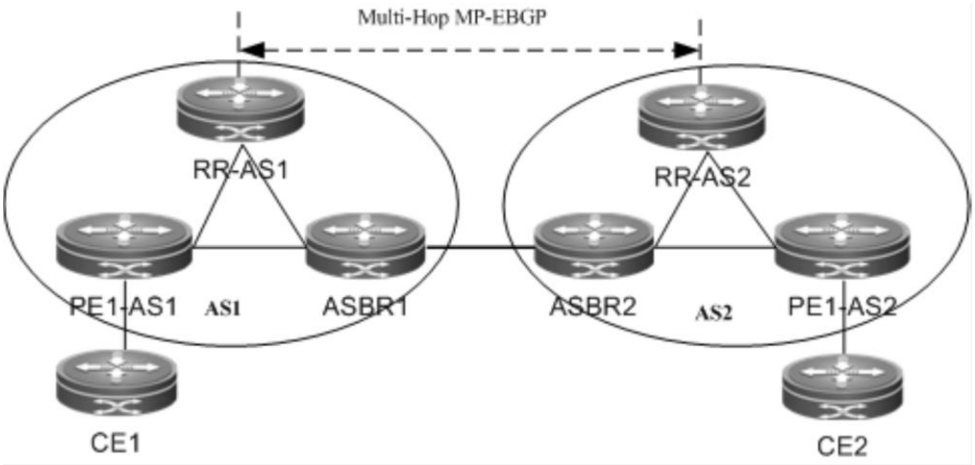
- Configuring a multi-hop MP-EBGP session

This procedure is similar to the corresponding procedure in Scheme 1 and is not described here.

Scheme 3: Setting Up a Multi-Hop MP-EBGP Session Between RRs

In the traditional OptionC scheme, the inter-AS VPN sites should be connected in full mesh mode. The addition of a single VPN site requires the setup of MP-MBGP connections with the PEs in other ASs, hindering the expansion of VPN sites. In this case, you can deploy an RR in each AS to solve this problem. Set up multi-hop MP-EBGP sessions between the RRs to exchange VPN routes.

Figure 11 Setting up a multi-hop MP-EBGP session between RRs in OptionC mode



As shown in the preceding figure, the RRs in the two ASs set up a multi-hop MP-EBGP session to exchange VPN routes. The configuration procedure is as follows:

36) Configuring route exchange between PEs and CEs in each AS

37) Configuring an IGP and MPLS signaling protocol in an AS

38) Setting up an MP-IBGP session between the RR and the PE and enabling label distribution for IPv4 routes

39) Setting up an IBGP session between the RR and the ASBR and enabling label distribution for IPv4 routes

40) Setting up an EBGP session between ASBRs to distribute labels for IPv4 routes

41) Configuring a multi-hop MP-EBGP session

- Configuring route exchange between PEs and CEs

This procedure is similar to configuring route exchange between PEs and CEs and is not described here.

- Configuring an IGP and MPLS signaling protocol in an AS

This procedure is similar to configuring an MPLS network and is not described here.

- Setting up an MP-IBGP session between the RR and the PE and enabling label distribution for IPv4 routes

Configure a PE to set up an MP-IBGP session with the RR to transmit VPN routes. At the same time, enable label distribution for IPv4 routes for the session.

Enter privileged EXEC mode and use the following commands.

Command	**Function**
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *asn-number*	Enables BGP and enters BGP configuration mode.
Ruijie(config-router)# **neighbor** *peer-address* **remote-as** *asn-number*	Sets up the IBGP session.
Ruijie(config-router)# **neighbor** *peer-address* **update-source** *interface-name*	Uses the address of the loopback address as the source address to set up an IBGP session.
Ruijie(config-router)# **address-family ipv4**	Enters the IPv4 address family.
Ruijie(config-router-af)# **neighbor** *peer-address* **Activate**	Enables IPv4 route exchange.
Ruijie(config-router-af)# **neighbor** *peer-address* **send-label**	Enables label distribution for IPv4 routes.
Ruijie(config-router-af)# n**eighbor** *peer-address* **route-reflector-client**	Configures all PE peers as the clients of the IPv4 RR.
Ruijie(config-router-af)# **exit**	Exits the IPv4 address family.
Ruijie(config-router)# **address-family vpnv4**	Enters the VPN address family.
Ruijie(config-router-af)# **neighbor** *peer-address* **Activate**	Enables the VPN route exchange with the peer.
Ruijie(config-router-af)# **neighbor** *peer-address* **route-reflector-client**	Configures all PE peers as the clients of the VPN RR.
Ruijie(config-router-af)# **show running-config**	Displays existing configuration information.

# Set up an MP-IBGP session between the RR and the PE. The configuration on the RR is as follows:

```
Ruijie# configure terminal
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 10.10.10.1 remote-as 1
Ruijie(config-router)# neighbor 10.10.10.1 update-source loopback 0
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 10.10.10.1 activate
Ruijie(config-router-af)# neighbor 10.10.10.1 send-label
Ruijie(config-router-af)# neighbor 10.10.10.1 route-reflector-client
Ruijie(config-router-af)# exit
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 10.10.10.1 activate
Ruijie(config-router-af)# neighbor 10.10.10.1 route-reflector-client
Ruijie(config-router-af)# end
```

- Setting up an IBGP session between the RR and the ASBR and distributing labels for IPv4 routes

Set up an MP-IBGP session between the ASBR and the RR to receive routes from the RR to the PEs in the local AS and send routes from the RR to the PEs in another AS. At the same time, enable label distribution for IPv4 routes for the session.

Enter privileged EXEC mode and use the following commands.

Command	**Function**
Ruijie# config terminal	Enters global configuration mode.
Ruijie(config)# **router bgp** *asn-number*	Enables BGP and enters BGP configuration mode.
Ruijie(config-router)# **neighbor** *peer-address* **remote-as** *asn-number*	Sets up the IBGP session.
Ruijie(config-router)# **neighbor** *peer-address* **update-source** interface-name	Uses the address of the loopback address as the source address to set up an IBGP session.
Ruijie(config-router)# **address-family ipv4**	Enters the IPv4 address family.
Ruijie(config-router-af)# **neighbor** *peer-address* **activate**	Enables IPv4 route exchange.
Ruijie(config-router-af)# **neighbor** *peer-address* **send-label**	Enables label distribution for IPv4 routes.
Ruijie(config-router)# **show running-config**	Displays existing configuration information.

Note For the IBGP session between an RR and an ASBR, you are generally not required to set the ASBR as the client of the RR unless the ASBR also serves as a PE.

# Set up an IBGP session between the RR and the ASBR. The configuration on the RR (the configuration on the ASBR is similar) is as follows:

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 10.10.10.2 remote-as 1
Ruijie(config-router)# neighbor 10.10.10.2 update-source loopback 0
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 10.10.10.2 activate
Ruijie(config-router-af)# neighbor 10.10.10.2 send-label
Ruijie(config-router-af)# end
```

- Setting up an EBGP session between ASBRs to enable label distribution for IPv4 routes

This procedure is similar to the corresponding procedure in Scheme 1 and is not described here.

- Configuring a multi-hop MP-EBGP session

Set up a multi-hop MP-EBGP session between the RRs of two ASs to exchange inter-AS VPN routes. At the same time, disable the transmission of IPv4 routes for the session. The PE routes are advertised to another AS through the ASBR.

Enter privileged EXEC mode and use the following commands.

Command	**Function**
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *asn-number*	Enables BGP and enters BGP configuration mode.
Ruijie(config-router)# **neighbor** *rr-address* **remote-as** ebgp-asn-numbe	Sets up the EBGP session.

Ruijie(config-router)# **neighbor** *rr-address* **update-source** *interface-name*	Uses the address of the loopback address as the source address to set up an EBGP session.
Ruijie(config-router)# **neighbor** *rr-address* **ebgp-multihop**	Configures multi-hop EBGP attributes.
Ruijie(config-router)# **address-family ipv4**	Enters the IPv4 address family.
Ruijie(config-router-af)# **no neighbor** *rr-address* **activate**	Disables IPv4 route exchange for the session.
Ruijie(config-router-af)# **exit**	Exits the IPv4 address family.
Ruijie(config-router)# **address-family vpnv4**	Enters the VPN address family.
Ruijie(config-router-af)# **neighbor** *rr-address* **Activate**	Enables the device to exchange VPN routes with the RR in another AS.
Ruijie(config-router-af)# **neighbor** *rr-address* **next-hop-unchanged**	(Optional) Configures the device not to change the next hop when advertising VPN routes to the peer.
Ruijie(config-router)# **show running-config**	Displays existing configuration information.

Caution

By default, the device changes the next hop of a route to its own address when advertising the route to an EBGP peer. Upon receipt of the VPN route, the PE site in another AS considers the next hop of the route as the RR. As a result, all inter-AS VPN traffic is transmitted through the RR. This is generally not the optimal forwarding path and has high requirements on the forwarding performance of the RR. To avoid the preceding situation, you can run the **neighbor next-hop-unchanged** command in VPNv4 address family configuration mode to configure the device not to change the next hop of a VPNv4 route sent to the BGP peer when you set up a multi-hop MP-EBGP session on the RR.

The exchange of IPv4 routes is not required in a multi-hop MP-EBGP session. At least the routes of the two addresses used to set up the BGP session should be avoided. Otherwise, a PE has two routes to the PE in another AS. One route is advertised by the ASBR in the local AS and the other is advertised by the multi-hop EBGP session. According to the BGP specification, the EBGP route has a higher priority over the IBGP route by default. As a result, BGP chooses the route advertised by the multi-hop BGP, resulting in continuous flapping of routes on the PE to the PE in another AS. The VPN routes are thus not reachable.

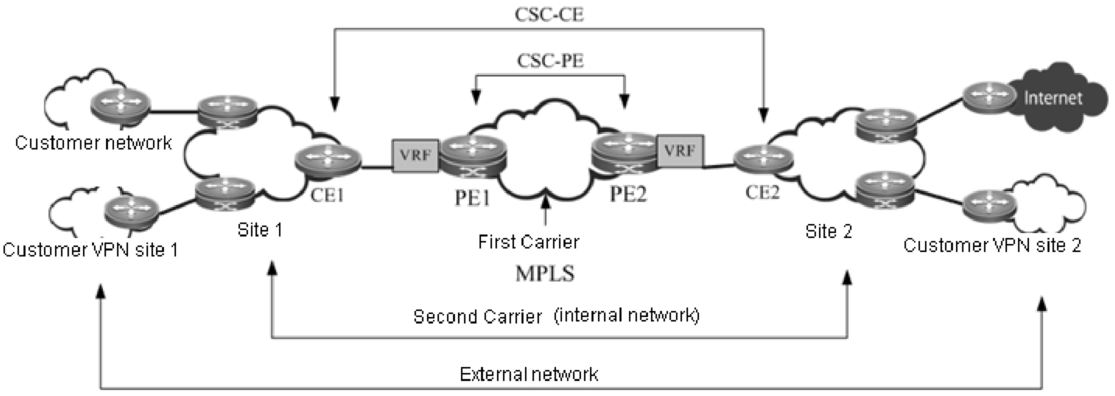
# Configure an RR to set up a multi-hop MP-EBGP session with the RR in another AS.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 30.30.30.2 remote-as 2
Ruijie(config-router)# neighbor 30.30.30.2 update-source loopback 0
Ruijie(config-router)# neighbor 30.30.30.2 ebgp-multihop
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# no neighbor 30.30.30.2 activate
Ruijie(config-router-af)# exit
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 30.30.30.2 activate
Ruijie(config-router-af)# neighbor 30.30.30.2 next-hop-unchanged
Ruijie(config-router-af)# end
```

Configuring Carrier's Carrier (CSC)

In a basic MPLS VPN, each site is a traditional IP network with a simple network structure. However, in there are some special VPN users. For example, a VPN user is also a service provider who leases the VPN service of an MPLS VPN service provider and then provides specific services for users. In this case, the MPLS VPN service provider is called a provider carrier or first carrier, while the VPN user who is also a service provider is called a customer carrier or second carrier. This networking model is called carrier's carrier (CSC).

Figure 12 Model of Carrier's Carrier



Basic Concepts

- First carrier

The first carrier is also called a provider carrier, who provides MPLS VPN services for second carriers. In order to support second carriers to provide services for their users, the PE device of the first carrier must support CSC. The first carrier PE that provides services for second carriers is also called a CSC-PE.

- Second carrier

The second carrier is also called a customer carrier, who leases the MPLS L3VPN service from the first carrier in order to build its own intranet and then provide services for users. The second carrier CE connected to the first carrier is also called a CSC-CE.

- Internal route

The internal routes refer to the routes inside the network of the second carrier, namely, the intranet routes. The internal routes are used to guarantee the intercommunication of the second carrier's own network. Such routes must be jointly maintained by the first carrier PE and the second carrier.

- External route

Because the second carrier is a service provider, its network may be connected to multiple third-party networks. The route between the second carrier and the third-party network is called an external route. If the second carrier provides traditional IP services for users, the external routes include routes of user networks; if the second carrier is connected to the Internet, the external routes include Internet routes; if the second carrier provides MPLS VPN services for users, the external routes include user VPN routes.

Generally, there are tremendous external routes. To maintain good scalability, the first carrier will not maintain external routes, and external routes will be maintained independently by the second carrier.

- VPN tunnel

A VPN tunnel is an LSP tunnel established between VPN devices. In the CSC model, the LSP tunnel between second carrier devices is the VPN tunnel.

Working Principle

PE-CE Route and Label Distribution

To achieve good scalability, the number of routes to be maintained by the first carrier must be reduced. Therefore, the CSC model hands over external route maintenance to the second carrier, while the external traffic must use the VPN tunnel to traverse the first carrier. To support the CSC model, the first carrier PE must support VPN tunnels.

To support VPN tunnels, the first carrier PE (CSC-PE) and the second carrier CE (CSC-CE) must distribute the label binding information to each other. Depending on whether the CSC-PE and CSC-CE are in the same AS, the following routing protocols may be used to exchange internal routes and distribute labels for the internal routes:

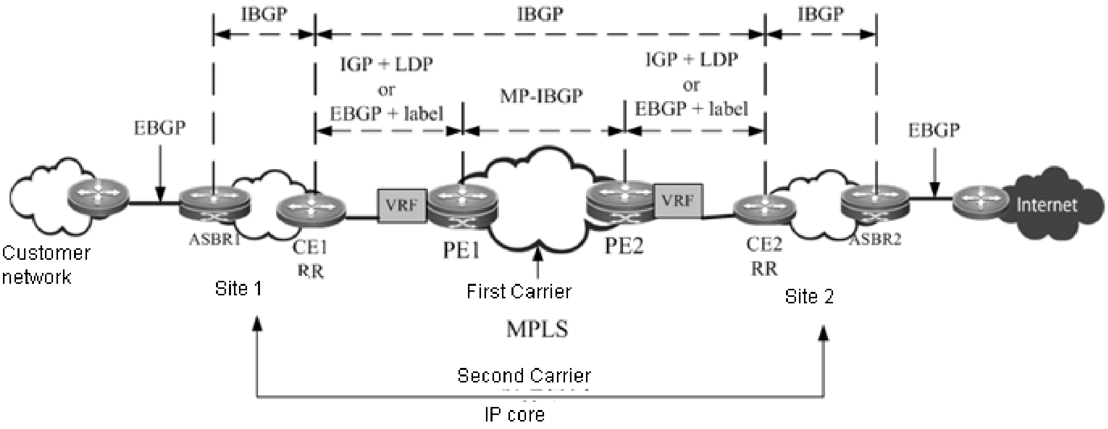
- If the CSC-PE and CSC-CE are in the same AS, IGP is generally used to exchange internal routes, and LDP is used to exchange label binding information.
- If the CSC-PE and CSC-CE are in different ASs, EBGP is generally used to exchange internal routes, and EBGP is enabled to perform label distribution for IPv4 routes and label distribution for internal routes.

Typical Application Scenarios

The second carrier can be an ordinary ISP or an MPLS service provider. Depending on the type of the second carrier network and the services provided by the second carrier for users, there are following typical application scenarios:

- Scenario I: IP core second ISP

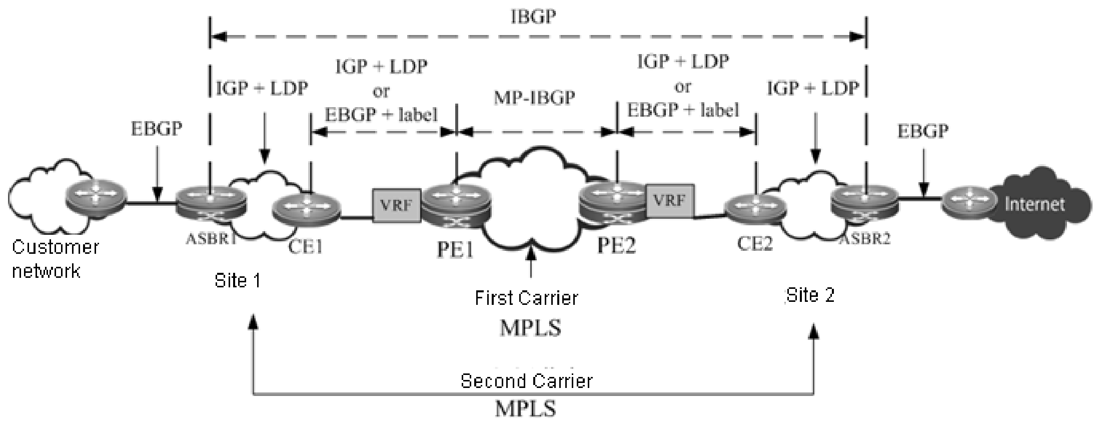
Figure 13 Scenario I: IP core second ISP



As shown in the figure, the second carrier is the IP core and provides network access services for users. IBGP neighbor relations are established between ASBR1, ASBR2, CE1 and CE2 to exchange external routes. CE1 and CE2 are RRs to reflect external routes between different sites. The Internet-access traffic of users flows from ASBR1 into the second carrier network and then flows out of the second carrier network from ASBR2. When the traffic flows from CE1 to CE2, the traffic is forwarded in the VPN LSP tunnel.

- Scenario II: MPLS core second ISP

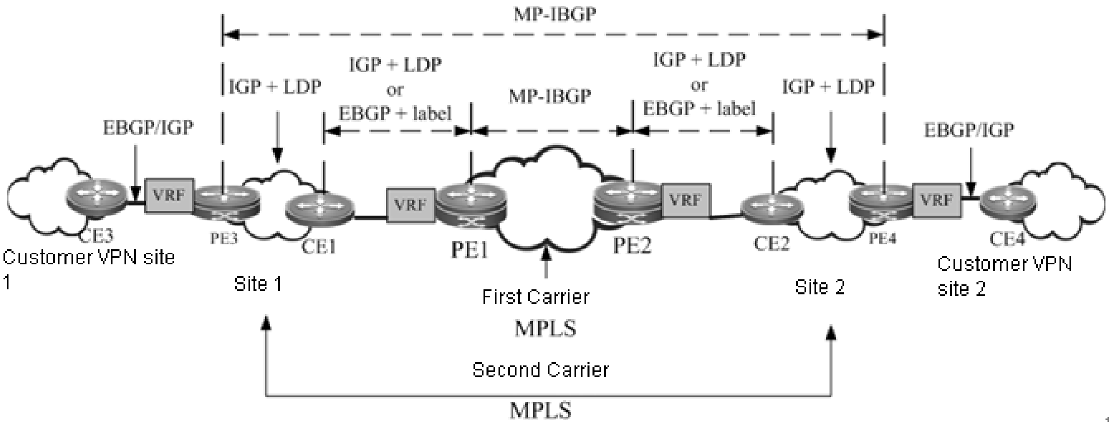
Figure 14 Scenario II: MPLS core second ISP



As shown in the figure, the second carrier is the MPLS core and provides network access services for users. An IBGP neighbor relation is established between ASBR1 and ASBR2 to exchange external routes. The Internet-access traffic of users flows from ASBR1 into the network of the second carrier and then flows out of the second carrier network from ASBR2. When the traffic flows from ASBR1 to ASBR2, the traffic is forwarded in the VPN LSP tunnel.

- Scenario III: MPLS core second VPN provider

Figure 15 Scenario III: MPLS core second VPN provider



As shown in the figure, the second carrier is the MPLS core and provides MPLS L3VPN services for users. An MP-IBGP neighbor relation is established between PE3 and PE4 to exchange user VPN routes. The VPN LSP between PE3 and PE4 acts as the external tunnel of a user VPN.

Configuration Steps

The CSC configuration includes:

- Configuring basic BGP/MPLS IP VPN functions for the first carrier
- Configuring the first carrier to enable CSC
- Configuring the second carrier
- Configuring user access for the second carrier

Configuring Basic BGP/MPLS IP VPN Functions for the First Carrier

The configuration of basic BGP/MPLS IP VPN functions includes:

42) Configuring an MPLS network

43) Configuring a VRF

44) Configuring an MP-IBGP neighbor

45) Configuring route exchange between PEs and CEs

- Configuring an MPLS network

The configuration in this section is similar to "Configuring an MPLS Network" in the "Configuring Basic BGP/MPLS IP VPN Functions" section.

- Configuring a VRF

The configuration in this section is similar to "Configuring a VPN Routing Instance" in the "Configuring Basic BGP/MPLS IP VPN Functions" section.

Caution

The CSC configuration requires "per-route" label allocation for each VRF. Therefore, you need to run the **alloc-label per-route** command in VRF configuration mode to select the label allocation mode.

- Configuring an MP-IBGP neighbor

The configuration in this section is similar to "Configuring PEs to Transmit VPN Routes" in the "Configuring Basic BGP/MPLS IP VPN Functions" section.

- Configuring route exchange between PEs and CEs

The configuration in this section is similar to "Configuring Route Exchange Between PEs and CEs" in the "Configuring Basic BGP/MPLS IP VPN Functions" section.

Caution

In Scenario I: In the network of the IP core second ISP, if the PE and CE use EBGP to exchange internal routes, because the external routes are exchanged using BGP and the CE is the route reflector, a route map needs to be configured for the PE and CE to filter external routes and avoid leaking external routes into the PE of the first carrier.

Configuring the First Carrier to enable CSC

Enable CSC on the first carrier PE. Depending on the protocol used for exchanging routes between a PE and a CE, the following two cases may apply:

46) The PE and CE use LDP to distribute labels.

47) The PE and CE use EBGP to distribute labels.

- The PE and CE use LDP to distribute labels.

If the PE and CE use IGP to exchange routes, run the following commands on the PE and CE respectively to configure the PE and CE to use LDP to distribute labels.

Use the following commands on the PE.

Command	Function

Command	Function
Ruijie(config)# **mpls router ldp** *vrf-name*	Enables LDP (PE) for the VRF.
Ruijie(config-mpls-router)# **ldp router-id interface** *interface-name* **force**	Configures the router ID of LDP.
Ruijie(config-mpls-router)# **advertise-labels for bgp-routes** [**acl** *acl-name*]	Configures LDP to distribute labels for BGP routes. LDP does not assign labels to BGP routes by default.
Ruijie(config-mpls-router)# **exit**	Exits LDP instance configuration mode.
Ruijie(config)# **interface** *interface-name*	Configures the interface connecting the CE.
Ruijie(config-if)# **label-switching**	Enables MPLS forwarding on the interface.
Ruijie(config-if)# **mpls ip**	Enables LDP on the interface.
Ruijie(config-if)# **ip ref**	☑ In case of a router, enables fast forwarding on the interface (not applicable to a switch).
Ruijie(config-if)# **end**	Exits interface configuration mode.
Ruijie# **show running**-config	Displays existing configuration information.
Ruijie# **show mpls ldp bindings vrf** *vrf-name*	Displays LDP label binding information under this VRF instance.

Use the following commands on the CE.

Command	Function
Ruijie(config)# **mpls router ldp**	Enables LDP (CE).
Ruijie(config-mpls-router)# **ldp router-id interface** *interface-name* **force**	Configures the router ID of LDP.
Ruijie(config-mpls-router)# **exit**	Exits LDP instance configuration mode.
Ruijie(config)# **interface** *interface-name*	Configures the interface connecting the PE.
Ruijie(config-if)# **label-switching**	Enables MPLS forwarding on the interface.
Ruijie(config-if)# **mpls ip**	Enables LDP on the interface.
Ruijie(config-if)# **end**	Exits interface configuration mode.
Ruijie# **show running-config**	Displays existing configuration information.
Ruijie(config-if)# **ip ref**	In case of a router, enables fast forwarding on the interface (not applicable to a switch).
Ruijie# **show mpls ldp bindings**	Displays LDP label binding information.

- The PE and CE use EBGP to distribute labels.

If the PE and CE use EBGP to exchange routes, run the following commands on the PE and CE respectively to configure the PE and CE to use EBGP to distribute labels.

Use the following commands on the PE.

Command	Function

Command	Function
Ruijie(config)# **interface** *interface-name*	Configures the interface connecting the CE.
Ruijie(config-if)# **ip ref**	☑ In case of a router, enables fast forwarding on the interface (not applicable to a switch).
Ruijie(config-if)# **label-switching**	Enables MPLS on the interface.
Ruijie(config-if)# **router bgp** *asn*	Enters BGP configuration mode.
Ruijie(config-router)# **address-family ipv4 vrf** *vrf-name*	Enters IPv4 address family configuration mode.
Ruijie(config-router-af)# **neighbor** {*peer-address* | *peer-group-name*} **send-label**	Enables BGP to carry labels for IP routes.
Ruijie(config-router-af)# **end**	Returns to privileged EXEC mode.
Ruijie# **show running-config**	Displays existing configuration information.
Ruijie# **show bgp vpnv4 unicast vrf** *vrf-name* labels	Displays BGP label information.

Use the following commands on the CE.

Command	Function
Ruijie(config)# **interface** *interface-name*	Configures the interface connecting the PE.
Ruijie(config-if)# **label-switching**	Enables MPLS on the interface.
Ruijie(config-if)# **ip ref**	☑ In case of a router, enables fast forwarding on the interface (not applicable to a switch).
Ruijie(config-if)# **router bgp** *asn*	Enters BGP configuration mode.
Ruijie(config-router)# **address-family ipv4**	Enters IPv4 address family configuration mode.
Ruijie(config-router-af)# **neighbor** {*peer-address* | *peer-group-name*} **send-label**	Enables BGP to carry labels for IP routes.
Ruijie(config-router-af)# **end**	Returns to privileged EXEC mode.
Ruijie# **show running-config**	Displays existing configuration information.
Ruijie# **show ip bgp labels**	Displays BGP label information.

Configuring the Second Carrier

Before the configuration, configure IGP for the second carrier network in order to guarantee the connectivity of the second carrier network. Depending on the application scenarios of the second carrier, different configuration schemes will be adopted:

- Scenario I: IP core second ISP
- Scenario II: MPLS core second ISP
- Scenario III: MPLS core second VPN provider

The Second Carrier Provides Internet Services Based on IP Core

In Scenario I, IBGP neighbor relations are established between ASBRs and CEs to exchange external routes. CEs are RRs to reflect external routes between different sites. The configuration task includes:

48) Configuring an intra-site BGP session

49) Configuring a BGP session between CSC-CEs of different sites

50) Configuring route map filtering

- Configuring an intra-site IBGP session

Use the following commands to configure an IBGP session between an intra-site ASBR and a CSC-CE, and configure the CSC-CE as an RR.

Command	**Function**
Ruijie(config)# **router bgp** *asn*	Configures a BGP router.
Ruijie(config-router)# **neighbor** {*peer-address* | *peer-group-name*} **remote-as** *asn*	Configures a BGP neighbor.
Ruijie(config-router)# **neighbor** {*peer-address* | *peer-group-name*} **route-reflector-client**	Configures the CSC-CE as the RR client.
Ruijie(config-router)# **neighbor** {*peer-address* | *peer-group-name*} **update-source** *interface-name*	Configures a BGP source address.
Ruijie(config-router)# **neighbor** {*peer-address* | *peer-group-name*} **next-hop-self**	For the ASBR, changes the next hop to the router itself when configuring the router to advertise BGP routes.

- Configuring an IBGP session between CSC-CEs of different sites

Use the following commands to set up a fully meshed IBGP session between CSC-CEs of different sites to exchange external routes of different sites.

Command	**Function**
Ruijie(config)# **router bgp** *asn*	Configures BGP.
Ruijie(config-router)# **neighbor** {*peer-address* | *peer-group-name*} **remote-as** *asn*	Configures a BGP neighbor.
Ruijie(config-router)# **neighbor** {*peer-address* | *peer-group-name*} **update-source** *interface-name*	Configures a BGP source address.
Ruijie(config-router)# **neighbor** {*peer-address* | *peer-group-name*} **route-reflector-client**	(Optional) Configures the CSC-CE of a peer site as the RR client.
Ruijie(config-router)# **exit**	Exits BGP configuration mode.
Ruijie(config)# **recursive-route lookup lsp**	Enables resolution of the next hop of a BGP route to an LSP tunnel.

- Configuring route map filtering

When BGP is used to exchange internal routes, because the CSC-CE is responsible for propagating both external routes and internal routes, you must guarantee that only the EBGP session between the CSC-CE and the CSC-PE can propagate internal routes, and that the IBGP session between CSC-CEs and between the CSC-CE and the ASBR can only propagate external routes; otherwise, routing loops or chaos may occur. To achieve this goal, you must run **neighbor route-map {in | out}** on the IBGP neighbor and EBGP neighbor to filter the corresponding routes, and the AS-path filtering rule is generally used. You can also use other rules.

Use the following commands to configure route map filtering.

Command	Function
Ruijie(config)# **ip as-path access-list** *access-list-number* {**permit** | **deny**} *regex*	Configures an AS-path ACL.
Ruijie(config)# **route-map** *route-map-name* {**permit** | **deny**} *sequence-number*	Configures a route map.
Ruijie(config-route-map)# **match as-path** *access-list-number*	Matches the AS-path ACL.
Ruijie(config-route-map)# **exit**	Returns to global configuration mode.
Ruijie(config)# **router bgp** *asn*	Configures a BGP router.
Ruijie(config-router)# **neighbor** {*peer-address* | *peer-group-name*} **route-map** *route-map-name* {**in** | **out**}	Applies the route map to a BGP neighbor.

The Second Carrier Provides Internet Services Based on MPLS

In Scenario II, the second carrier network is an MPLS core in which IBGP neighbor relations are established between ASBRs to exchange external routes. There is no need to propagate external routes via the CSC-CE. The configuration task includes:

51) Configuring an intra-site MPLS network

52) Configuring an inter-site IBGP session

■ Configuring an intra-site MPLS network

The configuration of the intra-site MPLS network of the second carrier is similar to "Configuring an MPLS Network" in the "Configuring Basic BGP/MPLS IP VPN Functions" section.

Note

You need to enable LDP on the CSC-CE in order to set up sessions with other intra-site devices to build an MPLS network. If the CSC-CE and CSC-PE use BGP to exchange routes, you must run **advertise-labels for bgp-routes** on the CSC-CE to enable LDP to distribute labels for BGP routes.

■ Configuring an IBGP session between ASBRs of different sites

Use the following commands to configure the BGP session between the local ASBR and the ASBR of a peer site in order to exchange external routes.

Command	Function
Ruijie(config)# **router bgp** *asn*	Configures BGP.
Ruijie(config-router)# **neighbor** {*peer-address* | *peer-group-name*} **remote-as** *asn*	Configures a BGP neighbor.
Ruijie(config-router)# **neighbor** {*peer-address* | *peer-group-name*} **update-source** *interface-name*	Configures a BGP source address.
Ruijie(config-router)# **neighbor** {*peer-address* | *peer-group-name*} **next-hop-self**	Changes the next hop to the router itself when configuring the ASBR router to advertise external routes.
Ruijie(config-router)# **exit**	Exits BGP configuration mode.
Ruijie(config)# recursive-route lookup lsp	Enables resolution of the next hop of a BGP route to an LSP tunnel.

Note

To reduce the configuration cost of a fully meshed IBGP session, you can configure the RR role inside the site. The intra-site ASBR can set up a BGP session with the RR, while an inter-site BGP session can only be set up between RRs.

The Second Carrier Provides VPN Services Based on MPLS Core

In Scenario III, the second carrier network is an MPLS core in which MP-IBGP neighbor relations are established between second carrier PEs to exchange user VPN routes. The configuration task includes:

53) Configuring an intra-site MPLS network

54) Configuring an MP-IBGP neighbor

■ Configuring an intra-site MPLS network

The configuration of the intra-site MPLS network of the second carrier is similar to "Configuring an MPLS Network" in the "Configuring Basic BGP/MPLS IP VPN Functions" section.

Note

You need to enable LDP on the CSC-CE in order to set up sessions with other intra-site devices to build MPLS network. If the CSC-CE and CSC-PE use BGP to exchange routes, you must run **advertise-labels for bgp-routes** on the CSC-CE to allow LDP to distribute labels for BGP routes.

■ Configuring PEs of each site to establish MP-IBGP neighbors

Configure PEs of each site to set up MP-IBGP sessions between intra-site PEs of the second carrier and between PEs of different sites in order to transmit VPN routes served by the second carrier. The configuration of the second carrier PE is similar to the PE configuration in the "Configuring Basic BGP/MPLS IP VPN Functions" section.

Note

To reduce the configuration cost of a fully meshed MP-IBGP session, you can configure the RR role inside the site. Intra-site PEs can set up an MP-IBGP session with the RR, while an inter-site MP-IBGP session can only be set up between RRs.

Configuring User Access for the Second Carrier

The configuration in this section relates to the services provided by the second carrier, and is irrelevant to the CSC model. If the second carrier provides IP services for users, see the "Configuring IP Routes" section. If the second carrier provides MPLS VPN services for users, see the "Configuring the MPLS VPN" section.

Configuring the MPLS VPN over GRE

☑ Currently, only router products of Ruijie support the MPLS VPN over GRE feature. This feature is not supported by Ruijie switch products.

Basic Concepts

The traditional MPLS VPN uses an LSP as the public tunnel, that is, VPN traffic flows from an upstream PE to a downstream PE by means of label switching. This requires the carrier's core network to fully support MPLS. For certain considerations or due to certain limitations, if the carrier's core network cannot fully support MPLS, the MPLS VPN over GRE can provide a mechanism to allow the carrier to use a GRE tunnel as a hop on the LSP tunnel to guarantee the integrity of the public LSP.

Figure 16 GRE tunnel

- GRE tunnel

GRE provides a mechanism to encapsulate the packets of one protocol (passenger protocol) into another protocol (carrier protocol). The encapsulated packets consist of: carrier protocol header, GRE header and original passenger protocol header. After being encapsulated by the carrier protocol, the passenger protocol packets can be forwarded in the carrier network. After the encapsulated packets reach the destination address of the carrier protocol, the destination device will decapsulate the packets and then forward the packets according to the inner-layer passenger protocol used by packets. Such an encapsulation technology allows passenger protocol packets to traverse a heterogeneous carrier network and reach the destination device. It is a tunnel encapsulation technology.

- Passenger protocol

The passenger protocol is the protocol being encapsulated during the process of GRE encapsulation. In the application scenario of MPLS VPN over GRE, the passenger protocol refers to packets carrying MPLS labels.

- Carrier protocol

The carrier protocol is the protocol used to encapsulate the passenger protocol during the process of GRE encapsulation. In the application scenario of MPLS VPN over GRE, the carrier protocol is generally IPv4.

- Source address and destination address

While encapsulating the passenger protocol, you need to know the source address and destination address of the carrier protocol, so that the encapsulated packets can be forwarded on the carrier network. The abovementioned source address and destination address are the source address and destination address of a GRE tunnel.

- Tunnel endpoint

When packets are transported on the tunnel, one device carries out carrier protocol encapsulation and another device carries out decapsulation. The passenger protocol information can only be known and processed by these two devices, while other carrier network devices between the two devices are unaware of the existence of the passenger protocol. These two devices are the endpoints of the GRE tunnel.

Working Principle

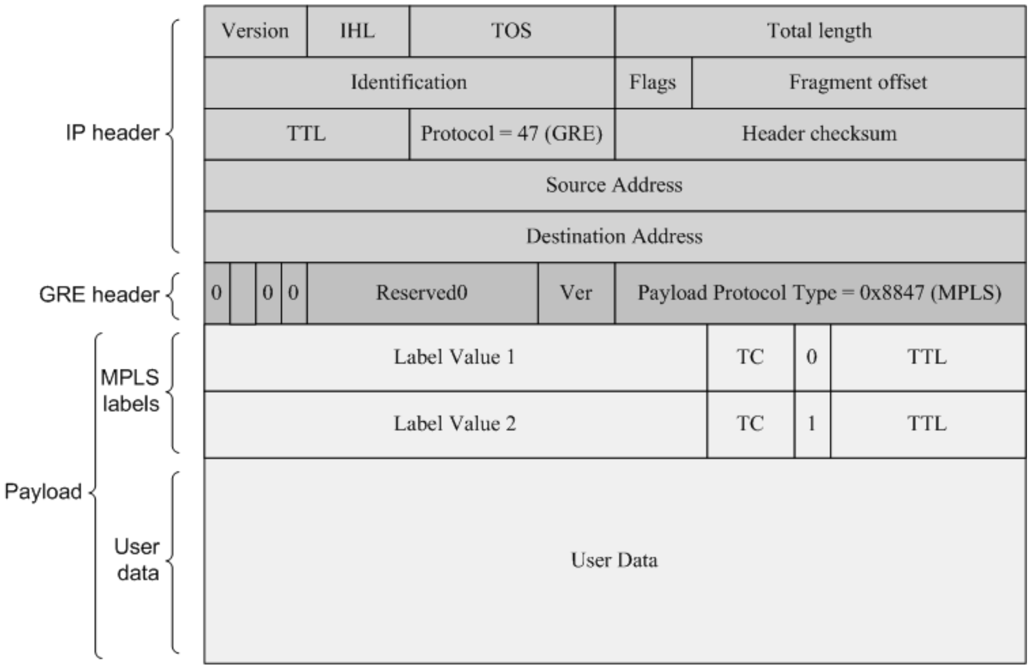
In the traditional MPLS VPN, private-network traffic carrying an inner-layer VPN label and an outer-layer public-network label reaches the peer PE by means of label switching. When a non-MPLS network exists in the backbone network, the LSP will become discontinuous. The GRE tunnel can help MPLS packets traverse a non-MPLS domain and realize a continuous LSP.

The GRE tunnel is a tunneling mechanism in an IP network and support GRE with MPLS as the passenger protocol, so that two devices on both sides of the IP network can exchange MPLS packets. Considering the GRE tunnel as a point-to-point logical link, devices at both ends of the tunnel directly establish IGP neighbor relations and LDP neighbor relations on this link to distribute routes and labels for the LSP, while the GRE tunnel becomes one hop of the LSP.

MPLS as a Passenger Protocol

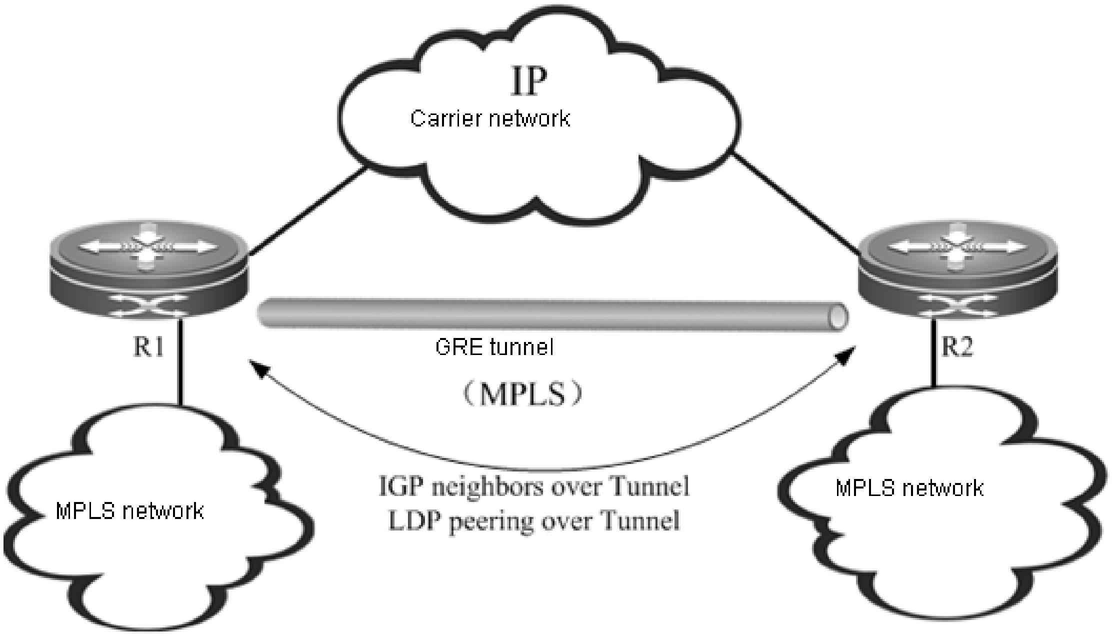
MPLS is used as the GRE tunnel of the passenger protocol so that two devices interconnected through a non-MPLS network can forward MPLS packets to each other. After a label operation at one end of the tunnel, MPLS packets are GRE-encapsulated and then transported over the carrier network to the other end of the tunnel; label switching is then carried out after packet decapsulation at the other end of the tunnel. The following figure shows the format of encapsulated packets with IPv4 being the carrier protocol and MPLS being the passenger protocol.

Figure 17 MPLS as the passenger protocol



GRE Tunnel as a Point-To-Point Link

Figure 18 GRE tunnel link



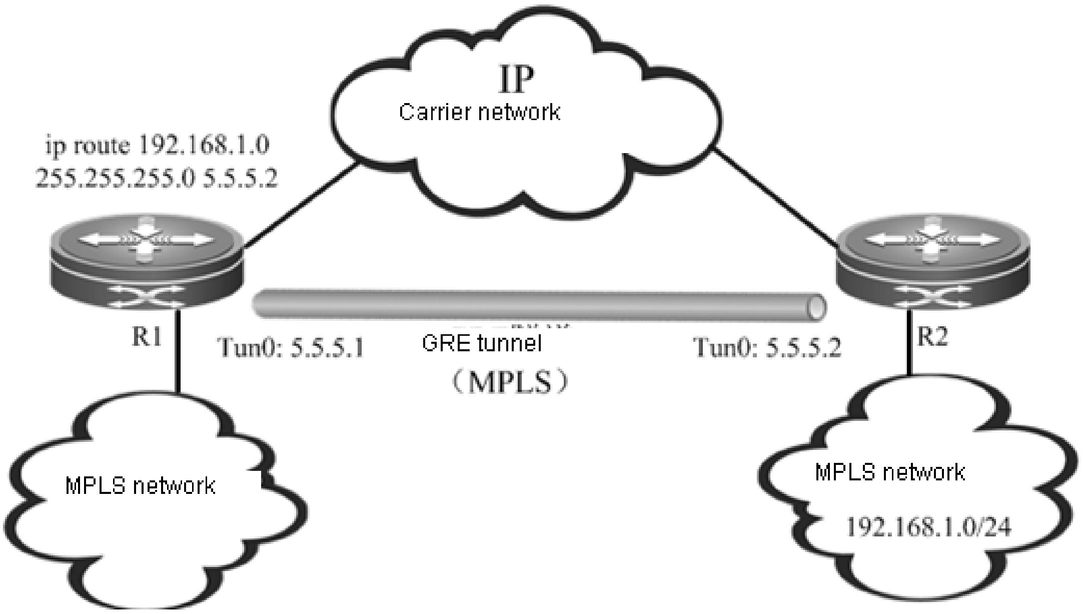
As shown in the figure, R1 and R2 are connected to an MPLS network respectively, while both routers are interconnected via a carrier network (IP). The GRE tunnel allows both endpoints (R1 and R2) to use the carrier network (IP) to transmit MPLS packets, so that two separated MPLS networks can be connected. The GRE tunnel is the point-to-point logical link between R1 and R2. It bypasses the carrier network (IP) and becomes one part of the MPLS network, so that the MPLS networks at both ends of the tunnel can maintain continuity. Considering the GRE tunnel as a point-to-point link, the IGP protocol can run on the link, while LDP can also distribute labels between R1 and R2.

Introduction of Tunnel Traffic

In either the carrier network (IP) or the MPLS network, traffic forwarding is driven by routers. Therefore, a dynamic routing protocol needs to be run in the carrier network (IP) and MPLS network. There are two possible schemes: single routing instance and dual routing instances.

- Single routing instance

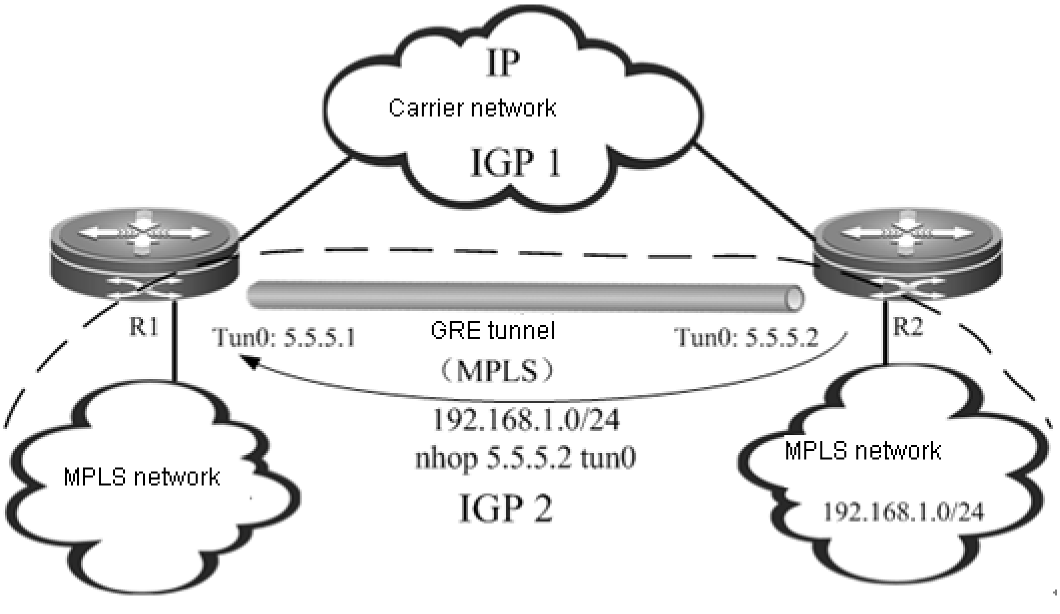
Figure 19 Single routing instance



In this scheme, the MPLS network and carrier network (IP) are in the same routing instance, and the entire network is in the plane form, as shown in Figure 15. By default, because the metric value of the GRE tunnel is far greater than that of an ordinary link, no traffic will be introduced into the GRE tunnel (which means that the GRE tunnel is not the next-hop egress interface of any route). Therefore, you must configure static routes in order to introduce MPLS traffic into the GRE tunnel. The static routes must be configured in this scheme, and the number of static routes depends on the number of route prefixes to be introduced into the GRE tunnel. The scalability is not satisfactory.

- Dual routing instances

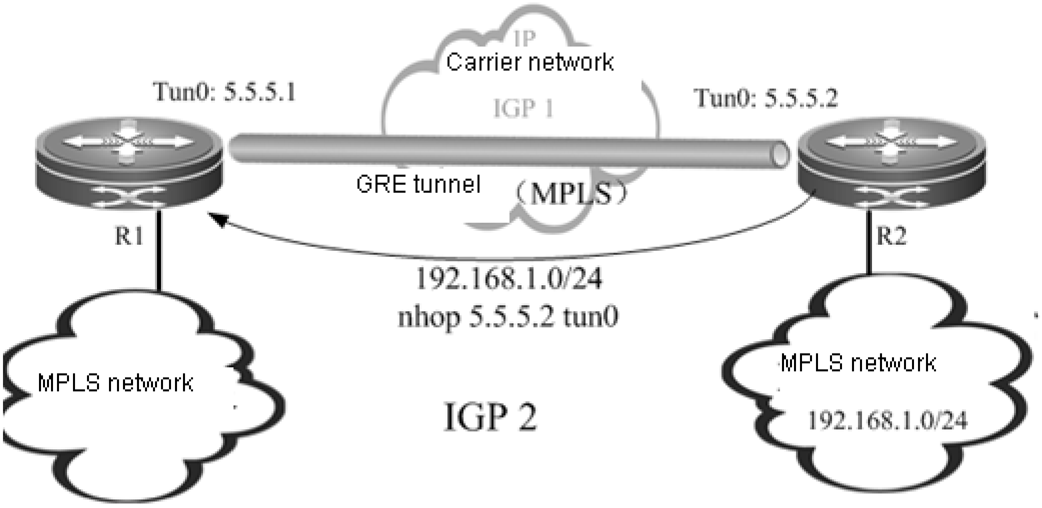
Figure 20 Dual routing instances



In this scheme, there are two different routing instances on each endpoint device of the GRE tunnel, as shown in Figure 16. One routing instance participates in route exchange in the carrier network (IP), while the other routing instance will participate in the route exchange in the MPLS network (including the GRE tunnel link). At this time, R1 learns the route to the remote MPLS network through the GRE tunnel, with the egress interface being the GRE tunnel. The traffic can be introduced into the GRE tunnel without configuring any static route.

Dual routing instances are actually dividing the network into different layers. As the upper-layer network, the MPLS network (including the GRE tunnel) acts as the backbone network running consistent IGP instances, supporting MPLS and providing MPLS VPN services. As the bottom-layer network, the carrier network (IP) is the local network between R1 and R2 and runs independent IGP instances. If the GRE tunnel is the "layer-3 interface" between R1 and R2, the IP network and the IGP instance between R1 and R2 will be the "layer-2 network" and "layer-2 link protocol" between R1 and R2, as they guarantee the link state of the GRE tunnel. The relation can be indicated in Figure 17.

Figure 21 Dual IGP instances

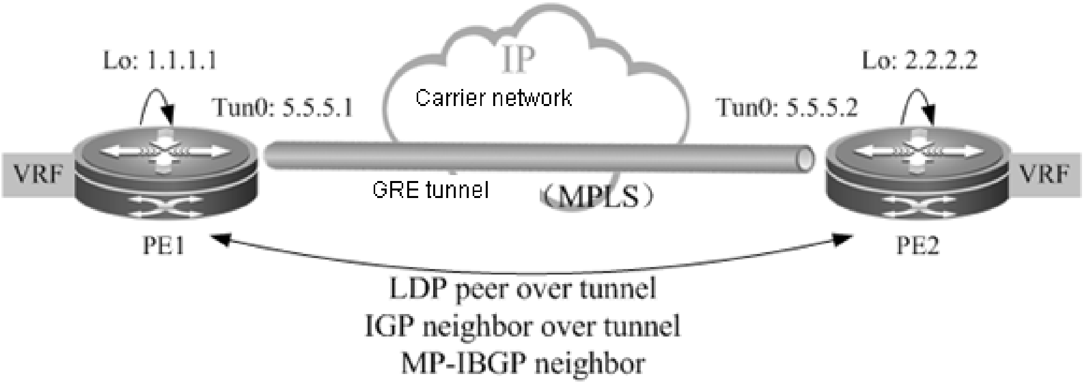


The scheme of dual routing instances divides the network into different layers and boasts better scalability. The following example is mainly based on this scheme.

Typical Applications

- Establishing a GRE tunnel between PEs

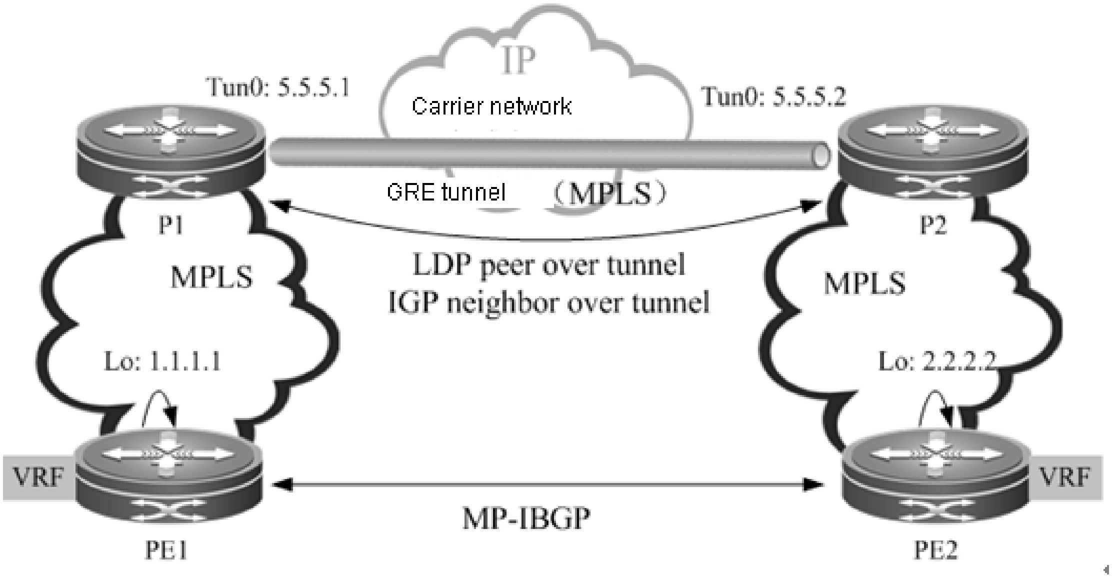
Figure 22 Scenario I: PE-PE



As shown in Figure 18, the core network between PEs is completely an IP network. The GRE tunnel is established between two PEs, and the LSP between PE1 and PE2 has only one hop.

- Establishing a GRE tunnel between Ps

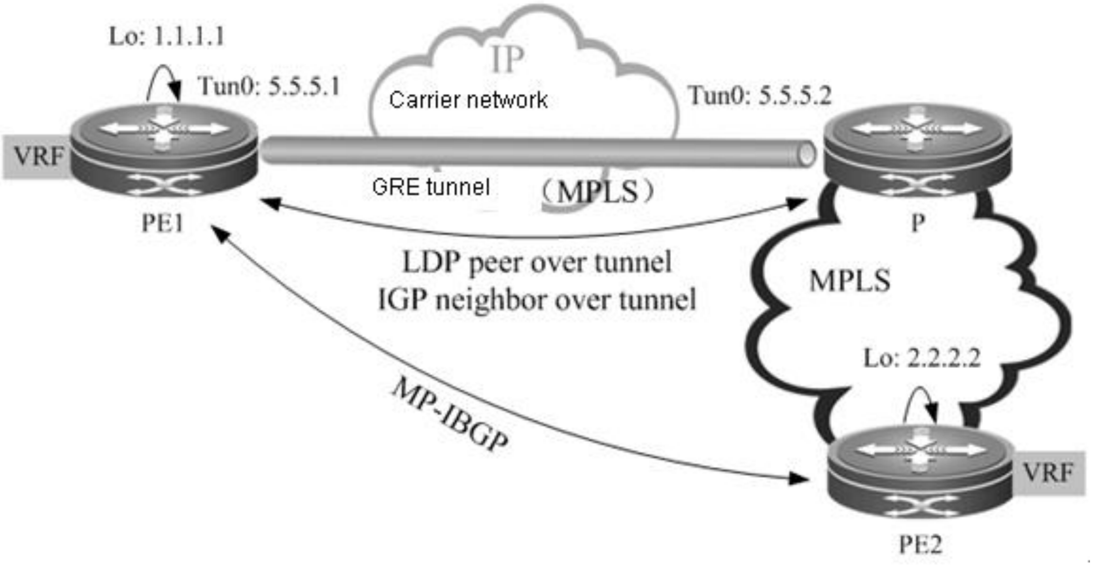
Figure 23 Scenario II: P-P



As shown in Figure 19, PE1 and PE2 are in two MPLS domains. P1 and P2 are interconnected through an IP network. The GRE tunnel is established between P1 and P2. The public LSP between PE1 and PE2 goes through P1 and P2, and the GRE tunnel between P1 and P2 is one hop of the LSP.

- Establishing a GRE tunnel between P and PE

Figure 24 Scenario III: P-PE



As shown in Figure 20, the network between PE1 and P does not support MPLS. The LSP is connected by establishing a GRE tunnel between PE1 and P.

Protocol Specification

- RFC 4023: Encapsulating MPLS in IP or GRE.

- RFC 4797: Use of Provider Edge to Provider Edge (PE-PE) Generic Routing Encapsulation (GRE) or IP in BGP/MPLS IP Virtual Private Networks.

Configuration Steps

The configuration of the MPLS VPN over GRE includes:

- Creating a tunnel interface
- Configuring an IGP route
- Configuring an MPLS network
- Configuring an MPLS VPN

Creating a Tunnel

Use the following commands to create a GRE tunnel (interface).

Command	Function
Ruijie(config)# **interface tunnel** *tunnel-id*	Creates a tunnel interface.
Ruijie(config)# **tunnel mode gre ip**	Configures the tunnel as a GRE in IP tunnel.
Ruijie(config-if)# **ip address** *ip-address address-mask*	Configures an address for the tunnel interface.
Ruijie(config-if)# **tunnel source** {*ip-address* | *interface-name*}	Configures the source address of the GRE tunnel.
Ruijie(config-if)# **tunnel destination** *ip-address*	Configures the destination address of the GRE tunnel.
Ruijie(config-if)# **no shutdown**	Enables the interface.

Configuring a Route to Introduce Traffic into the Tunnel

There are two ways to introduce traffic into the tunnel:

55) Configuring IGP

56) Configuring a static route

- Configuring IGP

Generally, multiple OSPF processes are used to create different routing instances. One OSPF process learns the route to the destination address of the tunnel, so that the tunnel interface is up if the route is reachable. Another OSPF process runs OSPF on the GRE tunnel to set up a session in order to learn the route to the destination address of the PE. For the configuration steps of multiple OSPF processes, see the "Configuring the Unicast Routing Protocol" section.

- Configuring a static route

Use the following command to configure a static route directly: Configure the tunnel interface as the egress of the host route to the specified PE address.

Command	Function
Ruijie(config)# **ip route** ip-address address-mask **tunnel** tunnel-id	Configures a static route.

Caution

If a static route is used to introduce traffic into the tunnel, the destination address of the tunnel cannot be the route prefix of the static route, that is, the address of the specified PE and the destination address of the tunnel must be different. This is because the state of the tunnel interface depends on the route to the destination address of the tunnel, while the static route will cause the route to the destination address to rely on the state of the tunnel interface, thus leading to the state flapping of the tunnel interface.

Configuring the Tunnel Interface to Enable MPLS

Use the following commands to enable LDP on the tunnel interface and enable MPLS forwarding.

Command	Function
Ruijie(config)# **mpls ip**	Enables MPLS globally. ☑ This command is not available on a switch chip.
Ruijie(config)# **mpls router ldp**	Enables LDP globally.
Ruijie(config-mpls-router)# **ldp router-id interface** *interface-name*	Configures the router ID of LDP.
Ruijie(config-mpls-router)# **exit**	Exits LDP configuration mode.
Ruijie(config)# **interface tunnel** *tunnel-id*	Enters tunnel interface configuration mode.
Ruijie(config-if)# **ip ref**	☑ In case of a router, enables fast forwarding (not applicable to a switch).
Ruijie(config-if)# **mpls ip**	Enables LDP on the interface.
Ruijie(config-if)# **label-switching**	Enables MPLS forwarding on the interface.
Ruijie(config-if)# **exit**	Exits interface configuration mode.

☑ Currently, only router products support the MPLS VPN over GRE-in-IPv4 tunnel. This feature is not supported by switch products.

Configuring the MPLS VPN

The configuration of the MPLS VPN includes:

- Configuring a VRF
- Configuring an MP-IBGP
- Configuring route exchange between PEs and CEs

For details, see the "Configuring Basic BGP/MPLS IP VPN Functions" section.

Configuring the OSPF VPN Extension

Understanding the L3VPN OSPF VPN Extension

PE-CE OSPF Feature

OSPF is a widely used IGP protocol. In most of the existing application schemes, VPN users generally select OSPF as the interior routing protocol. If OSPF is used between a PE and a CE, you do not need to run other routing protocols, thus simplifying CE configuration and management.

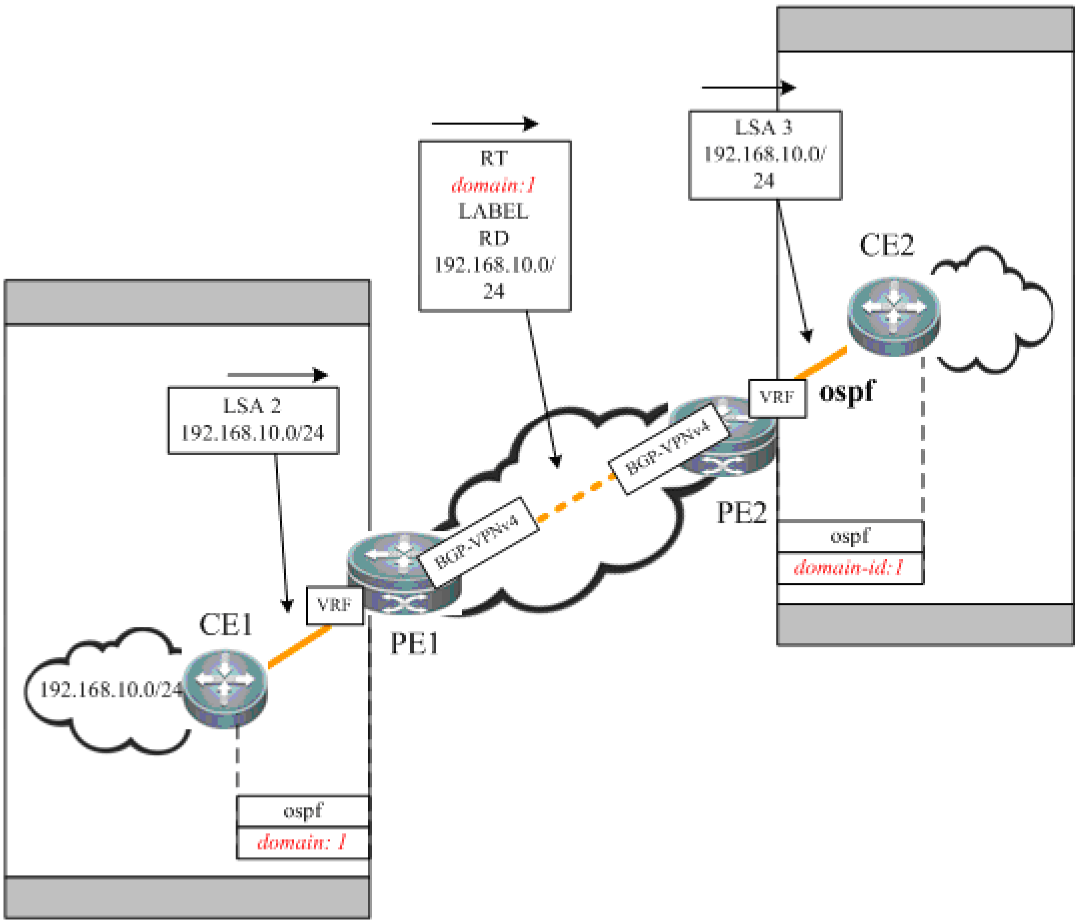
The PE-CE OSPF feature is described from the following four aspects.

- Domain ID

A domain ID refers to the OSPF domain to which the route belongs. When the CE has learned an OSPF route from an intra-VPN site, this route will be advertised to a PE in type-1, type-2 or type-3 link state advertisements (LSAs) and redistributed to BGP to form a VPN route. Meanwhile, the domain ID will also be redistributed to BGP together with the route and advertised as the extended community attribute in the VPN route. When other PEs receive this VPN route and redistribute it to the VRF OSPF instance, the domain ID will also be redistributed to the corresponding VRF OSPF instance together with this route. If the VRF OSPF instance confirms that the domain ID contained in the route is the same as the domain ID of this VRF OSPF instance, the route will be advertised to the CE as an internal route. Contrarily, if the VRF OSPF instance confirms the domain ID contained in the route is different from the domain ID of this VRF OSPF instance, the route will be advertised to the CE as an external route.

As shown in the following figure, for a route that belongs to the same OSPF domain, CE1 advertises the route to PE1 in a type-2 LSA and then a VPN route is formed and advertised to PE2. PE2 receives this route and redistributes it to the VRF OSPF instance. Because the VRF OSPF instance shares the same domain ID with this VPN route, this site will eventually be advertised to VPN sites in the form of an internal route.

Figure 25

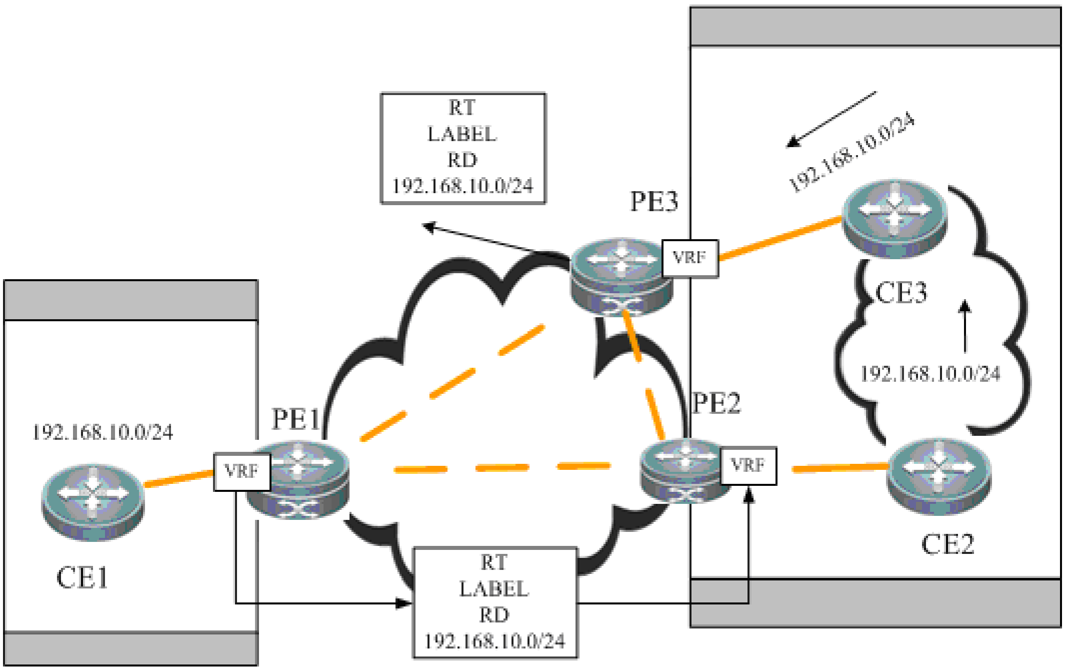


- DN bit

A DN bit is a loop detection technique when OSPF is run between the PE and the CE. In a certain scenario, running OSPF between the PE and the CE may cause loops. For example, when multiple PEs are connected to one VPN site, if one PE advertises the VPN route learned to the VPN site, and the route is further advertised to another PE by running OSPF inside the VPN site and then propagated, a routing loop may take place.

As shown in the following figure: The route from 192.168.10.0/24 is advertised by PE1 to PE2 and PE3. CE2 advertises the route to CE3 through OSPF. The route is then advertised to PE3 and redistributed to the BGP protocol of PE3. PE3 selects the route redistributed by OSPF and converts this route into a VPN-IPV4 route before advertising the route, thus causing a routing loop.

Figure 26



To avoid such potential loop, when the PE advertises a type-3, type-5 or type-7 LSA to the CE, it will set a DN bit in an optional field of the LSA. When other PEs receive any LSA containing a DN bit in the optional field, the OSPF protocol on the PE does not allow this LSA to participate in OSPF route computation.

- VPN route tag

A VPN route tag is another loop detection technique. When OSPF is run between the PE and the CE, the corresponding VRF OSPF instance on the PE will by default have a route tag called "VPN route tag". The VRF OSPF instance on the PE imports the VPN route and converts the route into a type-5 or type-7 LSA. When LSA is advertised to CE, this LSA will carry a VPN route tag. In the circumstance in which one VPN site is connected with multiple PEs, if a PE receives a type-5 or type-7 LSA that carries a VPN route tag and this VPN route tag is the same as the that of the OSPF instance, this LSA will not participate in OSPF route calculation.

- PE-CE inter-area deployment

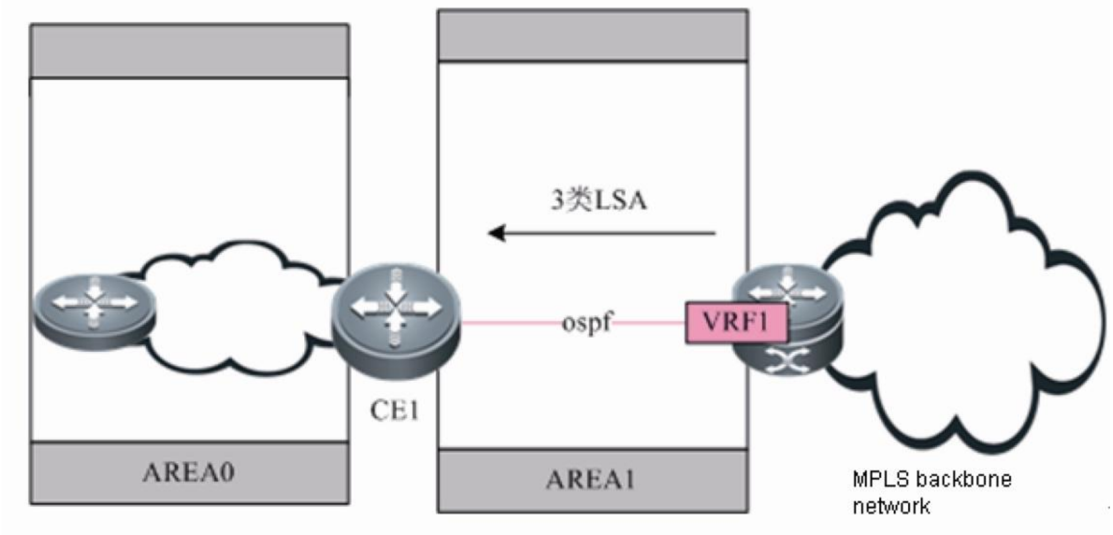
Under normal circumstances, the link between the PE and the CE can be in any OSPF area. However, if the link between the PE and the CE falls into a non-zero area, the PE is an area border router (ABR) to the OSPF area where the CE is located. This may cause some problems because the OSPF protocol acting as an ABR device has the following features:

57) The ABR only calculates the type-3 LSA in the backbone area.

58) The ABR only forwards the type-3 LSA in the backbone area to a non-backbone area.

As shown in the following figure, if the link between the PE and the CE is in a non-zero area, the PE will redistribute the VPNv4 route advertised by MP-BGP to OSPF and restore it to a type-3 LSA to be advertised to CE1. CE1 will not calculate the non-backbone area LSAs. Therefore, these LSAs will not be advertised to routers in Area 0, and intra-VPN sites may fail to learn the route to other sites. Therefore, pay special attention when deploying a non-zero area between the PE and the CE.

Figure 27

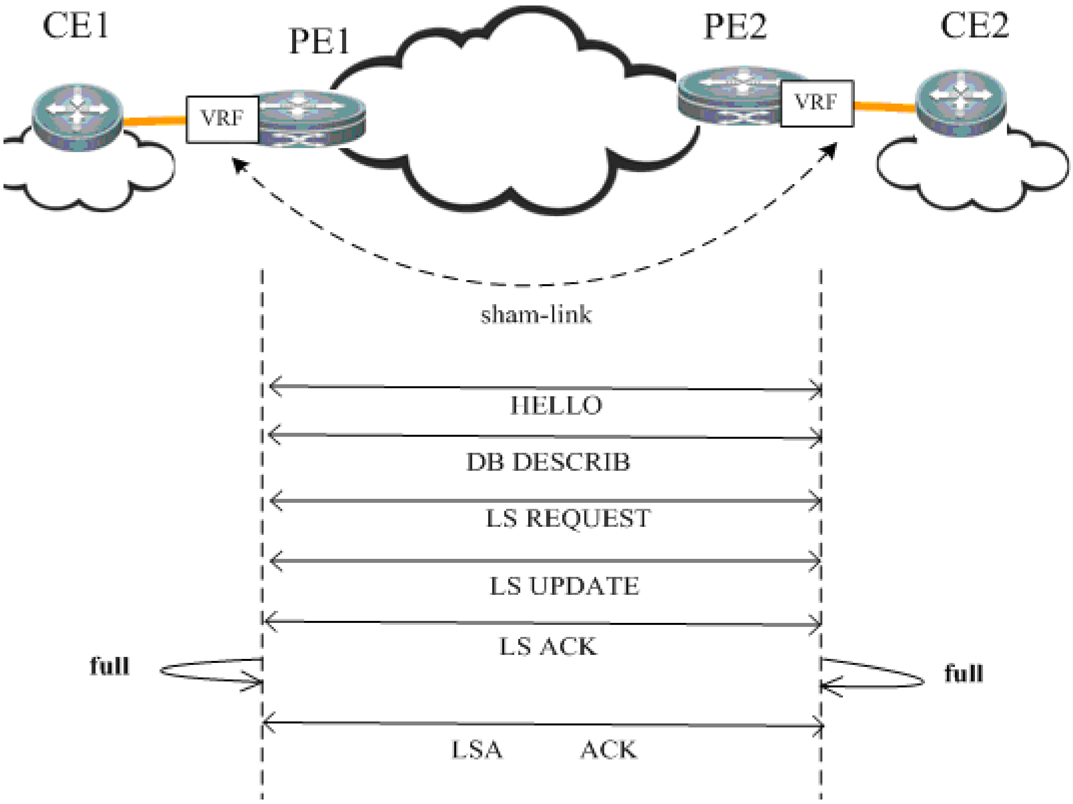


Generally, in L3VPN applications, if OSPF is run between the PE and the CE to exchange VPN routes, it is suggested not to deploy the backbone area at an intra-VPN site. In practice, if intra-VPN routers other than the PE sites also fall into the backbone area, there must be at least one router at this intra-VPN site to connect to the PE, and the link between the CE and the PE must belong to Area 0, so that intra-area routes and external routes can be propagated between the PE and the VPN site.

Sham Link

A sham link is not a real link. It refers to a "virtual link" established between the VRFs of two PEs. The sham link is the same as the normal OSPF link. With its own OSPF interface, it can send OSPF protocol packets, establish neighbors, and send LSAs. When LSAs are flooded over the sham link, all OSPF route types will not be changed, as shown in the following figure.

Figure 28



The purpose of establishing a sham link between VRF OSPF instances on different PEs is as follows:

- The approach of using MP-IBGP to carry a private route will only propagate the route, and the restoration after reaching the peer PE is only to import the original OSPF route information as far as possible, during which the OSPF topology information cannot be truly communicated. By establishing an OSPF link through a sham link, all OSPF instances inside each site can be truly connected and work out complete topology information.
- Different sites in the same VPN exchange information via the MPLS backbone network, but a link is established between VPN sites so that VPN sites can still communicate via this link when the MPLS backbone network fails. This link is called the "backdoor link". If two sites of VPN users fall into the same OSPF area and there is a "backdoor link" connecting these two sites, routes will be exchanged via both the MPLS backbone network and the "backdoor link". Because the routes exchanged via the MPLS backbone network are inter-area routes and the routes exchanged via the "backdoor link" are intra-area routes, and the intra-area routes are apparently superior to inter-area routes, the route forwarding between two sites will hence use the backdoor link. This goes against the purpose of establishing the "backdoor link". Therefore, the sham link must be used in such applications.

Protocol Specification

- RFC 4576 and RFC 4577 specify the mechanism to realize L3VPN OSPF.

Default Configuration

Function	Default Setting
domain-tag	AS number of local BGP
domain-id	Default value: NULL; default type: 0x0005

Function	Default Setting
capability vrf-lite	The PE-CE OSPF feature is supported by the VRF OSPF instance by default.
extcommunity-type	In the OSPF instance extended community attribute carried by BGP, the default type of route-id is 0x0107, and the default type of route-type is 0x0306.

Configuring a Domain ID (Optional)

The domain ID is used to indicate the domain to which the OSPF instance belongs. Generally, all VRF OSPF instances belonging to the same VPN must use the same domain ID.

Use the following commands to configure the domain ID.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router ospf** *ospf-id* **vrf** *vrf-name*	Creates an OSPF instance and enters OSPF configuration mode.
Ruijie(config-router)# **domain-id** {*ip-address* [secondary] | **null | type** {0005|0105|0205|8005} **value** *hex-value* **[secondary]**}	(Optional) Configures the domain ID of the OSPF instance. The OSPF domain ID is 0 by default.
Ruijie(config-router)# **show running-config**	Displays existing configuration information.

☑ Supported by RSR20 series running 10.4(3) or later versions

☑ Supported by RSR30 series running 10.4(3) or later versions

☑ Supported by RSR50 series running 10.4(3) or later versions

☑ Supported by RSR50E series running 10.4(3) or later versions

Note

This command is only applicable to an OSPF instance associated with a VRF.

A VRF OSPF instance can be configured with multiple domain IDs, but there is only one primary domain ID. Others are secondary domain IDs. The only primary domain ID is configured with the **domain-id** *value* command, while multiple secondary domain IDs are configured with the **domain-id** *value* **secondary** command. OSPF routes are advertised when converted into VPN routes, and VPN routes only contain the primary domain ID.

You can use the **domain-id** *ip-address* command or the **domain-id type {0005|0105|0205|8005}** *value* command to configure the primary and secondary domain IDs.

Different VRF OSPF instances can have the same domain ID. However, VRF OSPF instances in the same VPN must be configured with the same domain ID in order to guarantee the correctness of route advertisements.

# Configure the primary domain ID and secondary domain ID of the VRF OSPF protocol to 4.4.4.4 and 5.5.5.5 respectively.

```
Ruijie# configure terminal
```

```
Ruijie(config)# router ospf 10 vrf vrf1
Ruijie(config-router)# domain-id 4.4.4.4
Ruijie(config-router)# domain-id 5.5.5.5 secondary
Ruijie(config-router)# domain-id type 0005 value 010101010101 secondary
```

Configuring a VPN Route Tag (Optional)

Use the following commands to configure a VPN route tag.

Command	**Function**
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# r**outer ospf** *ospf-id* **vrf** *vrf-name*	Creates an OSPF instance and enters OSPF configuration mode.
Ruijie(config-router)# **domain-tag** *value*	(Optional) Configures a VPN route tag (1 to 4294967295) for the OSPF instance.
Ruijie(config-router)# **show running-config**	Displays existing configuration information.

☑ Supported by RSR20 series running 10.4(3) or later versions

☑ Supported by RSR30 series running 10.4(3) or later versions

☑ Supported by RSR50 series running 10.4(3) or later versions

☑ Supported by RSR50E series running 10.4(3) or later versions

Note

This command is only applicable to an OSPF instance associated with a VRF.

If the domain tag of a VRF is not configured manually, the default value is the AS number of the local BGP protocol.

In an L3VPN, if one VPN site is connected with multiple PEs, the VPN route learned by a PE through MP-BGP will be advertised to a VPN site in a type-5 or type-7 LSA. The route may also be learned by other PEs connecting to this VPN site and then advertised, hence causing a loop. To avoid such loop, the same VPN route tag must be configured on the PE for VRF OSPF instances connected to the same VPN site.

When a VRF OSPF instance sends a type-5 or type-7 LSA to the VPN site, this LSA will also carry the VPN route tag. When other PEs receive such type-5 or type-7 LSA containing the VPN route tag, if such route tag is the same as the route tag of the corresponding OSPF instance, this LSA will not participate in OSPF route computation.

Generally, OSPF instances associated with the same VPN must be configured with the same VPN route tag.

# Configure the domain tag of the VRF OSPF protocol to 10.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10 vrf vrf1
Ruijie(config-router)# domain-tag 10
```

Configuring a Sham Link (Optional)

The sham link is mainly used in the scenario where there is a backdoor link between VPN sites. If you still expect to transmit VPN data via the MPLS backbone network, you can establish a sham link between the VRF OSPF instances of two PEs. Both instances can establish OSPF neighbors through this sham link and distribute LSA packets over the sham link.

Use the following commands to configure a sham link.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router ospf** *ospf-id* **vrf** *vrf-name*	Creates an OSPF instance and enters OSPF configuration mode.
Ruijie(config-router)# **area area-id sham-link** *source-address destination-address* [**cost** *number*] [**dead-interval** *seconds*] [**hello-interval** *seconds*] [**retransmit-interval** *seconds*] [**transmit-delay** *seconds*] [**authentication** [**message-digest** | **null**]] [[**authentication-key [0|7]** *key*] | [**message-digest-key** *key-id* **md5 [0|7**] *key*]]	Configures the area ID, source address and destination address of the sham link.
Ruijie(config-router)# **show running-config**	Displays existing configuration information.

☑ Supported by RSR20 series running 10.4(3) or later versions

☑ Supported by RSR30 series running 10.4(3) or later versions

☑ Supported by RSR50 series running 10.4(3) or later versions

☑ Supported by RSR50E series running 10.4(3) or later versions

Note

The sham link must be configured on two PEs that intend to establish the sham link. The sham link cannot be established if only one PE is configured.

The following conditions must be met in order to establish the sham link between two PEs:

1.The area-id of the sham link configured on two PEs must be identical.

2.The source address and destination address of the sham link configured on one PE must correspond to the destination address and source address of the sham link configured on another PE.

3.The source address and destination address used to establish the sham link on the PE must be a 32-bit loopback address bound to a VRF.

Because OSPF routes advertised by a sham link do not carry VPN labels, the routes cannot be used to forward packets. Packets are forwarded through BGP VPNv4 routes. Therefore, there must be VPNv4 routes corresponding to the OSPF routes learned from the sham link.

The source address for a sham link is advertised in BGP VPNv4 routes, but not calculated in OSPF instances.

# Configure a sham link for a VRF OSPF instance, with the area ID being 0, the source address being 1.1.1.1, and the destination address being 2.2.2.2.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10 vrf vrf1
Ruijie(config-router)# area 0 sham-link 1.1.1.1 2.2.2.2
```

Configuring Capability vrf-lite (Optional)

The PE-CE OSPF feature of the VRF OSPF instance includes LSA conversion according to the domain ID, DN bit, and VPN route tag. In certain circumstances, if you do not expect the VRF OSPF instance to support the PE-CE OSPF feature, you can use the **capability vrf-lite** command to disable the feature.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router ospf** *ospf-id* **vrf** *vrf-name*	Creates an OSPF instance and enters OSPF configuration mode.
Ruijie(config-router)# **capability vrf-lite**	(Optional) Disables the PE-CE OSPF feature of the VRF OSPF instance.
Ruijie(config-router)# **show running-config**	Displays existing configuration information.

☑ Supported by RSR20 series running 10.4(3) or later versions

☑ Supported by RSR30 series running 10.4(3) or later versions

☑ Supported by RSR50 series running 10.4(3) or later versions

☑ Supported by RSR50E series running 10.4(3) or later versions

☑ Supported by 3760E series running 10.4(3) or later versions

☑ Supported by 5750 series running 10.4(3) or later versions

☑ Supported by 5760E series running 10.4(3) or later versions

Note

This command is only applicable to an OSPF instance associated with a VRF.

In certain scenarios, you may expect to disable the loop detection function of the VRF OSPF instance. For example: A VPN user uses an MCE device to exchange VPN routes with a PE. If the MCE and PE exchange VPN routes via OSPF, to allow the VPN site to learn the routes of other VPN sites, you must use the **capability vrf-lite** command on the MCE device to disable the loop detection function of the VRF OSPF instance.

# Disable the loop detection function of the VRF OSPF instance.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10 vrf vrf1
Ruijie(config-router)# capability vrf-lite
```

Configuring extcommunity-type (Optional)

When an OSPF route is redistributed to BGP to form a VPN route, the extended community attributes of the OSPF route are also attached, including router-id and route-type. By default, the type of the extended community attribute of router-id is 0x0107, and that of route-type is 0x0306.

You can use the following commands to manually configure the extended community attributes of rouer-id and route-type.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router ospf** *ospf-id* **vrf** *vrf-name*	Creates an OSPF instance and enters OSPF configuration mode.
Ruijie(config-router)# **extcommunity-type {router-id {0107|8001} | route-type {0306|8000}}**	(Optional) Configures the extended community attributes of OSPF router-id and route-type.
Ruijie(config-router)# **show running-config**	Displays existing configuration information.

☑ Supported by RSR20 series running 10.4(3) or later versions

☑ Supported by RSR30 series running 10.4(3) or later versions

☑ Supported by RSR50 series running 10.4(3) or later versions

☑ Supported by RSR50E series running 10.4(3) or later versions

Note

This command is only applicable to an OSPF instance associated with a VRF.

The type configuration of router-id provides good compatibility with multiple manufacturers. For example, some manufacturers support only the router-id type of 0x0107. When interconnecting with devices from such manufacturers, you must use the **extcommunity-type** command to set the type of router-id to 0x0107.

The type configuration of route-type provides good compatibility with multiple manufacturers. For example, some manufacturers support only the route-type type of 0x8000. When interconnecting with devices from such manufacturers, you must use the **extcommunity-type** command to set the type of route-type to 0x8000.

# Configure the type of router-id of the VRF OSPF protocol to 0x0107.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10 vrf vrf1
Ruijie(config-router)# extcommunity-type router-id 0107
```

Verifying the BGP/MPLS IP VPN Configurations

This section describes how to verify the L3VPN configurations and VPN routes.

Enter privileged EXEC mode and run the following commands.

Command	Function
Ruijie# **show ip vrf** [*vrf_name*]	Displays the VRF configuration information.
Ruijie# **show bgp vpnv4 unicast all** [*network* | **neighbor** [*peer-address*] | **summary | label]**	Displays the VPN route information.
Ruijie# **show ip route vrf** *vrf_name* [*ip-address* | **bgp | connected | isis | ospf | rip | static]**	Displays the information about the VRF forwarding table.

# Display the VPN route information.

```
Ruijie# show bgp vpnv4 unicast all
Network        Nexthop     Metric  Localprf           Path
Route Distinguisher : 100: 2
*>i 192.168.0.1/32  192.168.0.2  0      100    10 ?
*>i 192.168.1.0/32  192.168.0.2    0      100     ?
Route Distinguisher : 100:30
*>i 192.168.0.1/32  192.168.0.2  0      100    10 ?
*> 192.168.4.0  192.168.4.1         0            20 ?
* 192.168.4.0    0.0.0.0            0      32768     ?
```

Field	Description
*****	Indicates a valid route.
s (lower-case)	Indicates that the route is suppressed by an aggregate route.
s (upper-case)	Indicates that the route is a stale entry.
>	Indicates that the route is an optimal one.
I	Indicates that the route is learned from the IBGP.
Nexthop	Indicates the next hop information of the route.
Metric	Indicates the route metric.
Localprf	Indicates the local preference of the route.
Path	Indicates the AS path included in the route.
I	Indicates that the origin of the route is IGP.
E	Indicates that the origin of the route is EGP.
?	Indicates that the origin of the route is another attribute except IGP or EGP (for example, a redistributed BGP route).

# Display the information about the VRF routing table.

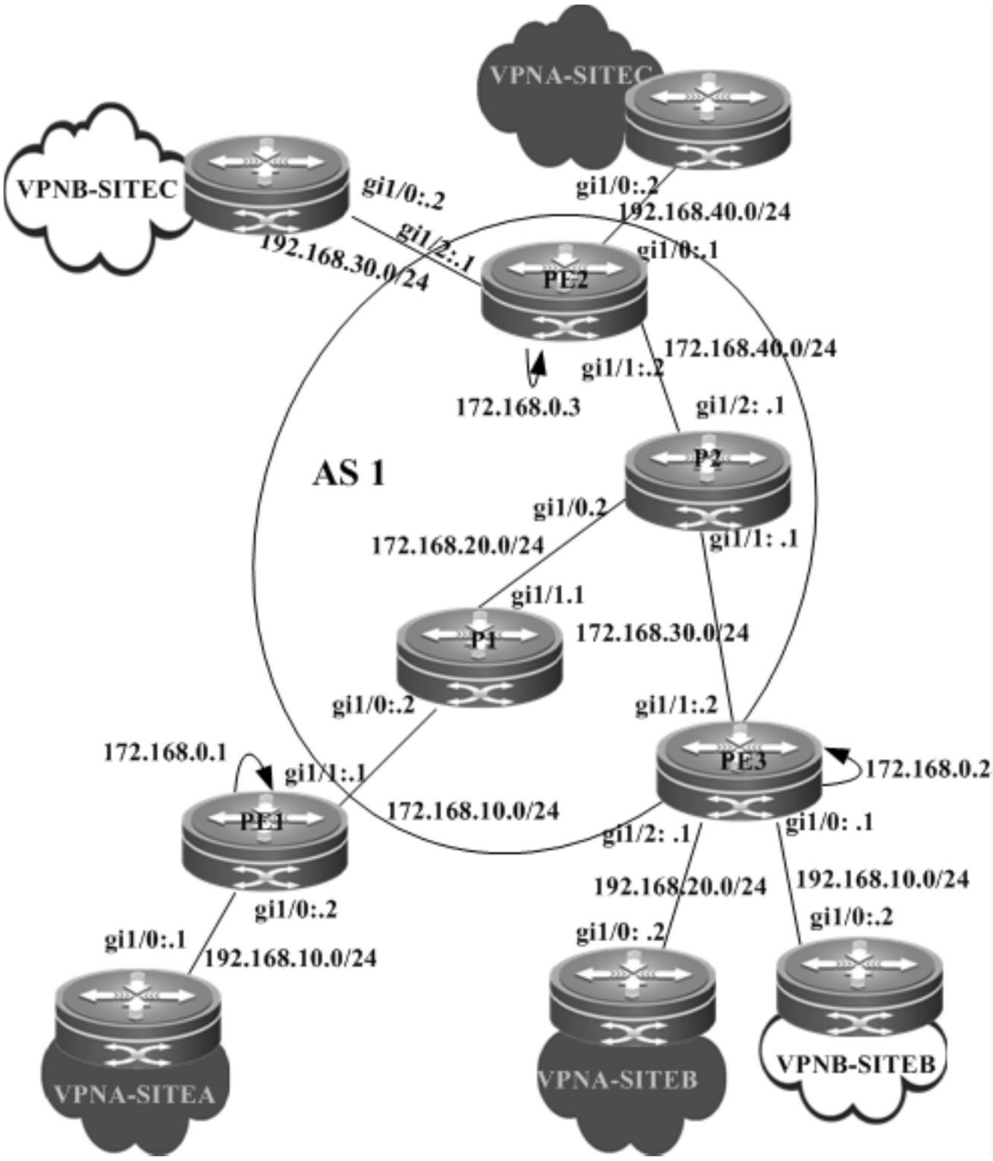
BGP/MPLS IP VPN Configuration Examples

Intranet Configuration Example

Networking Requirements

There are two VPN users: VPNA and VPNB. VPNA has sites at SITEA, SITEB, and SITEC and VPNB has sites at SITEB and SITEC. It is now required that: the users at different sites of VPNA access each other, the users at different sites of VPNB access each other, and the users at the two VPNs not access each other, as shown in the following figure.

Figure 29



Configuration Steps

PE1:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 172.168.0.1 255.255.255.255
```

# Configure the VRF.

Create one VRF instance: VPNA. Set the RD and RT values, and associate the VRF with the corresponding interface.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf VPNA
Ruijie(config-vrf)# rd 1:100
Ruijie(config-vrf)# route-target both 1:100
Ruijie(config-vrf)# end
```

# Associate the VRF with an interface.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/0
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/0)# no switchport
```

# Enable MPLS fast forwarding on a router. This command is unnecessary on a switch.

```
Ruijie(config-if-GigabitEthernet 1/0)# ip ref
Ruijie(config-if-GigabitEthernet 1/0)#ip vrf forwarding VPNA
Ruijie(config-if-GigabitEthernet 1/0)#ip address 192.168.10.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/0)# end
```

# Enable BGP and set up MP-IBGP sessions with PE2 and PE3.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 172.168.0.2 remote-as 1
Ruijie(config-router)# neighbor 172.168.0.2 update-source loopback 0
Ruijie(config-router)# neighbor 172.168.0.3 remote-as 1
Ruijie(config-router)# neighbor 172.168.0.3 update-source loopback 0
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 172.168.0.2 activate
Ruijie(config-router-af)# neighbor 172.168.0.3 activate
Ruijie(config-router-af)# end
```

# Configure CE neighbors through EBGP.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config)# address-family ipv4 vrf VPNA
Ruijie(config-router-af)# neighbor 172.168.10.1 remote-as 65002
Ruijie(config-router-af)# end
```

# Configure the MPLS signaling protocol on the backbone network and enable MPLS on the public network interface.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
```

# Enable MPLS fast forwarding on a router. This command is unnecessary on a switch.

```
Ruijie(config-if-GigabitEthernet 1/1)# ip ref
Ruijie(config-if-GigabitEthernet 1/1)# ip address 172.168.10.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)# label-switching
Ruijie(config-if-GigabitEthernet 1/1)# mpls ip
Ruijie(config-if-GigabitEthernet 1/1)# end
```

# Configure a routing protocol on the backbone network.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 172.168.10.0 0.0.0.255 area 0
Ruijie(config-router)# network 172.168.0.1 0.0.0.0 area 0
Ruijie(config-router)# end
```

PE2:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 172.168.0.3 255.255.255.255
```

# Configure the VRF.

Create two VRFs: VPNA and VPNB. Set the RD and RT values, and associate the VRFs with corresponding interfaces.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf VPNA
Ruijie(config-vrf)# rd 1:100
Ruijie(config-vrf)# route-target both 1:100
Ruijie(config-vrf)# exit
Ruijie(config)# ip vrf VPNB
Ruijie(config-vrf)# rd 1:200
Ruijie(config-vrf)# route-target both 1:200
Ruijie(config-vrf)# exit
```

# Associate the VRF with an interface.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/0
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/0)# no switchport
```

# Enable MPLS fast forwarding on a router. This command is unnecessary on a switch.

```
Ruijie(config-if-GigabitEthernet 1/0)# ip ref
Ruijie(config-if-GigabitEthernet 1/0)# ip vrf forwarding VPNB
Ruijie(config-if-GigabitEthernet 1/0)# ip address 192.168.10.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/0)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
```

# Enable MPLS fast forwarding on a router. This command is unnecessary on a switch.

```
Ruijie(config-if-GigabitEthernet 1/1)# ip ref
Ruijie(config-if-GigabitEthernet 1/1)#ip vrf forwarding VPNA
Ruijie(config-if-GigabitEthernet 1/1)#ip address 192.168.20.1
255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)# exit
```

# Enable BGP and set up MP-IBGP sessions with PE2 and PE3.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 172.168.0.1 remote-as 1
Ruijie(config-router)# neighbor 172.168.0.1 update-source loopback 0
Ruijie(config-router)# neighbor 172.168.0.3 remote-as 1
Ruijie(config-router)# neighbor 172.168.0.3 update-source loopback 0
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 172.168.0.1 activate
Ruijie(config-router-af)# neighbor 172.168.0.3 activate
Ruijie(config-router-af)# end
```

# Configure CE neighbors through EBGP.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config)# address-family ipv4 vrf VPNA
Ruijie(config-router-af)# neighbor 172.168.20.2 remote-as 65003
Ruijie(config-router-af)# exit
Ruijie(config)# address-family ipv4 vrf VPNB
Ruijie(config-router-af)# neighbor 172.168.10.2 remote-as 65004
Ruijie(config-router-af)# end
```

# Configure the MPLS signaling protocol on the backbone network and enable MPLS on the public network interface.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
```

# Enable MPLS fast forwarding on a router. This command is unnecessary on a switch.

```
Ruijie(config-if-GigabitEthernet 1/1)# ip ref
Ruijie(config-if-GigabitEthernet 1/1)# ip address 172.168.30.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)# label-switching
Ruijie(config-if-GigabitEthernet 1/1)# mpls ip
Ruijie(config-if-GigabitEthernet 1/1)# end
```

# Configure a routing protocol on the backbone network.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 172.168.30.0 255.255.255.0 area 0
Ruijie(config-router)# network 172.168.0.2 255.255.255.255 area 0
Ruijie(config-router)# end
```

PE3:

The configuration procedure is similar to that of PE2.

VPNA-SITEA:

Set up an EBGP session with PE1.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 65002
Ruijie(config-router)# neighbor 172.168.10.2 remote-as 1
Ruijie(config-router-af)# end
```

VPNA-SITEB:

The configuration procedure is similar to that of VPNA-SITEA.

VPNA-SITEC:

The configuration procedure is similar to that of VPNA-SITEA.

VPNB-SITEB:

The configuration procedure is similar to that of VPNA-SITEA.

VPNB-SITEC:

The configuration procedure is similar to that of VPNA-SITEA.

P1:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 172.168.0.5 255.255.255.255
```

# Configure the MPLS signaling protocol on the backbone network and enable MPLS on the public network interface.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/0
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/0)# no switchport
```

# Enable MPLS fast forwarding on a router. This command is unnecessary on a switch.

```
Ruijie(config-if-GigabitEthernet 1/0)# ip ref
Ruijie(config-if-GigabitEthernet 1/0)# ip address 172.168.10.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/0)# label-switching
Ruijie(config-if-GigabitEthernet 1/0)# mpls ip
Ruijie(config-if-GigabitEthernet 1/0)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
```

# Enable MPLS fast forwarding on a router. This command is unnecessary on a switch.

```
Ruijie(config-if-GigabitEthernet 1/1)# ip ref
Ruijie(config-if-GigabitEthernet 1/1)# ip address 172.168.20.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)# label-switching
Ruijie(config-if-GigabitEthernet 1/1)# mpls ip
Ruijie(config-if-GigabitEthernet 1/0)# end
```

# Configure a routing protocol on the backbone network.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 172.168.10.0 0.0.0.255 area 0
Ruijie(config-router)# network 172.168.20.0 0.0.0.255 area 0
Ruijie(config-router)# end
```

P2:

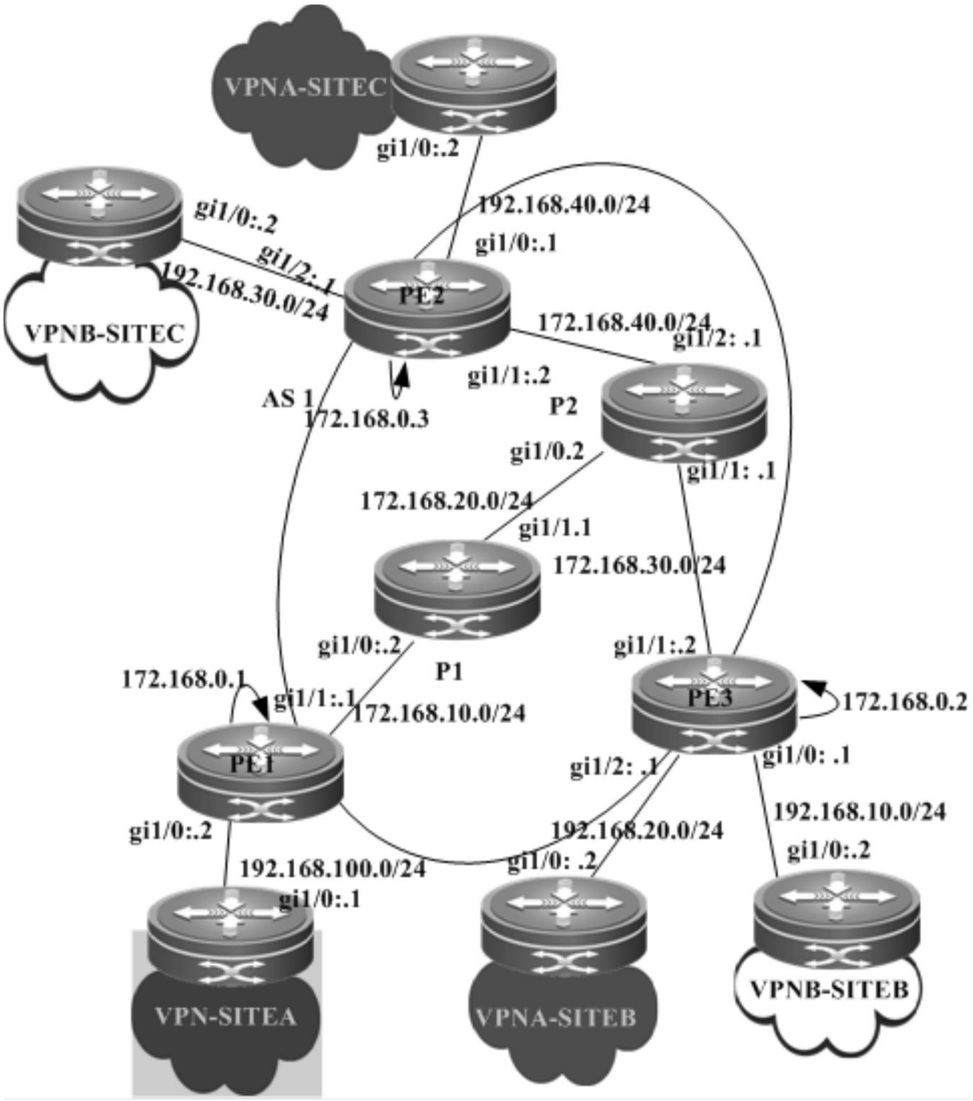
The configuration procedure is similar to that of P1.

Extranet Configuration Example

Networking Requirements

There are two VPN users: VPNA and VPNB. Mutual access is required in a VPN. The two VPNs cannot access each other but can access some shared resources. As shown in the following figure, VPNA and VPNB sites should access the resources of VPN-SITEA.

Figure 30



Configuration Steps

PE1:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 172.168.0.1 255.255.255.255
```

# Configure the VRF.

Create one VRF instance: VPN_EXTRA. Set the RD and RT values, and associate the VRF with the corresponding interface.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf VPN_EXTRA
Ruijie(config-vrf)# rd 1:100
Ruijie(config-vrf)# route-target both 1:100
Ruijie(config-vrf)# route-target both 1:200
Ruijie(config-vrf)# end
```

# Associate the VRF with an interface.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/0
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/0)# no switchport
```

# Enable MPLS fast forwarding on a router. This command is unnecessary on a switch.

```
Ruijie(config-if-GigabitEthernet 1/0)# ip ref
Ruijie(config-if-GigabitEthernet 1/0)# ip vrf forwarding VPN_EXTRA
Ruijie(config-if-GigabitEthernet 1/0)# ip address 192.168.100.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/0)# end

Ruijie(config-router)# network 172.168.0.2 0.0.0.0 area 0
Ruijie(config-router)# end
```

PE3:

The configuration procedure is similar to that of PE2.

VPNA-SITEA:

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 192.168.100.0 255.255.255.0 area 0
Ruijie(config-router)# end
```

VPNA-SITEB:

The configuration procedure is similar to that of VPNA-SITEA.

VPNA-SITEC:

The configuration procedure is similar to that of VPNA-SITEA.

VPNB-SITEB:

The configuration procedure is similar to that of VPNA-SITEA.

VPNB-SITEC:

The configuration procedure is similar to that of VPNA-SITEA.

P1:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 172.168.0.5 255.255.255.255
```

# Configure the MPLS signaling protocol on the backbone network and enable MPLS on the public network interface.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/0
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/0)# no switchport
```

# Enable MPLS fast forwarding on a router. This command is unnecessary on a switch.

```
Ruijie(config-if-GigabitEthernet 1/0)# ip ref
Ruijie(config-if-GigabitEthernet 1/0)# ip address 172.168.10.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/0)# label-switching
Ruijie(config-if-GigabitEthernet 1/0)# mpls ip
Ruijie(config-if-GigabitEthernet 1/0)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
```

# Enable MPLS fast forwarding on a router. This command is unnecessary on a switch.

```
Ruijie(config-if-GigabitEthernet 1/1)# ip ref
Ruijie(config-if-GigabitEthernet 1/1)# ip address 172.168.20.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)# label-switching
Ruijie(config-if-GigabitEthernet 1/1)# mpls ip
Ruijie(config-if-GigabitEthernet 1/0)# end
```

# Configure a routing protocol on the backbone network.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 1
Ruijie(config-router)# network 172.168.10.0 0.0.0.255 area 0
Ruijie(config-router)# network 172.168.20.0 0.0.0.255 area 0
Ruijie(config-router)# end
```

P2:

The configuration procedure is similar to that of P1.

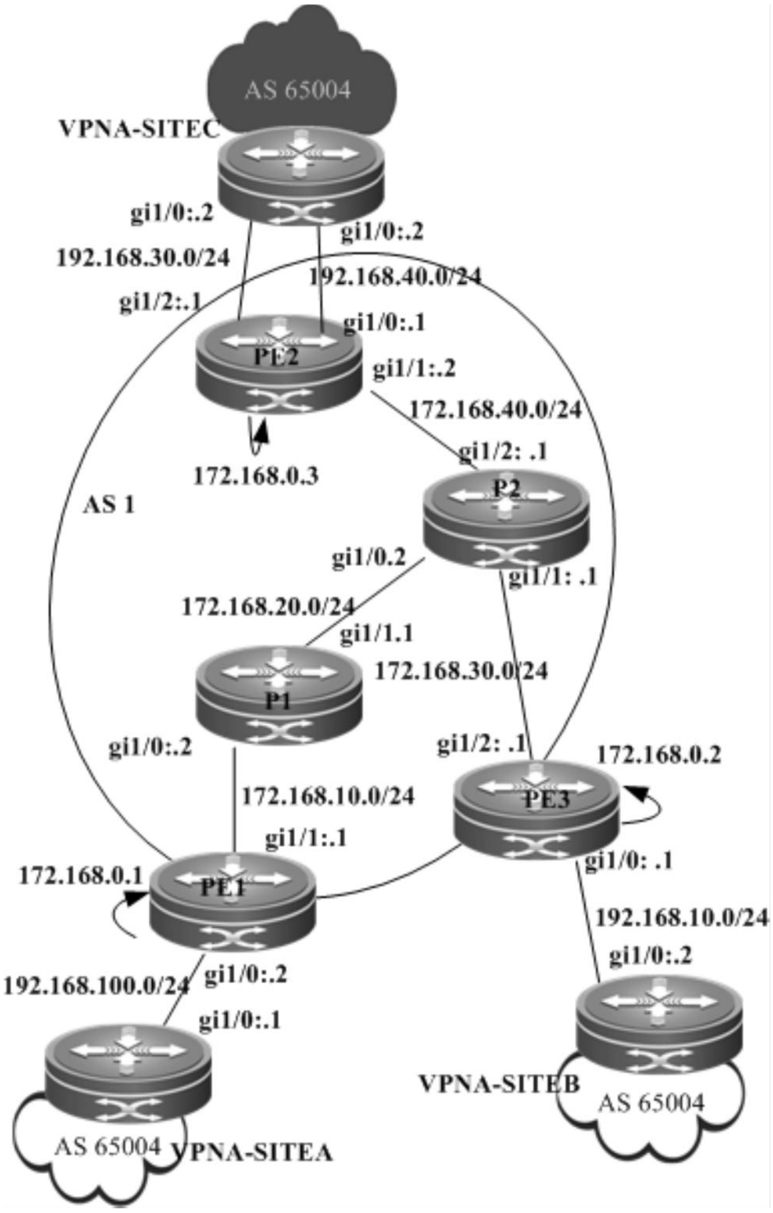
For the protocol between PEs and CEs, you can choose EBGP, OSPF, RIP, or other routing protocol as required.

Hub-and-Spoke Configuration Example

Networking Requirements

The VPN internal data should not be directly exchanged. Instead, the data must be exchanged through the unified control center. Only the control center is entitled to access all resources of a VPN. Any VPN users who want to obtain the VPN resources, must be notified through the control center. As shown in the following figure, to access VPNA-SITEB resources, VPNA-SITEA must pass the control center VPNA-SITEC. Direct access is not available.

Figure 31



Configuration Steps

PE1:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 172.168.0.1 255.255.255.255
```

# Configure the VRF.

Create one VRF instance: spoke1. Set the RD and RT values, and associate the VPNA with the corresponding interface.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf spoke1
Ruijie(config-vrf)# rd 1:100
Ruijie(config-vrf)# route-target export 1:200
Ruijie(config-vrf)# route-target import 1:100
Ruijie(config-vrf)# end
```

# Associate the VRF with an interface.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/0
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/0)# no switchport
```

# Enable MPLS fast forwarding on a router. This command is unnecessary on a switch.

```
Ruijie(config-if-GigabitEthernet 1/0)# ip ref
Ruijie(config-if-GigabitEthernet 1/0)# ip vrf forwarding spoke1
Ruijie(config-if-GigabitEthernet 1/0)# ip address 192.168.100.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/0)# end
```

# Enable BGP and set up MP-IBGP sessions with PE3.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 172.168.0.3 remote-as 1
Ruijie(config-router)# neighbor 172.168.0.3 update-source loopback 0
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 172.168.0.3 activate
Ruijie(config-router-af)# neighbor 172.168.0.3 allowas-in
Ruijie(config-router-af)# end
```

# Configure CE neighbors through EBGP.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config)# address-family ipv4 vrf spoke1
Ruijie(config-router-af)# neighbor 192.168.100.1 remote-as 65004
Ruijie(config-router-af)# neighbor 192.168.100.1 as-override
Ruijie(config-router-af)# end
```

# Configure the MPLS signaling protocol on the backbone network and enable MPLS on the public network interface.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
```

# Enable MPLS fast forwarding on a router. This command is unnecessary on a switch.

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
Ruijie(config-if-GigabitEthernet 1/1)# ip address 172.168.10.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)# label-switching
Ruijie(config-if-GigabitEthernet 1/1)# mpls ip
Ruijie(config-if-GigabitEthernet 1/1)# end
```

# Configure a routing protocol on the backbone network.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 172.168.10.0 0.0.0.255 area 0
Ruijie(config-router)# network 172.168.0.1 0.0.0.0 area 0
Ruijie(config-router)# end
```

PE2:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 172.168.0.3 255.255.255.255
```

# Configure the VRF.

Create one VRF instance: spoke2. Set the RD and RT values, and associate the VRF with the corresponding interface.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf spoke2
Ruijie(config-vrf)# rd 1:100
Ruijie(config-vrf)# route-target export 1:300
Ruijie(config-vrf)# route-target import 1:100
Ruijie(config-vrf)# exit
```

# Associate the VRF with an interface.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/0
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/0)# no switchport
```

# Enable MPLS fast forwarding on a router. This command is unnecessary on a switch.

```
Ruijie(config-if-GigabitEthernet 1/0)# no switchport
Ruijie(config-if-GigabitEthernet 1/0)# ip vrf forwarding spoke2
Ruijie(config-if-GigabitEthernet 1/0)# ip address 192.168.10.1
255.255.255.0
Ruijie(config-if-GigabitEthernet 1/0)# exit
```

# Enable BGP and set up MP-IBGP sessions with PE3.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 172.168.0.3 remote-as 1
Ruijie(config-router)# neighbor 172.168.0.3 update-source loopback 0
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 172.168.0.3 activate
Ruijie(config-router-af)# neighbor 172.168.0.3 allowas-in
Ruijie(config-router-af)# end
```

# Configure CE neighbors through EBGP.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# address-family ipv4 vrf spoke2
Ruijie(config-router-af)# neighbor 192.168.10.2 remote-as 65004
Ruijie(config-router-af)# neighbor 192.168.10.2 as-override
Ruijie(config-router-af)# end
```

# Configure the MPLS signaling protocol on the backbone network and enable MPLS on the public network interface.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
```

# Enable MPLS fast forwarding on a router. This command is unnecessary on a switch.

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
Ruijie(config-if-GigabitEthernet 1/1)# ip address 172.168.30.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)# label-switching
Ruijie(config-if-GigabitEthernet 1/1)# mpls ip
Ruijie(config-if-GigabitEthernet 1/1)# end
```

# Configure a routing protocol on the backbone network.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 172.168.30.0 0.0.0.255 area 0
Ruijie(config-router)# network 172.168.0.2 0.0.0.0 area 0
Ruijie(config-router)# end
```

PE3:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 172.168.0.2 255.255.255.255
```

# Configure the VRF.

Create two VRF instances: from-spoke and from-hub. Set the RD and RT values, and associate the VRFs with corresponding interfaces.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf from-spoke
Ruijie(config-vrf)# rd 1:100
Ruijie(config-vrf)# route-target import 1:300
Ruijie(config-vrf)# route-target import 1:200
Ruijie(config-vrf)# exit
Ruijie(config)# ip vrf from-hub
Ruijie(config-vrf)# rd 1:200
Ruijie(config-vrf)# route-target export 1:100
Ruijie(config-vrf)# exit
```

# Associate the VRF with an interface.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/0
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/0)# no switchport
```

# Enable MPLS fast forwarding on a router. This command is unnecessary on a switch.

```
Ruijie(config-if-GigabitEthernet 1/0)# no switchport
Ruijie(config-if-GigabitEthernet 1/0)# ip vrf forwarding from-hub
Ruijie(config-if-GigabitEthernet 1/0)# ip address 192.168.40.1
255.255.255.0
Ruijie(config-if-GigabitEthernet 1/0)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
```

# Enable MPLS fast forwarding on a router. This command is unnecessary on a switch.

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
Ruijie(config-if-GigabitEthernet 1/1)# ip vrf forwarding from-spoke
Ruijie(config-if-GigabitEthernet 1/1)# ip address 192.168.30.1
255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)# exit
```

# Enable BGP and set up MP-IBGP sessions with PE1 and PE2.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 172.168.0.1 remote-as 1
Ruijie(config-router)# neighbor 172.168.0.1 update-source loopback 0
Ruijie(config-router)# neighbor 172.168.0.2 remote-as 1
Ruijie(config-router)# neighbor 172.168.0.2 update-source loopback 0
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 172.168.0.3 activate
Ruijie(config-router-af)# neighbor 172.168.0.2 activate
Ruijie(config-router-af)# end
```

# Configure CE neighbors through EBGP.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# address-family ipv4 vrf from-spoke
Ruijie(config-router-af)# neighbor 192.168.30.2 remote-as 65004
Ruijie(config-router-af)# neighbor 192.168.30.2 as-override
Ruijie(config-router-af)# exit
Ruijie(config-router)# address-family ipv4 vrf from-hub
Ruijie(config-router-af)# neighbor 192.168.40.2 remote-as 65004
Ruijie(config-router-af)# neighbor 192.168.40.2 allows-in
Ruijie(config-router-af)# exit
```

# Configure the MPLS signaling protocol on the backbone network and enable MPLS on the public network interface.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
```

# Enable MPLS fast forwarding on a router. This command is unnecessary on a switch.

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
Ruijie(config-if-GigabitEthernet 1/1)# ip address 172.168.30.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)# label-switching
Ruijie(config-if-GigabitEthernet 1/1)# mpls ip
Ruijie(config-if-GigabitEthernet 1/1)# end
```

# Configure a routing protocol on the backbone network.

```
Ruijie# configure terminal
```

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 172.168.30.0 0.0.0.255 area 0
Ruijie(config-router)# network 172.168.0.2 0.0.0.0 area 0
Ruijie(config-router)# end
```

VPNA-SITEA:

# Configure a PE session through EBGP.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 65004
Ruijie(config-router)# neighbor 192.168.100.2 remote-as 1
Ruijie(config-router)# exit
```

The configuration of VPNA-SITEB is similar to that of VPNA-SITEA.

VPNA-SITEC:

# Configure a PE session through EBGP.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 65004
Ruijie(config-router)# neighbor 192.168.30.1 remote-as 1
Ruijie(config-router)# neighbor 192.168.40.1 remote-as 1
Ruijie(config-router)# exit
```

Internet Unified Egress Interface Configuration Example

Networking Requirements

Several VPNs cannot access each other, but the VPNs need to access the Internet through a device. As shown in Figure 32 and Figure 33, VPN1 and VPN2 cannot access each other but can access the Internet through PE1.

To isolate VPN1 and VPN2, you can use centralized isolation or distributed isolation. The differences between the above schemes are as follows:

For the centralized isolation, add filtering rules on only a CE egress interface for subsequently added VPN sites to access the Internet through the unified egress interface. Other VPN sites do not need any change of configuration. This scheme features good scalability. The disadvantage of this scheme is that isolated packets can be discarded only when they reach the CE egress interface, which consumes network bandwidth.

For the distributed isolation, add filtering rules on the CE of each VPN site that needs to access the Internet through the unified egress interface. This scheme features poor scalability. The advantage of this scheme is that isolated packets are discarded on the CE of a VPN site, which saves network bandwidth.

Networking Requirements

Several VPNs cannot access each other, but the VPNs need to access the Internet through a device. As shown in Figure 32 and Figure 33, VPN1 and VPN2 cannot access each other but can access the Internet through PE1.

To isolate VPN1 and VPN2, you can use centralized isolation or distributed isolation. The differences between the above schemes are as follows:

For the centralized isolation, add filtering rules on only a CE egress interface for subsequently added VPN sites to access the Internet through the unified egress interface. Other VPN sites do not need any change of configuration. This scheme features good scalability. The disadvantage of this scheme is that isolated packets can be discarded only when they reach the CE egress interface, which consumes network bandwidth.

For the distributed isolation, add filtering rules on the CE of each VPN site that needs to access the Internet through the unified egress interface. This scheme features poor scalability. The advantage of this scheme is that isolated packets are discarded on the CE of a VPN site, which saves network bandwidth.

Centralized Isolation

Configuration Steps

- Configuring PE2

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 2.2.2.2 255.255.255.255
```

# Configure the VRF.

Create a VRF, create VPN1, and set the RD and RT values.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf VPN1
Ruijie(config-vrf)# rd 1:100
Ruijie(config-vrf)# route-target both 1:100
Ruijie(config-vrf)# end
```

# Associate the VRF with an interface.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/2
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/2)# no switchport
Ruijie(config-if-GigabitEthernet 1/2)# ip vrf forwarding VPN1
Ruijie(config-if-GigabitEthernet 1/2)# ip address 191.10.10.2
255.255.255.0
Ruijie(config-if-GigabitEthernet 1/2)# end
```

# Configure OSPF route exchange with CE2.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10 vrf VPN2
Ruijie(config-router)# network 191.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# default-information originate
Ruijie(config-router)# redistribute bgp subnets
Ruijie(config-router)# exit
```

# Establish an IBGP neighbor relation with PE1.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 1.1.1.1 remote-as 1
Ruijie(config-router)# neighbor 1.1.1.1 update-source loopback 0
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 1.1.1.1 activate
Ruijie(config-router-af)# end
```

# Configure IP route distribution.

```
Ruijie(config)# router bgp 1
Ruijie(config-router)# address-family ipv4 vrf VPN1
Ruijie(config-router-af)# redistribute ospf 10
Ruijie(config-router-af)# end
```

# Configure MPLS signaling for the backbone network and enable MPLS on the public network interface.

```
Ruijie# configure terminal
```

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
Ruijie(config-if-GigabitEthernet 1/1)# ip address 59.10.11.2
255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)# label-switching
Ruijie(config-if-GigabitEthernet 1/1)# mpls ip
Ruijie(config-if-GigabitEthernet 1/1)# end
```

# Configure a routing protocol on the backbone network.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 1
Ruijie(config-router)# network 59.10.11.0 0.0.0.255 area 0
Ruijie(config-router)# network 2.2.2.2 0.0.0.0 area 0
Ruijie(config-router)# end
```

- Configuring CE2

# Configure the IP address of an interface connected to PE2.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
Ruijie(config-if-GigabitEthernet 1/1)# ip address 191.10.10.1 255.255.255.0
```

# Configure OSPF route exchange with PE2.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 1
Ruijie(config-router)# network 191.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# network 172.11.0.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

- Configuring PE3

The configuration is similar to the PE2 configuration. Assume that the export and import RT of VPN2 is 1: 200.

- Configuring PE1

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255
```

# Create the trunk interface.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/3
Ruijie(config)# switch mode trunk
Ruijie(config)# switch trunk vlan allow remove vlan 1-9,11-19,21-4094
```

# Configure the out_vrf as the outgoing interface for accessing the Internet.

Create a VRF, configure the vrf_out, set the RD and RT values, and associate the VRF with the corresponding interface.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf vrf_out
Ruijie(config-vrf)# rd 1:300
Ruijie(config-vrf)# route-target export 1:100
Ruijie(config-vrf)# route-target export 1:200
Ruijie(config-vrf)# end
```

# Bind the interface to the VRF.

```
Ruijie# configure terminal
Ruijie(config)#interface vlan 20
Ruijie(config-if-Vlan 20)# ip vrf forwarding vrf_out
Ruijie(config-if-Vlan 20)# ip address 20.10.10.1 255.255.255.0
```

# Configure the default route to the Internet.

```
Ruijie# configure terminal
Ruijie(config)# ip route vrf vrf_out 0.0.0.0 0.0.0.0 vlan 20 20.10.10.2
```

# Configure in_vrf as the incoming interface of traffic returned from the Internet.

Create a VRF, configure the vrf_in, set the RD and RT values, and associate the VRF with the corresponding interface.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf vrf_in
Ruijie(config-vrf)# rd 1:400
Ruijie(config-vrf)# route-target import 1:100
Ruijie(config-vrf)# route-target import 1:200
Ruijie(config-vrf)# end
```

# Bind the interface to the VRF.

```
Ruijie# configure terminal
Ruijie(config)#interface vlan 10
Ruijie(config-if-Vlan 20)# ip vrf forwarding vrf_in
Ruijie(config-if-Vlan 20)# ip address 30.10.10.1 255.255.255.0
```

# Configure EBGP route exchange with CE1.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# address-family ipv4 vrf vrf_in
Ruijie(config-router-af)# neighbor 30.10.10.2 remote-as 100
```

# Establish IBGP neighbor relations with PE2 and PE3.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 2.2.2.2 remote-as 1
Ruijie(config-router)# neighbor 2.2.2.2 update-source loopback 0
Ruijie(config-router)# neighbor 3.3.3.3 remote-as 1
Ruijie(config-router)# neighbor 3.3.3.3 update-source loopback 0
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 2.2.2.2 activate
Ruijie(config-router-af)# neighbor 3.3.3.3 activate
Ruijie(config-router-af)# end
```

# Configure VRF vrf_out route exchange.

```
Ruijie(config)# router bgp 1
Ruijie(config-router)# address-family ipv4 vrf vrf_out
Ruijie(config-router-af)# default-information originate
Ruijie(config-router-af)# redistribute static
Ruijie(config-router-af)# end
```

# Configure MPLS signaling for the backbone network and enable MPLS on the public network interface.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/2
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/2)# no switchport
Ruijie(config-if-GigabitEthernet 1/2)# ip address 59.10.11.1
255.255.255.0
Ruijie(config-if-GigabitEthernet 1/2)# label-switching
Ruijie(config-if-GigabitEthernet 1/2)# mpls ip
Ruijie(config-if-GigabitEthernet 1/2)# end
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
Ruijie(config-if-GigabitEthernet 1/1)# ip address 59.10.10.1
255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)# label-switching
Ruijie(config-if-GigabitEthernet 1/1)# mpls ip
Ruijie(config-if-GigabitEthernet 1/1)# end
```

# Configure a routing protocol on the backbone network.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 1
Ruijie(config-router)# network 59.10.11.0 0.0.0.255 area 0
Ruijie(config-router)# network 59.10.10.0 0.0.0.255 area 0

Ruijie(config)# access-list 2000 permit ip any any
```

# Apply the ACL rule to the interface.

```
Ruijie(config)# interface gigabitethernet 0/1
Ruijie(config-if-Gigabitethernet 0/1)# ip access-group 2000 out
```

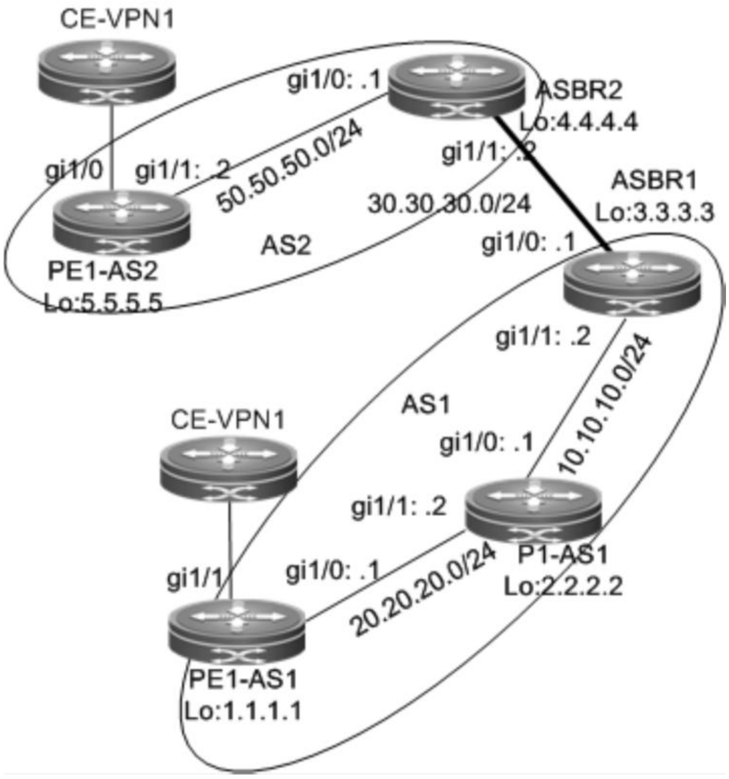
# Other configurations are the same as Centralized Isolation.

Inter-AS VPN OptionB: Next Hop Unchanged

Networking Requirements

One VPN user has sites at both ASs. It is required that the VPN sites in different ASs access each other.

Figure 34 OptionB: Next Hop Unchanged



The configuration scheme is as follows:

PE1-AS1:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255
```

# Configure the VRF.

Create one VRF instance: VPN1. Set the RD and RT values, and associate the VRF with the corresponding interface.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf VPN1
Ruijie(config-vrf)# rd 1:100
Ruijie(config-vrf)# route-target both 1:100
Ruijie(config-vrf)# end
```

# Associate the VRF with an interface.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
Ruijie(config-if-GigabitEthernet 1/1)# ip vrf forwarding VPN1
Ruijie(config-if-GigabitEthernet 1/1)# ip address 192.168.16.2
255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)# end
```

# Enable BGP and set up MP-IBGP sessions with ASBR1.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 3.3.3.3 remote-as 1
Ruijie(config-router)# neighbor 3.3.3.3 update-source loopback 0
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 3.3.3.3 activate
Ruijie(config-router-af)# end
```

# Configure CE neighbors through EBGP.

See the configuration procedure in the "Running BGP Between PEs and CEs to Transmit Route Information" section and the related configurations in the "Intranet Configuration Examples" section.

# Configure the MPLS signaling protocol on the backbone network and enable MPLS on the public network interface.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/0
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/0)# no switchport
Ruijie(config-if-GigabitEthernet 1/0)# ip address 20.20.20.1
255.255.255.0
Ruijie(config-if-GigabitEthernet 1/0)# label-switching
Ruijie(config-if-GigabitEthernet 1/0)# mpls ip
Ruijie(config-if-GigabitEthernet 1/0)# end
```

# Configure a routing protocol on the backbone network.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)# end
```

The configuration procedure of **PE1-AS2** is similar to the preceding one.

P1-AS1:

# Configure the loopback interface.

```
Ruijie# configure terminal
```

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 2.2.2.2 255.255.255.255
```

# Configure the MPLS signaling protocol on the backbone network and enable MPLS on the public network interface.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/0
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/0)# no switchport
Ruijie(config-if-GigabitEthernet 1/0)# ip address 10.10.10.1
255.255.255.0
Ruijie(config-if-GigabitEthernet 1/0)# label-switching
Ruijie(config-if-GigabitEthernet 1/0)# mpls ip
Ruijie(config-if-GigabitEthernet 1/0)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
Ruijie(config-if-GigabitEthernet 1/1)# ip address 20.20.20.2
255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)# label-switching
Ruijie(config-if-GigabitEthernet 1/1)# mpls ip
```

# Configure a routing protocol on the backbone network.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# network 2.2.2.2 0.0.0.0 area 0
Ruijie(config-router)# end
```

ASBR1:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 3.3.3.3 255.255.255.255
```

# Enable BGP, disable the BGP RT filtering function, and establish neighbor relations with PE1-AS1 and ASBR2.

```
Ruijie# configure terminal
```

```
Ruijie(config)# router bgp 1
Ruijie(config-router)# no bgp default route-target filter
Ruijie(config-router)# neighbor 1.1.1.1 remote-as 1
Ruijie(config-router)# neighbor 1.1.1.1 update-source loopback 0
Ruijie(config-router)# neighbor 30.30.30.2 remote-as 2
Ruijie(config-router)# address-family vpnv4 unicast
Ruijie(config-router-af)# neighbor 1.1.1.1 activate
Ruijie(config-router-af)# neighbor 30.30.30.2 activate
Ruijie(config-router-af)# end
```

# Configure MPLS signaling and enable MPLS on a public network interface.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
Ruijie(config-if-gigabitethernet 1/1)# ip address 10.10.10.2
255.255.255.0
Ruijie(config-if-gigabitethernet 1/1)# label-switching
Ruijie(config-if-gigabitethernet 1/1)# mpls ip
Ruijie(config-if-gigabitethernet 1/1)# end
```

# Run OSPF on the backbone network to transmit routes and redistribute directly connected subnet routes.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# network 3.3.3.3 0.0.0.0 area 0
Ruijie(config-router)# redisteibute connected subnets
Ruijie(config-router)# end
```

# Assign an IP address to the interface connected to ASBR2.

```
Ruijie(config)# interface gigabitethernet 1/0
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/0)# no switchport
Ruijie(config-if-gigabitethernet 1/0)# ip address 30.30.30.1
255.255.255.0
```

# Enable label switching on an interface.

```
Ruijie(config-if-gigabitethernet 1/0)# label-switching
```

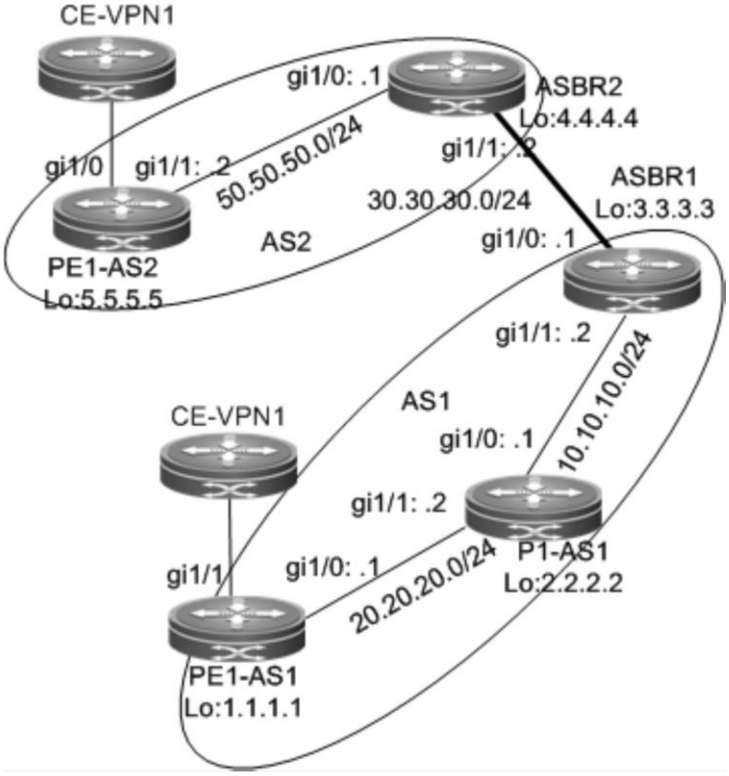
The configuration scheme of ASBR2 is similar to that of ASBR1.

Inter-AS VPN OptionB: Next Hop Changed

Networking Requirements

One VPN user has sites at both ASs. It is required that the VPN sites in different ASs access each other.

Figure 35 OptionB: Next Hop Changed



The configuration scheme is as follows:

PE1-AS1:

The configuration procedure is similar to that of PE1-AS1 in the "Inter-AS VPN OptionB: Next Hop Unchanged" section and is not described here.

P1-AS1:

The configuration procedure is similar to that of P1-AS1 in the "Inter-AS VPN OptionB: Next Hop Unchanged" section and is not described here.

ASBR1:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 3.3.3.3 255.255.255.255
```

# Enable BGP, disable the BGP RT filtering function, establish neighbor relations with the PE and ASBR, and change the next hop of routes to the neighbor PE into the local address.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# no bgp default route-target filter
Ruijie(config-router)# neighbor 1.1.1.1 remote-as 1
Ruijie(config-router)# neighbor 1.1.1.1 update-source loopback 0
Ruijie(config-router)# neighbor 30.30.30.2 remote-as 2
Ruijie(config-router)# address-family vpnv4 unicast
Ruijie(config-router-af)# neighbor 1.1.1.1 activate
Ruijie(config-router-af)# neighbor 1.1.1.1 next-hop-self
Ruijie(config-router-af)# neighbor 30.30.30.2 activate
Ruijie(config-router-af)# end
```

# Configure MPLS signaling and enable MPLS on a public network interface.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-gigabitethernet 1/1)# no switchport
Ruijie(config-if-gigabitethernet 1/1)# ip address 10.10.10.2
255.255.255.0
Ruijie(config-if-gigabitethernet 1/1)# label-switching
Ruijie(config-if-gigabitethernet 1/1)# mpls ip
Ruijie(config-if-gigabitethernet 1/1)# end
```

# Run OSPF on the backbone network to transmit route information.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# network 3.3.3.3 0.0.0.0 area 0
Ruijie(config-router)# end
```

# Assign an IP address to the interface connected to ASBR2.

```
Ruijie(config)# interface gigabitethernet 1/0
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/0)# no switchport
Ruijie(config-if-gigabitethernet 1/0)# ip address 30.30.30.1
255.255.255.0
```

# Enable label switching on an interface.

```
Ruijie(config-if-gigabitethernet 1/0)# label-switching
```

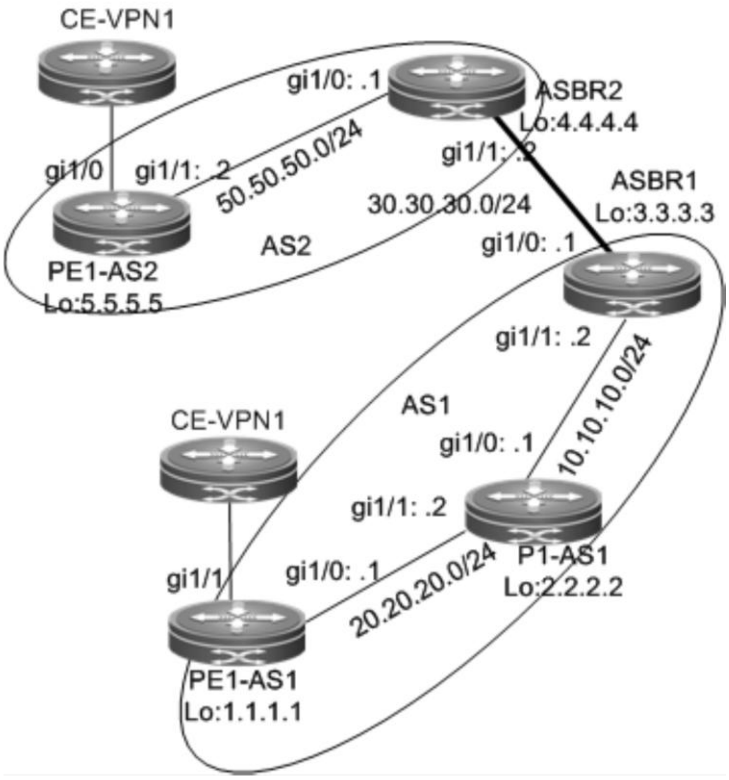
The configuration scheme of ASBR2 is similar to that of ASBR1.

Inter-AS VPN OptionC: Enabling IPv4 Label Switching Between EBGP Neighbors

Networking Requirements

One VPN user has sites at both ASs. It is required that the VPN sites in different ASs access each other.

Figure 36 OptionC: enabling IPv4 label switching between EBGP neighbors



The configuration scheme is as follows:

PE1-AS1:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255
```

# Configure the VRF.

The configuration procedure is similar to that of PE1-AS1 in the "Inter-AS VPN OptionB: Next Hop Unchanged" section and is not described here.

# Configure a multi-hop MP-EBGP session and disable IPv4 route exchange for the session.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 5.5.5.5 remote-as 2
Ruijie(config-router)# neighbor 5.5.5.5 update-source loopback 0
Ruijie(config-router)# neighbor 5.5.5.5 ebgp-multihop
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# no neighbor 5.5.5.5 activate
Ruijie(config-router-af)# exit
Ruijie(config-router)# address-family vpnv4 unicast
Ruijie(config-router-af)# neighbor 5.5.5.5 activate
Ruijie(config-router-af)# end
```

# Configure CE neighbors through EBGP.

See the configuration procedure in the "Running BGP Between PEs and CEs to Transmit Route Information" section and the related configurations in the "Intranet Configuration Examples" section.

# Configure MPLS signaling and enable MPLS on a public network interface.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-gigabitethernet 1/1)# no switchport
Ruijie(config-if-gigabitethernet 1/1)# ip address 20.20.20.1
255.255.255.0
Ruijie(config-if-gigabitethernet 1/1)# label-switching
Ruijie(config-if-gigabitethernet 1/1)# mpls ip
Ruijie(config-if-gigabitethernet 1/1)# end
```

# Run OSPF on the backbone network to transmit route information.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)# end
```

P1-AS1:

The configuration mainly includes the MPLS signaling protocol and IGP and is not described here. See the P1-AS1 configuration scheme in the "Inter-AS VPN OptionB: Next Hop Unchanged" section.

ASBR1:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 3.3.3.3 255.255.255.255
```

# Configure ACL rules and route map rules to distribute or set labels only for routes that match the rules.

```
Ruijie# configure terminal

Ruijie(config)# route-map external-pe-route
Ruijie(config-route-map)# match ip address 102
Ruijie(config-route-map)# end
```

# Set up an EBGP session with ASBR2 and configure route map rules to distribute labels for PE routes that match the rules (the route map rules are optional and allow BGP to distribute labels for only certain routes), and configure static routes to PEs in the local AS.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 30.30.30.2 remote-as 2
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 30.30.30.2 send-label
Ruijie(config-router-af)# neighbor 30.30.30.2 route-map set-mpls out
Ruijie(config-router-af)# network 1.1.1.1 mask 255.255.255.255
Ruijie(config-router-af)# end
```

# Configure MPLS to distribute label for certain BGP routes through ACL rules (the ACL rules are optional and allow you to reduce the number of unnecessary routes).

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# advertise-labels for bgp-routes acl 102
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-Gigabitethernet 1/1)# no switchport
Ruijie(config-if-Gigabitethernet 1/1)# ip address 10.10.10.2 255.255.255.0
Ruijie(config-if-Gigabitethernet 1/1)# label-switching
Ruijie(config-if-Gigabitethernet 1/1)# mpls ip
Ruijie(config-if-Gigabitethernet 1/1)# end
```

# Configure a routing protocol on the backbone network to redistribute only BGP routes that match the route map rules (the route map rules are optional and allow you to reduce the number of unnecessary routes).

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# network 3.3.3.3 0.0.0.0 area 0
Ruijie(config-router)# redisteibute bgp subnets route-map external-pe-route
Ruijie(config-router)# end
```

# Assign an IP address to the interface connected to ASBR2.

```
Ruijie(config)# interface gigabitethernet 1/0
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/0)# no switchport
Ruijie(config-if-gigabitethernet 1/0)# ip address 30.30.30.1
255.255.255.0
```

# Enable label switching on an interface.

```
Ruijie(config-if-gigabitethernet 1/0)# label-switching
```

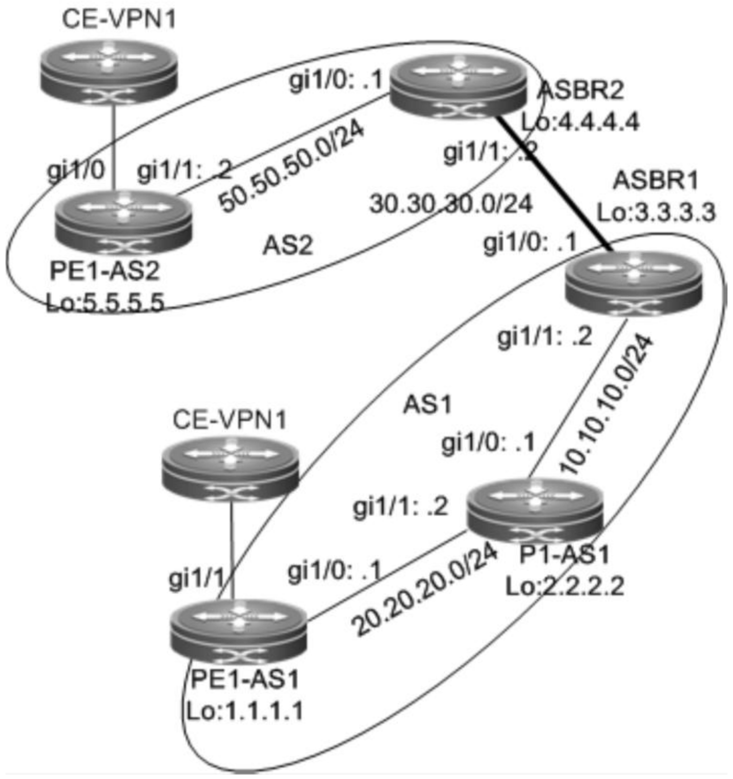
The configuration scheme of ASBR2 is similar to that of ASBR1.

Inter-AS VPN OptionC: Enabling IPv4 Label Switching Between Both EBGP and IBGP Neighbors

Networking Requirements

One VPN user has sites at both ASs. It is required that the VPN sites in different ASs access each other.

Figure 37 OptionC: enabling IPv4 label switching between both EBGP and IBGP neighbors



The configuration scheme is as follows:

PE1-AS1:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255
```

# Configure the VRF.

The configuration procedure is similar to that of PE1-AS1 in the "Inter-AS VPN OptionB: Next Hop Unchanged" section and is not described here.

# Configure a multi-hop MP-EBGP session and disable IPv4 route exchange for the session.

The configuration procedure is similar to that of "Inter-AS VPN OptionC: Enabling IPv4 Label Switching Between EBGP Neighbors" and is not described here.

# Set up an IBGP session with the ASBR and enable IPv4 label switching.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 3.3.3.3 remote-as 1
Ruijie(config-router)# neighbor 3.3.3.3 update-source loopback 0
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 3.3.3.3 activate
Ruijie(config-router-af)# neighbor 3.3.3.3 send-label
Ruijie(config-router-af)# end
```

# Configure CE neighbors through EBGP.

See the configuration procedure in the "Running BGP Between PEs and CEs to Transmit Route Information" section and the related configurations in the "Intranet Configuration Examples" section.

# Configure MPLS signaling and enable MPLS on a public network interface.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/0
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-gigabitethernet 1/0)# no switchport
Ruijie(config-if-gigabitethernet 1/0)# ip address 20.20.20.1
255.255.255.0
Ruijie(config-if-gigabitethernet 1/0)# label-switching
Ruijie(config-if-gigabitethernet 1/0)# mpls ip
Ruijie(config-if-gigabitethernet 1/0)# end
```

# Run OSPF on the backbone network to transmit route information.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)# end
```

The configuration of PE1-AS2 is similar to that of PE1-AS1.

P1-AS1:

The configuration mainly includes the MPLS signaling protocol and IGP and is not described here. It is similar to "Example of Configuring Basic MPLS Functions".

ASBR1:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 3.3.3.3 255.255.255.255
```

# Configure ACL rules and route map rules to distribute or set labels only for routes that match the rules.

```
Ruijie# configure terminal
Ruijie(config)# ip access-list extended 101
Ruijie(config)# permit ip host 1.1.1.1 any
Ruijie(config)# exit
Ruijie(config)# ip access-list extended 102
Ruijie(config)# permit ip host 5.5.5.5 any
Ruijie(config)# route-map internal-mpls-route permit 10
Ruijie(config-route-map)# match ip address 101
Ruijie(config-route-map)# set mpls-label
Ruijie(config-route-map)# exit
Ruijie(config)# route-map external-mpls-route permit 10
Ruijie(config-route-map)#  match ip address 102
Ruijie(config-route-map)#  set mpls-label
Ruijie(config-route-map)#  end
```

# Set up an EBGP session with the ASBR and configure route map rules to distribute labels for PE routes that match the rules (the route map rules are optional and allow BGP to distribute labels for only certain routes), and configure static routes to PEs in the local AS.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 30.30.30.2 remote-as 2
Ruijie(config-router)# neighbor 1.1.1.1 remote-as 1
Ruijie(config-router)# neighbor 1.1.1.1 update-source loopback 0
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 30.30.30.2 send-label
Ruijie(config-router-af)# neighbor 30.30.30.2 route-map internal-mpls-route out
Ruijie(config-router-af)# neighbor 1.1.1.1 send-label
Ruijie(config-router-af)# neighbor 1.1.1.1 route-map external-mpls-route out
Ruijie(config-router-af)#  network 1.1.1.1 mask 255.255.255.255
Ruijie(config-router-af)# end
```

# Configure MPLS signaling and enable MPLS on an interface.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-Gigabitethernet 1/1)# no switchport
Ruijie(config-if-Gigabitethernet 1/1)# ip address 10.10.10.2
255.255.255.0
Ruijie(config-if-Gigabitethernet 1/1)# label-switching
Ruijie(config-if-Gigabitethernet 1/1)# mpls ip
Ruijie(config-if-Gigabitethernet 1/1)# end
```

# Run OSPF on the backbone network to transmit route information.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 10.10.10.0 255.255.255.0 area 0
Ruijie(config-router)# network 3.3.3.3 0.0.0.0 area 0
Ruijie(config-router)# end
```

# Assign an IP address to the interface connected to ASBR2.

```
Ruijie(config)# interface gigabitethernet 1/0
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/0)# no switchport
Ruijie(config-if-gigabitethernet 1/0)# ip address 30.30.30.1
255.255.255.0
```

# Enable label switching on an interface.

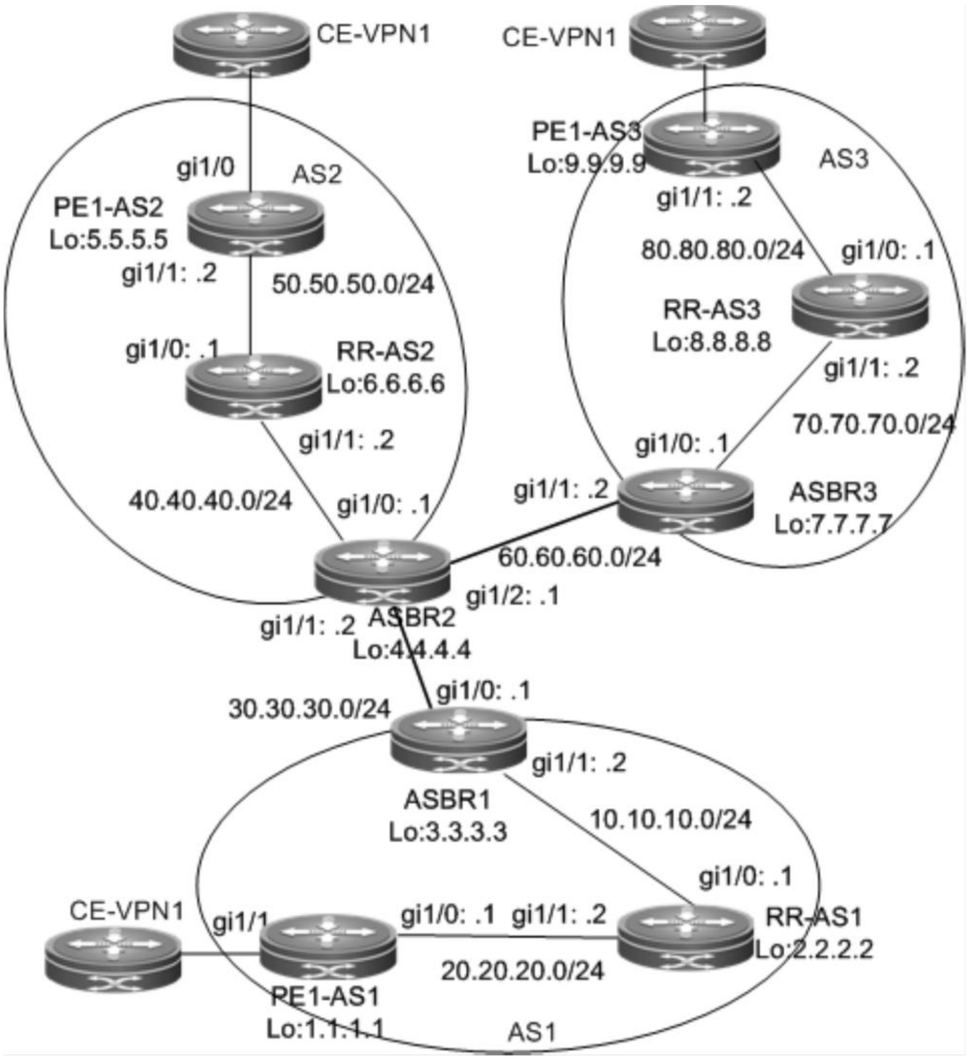
```
Ruijie(config-if-gigabitethernet 1/0)# label-switching
```

The configuration scheme of ASBR2 is similar to that of ASBR1.

Inter-AS VPN OptionC: RR Networking Scheme

In the two implementation modes of OptionC, another problem exists. If the sites of the same VPN user are located at different ASs, a common OptionC scheme requires full mesh BGP connections for the inter-AS PEs to ensure the reachability of the VPN sites. As shown in the following figure, the sites of the VPN user are located at three different ASs. If a new VPN site is added, the new site needs to set up BGP connections with the other VPN sites. This restricts the application of the common OptionC scheme. To solve the preceding expansion problem, you can add an RR to each AS in the OptionC scheme. The RRs set up multi-hop MP-EBGP connections to exchange inter-AS VPN routes. At the same time, you can set up MP-IBGP sessions between PEs and the RR in the AS.

Figure 38 Setting up multi-hop MP-EBGP sessions between RRs in the OptionC scheme



The configuration scheme is as follows:

PE1-AS1:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255
```

# Configure the VRF.

The configuration procedure is similar to that of PE1-AS1 in the "Inter-AS VPN OptionB: Next Hop Unchanged" section and is not described here.

# Set up an MP-IBGP session with the RR and enable label distribution for IPv4 routes.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 2.2.2.2 remote-as 1
Ruijie(config-router)# neighbor 2.2.2.2 update-source loopback 0
Ruijie(config-router)# address-family vpnv4 unicast
Ruijie(config-router-af)# neighbor 2.2.2.2 activate
Ruijie(config-router-af)# exit
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 2.2.2.2 activate
Ruijie(config-router-af)# neighbor 2.2.2.2 send-label
Ruijie(config-router-af)# end
```

# Configure CE neighbors through EBGP.

See the configuration procedure in the "Running BGP Between PEs and CEs to Transmit Route Information" section and the related configurations in the "Intranet Configuration Examples" section.

The configurations of PE1-AS2 and PE1-AS3 are similar to that of PE1-AS1.

RR-AS1

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 2.2.2.2 255.255.255.255
```

# Set up an MP-IBGP session with the PE, specify the PE as the RR client, and enable label distribution for IPv4 routes.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 1.1.1.1 remote-as 1
Ruijie(config-router)# neighbor 1.1.1.1 update-source loopback 0
Ruijie(config-router)# address-family vpnv4 unicast
Ruijie(config-router-af)# neighbor 1.1.1.1 activate
Ruijie(config-router-af)# neighbor 1.1.1.1 route-reflector-client
Ruijie(config-router-af)# exit
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 1.1.1.1 activate
Ruijie(config-router-af)# neighbor 1.1.1.1 send-label
Ruijie(config-router-af)# neighbor 1.1.1.1 route-reflector-client
Ruijie(config-router-af)# end
```

# Set up a multi-hop MP-EBGP session with the RR, do not change the next hop of VPN routes exchanged with the RR, and disable the IPv4 route exchange with the RR.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 6.6.6.6 remote-as 2
Ruijie(config-router)# neighbor 6.6.6.6 update-source loopback 0
Ruijie(config-router)# neighbor 6.6.6.6 ebgp-multihop
Ruijie(config-router)# neighbor 8.8.8.8 remote-as 3
Ruijie(config-router)# neighbor 8.8.8.8 update-source loopback 0
Ruijie(config-router)# neighbor 8.8.8.8 ebgp-multihop
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# no neighbor 6.6.6.6 activate
Ruijie(config-router-af)# no neighbor 8.8.8.8 activate
Ruijie(config-router-af)# exit-address-family
Ruijie(config-router)# address-family vpnv4 unicast
Ruijie(config-router-af)# neighbor 6.6.6.6 activate
Ruijie(config-router-af)# neighbor 6.6.6.6 next-hop-unchanged
Ruijie(config-router-af)# neighbor 8.8.8.8 activate
Ruijie(config-router-af)# neighbor 8.8.8.8 next-hop-unchanged
Ruijie(config-router-af)# end
```

# Set up an IBGP session with the ASBR and enable IPv4 label switching.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 3.3.3.3 remote-as 1
Ruijie(config-router)# neighbor 3.3.3.3 update-source loopback 0
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 3.3.3.3 activate
Ruijie(config-router-af)# neighbor 3.3.3.3 send-label
Ruijie(config-router-af)# end
```

# Configure MPLS.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-gigabitethernet 1/1)# no switchport
Ruijie(config-if-gigabitethernet 1/1)# ip address 20.20.20.2
255.255.255.0
Ruijie(config-if-gigabitethernet 1/1)# label-switching
Ruijie(config-if-gigabitethernet 1/1)# mpls ip
Ruijie(config-if-gigabitethernet 1/1)# exit
Ruijie(config)# interface gigabitethernet 1/0
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-gigabitethernet 1/0)# no switchport
Ruijie(config-if-gigabitethernet 1/0)# ip address 10.10.10.1
255.255.255.0
Ruijie(config-if-gigabitethernet 1/0)# label-switching
Ruijie(config-if-gigabitethernet 1/0)# mpls ip
Ruijie(config-if-gigabitethernet 1/0)# end
```

# Run OSPF on the backbone network to transmit route information.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# network 2.2.2.2 0.0.0.0 area 0
Ruijie(config-router)# network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# end
```

The procedures of RR-AS2 and RR-AS3 are similar to the preceding procedure.

ASBR1:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 3.3.3.3 255.255.255.255
```

# Configure ACL rules and route map rules.

```
Ruijie# configure terminal
Ruijie(config)# ip access-list extended 101
Ruijie(config-ext-nacl)# permit ip host 1.1.1.1 any
Ruijie(config-ext-nacl)# exit
Ruijie(config)# ip access-list extended 102
Ruijie(config-ext-nacl)# permit ip host 5.5.5.5 any
Ruijie(config-ext-nacl)# permit ip host 9.9.9.9 any
Ruijie(config-ext-nacl)# exit
Ruijie(config)# route-map internal-mpls-route permit 10
Ruijie(config-route-map)# match ip address 101
Ruijie(config-route-map)# set mpls-label
Ruijie(config-route-map)# exit
Ruijie(config)# route-map external-mpls-route permit 10
Ruijie(config-route-map)# match ip address 102
Ruijie(config-route-map)# set mpls-label
Ruijie(config-route-map)# end
```

# Set up an EBGP session with the ASBR, enable label distribution for IPv4 routes, and configure route map rules to distribute labels for PE routes that match the rules (the route map rules are optional and allow the BGP to distribute labels for only certain routes). Set up an IBGP session with the RR, enable label distribution for IPv4 routes, and configure route map rules to distribute labels for inter-AS PE routes that match the rules. Configure static routes to the PEs in the local AS.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 30.30.30.2 remote-as 2
Ruijie(config-router)# neighbor 2.2.2.2 remote-as 1
Ruijie(config-router)# neighbor 2.2.2.2 update-source loopback 0
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 30.30.30.2 send-label
Ruijie(config-router-af)# neighbor 30.30.30.2 route-map internal-mpls-route out
Ruijie(config-router-af)# neighbor 2.2.2.2 send-label
Ruijie(config-router-af)# neighbor 2.2.2.2 route-map external-mpls-route out
Ruijie(config-router-af)# network 1.1.1.1 mask 255.255.255.255
Ruijie(config-router-af)# end
```

# Configure MPLS signaling and enable MPLS on an interface.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-Gigabitethernet 1/1)# no switchport
Ruijie(config-if-Gigabitethernet 1/1)#ip address 10.10.10.2
255.255.255.0
Ruijie(config-if-Gigabitethernet 1/1)# label-switching
Ruijie(config-if-Gigabitethernet 1/1)# mpls ip
Ruijie(config-if-Gigabitethernet 1/1)# end
```

# Run OSPF on the backbone network to transmit route information.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# network 3.3.3.3 0.0.0.0 area 0
Ruijie(config-router)# end
```

# Assign an IP address to the interface connected to ASBR2.

```
Ruijie(config)# interface gigabitethernet 1/0
```

# Use the **no switchport** command to switch the port mode on the switch series to the Routed Port mode. This command is not applicable to routers.

```
Ruijie(config-if-GigabitEthernet 1/0)# no switchport
Ruijie(config-if-gigabitethernet 1/0)# ip address 30.30.30.1
255.255.255.0
```

# Enable label switching on an interface.

```
Ruijie(config-if-gigabitethernet 1/0)# label-switching
```

The configuration schemes of ASBR2 and ASBR3 are similar to that of ASBR1.

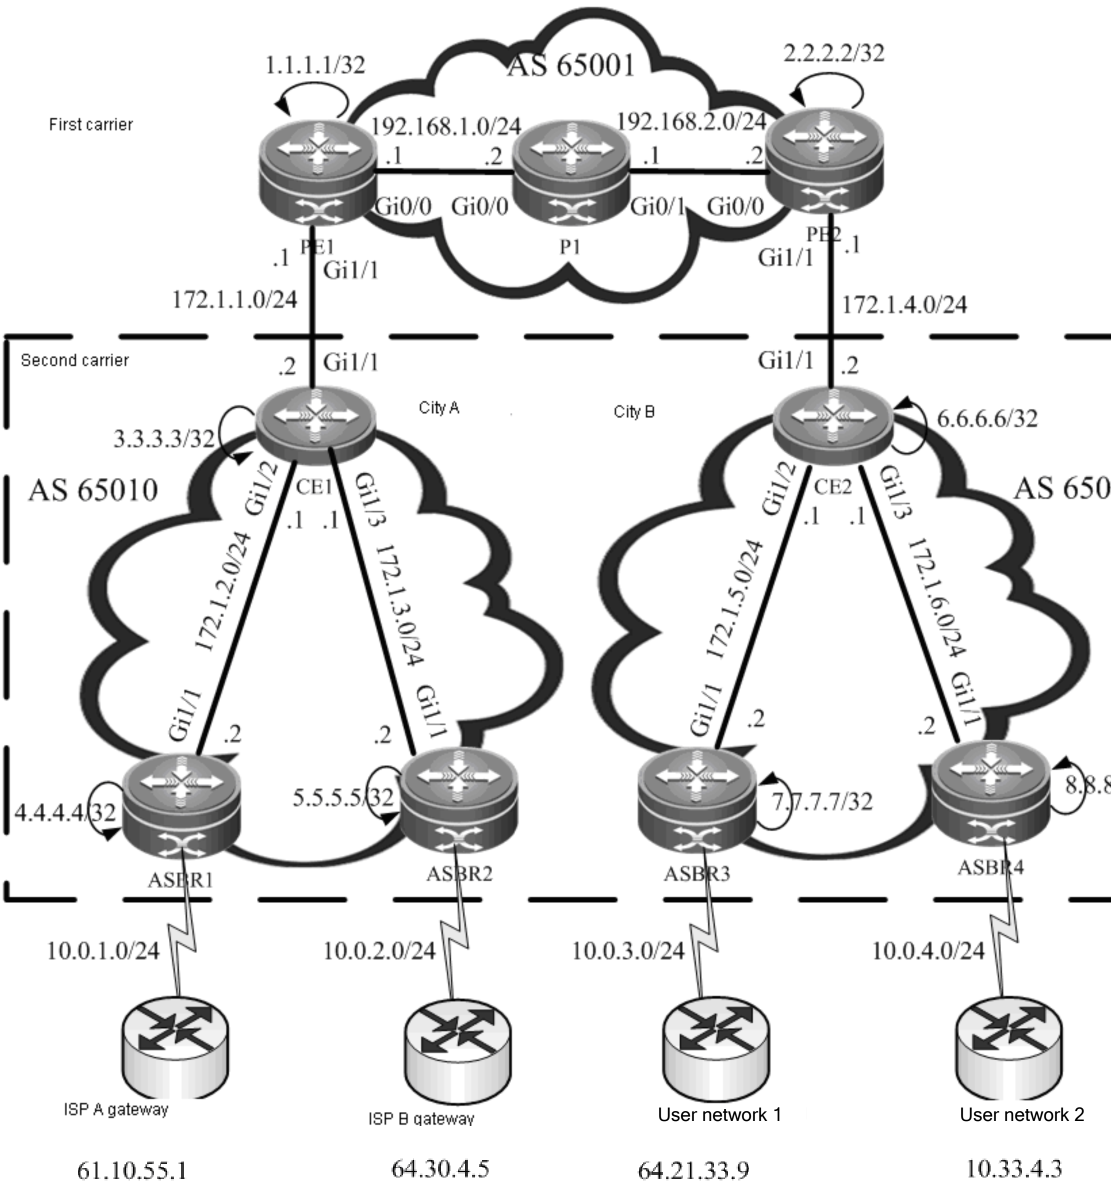
CSC: The Second Carrier Provides Internet Services Based on IP Core

Networking Requirements

A carrier owns an intranet in City A, and this network has the BGP gateways to ISP A and ISP B. This carrier utilizes its intranet to provide Internet services for users in City A. Currently, this carrier expects to expand services to City B, and therefore leases MPLS VPN services from a VPN carrier in the hope of connecting the sites of two cities via VPN, so that users in City B can access the Internet through the existing Internet gateways. The internal routes are exchanged via IGP (OSPF), and the external routes are exchanged via BGP.

Networking Topology

Figure 39 Network topology of scenario I



Configuration Tips

- Configuring basic BGP/MPLS IP VPN functions for the first carrier
- Enabling the CSC function
- Configuring the second carrier

- Configuring user access

Configuration Steps

- Configuring basic BGP/MPLS IP VPN functions for the first carrier

# Configure an MPLS network: PE1 is used as an example. The configurations of P1 and PE2 are similar.

## Configure a loopback interface.

```
Ruijie(config)# interface Loopback 0
Ruijie(config-if)# ip address 1.1.1.1 255.255.255.255
Ruijie(config-if)# exit
```

## Globally enable MPLS and LDP.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp rouer-id interface Loopback 0
Ruijie(config-mpls-router)# exit
```

## Enable MPLS and LDP on the interface.

```
Ruijie(config)# interface gigabitEthernet 0/0
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# ip address 192.168.1.1 255.255.255.0
Ruijie(config-if)# label-switching
Ruijie(config-if)# mpls ip
Ruijie(config-if)# no shutdown
Ruijie(config-if)# exit
```

## Configure IGP (OSPF).

```
Ruijie(config)# router ospf 1
Ruijie(config-router)# network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)# network 192.168.1.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure an MP-IBGP neighbor: PE1 is used as an example. The configurations of PE2 are similar.

```
Ruijie(config)# router bgp 65001
Ruijie(config-router)# neighbor 2.2.2.2 remote-as 65001
Ruijie(config-router)# neighbor 2.2.2.2 update-source Loopback 0
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 2.2.2.2 activate
Ruijie(config-router-af)# neighbor 2.2.2.2 send-community both
```

# Configure a VRF: PE1 is used as an example. The configurations of PE2 are similar.

```
Ruijie(config)# ip vrf vpn1
Ruijie(config-vrf)# rd 65001:20
Ruijie(config-vrf)# route-target both 65001:20
Ruijie(config-vrf)# alloc-label per-route
Ruijie(config-vrf)# exit
Ruijie(config)# interface loopback 1
Ruijie(config-if)# ip vrf forwarding vpn1
Ruijie(config-if)# ip address 10.1.1.1 255.255.255.255
Ruijie(config-if)# no shutdown
Ruijie(config-if)# exit
Ruijie(config)# interface gigabitEthernet 1/1
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# ip vrf forwarding vpn1
Ruijie(config-if)# ip address 172.1.1.1 255.255.255.0
Ruijie(config-if)# no shutdown
```

# Configure a CE to connect to a PE: CE1 is used as an example. The configurations of CE2 are similar.

```
Ruijie(config)# interface gigabitEthernet 1/1
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# ip address 172.1.1.2 255.255.255.0
Ruijie(config-if)# no shutdown
```

# Configure route exchange between PEs and CEs: Route exchange between PE1 and CE1 is used as an example. The configurations of route exchange between PE2 and CE2 are similar.

## First, configure PE1.

```
Ruijie(config)# router ospf 100 vrf vpn1
Ruijie(config-router)# network 172.1.1.0 0.0.0.255 area 0
Ruijie(config-router)# redistribute bgp 65001 subnets
Ruijie(config-router)# exit
Ruijie(config)# router bgp 65001
Ruijie(config-router)# address-family ipv4 vrf vpn1
Ruijie(config-router-af)# redistribute ospf 100 vrf vpn1
Ruijie(config-router-af)# exit
Ruijie(config-router)# exit
```

## Then, configure CE1.

```
Ruijie(config)# router ospf 1
Ruijie(config-router)# network 172.1.1.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

- Enabling the CSC function

# Enable CSC on the PE: PE1 is used as an example. The configurations of PE2 are similar.

```
Ruijie(config)# mpls router ldp vpn1
Ruijie(config-mpls-router)# ldp rouer-id interface Loopback 1
Ruijie(config-mpls-router)# advertise-labels for bgp-routes
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitEthernet 1/1
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# label-switching
Ruijie(config-if)# mpls ip
```

# Enable MPLS and LDP on the CE: CE1 is used as an example. The configurations of CE2 are similar.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp rouer-id interface Loopback 0
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitEthernet 1/1
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# label-switching
Ruijie(config-if)# mpls ip
```

- Configuring the second carrier

# Configure the interface and IGP: CE1 is used as an example. The configurations of CE2, ASBR1, ASBR2, ASBR3 and ASBR4 are similar.

```
Ruijie(config)# interface gigabitEthernet 1/2
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```

Ruijie(config-router)# neighbor 5.5.5.5 update-source Loopback 0
Ruijie(config-router)# neighbor 5.5.5.5 route-reflector-client
Ruijie(config-router)# neighbor 6.6.6.6 remote-as 65010
Ruijie(config-router)# neighbor 6.6.6.6 update-source Loopback 0
Ruijie(config-router)# neighbor 6.6.6.6 route-reflector-client
Ruijie(config-router)# exit
Ruijie(config)# recursive-route lookup lsp
```

- Configuring user access

# It is assumed that user network 1 is connected to ASBR3. The configurations of other external networks (user network and Internet gateway) are similar.

## On ASBR3, use the following command.

```
Ruijie(config)# interface gigabitEthernet 1/2
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# ip address 10.0.3.1 255.255.255.0
Ruijie(config-if)# no shutdown
Ruijie(config-if)# exit
Ruijie(config)# router bgp 65010
Ruijie(config-router)# neighbor 10.0.3.2 remote-as 100
Ruijie(config-router)# exit
```

## On the edge router of user network 1, use the following command.

```
Ruijie(config)# interface gigabitEthernet 0/0
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# ip address 10.0.3.2 255.255.255.0
Ruijie(config-if)# no shutdown
Ruijie(config-if)# exit
Ruijie(config)# interface gigabitEthernet 0/1
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# ip address 64.21.33.9 255.255.255.0
Ruijie(config-if)# no shutdown
Ruijie(config-if)# exit
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 10.0.3.1 remote-as 65010
Ruijie(config-router)# network 64.21.33.0 mask 255.255.255.0
```

Verification

# Display VRF routes and labels on the PE: PE1 is used as an example. The verification of PE2 is similar.

// In the VRF routing table of the PE, there are only internal routes of the second carrier. There is no external route (for example, 64.30.4.0/24).

```

CSC: The Second Carrier Provides Internet Services Based on MPLS Core

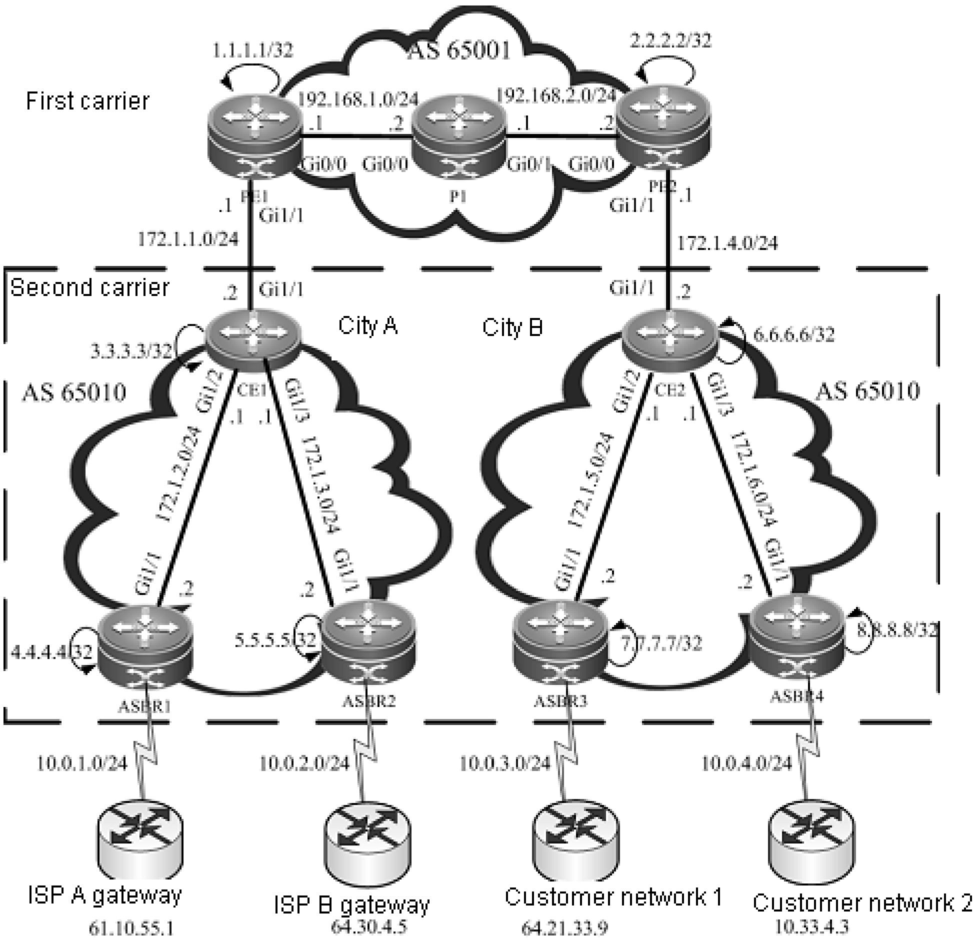
Networking Requirements

A carrier provides Internet services for users in City A. Considering that it may need to provide MPLS services for users in the future, this carrier has deployed MPLS on its backbone network. Now this carrier intends to expand its service to City B, and has built an MPLS network in City B. To interconnect the core networks in the two cities, this carrier leases the VPN service from another MPLS VPN service provider. Therefore, this carrier has become a second carrier, while the MPLS VPN service provider is the first carrier.

The first carrier PE and second carrier CE will exchange (internal) routes via BGP. The second carrier will directly establish BGP neighbors between ASBRs to exchange external routes. The traffic will flow from the external network into the second carrier network and be forwarded on the tunnel until the traffic leaves the second carrier network.

Networking Topology

Figure 40 Network topology of scenario II



Configuration Tips

- Configuring basic BGP/MPLS IP VPN functions for the first carrier
- Enabling the CSC function
- Configuring the second carrier
- Configuring user access

Configuration Steps

- Configuring basic BGP/MPLS IP VPN functions for the first carrier

The configuration steps are similar to those in Scenario I. The difference is that routes are exchanged between PEs and CEs. Only configurations of route exchange between PEs and CEs will be shown below. For other configurations, see "Configuring basic BGP/MPLS IP VPN functions" in the example of "The Second Carrier Provides Internet Services Based on IP Core".

# Configure route exchange between PEs and CEs.

## First, configure the PE (using PE1 as an example).

```
Ruijie(config)# router bgp 65001
Ruijie(config-router)# address-family ipv4 vrf vpn1
Ruijie(config-router-af)# neighbor 172.1.1.2 remote-as 65010
Ruijie(config-router-af)# neighbor 172.1.1.2 as-override
Ruijie(config-router-af)# exit
Ruijie(config-router)# exit
```

## Then, configure the CE (using CE1 as an example).

```
Ruijie(config)# router bgp 65010
Ruijie(config-router)# neighbor 172.1.1.2 remote-as 65001
Ruijie(config-router)# redistribute ospf 1
Ruijie(config-router)# exit
Ruijie(config)# router ospf 1
Ruijie(config-router)# redistribute bgp 65010 subnets
Ruijie(config-router)# exit
```

- Enabling the CSC function

# Enable CSC on the PE: PE1 is used as an example. The configurations of PE2 are similar.

```
Ruijie(config)# interface gigabitEthernet 1/1
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# ip vrf forwarding vpn1
Ruijie(config-if)# ip address 172.1.1.1 255.255.255.0
Ruijie(config-if)# no shutdown
Ruijie(config-if)# exit
Ruijie(config)# router bgp 65001
Ruijie(config-router)# address-family ipv4 vrf vpn1
Ruijie(config-router-af)# neighbor 172.1.1.2 send-label
Ruijie(config-router-af)# exit
Ruijie(config-router)# exit
```

# Enable MPLS and BGP label distribution on the CE.

```
Ruijie(config)# interface gigabitEthernet 1/1
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# label-switching
Ruijie(config-if)# ip address 172.1.1.2 255.255.255.0
Ruijie(config-if)# no shutdown
Ruijie(config-if)# exit
Ruijie(config)# router bgp 65010
Ruijie(config-router)# neighbor 172.1.1.1 send-label
Ruijie(config-router)# exit
```

- Configuring the second carrier

# Configure an MPLS network: See "Configuring an MPLS network" in the example of "The Second Carrier Provides Internet Services Based on IP Core". Configuration objects are CE1, CE2 and ASBRs (1 to 4).

Note

You need to enable LDP on the CSC-CE in order to set up sessions with other intra-site devices to build an MPLS network. If the CSC-CE and CSC-PE use BGP to exchange routes, you must use the **advertise-labels for bgp-routes** command on the CSC-CE to allow LDP to distribute labels for BGP routes.

# Configure a BGP neighbor: Establish a BGP neighbor relation between two ASBRs.

## Configure ASBR2 as the BGP neighbor on ASBR1. The configurations of other ASBRs are similar.

```
Ruijie(config)# router bgp 65010
Ruijie(config-router)# neighbor 5.5.5.5 remote-as 65010
Ruijie(config-router)# neighbor 5.5.5.5 update-source Loopback 0
Ruijie(config-router)# neighbor 5.5.5.5 next-hop-self
Ruijie(config-router)# exit
Ruijie(config)# recursive-route lookup lsp
```

- Configuring user access

See "Configuring user access" in the example of "The Second Carrier Provides Internet Services Based on IP Core".

Verification

# Display VRF routes and labels on the first carrier PE: PE1 is used as an example. The verification of PE2 is similar.

// In the VRF routing table of PE1, there are only internal routes of the second carrier. There is no external routes (for example, 64.30.4.0/24).

```
Ruijie# show ip route vrf vpn1
Routing Table: vpn1

Codes:  C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default

Gateway of last resort is no set
B    3.3.3.3/32 [200/0] via 172.1.1.2, 00:00:07
C    172.1.1.0/24 is directly connected, gigabitEthernet 1/1
C    172.1.1.1/32 is local host.
B    172.1.2.0/24 [200/0] via 172.1.1.2, 00:00:07
B    172.1.4.0/24 [200/0] via 2.2.2.2, 00:00:30
......
Ruijie# show bgp vpnv4 unicast vrf vpn1 labels
```

```
BGP table version is 1, local router ID is 1.1.1.1

C    64.21.33.0/24 is directly connected, gigabitEthernet 0/1
C    64.21.33.9/32 is local host.
......
```

# Verify that the external networks are interconnected.

// On the edge device of user network 1, use the following command.

```
Ruijie# ping 61.10.55.1 source 64.21.33.9
Sending 5, 100-byte ICMP Echoes to 61.10.55.1, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 10/20/40 ms
```

CSC: The Second Carrier Provides VPN Services Based on MPLS Core

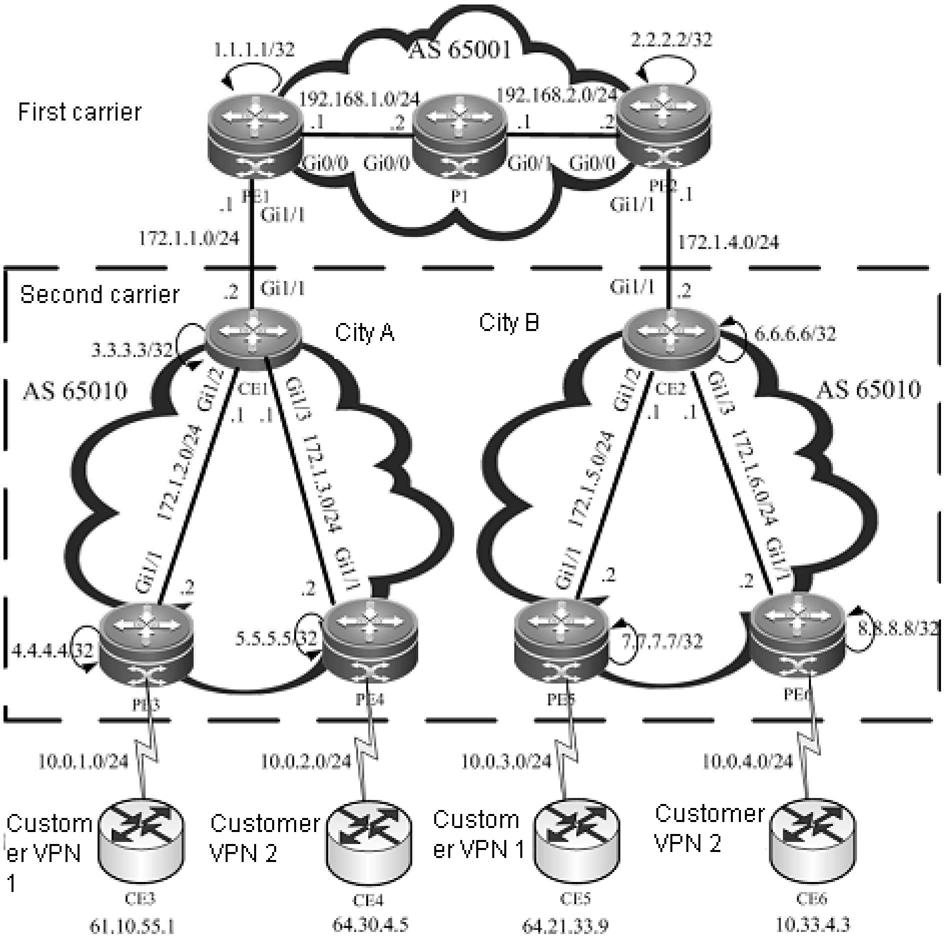
Networking Requirements

A carrier owns an MPLS core network in City A and provides MPLS VPN services for users in this city. Now this carrier intends to expand the service to City B, and has built an MPLS core network in City B. In order to interconnect the core networks in these two cities, this carrier leases the VPN service from another MPLS VPN service provider, thus forming the CSC networking model.

The first carrier PE and second carrier CE will exchange (internal) routes via BGP. An MP-IBGP neighbor relation is established between second carrier PEs to exchange user VPN routes. OSPF is deployed between the second carrier PE and the user VPN CE to exchange routes.

Networking Topology

Figure 41 MPLS core second VPN provider



Configuration Tips

- Configuring basic BGP/MPLS IP VPN functions for the first carrier
- Enabling the CSC function
- Configuring the second carrier
- Configuring user access

Configuration Steps

- Configuring basic BGP/MPLS IP VPN functions for the first carrier

See "Configuring basic BGP/MPLS IP VPN functions" in the example of "The Second Carrier Provides Internet Services Based on MPLS Core".

- Enabling the CSC function

See "Enabling the CSC function" in the example of "The Second Carrier Provides Internet Services Based on MPLS Core".

- Configuring the second carrier

Configure an MPLS network: See "Configuring an MPLS network" in the example of "The Second Carrier Provides Internet Services Based on MPLS Core". Configuration objects are CE1, CE2 and PEs (3 to 6).

Note

You need to enable LDP on the CSC-CE in order to set up sessions with other intra-site devices to build an MPLS network. If the CSC-CE and CSC-PE use BGP to exchange routes, you must run **advertise-labels for bgp-routes** on the CSC-CE to allow LDP to distribute labels for BGP routes.

Configure an MP-IBGP neighbor: See "Configuring an MP-IBGP neighbor" in the example of "The Second Carrier Provides Internet Services Based on IP Core". Configure the MP-IBGP neighbor relations between PE3, PE4, PE5 and PE6.

- Configuring user access

The configurations include configuring a VRF, configuring route exchange between PEs and CEs, and so on. These configurations are the same as those of the BGP/MPLS IP VPN. It is assumed that CE3 is connected to PE3.

# On PE3, use the following commands.

```
Ruijie(config)# ip vrf customer_vpn1
Ruijie(config-vrf)# rd 65010:1
Ruijie(config-vrf)# route-target both 65010:1
Ruijie(config-vrf)# exit
Ruijie(config)# interface gigabitEthernet 1/2
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if)# no switchport
```

# In case of a router, enable MPLS fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# ip vrf forwarding customer_vpn1
Ruijie(config-if)# ip address 10.0.1.1 255.255.255.0
Ruijie(config-if)# no shutdown
Ruijie(config-if)# exit
Ruijie(config)# router ospf 10 vrf customer_vpn1
Ruijie(config-router)# network 10.0.1.0 0.0.0.255 area 0
Ruijie(config-router)# redistribute bgp 65010 subnets
Ruijie(config-router)# exit
Ruijie(config)# router bgp 65010
Ruijie(config-router)# address-family ipv4 vrf customer_vpn1
Ruijie(config-router-af)# redistribute ospf 10 vrf customer_vpn1
Ruijie(config-router-af)# exit
Ruijie(config-router)# exit
```

# On CE3, use the following command.

```
Ruijie(config)# interface gigabitEthernet 0/0
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# ip address 10.0.1.2 255.255.255.0
Ruijie(config-if)# no shutdown
Ruijie(config)# interface gigabitEthernet 0/1
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# ip address 61.10.55.1 255.255.255.0
Ruijie(config-if)# no shutdown
Ruijie(config-if)# exit
Ruijie(config)# router ospf 1
Ruijie(config-router)# network 10.0.1.0 0.0.0.255 area 0
Ruijie(config-router)# network 61.10.55.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

Verification

# Display VRF routes and labels on the first carrier PE: PE1 is used as an example. The verification of PE2 is similar.

// In the VRF routing table of PE1, there are only internal routes of the second carrier. There is no VPN route (for example, 64.30.4.0/24).

```
Ruijie# show ip route vrf vpn1
Routing Table: vpn1

Success rate is 100 percent (5/5), round-trip min/avg/max = 10/20/40 ms
```

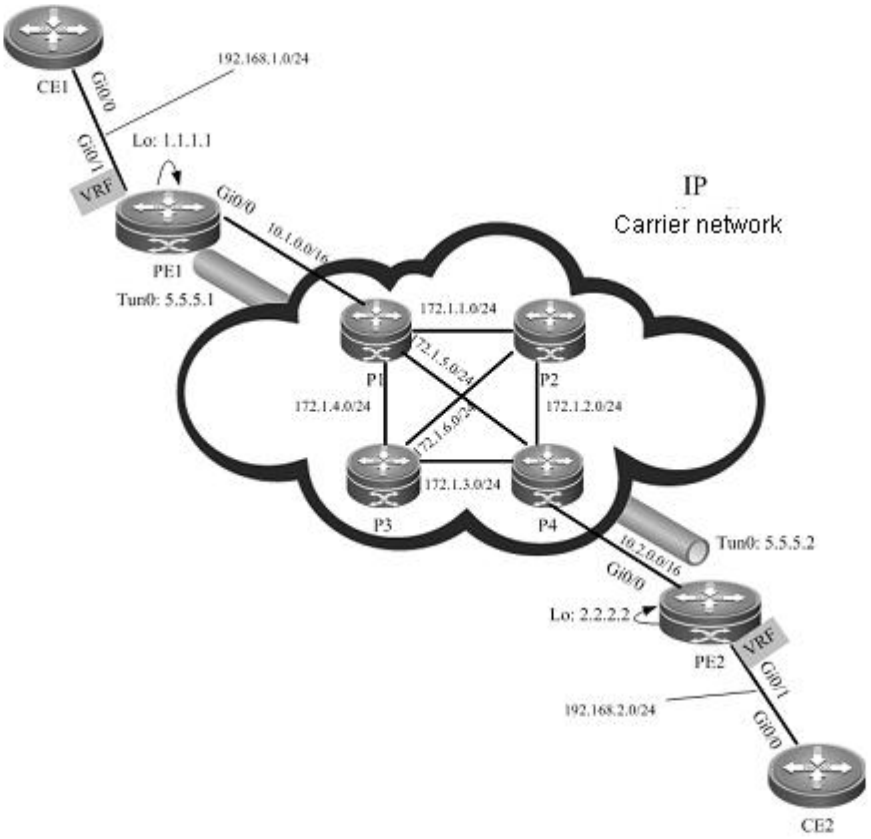
MPLS VPN over GRE

Networking Requirements

In an IP core network, the edge router PE supports the MPLS VPN. Now it is required to use the MPLS VPN over GRE technology to use the IP core network to provide MPLS VPN services for users. The IP core network adopts dual OSPF instances to introduce VPN traffic into the GRE tunnel, while the PE and CE exchange routes via OSPF.

Networking Topology

Figure 42 Network topology



Configuration Tips

- Creating a GRE tunnel
- Configuring an IGP route
- Configuring an MPLS network
- Configuring an MPLS VPN

Configuration Steps

- Configure the P device. P1 is used as an example. The configurations of other devices are similar.

# Configure an interface and IP address.

```
Ruijie(config)# interface gigabitEthernet 0/0
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# ip address 10.1.0.2 255.255.0.0
Ruijie(config-if)# no shutdown
Ruijie(config-if)# exit
Ruijie(config)# interface gigabitEthernet 0/1
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# ip address 172.1.1.1 255.255.255.0
Ruijie(config-if)# no shutdown
Ruijie(config-if)# exit
Ruijie(config)# interface gigabitEthernet 1/1
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# ip address 172.1.5.1 255.255.255.0
Ruijie(config-if)# no shutdown
Ruijie(config-if)# exit
Ruijie(config)# interface gigabitEthernet 0/3
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# ip address 172.1.4.1 255.255.255.0
Ruijie(config-if)# no shutdown
Ruijie(config-if)# exit
```

# Configure an IGP routing instance.

```
Ruijie(config)# router ospf 1
Ruijie(config-router)# network 172.1.1.0 0.0.0.255 area 0
Ruijie(config-router)# network 172.1.5.0 0.0.0.255 area 0
Ruijie(config-router)# network 172.1.4.0 0.0.0.255 area 0
Ruijie(config-router)# network 10.1.0.0 0.0.255.255 area 0
Ruijie(config-router)# exit
```

- Configure the PE device. PE1 is used as an example. The configurations of other devices are similar.

# Configure a public network interface and IP address.

```
Ruijie(config)# interface Loopback 0
Ruijie(config-if)# ip address 1.1.1.1 255.255.255.255
Ruijie(config-if)# exit
Ruijie(config)# interface gigabitEthernet 0/0
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# ip address 10.1.0.1 255.255.0.0
Ruijie(config-if)# no shutdown
Ruijie(config-if)# exit
```

# Create a GRE tunnel.

```
Ruijie(config)# interface tunnel 0
Ruijie(config-if)# ip address 5.5.5.1 255.255.255.0
Ruijie(config-if)# tunnel mode gre ip
Ruijie(config-if)# tunnel source 10.1.0.1
Ruijie(config-if)# tunnel destination 10.2.0.1
Ruijie(config-if)# exit
```

# Configure an IGP route.

```
Ruijie(config)# router ospf 1
Ruijie(config-router)# network 10.1.0.0 0.0.255.255 area 0
Ruijie(config-router)# exit
Ruijie(config)# router ospf 2
Ruijie(config-router)# network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)# network 5.5.5.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure an MPLS network.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface tunnel 0
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# mpls ip
Ruijie(config-if)# label-switching
Ruijie(config-if)# exit
```

# Configure an MPLS VPN.

## Configure a VRF.

```
Ruijie(config)# ip vrf vpn1
Ruijie(config-vrf)# rd 100:1
Ruijie(config-vrf)# route-target both 100:1
Ruijie(config-vrf)# exit
Ruijie(config)# interface gigabitEthernet 0/1
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# ip vrf forwarding vpn1
Ruijie(config-if)# ip address 192.168.1.1 255.255.255.0
Ruijie(config-if)# no shutdown
Ruijie(config-if)# exit
```

## Configure MP-IBGP.

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 2.2.2.2 remote-as 100
Ruijie(config-router)# neighbor 2.2.2.2 update-source Loopback 0
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 2.2.2.2 active
Ruijie(config-router-af)# neighbor 2.2.2.2 send-community both
Ruijie(config-router-af)# exit
Ruijie(config-router)# address-family ipv4 vrf vpn1
Ruijie(config-router-af)# redistribute ospf 10 vrf vpn1
Ruijie(config-router-af)# exit
Ruijie(config-router)# exit
```

## Configure route exchange between PEs and CEs.

```
Ruijie(config)# router ospf 10 vrf vpn1
Ruijie(config-router)# network 192.168.1.0 0.0.0.255 area 0
Ruijie(config-router)# redistribute bgp 100 subnets
Ruijie(config-router)# exit
```

- Configure the CE. CE1 is used as an example. The configurations of CE2 are similar.

```
Ruijie(config)# interface gigabitEthernet 0/0
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if)# ip ref
Ruijie(config-if)# ip address 192.168.1.2 255.255.255.0
Ruijie(config-if)# no shutdown
Ruijie(config-if)# exit
Ruijie(config)# router ospf 1
Ruijie(config-router)# network 192.168.1.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

Verification

# On the PE, check routing entries. PE1 is used as an example. The next-hop interface of route 2.2.2.2/32 is Tunnel 0.

```
Ruijie# show ip route

Sending 5, 100-byte ICMP Echoes to 192.168.2.2, timeout is 2 seconds:
  < press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 10/20/40 ms
```

OSPF VPN Configuration Examples

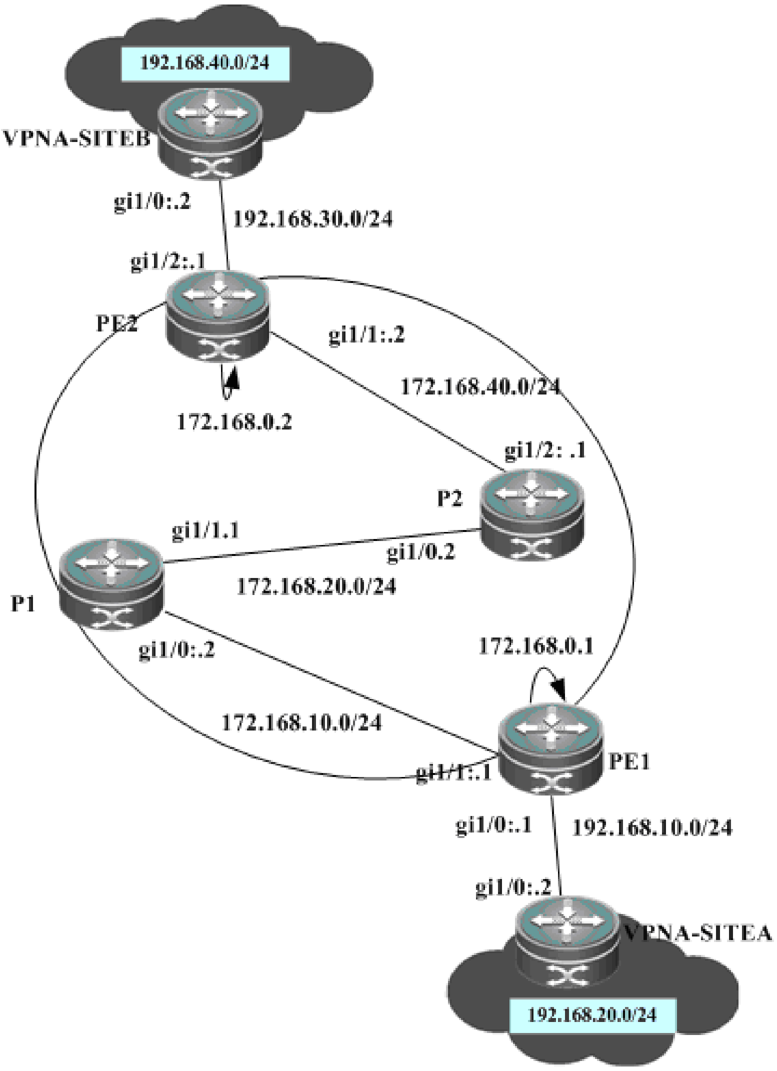
Domain-id Configuration Example

Networking Requirements

Two different sites of a customer exchange VPN routes via an MPLS backbone network. The customer's sites are connected to a PE via OSPF. It is required that the customer's OSPF routes can be restored to the OSPF routes of original sites after being exchanged over the MPLS backbone network.

Networking Topology

Figure 43



To meet the requirements, configure two VRF OSPF instances with the same domain ID on two PEs, as shown below:

Configuration Steps

SITEA:

# Configure the OSPF protocol between the PE and the CE.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 192.168.10.0 255.255.255.0 area 0
```

PE1:

# Configure a loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 172.168.0.1 255.255.255.255
```

# Configure a VRF.

Create a VRF named VPNA, set the RD and RT values, and associate the VRF with the corresponding interface.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf VPNA
Ruijie(config-vrf)# rd 1:100
Ruijie(config-vrf)# route-target both 1:100
Ruijie(config-vrf)# end
```

# Associate the CE-connecting interface with the VRF.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/0
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if-GigabitEthernet 1/0)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if-GigabitEthernet 1/0)# ip ref
Ruijie(config-if-GigabitEthernet 1/0)# ip vrf forwarding VPNA
Ruijie(config-if-GigabitEthernet 1/0)# ip address 192.168.10.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/0)# end
```

# Configure the BGP protocol to set up an MP-IBGP session with PE2.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 172.168.0.2 remote-as 1
Ruijie(config-router)# neighbor 172.168.0.2 update-source loopback 0
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 172.168.0.2 activate
Ruijie(config-router-af)# end
```

# Exchange routes with the CE via OSPF; set the domain ID of the OSPF instance to 10.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10 VPNA
Ruijie(config-router)# network 192.168.10.0 255.255.255.0 area 0
Ruijie(config-router)# redistribute bgp subnets
Ruijie(config-router)# domain-id 10
Ruijie(config-router)# exit
Ruijie(config)# router bgp 1
Ruijie(config-router)# address-family ipv4 vrf VPNA
Ruijie(config-router-af)# redistribute ospf 10
Ruijie(config-router-af)# end
```

# Configure MPLS signaling on the backbone network. Enable MPLS on the public network interface.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if-GigabitEthernet 1/1)# ip ref
Ruijie(config-if-GigabitEthernet 1/1)# ip address 172.168.10.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)# label-switching
Ruijie(config-if-GigabitEthernet 1/1)# mpls ip
Ruijie(config-if-GigabitEthernet 1/1)# end
```

# Configure a routing protocol on the backbone network.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 1
Ruijie(config-router)# network 172.168.10.0 0.0.0.255 area 0
Ruijie(config-router)# network 172.168.0.1 0.0.0.0 area 0
Ruijie(config-router)# end
```

P1 and P2:The configuration steps are similar to the configuration steps of P in the MPLS backbone network.

SITEB:

# Run OSPF with PE2.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 192.168.30.0 255.255.255.0 area 0
```

PE2:

# Configure a loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 172.168.0.2 255.255.255.255
```

# Configure a VRF.

Create a VRF named VPNA, set the RD and RT values, and associate the VRF with the corresponding interface.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf VPNA
Ruijie(config-vrf)# rd 1:100
Ruijie(config-vrf)# route-target both 1:100
Ruijie(config-vrf)# exit
```

# Associate the CE-connecting interface with the VRF.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/2
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if-GigabitEthernet 1/2)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if-GigabitEthernet 1/2)# ip ref
Ruijie(config-if-GigabitEthernet 1/2)# ip vrf forwarding VPNA
Ruijie(config-if-GigabitEthernet 1/2)# ip address 192.168.30.1
255.255.255.0
Ruijie(config-if-GigabitEthernet 1/0)# exit
```

# Configure the BGP protocol to set up an MP-IBGP session with PE2.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 172.168.0.1 remote-as 1
Ruijie(config-router)# neighbor 172.168.0.1 update-source loopback 0
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 172.168.0.1 activate
Ruijie(config-router-af)# end
```

# Exchange VPN routes with the CE via OSPF; set the domain ID to 10.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10 VPNA
Ruijie(config-router)# network 192.168.30.0 255.255.255.0 area 0
Ruijie(config-router)# redistribute bgp subnets
Ruijie(config-router)# domain-id 10
Ruijie(config-router)# exit
Ruijie(config)# router bgp 1
Ruijie(config-router)# address-family ipv4 vrf VPNA
Ruijie(config-router-af)# redistribute ospf 10
Ruijie(config-router-af)# exit
```

# Configure MPLS signaling on the backbone network. Enable MPLS on the public network interface.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if-GigabitEthernet 1/1)# ip ref
Ruijie(config-if-GigabitEthernet 1/1)# ip address 172.168.40.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)# label-switching
Ruijie(config-if-GigabitEthernet 1/1)# mpls ip
Ruijie(config-if-GigabitEthernet 1/1)# end
```

# Configure a routing protocol on the backbone network.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 1
Ruijie(config-router)# network 172.168.40.0 0.0.0.255 area 0
Ruijie(config-router)# network 172.168.0.2 0.0.0.0 area 0
Ruijie(config-router)# end
```

Verification

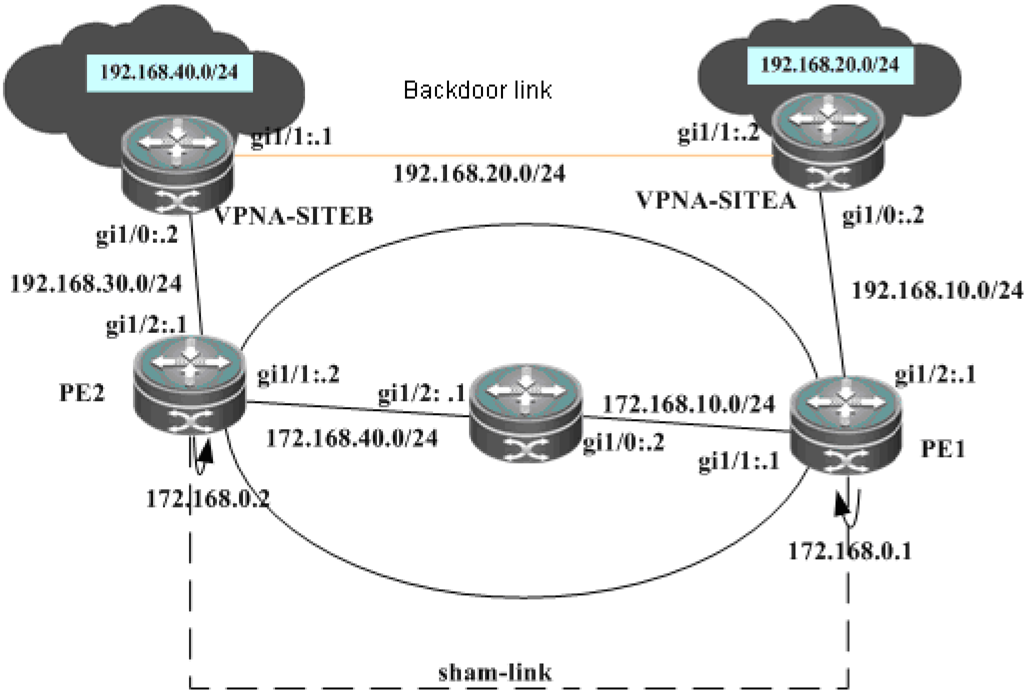
Sham Link Configuration Example

Networking Requirements

Two different sites of a customer exchange VPN routes via an MPLS backbone network. At the same time, a "backdoor link" is also established between these two sites to ensure that information can still be exchanged between both sites through this backup link when the MPLS backbone network fails.

Networking Topology

Figure 44



Configuration Steps

SITEA:

# Run the OSPF protocol with PE1 and SITEB. The OSPF protocol runs over the backdoor link with SITEB.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 192.168.10.0 255.255.255.0 area 0
Ruijie(config-router)# network 192.168.20.0 255.255.255.0 area 0
```

# Configure the OSPF cost on an interface.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/0
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if-GigabitEthernet 1/0)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if-GigabitEthernet 1/0)# ip ref
Ruijie(config-if-GigabitEthernet 1/0)# ip address 192.168.10.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/0)# ip ospf cost 1
Ruijie(config)# interface gigabitethernet 1/1
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if-GigabitEthernet 1/1)# ip ref
Ruijie(config-if-GigabitEthernet 1/1)# ip address 192.168.20.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)# ip ospf cost 200
```

PE1:

# Configure a loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 172.168.0.1 255.255.255.255
```

# Configure a VRF.

Create a VRF named VPNA, set the RD and RT values, and associate the VRF with the corresponding interface.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf VPNA
Ruijie(config-vrf)# rd 1:100
Ruijie(config-vrf)# route-target both 1:100
Ruijie(config-vrf)# end
```

# Associate the CE-connecting interface with the VRF.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/2
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if-GigabitEthernet 1/2)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if-GigabitEthernet 1/2)# ip ref
Ruijie(config-if-GigabitEthernet 1/2)# ip vrf forwarding VPNA
Ruijie(config-if-GigabitEthernet 1/2)# ip address 192.168.10.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/2)# end
```

# Configure the VRF loopback interface to establish a sham link.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 10
Ruijie(config-if-Loopback 10)# ip vrf forwarding VPNA
Ruijie(config-if-Loopback 10)# ip address 192.168.0.1 255.255.255.255
```

# Configure the BGP protocol to set up an MP-IBGP session with PE2.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 172.168.0.2 remote-as 1
Ruijie(config-router)# neighbor 172.168.0.2 update-source loopback 0
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 172.168.0.2 activate
Ruijie(config-router-af)# end
```

# Exchange routes with the CE via OSPF, and establish a sham link with the OSPF instance on PE2.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10 VPNA
Ruijie(config-router)# network 192.168.10.0 255.255.255.0 area 0
Ruijie(config-router)# redistribute bgp subnets
Ruijie(config-router)# area 0 sham-link 192.168.0.1 192.168.0.2
Ruijie(config-router)# exit
Ruijie(config)# router bgp 1
Ruijie(config-router)# address-family ipv4 vrf VPNA
Ruijie(config-router-af)# redistribute ospf 10
Ruijie(config-router-af)# redistribute connected
Ruijie(config-router-af)# end
```

# Configure MPLS signaling on the backbone network. Enable MPLS on the public network interface.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if-GigabitEthernet 1/1)# ip ref
Ruijie(config-if-GigabitEthernet 1/1)# ip address 172.168.10.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)# label-switching
Ruijie(config-if-GigabitEthernet 1/1)# mpls ip
Ruijie(config-if-GigabitEthernet 1/1)# end
```

# Configure a routing protocol on the backbone network.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 1
Ruijie(config-router)# network 172.168.10.0 0.0.0.255 area 0
Ruijie(config-router)# network 172.168.0.1 0.0.0.0 area 0
Ruijie(config-router)# end
```

P1:

The configuration steps are similar to the configuration steps of P in the MPLS backbone network.

SITEB:

# Run the OSPF protocol with PE2 and SITEA. The OSPF protocol runs over the backup link with SITEA.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 192.168.30.0 255.255.255.0 area 0
Ruijie(config-router)# network 192.168.20.0 255.255.255.0 area 0
```

# Configure the OSPF cost on an interface.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/0
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if-GigabitEthernet 1/0)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if-GigabitEthernet 1/0)# ip ref
Ruijie(config-if-GigabitEthernet 1/0)# ip address 192.168.30.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/0)# ip ospf cost 1
Ruijie(config)# interface gigabitethernet 1/1
```

# In case of a switch, configure the interface to a RoutedPort interface (not applicable to a router).

```
Ruijie(config-if-GigabitEthernet 1/1)# no switchport
```

# In case of a router, enable fast forwarding on the interface (not applicable to a switch).

```
Ruijie(config-if-GigabitEthernet 1/1)# ip ref
Ruijie(config-if-GigabitEthernet 1/1)# ip address 192.168.20.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)# ip ospf cost 200
```

PE2:

# Configure a loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 172.168.0.2 255.255.255.255
```

# Configure a VRF.

Create a VRF named VPNA, set the RD and RT values, and associate the VRF with the corresponding interface.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf VPNA

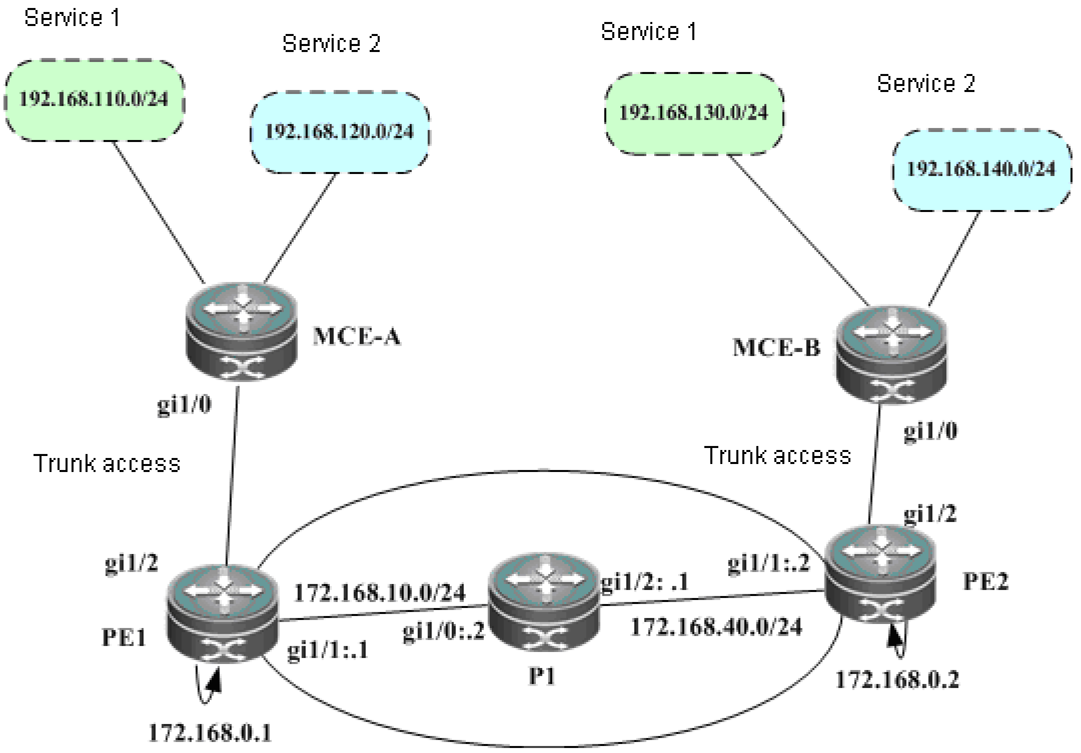
Configuring Multiple OSPF Instances on an MCE

Networking Requirements

A customer site involves multiple services. The same services communicate with each other over an MPLS backbone network and different services are isolated from each other.

Networking Topology

Figure 45



Configuration Steps

MCE-A:

# Configure a trunk link between a PE and a CE.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/0
```

# **VLAN** is a configuration command used on switch products, and is not applicable to routers (except for the switching card interface). Routers can use the routing interface to connect to the PE.

```
Ruijie(config-if-GigabitEthernet 1/0)# switchport mode trunk
Ruijie(config-if-GigabitEthernet 1/0)# end
```

# Configure two VRFs to represent different services and bind respective interfaces.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf VPN1
Ruijie(config-vrf)# exit
Ruijie(config)# VLAN 10
Ruijie(config)# interface vlan 10
```

# **VLAN** is a configuration command used on switch products, and is not applicable to routers (except for the switching card interface). Routers can use the sub-interface to bind the VRF.

```
Ruijie(config-if-vlan 10)# ip vrf forwarding VPN1
Ruijie(config-if-vlan 10)# ip address 192.168.10.2 255.255.255.0
Ruijie(config)# ip vrf VPN2
Ruijie(config-vrf)# exit
Ruijie(config)# VLAN 20
Ruijie(config)# interface vlan 20
```

# **VLAN** is a configuration command used on switch products, and is not applicable to routers (except for the switching card interface). Routers can use the sub-interface to bind the VRF.

```
Ruijie(config-if-vlan 20)# ip vrf forwarding VPN2
Ruijie(config-if-vlan 20)# ip address 192.168.20.2 255.255.255.0
```

# Run the OSPF protocol with the PE for two VRFs.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10 VPN1
Ruijie(config-router)# network 192.168.10.0 255.255.255.0 area 0
Ruijie(config-router)# capability vrf-lite
```

```
Ruijie(config)# router ospf 10 VPN2
Ruijie(config-router)# network 192.168.20.0 255.255.255.0 area 0
Ruijie(config-router)# capability vrf-lite
```

PE1:

# Configure a loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 172.168.0.1 255.255.255.255
```

# Configure the trunk link between the PE and the CE.

```
Ruijie(config)# interface gigabitethernet 1/2
Ruijie(config-if-GigabitEthernet 1/2)# switchport mode trunk
Ruijie(config-if-GigabitEthernet 1/2)# end
```

# Configure VRFs.

Create two VRFs named VPN1 and VPN2 to represent different services, and associate the VRFs with the corresponding interfaces.

```
Ruijie# configure terminal
Ruijie(config)# ip vrf VPN1
Ruijie(config-vrf)# rd 1:100
Ruijie(config-vrf)# route-target both 1:100
Ruijie(config-vrf)# end
Ruijie# configure terminal
Ruijie(config)# ip vrf VPN2
Ruijie(config-vrf)# rd 1:200
Ruijie(config-vrf)# route-target both 1:200
Ruijie(config-vrf)# end
```

# Associate the CE-connecting interface with the VRF.

```
Ruijie(config)# VLAN 10
Ruijie(config)# interface vlan 10
```

# **VLAN** is a configuration command used on switch products, and is not applicable to routers (except for the switching card interface). Routers can use the sub-interface to bind the VRF.

```
Ruijie(config-if-vlan 10)# ip vrf forwarding VPN1
Ruijie(config-if-vlan 10)# ip address 192.168.10.1 255.255.255.0

Ruijie(config)# VLAN 20
Ruijie(config)# interface vlan 20
```

# **VLAN** is a configuration command used on switch products, and is not applicable to routers (except for the switching card interface). Routers can use the sub-interface to bind the VRF.

```

Configuring L2VPN

☑ For the router with the L2VPN service enabled, the L2VPN service can be properly forwarded if the fast forwarding function is enabled both on the interfaces connected to the user and the public network.

Understanding L2VPN

Similar to an MPLS/BGP L3VPN, an L2VPN also uses the existing public network to extend the private network of a user. For an MPLS L2VPN, Layer 2 user data (such as ATM cells, FR frames, and Ethernet frames) is transparently transmitted on an MPLS network. As far as the user is concerned, the MPLS network is a Layer 2 switching network where different sites set up Layer 2 connections on the MPLS network.

Compared with L3VPN, L2VPN has the following advantages:

- Supports various link layer protocols. On an MPLS network, you can provide Layer 2 VPN services based on various protocols including ATM, FR, VLAN, Ethernet, PPP, and HDLC. L2VPN also supports multiple network layer protocols, including IP, IPv6, IPX, and SNA.
- A provider edge (PE) does not store the information about user VPNs, reducing the overhead on the PE. This largely lessens the burden of PEs and the entire service provider (SP) network and allows the carriers to support more VPNs and access more users.
- Allows a user to control the advertising of VPN routes and frees the PE from managing VPN routes. This guarantees reliability and confidentiality of user routes and lessens the management burden of carriers.

At present, an MPLS L2VPN has the following two service models:

- Virtual Private Wire Service (VPWS)

You can set up a Pseudo Wire (PW), also called Virtual Circuit (VC), on an IP/MPLS network to simulate Layer 2 point-to-point services, including Ethernet, PPP, HDLC, AAL5 frames, ATM cells, FR, and SONET/SDH. For a user, the VPWS resembles a physical line provided for the user on the carrier's network.

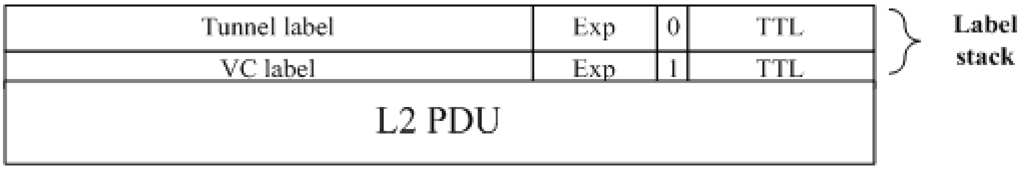
- Virtual Private LAN Service (VPLS)

Simulate LAN services on an IP/MPLS network to implement Ethernet connections on the WAN. For a user, its Layer 2 devices are connected to each other across the IP/MPLS core network and the core network is like a virtual switch.

Frame Format of an MPLS L2VPN Packet

As shown in the following figure, an MPLS L2VPN packet is generally encapsulated in two layers of labels. The outer layer is a public label that is responsible for forwarding the packet on the public network. The inner layer is the VC label that is used to identify a VC instance on a PE.

Figure 46

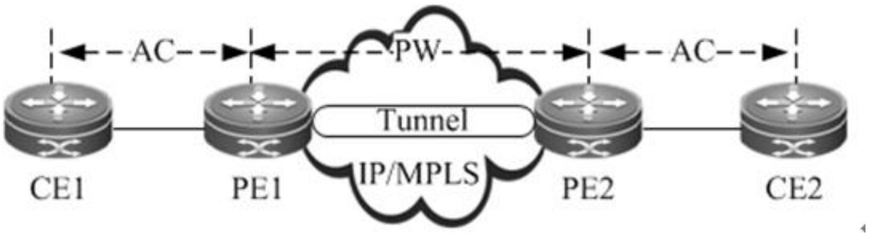


Tunnel label	Exp	0	TTL
VC label	Exp	1	TTL
L2 PDU			

Basic Concepts

The following figure shows the components of an L2VPN.

Figure 47



CE

A custom edge (CE) is a user device directly connected to the SP.

PE

A PE, an edge device on the SP network, is connected to CEs and is responsible for the access of VPN services. It forwards packets from a private network to a public tunnel and from the public tunnel to the private network.
On a hierarchical VPLS network, PEs are classified into User Facing Provider Edge devices (U-PEs) and Network Facing Provider Edge devices (N-PEs).

- U-PE

A U-PE is a PE next to the user side as the hierarchical VPLS network. It is an aggregation device for users to access a VPN.

- N-PE

An N-PE is a core PE device on the hierarchical VPLS network. It is located at the edge of core VPLS domains to provide transparent transmission of VPLS services between core networks.

AC

On an L2VPN of any type (VPWS/VPLS), CEs must be connected to PEs through physical lines or virtual lines. These physical or virtual lines are referred to as the ACs. For example, an AC can be an Ethernet cable, a VLAN, or an MPLS LSP. All user packets on the AC are generally forwarded to the peer CE without any changes.

PW

A PW is responsible for setting up and maintaining the signaling protocol between PEs. The AC transmits frames from a CE to a PE and the PW sends user frames from one PE to another PE.

On a hierarchical VPLS network, PWs are classified into Hub PWs and Spoke PWs.

- Hub PW

A Hub PW indicates a PW set up between N-PEs.

- Spoke PW

A Spoke PW indicates a PW set up between a U-PE and an N-PE, or a PW with which a user accesses the PE on a basic VPLS network.

Forwarder

On an L2VPN, every frame received by a PE from the AC must be forwarded to the corresponding PW. Similarly, the frames received by the PE from the PW are sent to the corresponding AC. This process of making forwarding decisions is called the forwarder.

In VPWS, the forwarder performs the one-to-one mapping between ACs and PWs.

In VPLS, the forwarder is also called the Virtual Switch Instance (VSI) or Virtual Forwarding Instance (VFI), which is the VPLS forwarding table. Through the VFI, you can map the ACs of actual VPLS users to PWs.

Tunnel

The traffic of PWs between PEs is transmitted over the tunnel. One tunnel can carry multiple PWs. The tunnels mentioned in this chapter refer to MPLS LSPs.

Encapsulation

The L2VPN payload is transmitted over PWs. The PWE3 defines the encapsulation formats and transmission technologies of various packets transmitted over PWs. The PW supports two encapsulation modes: raw and tag. In raw mode, the service distinguishers are removed from the PDUs transmitted on PWs. In tag mode, the service distinguishers are included in the PDUs transmitted on PWs. For Ethernet emulated services, the service distinguisher is generally a VLAN tag. Encapsulation and transmission methods of PPP and HDLC packets are defined in the RFC4618.

PW Signaling

PW signaling protocols include LDP and BGP. They are responsible for creating and maintaining PWs.

- When using LDP sessions to set up PWs

When using LDP sessions to set up PWs, you should set up two types of LDP sessions: LDP sessions set up through the basic discovery mechanism and LDP sessions set up through the extended discovery mechanism. The former is used to set up public LSPs and the latter to transmit the label mapping messages of PWs. The setup and disconnection of a PW are as follows:

- PEs exchange Hello packets through the target LDP session (through the extended LDP discovery mechanism) and set up the LDP session.
- When the status of the AC at one PE end is Up, the PE assigns a label to the corresponding PW.
- The PE encodes the label value and the PW ID into the FEC TLV and sends a label mapping message to the peer PE through the target LDP session.

- Upon receipt of the label mapping message, the peer PE decodes the PW ID and label value and checks whether the interface parameters (such as MTU) and PW types are consistent.
- The PW is set up after both ends exchange their label values and verify the validity of PW IDs and interface parameters.
- To disconnect a PW, a PE sends a label withdrawal message to the peer PE. Then the PW is disconnected.

Caution

The following conditions must be met when you set up a PW through LDP; otherwise, the PW cannot be set up:

1) The MTUs and PW types on the devices at both ends of the PW must be consistent.

2) The PW IDs on the devices at both ends of the PW must be consistent.

- Using BGP signaling to set up PWs

Unlike using LDP signaling, this method does not require static configuration of the connection between CEs. Instead, the entire carrier network is divided into different VPNs and CEs are numbered globally in VPN sites. Similar to BGP/MPLS L3VPN, BGP signaling uses VPN Target to identify CE sites that belong to the same VPN. The process of discovering VPN sites by using VPN Target is called the automatic discovery. If BGP is used as the signaling protocol, there will be two stages. The first stage is automatic discovery and the second stage is to set up bidirectional PWs between PEs based on the result of the automatic discovery.

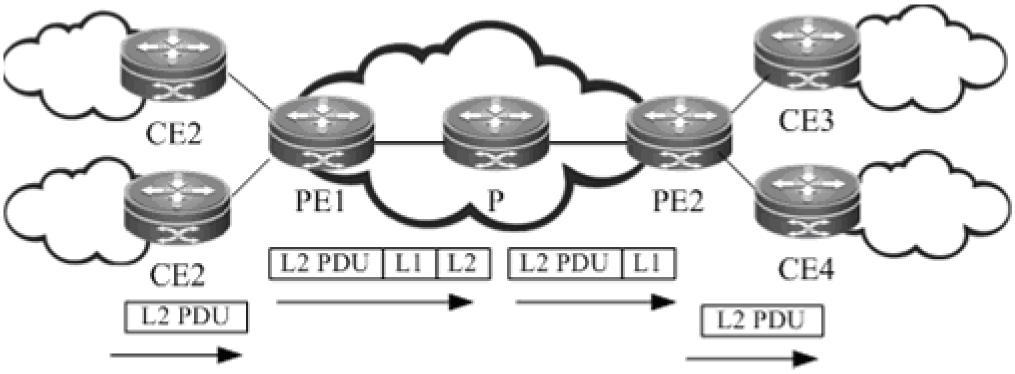
The method of establishing PWs by using BGP has brought in a concept of the label blocks. It uses the label block to allocate labels for multiple links at a time. Users can specify the site range for a local CE, indicating the number of remote CEs that can be connected with the CE. The system allocates one label block to the CE at a time. The label block's size is equal to the site range. In this way, users can allocate extra labels for VPN. This may cause waste of the label resource in a short term but can reduce the configuration workload for VPN expansion.

Given the BGP's characteristics, such as the route reflector's characteristics, this method of setting up PWs can reduce the full inter-connection of BGP sessions, facilitating the expansion of capacity.

Basic Forwarding Process

An L2VPN adopts the two-layer label stack to transmit services on the backbone network. The outer label is used to forward packets on the backbone network and the inner VC label is used to identify VC instances on PEs. Based on the inner VC label, a PE determines the CE to which the packets needs to be sent. The following figure shows the forwarding process.

Figure 48



After receiving a Layer 2 packet from CE2, PE1 searches for the PW forwarding entry based on the PW associated with the AC and learns that the next hop is PE2 and the PW label is L1. PE1 then searches for the public LSP based on the next hop (PE2) and obtains the outer label L2. As a result, PE1 encapsulates an MPLS header and pushes the inner label L1 and outer label L2 to the Layer packet and sends the packet to P. P forwards the MPLS packet based on the label and the penultimate hop popping (PHP) P pops out the outer label and sends the packet to PE2. Upon receipt of the packet, PE2 searches for the PW ID entry based on the inner label L1, learns the output interface (that is, the egress AC), pops out the inner label, and directly sends the Layer 2 packet to the destination CE4.

VCCV

Virtual circuit connectivity verification (VCCV) is a PW end-to-end connectivity fault detection and diagnosis mechanism. In brief, VCCV sends VCCV packets from the ingress node to the egress node of the PW to verify the end-to-end data plane connectivity of the PW and locate a connectivity fault in the PW. VCCV defines a series of messages to verify the connectivity of the PW. The VCCV packets must be encapsulated in the same way and pass the same tunnel as the PW packets to ensure that the VCCV packets are transmitted in the same path as the PW data packets. Therefore, VCCV needs to create a control channel that is associated with the PW and has the same path as the PW data if possible. The VCCV packets are transmitted in this control channel. The data in the control channel is not forwarded to the CE device, but is intercepted and processed on the PE device.

There are two VCCV modes: VCCV ping and VCCV traceroute. The VCCV ping mode can detect the PW connectivity. The VCCV traceroute mode can track the PW path to locate a connectivity fault in the PW.

VCCV Control Channel Type

VCCV packets are transmitted on the same PW bidirectional virtual circuit (VC) as PW service data packets, and have the same public network tunnel label and VC label encapsulated as common PW data packets. In addition, VCCV packets are transmitted in the same path as the PW data packets. The channel that transmits VCCV packets is called the control channel, and VCCV supports the following three types of control channels:

- Type 1: control word control channel.

VCCV packets that are transmitted in the control word control channel carry a control word. The first nibble of the control word carried in a VCCV packet is 0001b, indicating that this packet is a VCCV packet, which is different from the first nibble 0000b of the control word of a PW data packet. The control word can be used to distinguish the VCCV packet from common PW data packets and instruct the outbound PE router to process the VCCV packet.

- Type 2: router alert label control channel.

A control channel of this type is also referred to as router alert (RA) label control channel. An RA label is added to the PW label of a VCCV packet to force the outbound PE router to process the VCCV packet.

- Type 3: TTL timeout control channel.

For a single-segment PW, the time to live (TTL) of the PW label of a VCCV packet is set to 1. The TTL will expire on the outbound PE router, and as a result, the packet will be delivered to the CPU, which is forced to process the VCCV packet.

For a multi-segment pseudo wire (MS-PW), the TTL of the PW label of a VCCV packet is set according to the number of the PW segments. The TTL of the first segment is set to 1, the TTL of the second segment set to 2, and so on. The TTL will expire on the outbound PE router (S-PE or T-PE) in the PW segment, and as a result, the VCCV packet will be delivered to the CPU, which is forced to process the VCCV packet.

Caution Ruijie products do not support Type 1 and only support Types 2 and 3.

VCCV Ping

VCCV ping is used to verify the PW data plane connectivity. It is an extension of MPLS LSP ping. A PE device sends a VCCV ping request packet to the peer PE by running the user command. If no connectivity fault exists on the PW, the packet is forwarded to the egress PE device on the PW and delivered to the control plane. Otherwise, the packet will be discarded by the intermediate label switch router (LSR), which is also called transit LSR, or sent to its control plane. When receiving the packet on the control plane, the LSR verifies whether itself is the egress PE device of the PW based on the PW FEC information carried in the packet and responds to the source PE device. The VCCV response packet contains the relevant return code, which indicates the network status of the LSR. With VCCV ping, the source LSR possibly obtains a series of results based on the return code (indicating that the packet reaches the target PW egress and a response is returned successfully, the packet reaches a wrong PW egress, the PW path is disconnected, the transmission times out, and so on.), so as to check the PW connectivity.

VCCV Traceroute

VCCV traceroute is used to track the PW path and check the consistency between the control plane and data plane of all LSRs on the PW. VCCV traceroute is an extension of MPLS LSP traceroute.

VCCV traceroute also uses the MPLS echo request packets and response packets to track the PW path. In VCCV traceroute mode, multiple MPLS echo request packets are successively sent and the TTLs of the VC labels of these packets increase progressively. The TTL of the tunnel label of the first VCCV traceroute packet is 255, and the TTL value of the VC label is 1. The TTL of the VC label of each subsequent echo request packet increases by 1 compared with the previous one.

For a single-segment PW, if no connectivity fault exists on the PW, the packet is forwarded to the egress PE device on the PW and delivered to the control plane. The egress PE device verifies itself as the outbound PE device and directly returns a response packet as the egress PE device. Otherwise, the packet will be discarded by the intermediate LSR or sent to its control plane. When receiving the packet on the control plane, the LSR performs verification based on the information carried in the packet and responds to the source PE device.

For a MS-PW, if no connectivity fault exists on the MS-PW, the echo request packet sent in VCCV traceroute mode is forwarded to the intermediate S-PE device and the egress PE device and to the control plane. The intermediate S-PE device verifies the forwarding as an intermediate S-PE forwarding behavior and returns L to indicate that itself is the intermediate S-PE device on the MS-PW. The egress PE device verifies itself as the egress PE and returns a response packet as the egress PE device. Otherwise, the packet will be discarded by the intermediate LSR or sent to its control plane for processing. The intermediate LSR implements verification based on the information carried in the packet and then responds to the source PE device.

VPWS

Understanding VPWS

As an end-to-end bearer technology of Layer 2 services, VPWS is a P2P L2VPN. VPWS provides MPLS network-based L2VPN services so that carriers can provide L2VPN services based on various protocols including ATM, FR, VLAN, Ethernet and PPP over a unified MPLS network. Moreover, the MPLS network can provide traditional IP, MPLS L3VPN and other services. Simply speaking, MPLS L2VPN is to transmit users' layer-2 data transparently on the MPLS network.

- Signaling protocol of VPWS

VPWSs can be divided into Martini and Kompella VPWSs by signaling protocol. Martini VPWSs use LDP as the signaling protocol while Kompella VPWSs use BGP as the signaling protocol.

- Intercommunication of heterogeneous media of VPWSs

If CEs on two ends of the same L2VPN feature different link types, L2VPN's feature of heterogeneous media intercommunication are needed. According to the suggestion of draft-kompella-ppvpn-l2vpn, the encapsulation type of the L2VPN interface of PEs needs to be ip-interworking during the establishment of the L2VPN connection. Users' layer-3 data (IP packets) is transmitted on the MPLS network transparently.

Configuring Martini VPWS

Configuring a Public Tunnel

You must set up an LSP on the public network to carry VC services. To run MPLS on the backbone network, you must enable LDP on Ps and PEs to establish a public network tunnel. This means that you have to configure LDP on the routers and enable MPLS forwarding on each interface. The configuration procedure is as follows:

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **mpls ip**	Enables MPLS globally. ⚠ Caution This command is not applicable to switch chip forwarding.
Ruijie(config)# **mpls router ldp**	Enables LDP and enters MPLS routing configuration mode.
Ruijie(config-**mpls-router)# ldp router-id interface loopback** *id* [**force**]	Configures the LDP router ID. The IP address of the loopback interface is generally used as the router ID.
Ruijie(config-mpls-router)# **exit**	Exits MPLS routing configuration mode.
Ruijie(config)# **interface** *type ID*	Enters public network interface configuration mode.
Ruijie(config-**if**-*type ID*)# **ip address** *ip-address mask*	Assigns an IP address to the interface.
Ruijie(config-if-*type ID*)# **label-switching**	Enables MPLS forwarding on the interface at the public network side.
Ruijie(config-if-*type ID*)# **mpls ip**	Enables LDP on the interface.

Ruijie(config-if-*type ID*)# **ip ref**	☑ For routers, the fast forwarding function of the interface must be enabled. You do not need to use this command on switches.
Ruijie(config-if-*type ID*)# **show running-config**	Displays all configuration information.

# Configure an MPLS network.

```
Ruijie# configure terminal
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# )# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/1
```

# The **no switchport** command is used on switches to switch the port mode to routed port mode. It does not apply to routers and does not need to be used on routers.

```
Ruijie(config-if-gigabitethernet 1/1)# no switchport
```

# Enable the fast forwarding function of the interface on routers. You do not need to use this command on switches.

```
Ruijie(config-if-gigabitethernet 1/1)# no switchport
Ruijie(config-if-gigabitethernet 1/1)# ip address 192.168.10.1 255.255.255.0
Ruijie(config-if-gigabitethernet 1/1)# label-switching
Ruijie(config-if-gigabitethernet 1/1)# mpls ip
```

Configuring Remote LDP Peers

A PW is set up and maintained by the extended LDP. If other LSRs exist between two PEs, use the extended LDP discovery mechanism to set up a remote LDP session between the PEs and assign PW labels in the session. The procedures for configuring a remote LDP peer and setting up a remote LDP session are as follows:

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **mpls router ldp**	Enables LDP and enters LDP configuration mode.
Ruijie(config-mpls-router)# **neighbor** *ip-address*	Configures a remote LDP session.
Ruijie(config-mpls-router)# **show running-config**	Displays all configuration information.

# Configure a remote LDP peer at 3.3.3.3.

```
Ruijie# configure terminal
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# neighbor 3.3.3.3
Ruijie(config)# exit
```

⚠ Caution

The PW label messages of the LDP are not affected by the LDP label distribution mode or label retention mode. The LDP is forced to work in DU and liberal label retention mode.

Configuring User Access VPWS

VPWS Access Modes for Switches

Only Ethernet VPWS services are provided on switches. According to whether the packet carries a VLAN tag, user access can be divided into the following modes:

59) Access interface access
60) Trunk interface access
61) Dot1q Tunnel interface access

Caution

VPWS services are supported by only VLAN interfaces (that is, SVI interfaces on switches). In addition, the VLAN can have only one member interface. You have trouble in enabling both IP and VPWS services on VLAN interfaces at the same time.

One VLAN interface can be bound to only one VC instance. The same VC instance cannot be bound to different VLAN interfaces.

When the **xconnect** command is used to specify the neighbor address of the VC peer end, you must use the router ID of this peer end as the peer address. The router ID of this peer end must be the 32-bit address of the loopback interface.

After the port protection mode is enabled on the member ports of the AC end of L2VPN, the port protection mode does not take effect for non-Tunk member ports.

These access modes are described in details as follows:

- VLAN access interface access

This mode applies when user packets transmitted on ACs are not encapsulated through 802.1Q (that is, packets without VLAN tags). Use the following commands to configure VLAN access interface access in privileged mode.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters interface configuration mode.
Ruijie(config-if-*type ID*)# **switchport mode access**	Enables the interface to work in access mode.
Ruijie(config-if-*type ID*)# **switchport access vlan** *vlan-id*	Sets the interface as a member interface of a VLAN.
Ruijie(config-if-*type ID*)# **exit**	Exits interface configuration mode.
Ruijie(config)# **interface vlan** *vlan-id*	Creates and enters VLAN interface configuration mode.
Ruijie(config-if-*type ID*)# **xconnect** *vc_id vc_peer* **encapsulation mpls** {**ethernet|ethernetvlan**} **raw**	Creates a VC and configures the raw encapsulation mode.
Ruijie(config-if-*type ID*)# **show running-config**	Displays all configuration information.

# Configure **Gigabitethernet** *1/1* as an access interface and configure VPWS services for the corresponding VLAN interface.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/1
Ruijie(config-if-gigabitethernet 1/1)# switchport mode access
Ruijie(config-if-gigabitethernet 1/1)# switchport access vlan 2
Ruijie(config-if-gigabitethernet 1/1)# exit
Ruijie(config)# interface vlan 2
Ruijie(config-if-vlan 2)# xconnect 2  2.2.2.2 encapsulation mpls ethernet raw
```

Caution

In access interface access mode, we recommend setting the PW type to Ethernet, and the PW encapsulation mode must be raw.

■ VLAN trunk interface access

This mode applies to the transmission of VPWS services from multiple users on the same AC. The PE determines the VPWS services for user packets based on their VLAN tags to provide the multiplexing of access interfaces.

Use the following commands to configure VLAN trunk interface access in privileged mode.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters interface configuration mode.
Ruijie(config-if-*type ID*)# **switchport mode trunk**	Enables the interface to work in trunk mode.
Ruijie(config-if-*type ID*)# **switchport trunk allow vlan add** *vlan-list*	Enables the trunk link to allow VLAN traffic.
Ruijie(config-if-*type ID*)# **exit**	Exits the interface configuration mode.
Ruijie(config)# **interface vlan** *vlan-id*	Creates and enters VLAN interface configuration mode.
Ruijie(config-if-*type ID*)# **xconnect** *vc_peer vc_id* **encapsulation mpls ethernetvlan tagged**	Creates a VC and configures the tagged encapsulation mode.
Ruijie(config-if-*type ID*)# **show running-config**	Displays all configuration information.

# Configure **Gigabitethernet** *1/1* as a trunk port and configure VPWS services for the corresponding VLAN interface.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/1
Ruijie(config-if-gigabitethernet 1/1)# switchport mode trunk
Ruijie(config-if-gigabitethernet 1/1)# switchport trunk  allowed vlan add  2 3
Ruijie(config-if-gigabitethernet 1/1)# exit
Ruijie(config)# interface vlan 2
Ruijie(config-if-vlan 2)# xconenct 2  2.2.2.2 encapsulation mpls ethernetvlan tagged
Ruijie(config-if-vlan 2)# exit
Ruijie(config)# interface vlan 3
Ruijie(config-if-vlan 2)# xconenct 3  2.2.2.2 encapsulation mpls ethernetvlan tagged
```

Caution

In trunk interface access mode, we recommend setting the PW type to **ethernetvlan**, and the PW encapsulation mode must be tagged.

The L2VPN service cannot be bound to the Native VLAN of the Trunk interface.

- VLAN tunnel interface access

This mode applies when user service packets transmitted on ACs carry private VLAN tags if users access VPWS services. In this mode, the PE forwards all packets received from the VLAN tunnel interface without any changes. This mode requires the VLAN member interfaces that connect PEs with CEs to work in tunnel mode.

Use the following commands to configure VLAN tunnel interface access in privileged mode.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters interface configuration mode.
Ruijie(config-if-*type ID*)# **switchport access** *vlan-id*	Sets the interface as a VLAN member interface.
Ruijie(config-if-*type ID*)# **switchport mode dot1q-tunnel**	Sets the interface to work in tunnel mode.
Ruijie(config-if-*type ID*)# **exit**	Exits interface configuration mode.
Ruijie(config)# **interface** vlan *vlan-id*	Creates and enters VLAN interface configuration mode.
Ruijie(config-if-*type ID*)# **xconnect** *vc_id vc_peer* **encapsulation mpls ethernet raw**	Creates a VC and configures the raw encapsulation mode.
Ruijie(config-if-*type ID*)# **show running-config**	Displays all configuration information.

# Configure **Gigabitethernet** *1/1* as a VLAN tunnel interface and configure VPWS services for the corresponding VLAN interface.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/1
Ruijie(config-if-gigabitethernet 1/1)# switchport mode dot1q-tunnel
Ruijie(config-if-gigabitethernet 1/1)# switchport access 2
Ruijie(config-if-gigabitethernet 1/1)# exit
Ruijie(config)# interface vlan 2
Ruijie(config-if-vlan 2)# xconenct 2  2.2.2.2 encapsulation mpls ethernet raw
Ruijie(config-if-vlan 2)# exit
```

Caution

For the access mode of the VLAN tunnel port, we recommend setting the PW type to **ethernet** and the encapsulation mode must be raw.

For the access mode of the VLAN tunnel interface, only the basic QinQ is supported.

VPWS Access Modes for Routers

There are several ways for users to access VPWS services provided by routers. Users can choose access modes according to actual application needs. Services provided by the VPWS depend on the link protocol adopted by the interface that connects the PE with the CE. Currently, the following four point-to-point L2VPN services are supported:

1) Simulative Ethernet line service
2) Simulative 802.1Q line service
3) Simulative PPP line service
4) Simulative HDLC line service

For the PE, the four L2VPN line services correspond to four access modes.

⚠ Caution

You have trouble in enabling both IP and VPWS services on VLAN interfaces at the same time.

One VLAN interface can be bound to only one VC instance. The same VC instance cannot be bound to different VLAN interfaces.

☑ For the router product, VPWS services can be properly forwarded only when the fast forwarding function is enabled on the interfaces connected to the access user VPWS and to the public network.

⚠ Caution

When the **xconnect** command is used to specify the neighbor address of the VC peer end, you must use the router ID of this peer end as the peer address. The router ID of this peer end must be the 32-bit address of the loopback interface.

- Ethernet access

In this mode, the interface between a PE and a CE encapsulates the Ethernet link protocol and provides VPWS services. The CE connects to the PE through the Ethernet link and requests Ethernet frames transmitted transparently by the PE. The Ethernet interface access mode applies when user service packets transmitted on ACs carry private VLAN tags or do not carry VLAN tags in the case of VPWS service access. In this mode, all packets received by PEs from the interface are forwarded without any changes.

Use the following commands to configure Ethernet access in privileged mode.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters interface configuration mode.
Ruijie(config-if-*type ID*)# **xconnect** *vc_peer vc_id* **encapsulation mpls ethernet raw**	Creates a VC, and configure the Ethernet PW type and the raw encapsulation mode.
Ruijie(config-if-*type ID*)# **ip ref**	☑ For routers, the fast forwarding function of the interface must be enabled. You do not need to use this command on switches.
Ruijie(config-if-*type ID*)# **show running-config**	Displays all configuration information.

# Configure VPWS services for the Ethernet access interface **Gigabitethernet** *1/1*.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 0/1
```

# Enable the fast forwarding function of the interface on routers. You do not need to use this command on switches.

```
Ruijie(config-if-gigabitethernet 1/1)# ip ref
Ruijie(config-if-gigabitethernet 0/1)# xconnect 2.2.2.2 2 encapsulation mpls ethernet raw
Ruijie(config-if-gigabitethernet 0/1)# exit
```

- Ethernet sub-interface access

In this mode, the interface between a PE and a CE encapsulates the 802.1Q link protocol and provides VPWS services. The CE connects to the PE through the Ethernet sub-interface and requests Ethernet frames transmitted transparently by the PE. The Ethernet sub-interface access mode applies when several VPWS services for multiple users are transmitted on an access physical link. The PE matches packets with VPWS services according to dot1q tags carried by the user packets to provide the multiplexing of access interfaces. In this access mode, packets sent by CEs to PEs must carry VLAN tags.

Use the following commands to configure Ethernet sub-interface access in privileged mode.

Command	**Function**
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters interface configuration mode.
Ruijie(config-if-*type ID*)# **xconnect** *vc_peer vc_id* **encapsulation mpls ethernetvlan tagged**	Creates a VC, and configures the Ethernet VLAN PW type and the tagged encapsulation mode.
Ruijie(config-if-*type ID*)# **ip ref**	☑ For routers, the fast forwarding function of the interface must be enabled. You do not need to use this command on switches. Use the command to configure the sub-interface's fast forwarding function on its master interface.
Ruijie(config-**if**-*type ID*)# **show running-config**	Displays all configuration information.

# Configure **Gigabitethernet** *1/1* as an access interface and configure VPWS services for the corresponding VLAN interface.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 0/1.1
Ruijie(config-if-gigabitethernet 0/1.1)#encapsulation dot1Q 1
```

# Enable the fast forwarding function of the interface on routers. You do not need to use this command on switches.

```
Ruijie(config-if-gigabitethernet 1/1)# ip ref
Ruijie(config-if-gigabitethernet 0/1.1)# xconnect 2.2.2.2 2 encapsulation mpls ethernetvlan
tagged
Ruijie(config-if-gigabitethernet 0/1.1)# exit
```

⚠ Caution

If the VPWS service is enabled on both the master interface and sub-interface, or is enabled on one of them, packets without VLAN tags received by the Ethernet interface belong to the service provided by the master interface. If they carry VLAN tags and match with the sub-interface's VLAN ID, they belong to the service provided by the sub-interface.

To enable the sub-interface to support the fast forwarding function, use the **ip ref** command to enable the fast forwarding function on its master interface.

Users can use **mpls mtu** command to modify the **mpls mtu** value. By default, the value is equal to the **mtu** value of the interface.

- PPP access

In this mode, the interface that connects a PE with a CE encapsulates the PPP link protocol and provides VPWS services. The CE connects to the PE in PPP mode and requests the PPP frames transmitted transparently by the PE. The interface that encapsulates the PPP protocol is bound with the L2VPN service and its PE-end PPP protocol will be disabled. Therefore, the LCP and NCP of one CE will not interact with each other. The PE will transparently transmit the PPP negotiation controlling packet sent by CE. The PPP negotiation will be conducted between CEs.

Use the following commands to configure PPP access in privileged mode.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters interface configuration mode.
Ruijie(config-if-*type ID*)# **encapsulation ppp**	Enables the interface to encapsulate PPP.
Ruijie(config-if-*type ID*)# **xconnect** *vc_peer vc_id* **encapsulation mpls ppp**	Creates the VC and configures the PW type as PPP.
Ruijie(config-if-*type ID*)# **ip ref**	☑ For routers, the fast forwarding function of the interface must be enabled. You do not need to use this command on switches.
Ruijie(config-if-*type ID*)# **show running-config**	Displays the existing configuration information.

# Configure **serial** *1/0* to provide the VPWS service of transparently transmitting PPP frames.

```
Ruijie# configure terminal
Ruijie(config)# interface serial 1/0
Ruijie(config-if-serial 1/0)# encapsulation ppp
Ruijie(config-if-serial 1/0)# xconnect 2.2.2.2 2 encapsulation mpls ppp
Ruijie(config-if-serial 1/0)# exit
```

- HDLC access

In this mode, the interface that connects a PE with a CE encapsulates the HDLC link protocol and provides VPWS services. The CE connects to the PE in HDLC mode and requests the HDLC frames transmitted transparently by the PE.

Use the following commands to configure HDLC access in privileged mode.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters interface configuration mode.
Ruijie(config-if-*type ID*)# **encapsulation hdlc**	Enables the interface to encapsulate HDLC.
Ruijie(config-if-*type ID*)# **xconnect** *vc_peer vc_id* **encapsulation mpls hdlc**	Creates the VC and configures the PW type as HDLC.
Ruijie(config-if-*type ID*)# **show running-config**	Disables the existing configuration information.

# Configure **serial** *1/0* to provide the VPWS service of transparently transmitting HDLC.

```
Ruijie# configure terminal
Ruijie(config)# interface serial 1/0
```

# Enable the fast forwarding function of the interface on routers. You do not need to use this command on switches.

```
Ruijie(config-if-serial 1/0)# ip ref
Ruijie(config-if-serial 1/0)# encapsulation hdlc
Ruijie(config-if-serial 1/0)# xconnect 2.2.2.2 2 encapsulation mpls ppp
Ruijie(config-if-serial 1/0)# exit
```

Configuring Heterogeneous Media Communication VPWS

If CEs on two ends of the same L2VPN feature different link types, the L2VPN's feature of heterogeneous media intercommunication is needed. According to the suggestion of draft-kompella-ppvpn-l2vpn, the encapsulation type of the L2VPN interface of PEs needs to be ip-interworking during the establishment of the L2VPN connection. Users' IP packets are transmitted on the MPLS network transparently. When the L2VPN's heterogeneous media communication function is used, VPWS service interfaces of PEs on both ends must encapsulate ip-interworking. After PW connection is set up, packets are processed as follows:

62) After a PE receives packets from a CE and decapsulates the link layer, the PE transmits IP packets to the MPLS network.
63) IP packets are transmitted transparently through the MPLS network to the peer PE.
64) The peer PE re-encapsulates the IP packets according to its link layer protocol type and sends them to the CE connected to it.
65) The link layer control packet (such as PPP's IPCP) sent by the CE are processed by the PE without being transmitted on the MPLS network.
66) Non-IP packets (such as MPLS packets) are discarded and do not enter the MPLS network.

- Among the Ethernet interfaces on the PE, the following L2VPN interfaces can be encapsulated in ip-interworking mode:

67) Ethernet interface or sub-interface
68) GigabitEthernet interface or sub-interface

Note the following points:

69) After being encapsulated as ip-interworking, the PE's Ethernet interface processes only ARP and IP packets received by the local CE and discards the others including IPv6 packets.
70) When the PE receives IP packets from the CE, the dynamic MAC is not updated.
71) If the VPWS inbound interface that encapsulates ip-interworking on the PE receives the CE's ARP request packets, the VPWS inbound interface uses the PE's MAC address to reply regardless of the destination IP address.
72) Each Ethernet interface or sub-interface of the PE can be connected to only one CE and cannot be connected to multiple CEs or other devices through a hub or a layer-2 switch. Otherwise, MAC addresses learned by the PE will be covered, obstructing the forwarding.

- If a CE uses the PPP link protocol to access a PE, pay attention to the following points:

73) Unlike the negotiation that provides the homogeneous media L2VPN PPP simulative line service, the negotiation of PPP is conducted between the CE and the PE, rather than CEs; the address of the negotiation between PE and CE will not generate the corresponding route.
74) It supports PAP and CHAP authentication. The authentication method is the same as the common situation.
75) It does not support IPHC compression.

76) It supports transparent transmission of IP packets from the local CE to the peer CE and does not support transparent transmission though protocols such as MPLS and IPv6.

77) The **ppp ipcp address proxy** command must be used on the PE to specify the remote CE's IP address, which is the same as the IPCP proxy address of the PE as the remote CE. The address will not generate a route on the PE.

Use the following commands to configure the heterogeneous media communication VPWS access service in privileged mode.

Command	**Function**
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters interface configuration mode.
Ruijie(config-if-*type ID*)# **ppp ipcp address proxy** *remote-ce-ip-addr*	(Optional) When the interface that connects the PE to the CE encapsulates the PPP link protocol, configure the remote CE's IP address on the PE as the proxy address for the remote CE to conduct IPCP negotiation with the local CE.
Ruijie(config-if-*type ID*)# **xconnect** *vc_peer vc_id* **encapsulation mpls ip-interworking** [**local-ce mac** *mac*]	Creates VC and configures the PW type as the heterogeneous media communication. (Optional) **local-ce mac** *mac*: When the interface that connects PE to CE encapsulates the Ethernet protocol, the local CE's MAC address must be configured.
Ruijie(config-if-*type ID*)# **ip ref**	☑ For routers, the fast forwarding function of the interface must be enabled. You do not need to use this command on switches.
Ruijie(config-if-*type ID*)# **show running-config**	Displays the existing configuration information.

# Configure **serial** *1/0* to provide the heterogeneous media VPWS service of the PPP access mode.

```
Ruijie# configure terminal
Ruijie(config)# interface serial 1/0
Ruijie(config-if-serial 1/0)# encapsulation ppp
```

# Enable the fast forwarding function of the interface on routers. You do not need to use this command on switches.

```
Ruijie(config-if-gigabitethernet 1/1)# ip ref
Ruijie(config-if-serial 1/0)# ppp ipcp address proxy 192.168.1.1
Ruijie(config-if-serial 1/0)# xconnect 2.2.2.2 2 encapsulation mpls ip-interworking
Ruijie(config-if-serial 1/0)# exit
```

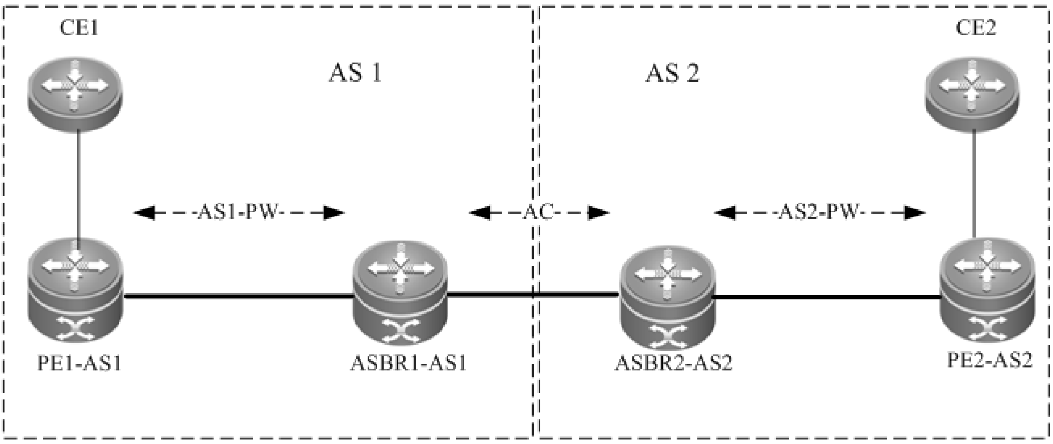
Configuring Inter-AS VPWS

There are two solutions for configuring Inter-AS Martini VPWS:

- Inter-AS Option A: This solution is simple and can be adopted when the number of inter-AS L2VPNs on ASBR is small.
- Inter-AS Option C: You do not need to create or maintain any VCs on ASBR. When each AS has numerous inter-AS L2VPNs, this solution can be applied to solve the bottleneck of the ASBR's scalability.

Inter-AS Option A

Figure 49 Option A Inter-AS VPWS



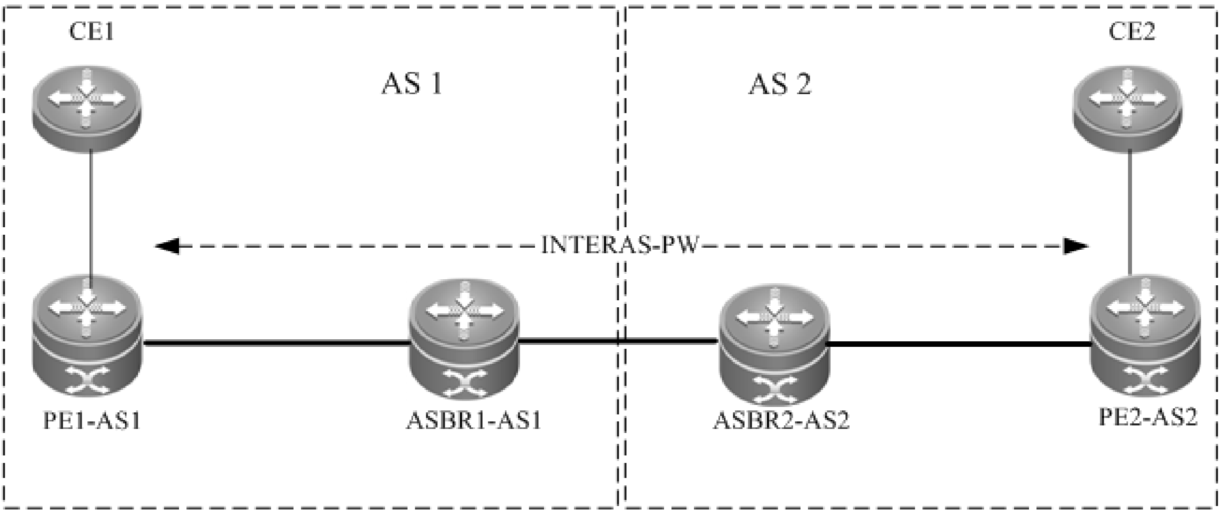
In the solution, ASBRs of two ASs are connected with each other and are PEs of their respective autonomous systems. Each ASBR considers the peer ASBR as its CE device. As shown in the preceding figure, for ASBR1-AS1 of AS1, ASBR2-AS2 of AS2 is only an accessed CE device; for ASBR2-AS2 of AS2, ASBR1-AS1 is also only an accessed CE device.

The Option A solution is easy to implement. You do not need to especially configure two PEs that serve as ASBRs or configure an IP address for the interface between ASBRs. For each inter-AS L2VPN or each Inter-AS PW, a logical or physical link must be allocated between ASBRs of two ASs. When there are numerous inter-AS PWs, great pressure is caused to ASBRs, hindering the expansion.

The solution's configuration is similar to the aforementioned basic VPWS configuration.

Inter-AS Option C

Figure 50 Option C Inter-AS VPWS



As shown in the preceding figure, Option C solution is to set up an inter-AS PW on two ASs directly and exchange PW tags. The principle is described as follows:

By sending tag IPv4 routes to the PE in respective ASs and sending tag IPv4 routes received by PEs in respective ASs to the ASBR peers of peer ASs, ASBRs connect the tunnel between two ASs and set up an LSP tunnel between the ingress PE and egress PE. Then, the inter-AS LDP remote session are set up between PEs in different ASs and PW information are exchanged.

In the solution, ASBRs do not need to maintain inter-AS L2VPN information or prepare a physical or logical interface for the inter-AS L2VPN. However, it needs to provide an MPLS tunnel. The L2VPN information is directly exchanged between PEs, decreasing the pressure on ASBRs and facilitating the scalability.

The configuration procedure is as follows:

78) Configure MPLS signaling.
79) Configure PEs.
80) Configure ASBRs.
81) Configure the remote LDP session.
82) Configure the user access VPWS.

- Configure MPLS signaling.

In each AS, enable the MPLS and LDP functions on PE and P devices and the interface that connects to the P or PE device in AS of the ABSR to set up a basic MPLS network. For the configuration procedures, see the chapter about basic MPLS configuration.

- Configuring PEs

Configure the PEs in ASs, set up an IBGP session between the PE and the AS, and exchange IPv4 routes that carry tags.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *asn-number*	Configures BGP and enters BGP configuration mode.
Ruijie(config-router)# **neighbor** *asbr-address* **remote-as** *asbr-asn-number*	Sets up IBGP sessions between the PE and ASBR.
Ruijie(config-router)# **neighbor** *asbr-adddress* **update-sourc**e *interface-name*	Uses the loopback address as the source address of the BGP session set up between peers.
Ruijie(config-router)# **address-family ipv4**	Enters the IPv4 address family.
Ruijie(config-router-af)# **neighbor** *asbr-address* **send-label**	Enables IPv4 route tag switching.
Ruijie(config-router-af)# **show running-config**	Displays configuration information.

# Set up the IBGP session with the ASBR device 10.10.10.2 and enable the IPv4 route tag switching function.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 10.10.10.2 remote-as 1
Ruijie(config-router)# neighbor 10.10.10.2  update-source loopback 0
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 10.10.10.2 activate
Ruijie(config-router-af)# neighbor 10.10.10.2 send-label
Ruijie(config-router-af)# exit
```

- Configuring ASBRs

Configure ASBRs to set up the IBGP session with the PE in the same AS and with the ASBR in the other AS. Enable the IPv4 route tag switching function on both sessions. Configure the PE address to be transmitted to another ASBR on the ASBR.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **mpls ip**	Enables the device to support MPLS forwarding. This command is not applicable to switch chip forwarding.
Ruijie(config)# **mpls router ldp**	Enables LDP globally.
Ruijie(config-mpls-router)# **ldp router-id interface Loopback** *id* **force**	Configures the IP address of the loopback interface as the router ID.
Ruijie(config-mpls-router)# **advertise-labels for bgp-routes**	Allocates tags for BGP's route.
Ruijie(config-mpls-router)# **exit**	Returns to config mode.
Ruijie(config)# r**outer bgp** *asn-number*	Configures BGP and enters BGP configuration mode.
Ruijie(config-router)# **neighbor** *asbr-address* **remote-as** *asbr-asn-number*	Sets up EBGP session with ASBRs.
Ruijie(config-router)# **neighbor** *pe-address* **remote-as** *asn-number*	Sets up EBGP session with PEs.
Ruijie(config-router)# **neighbor** *pe-adddress* **update-source loopback** *id*	Uses the loopback address as the source address of the BGP session set up between PE peer.
Ruijie(config-router)# **address-family ipv4**	Enters the IPv4 address family.
Ruijie(config-router-af)# **network** *pe-address* **mask** *mask-value*	(Optional) Uses the **network** command to import the PE route received to BGP. The IGP protocol can be re-distributed to import the route.
Ruijie(config-router-af)# **neighbor** *asbr-address* **send-label**	Enables the IPv4 route tag switching function on BGP that is set up with the ASBR in another AS.
Ruijie(config-router-af)# **neighbor** *pe-address* **send-label**	Enables the IPv4 route tag switching function on BGP that is set up with the PE in the same AS.
Ruijie(config-router-af)# **neighbor** *asbr-ip-address* **route-map** *name* **out**	(Optional) Configures the route allocation policy. You can define route map rules (routemap) to control allocation of routes to neighbors and control whether these routes carry tags when they are sent.
Ruijie(config-router-af)# **neighbor** *asbr-ip-address* **route-map** *name* **in**	(Optional) Configures the route allocation policy. You can define route map rules (routemap) to control only routes that carry tags.
Ruijie(config-router-af)# **show running-config**	Displays configuration information.

# In the following example, the configured ASBR sets up an EBGP session with the ASBR in another AS (30.30.30.2) and the tag switching function is enabled for IPv4 routes. The IBG neighbor is created between the ASBR and the PE in the same AS (10.10.10.1) and the tag switching function is enabled for IPv4 routes.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 30.30.30.2 remote-as 2
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 30.30.30.2 activate
Ruijie(config-router-af)# neighbor 30.30.30.2 send-label
Ruijie(config-router-af)# exit
Ruijie(config-router)# neighbor 10.10.10.1 remote-as 1
Ruijie(config-router)# neighbor 10.10.10.1 update-source loopback 0
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 10.10.10.1 send-label
Ruijie(config-router-af)# exit
```

Caution

For the IBGP session set up between ASBR and the PE in the same AS, the **neighbor** *peer-address* **update-source** *loopback id* command must be used on the ASBR and PE to configure the address of the device's loopback interface as the source address of the session. Otherwise, the inter-AS LSP tunnel cannot be established.

The direct EBGP session established between ASBRs usually uses the direct connection interface's address as the source address of the BGP session to ensure that both ASBRs have routes that lead to each other. Therefore, you are not advised to use the **neighbor** *peer-address* **update-source** *loopback id* command on the EBGP session established based on direct connection to configure the address of the device's loopback interface as the source address of the session. If necessary, use the **neighbor ebgp-multihop** command to enable the multi-hop EBGP function, configure the static route on ASBR to ensure that the route can lead to the peer, and configure the static FTN to ensure that the inter-AS LSP's tunnel is available.

The **label-switching** command must be used on the interface between ASBRs to enable the interface's MPLS packet forwarding capability.

- Configuring the LDP remote session

Set up an inter-AS LDP remote session between PEs in two ASs. See the Configuring LDP Remote Peer chapter.

- Configuring the user access VPWS

For detailed configuration, see the Configuring User Access VPWS chapter.

- Checking the configuration result

Command	Function
show bgp ipv4 unicast labels	Displays label information allocated by BGP for IPv4 routes.
show mpls ldp neighbor	Displays neighbor information of LDP.
show mpls l2transport vc [**detail**]	Displays VC status information.

# View route and label information on an ASBR or a PE.

```
Ruijie # show bgp ipv4 unicast labels
Network         Next Hop        In Label/Out Label
1.1.1.1/32       192.167.1.1     17/18
1.1.1.2/32       192.167.1.1     nolabel/19
```

Field	Definition
Network	Route prefix

Nexthop	Route's next hop
In Label	Label (if any) allocated by the router
Out Label	Label (if any) learned from the next-hop router of the route

# View LDP session information on a PE.

```
Ruijie # show mpls ldp neighbor
Default VRF:
    Peer LDP Ident: 10.20.10.10:0; Local LDP Ident: 8.8.8.8:0
        TCP connection: 10.20.10.10.62488 - 8.8.8.8.646
        State: OPERATIONAL; Msgs sent/recv: 42/45; UNSOLICITED
        Up time: 00:33:49
        LDP discovery sources:
          Link Peer on GigabitEthernet 2/1, Src IP addr: 192.168.201.220
          Targeted Hello 8.8.8.8 -> 10.20.10.10
        Addresses bound to peer LDP Ident:
          10.20.10.10   192.168.201.220 192.168.198.1   10.5.0.1
```

Field	Definition
Peer LDP Ident	LDP identifier of the peer neighbor of the LDP session
Local LDP Identifier	Router's LDP identifier
TCP connection	TCP connection that supports the LDP session
State	Status of the LDP session
Msgs sent/recv	Quantity of LDP messages sent to/received by the session peer
UNSOLICITED and ONDEMAND	Label allocation mode

# View VC status information.

```
Ruijie # show mpls l2transport vc detail
Local interface : VLAN 2, AC state: up
Peer address: 192.168.0.1 ,VC ID: 2, VC status: up
VC type: vlan     VC mode:tagged
Group id: 0    MTU: 1500
Control Word not support
Output interface: VLAN 300 , imposed label stack {22 ,501 }
MPLS VC label:  local 22, remote 22
```

Field	Definition
Local interface	Local interface bound to VC
AC state	AC status, up or down
Peer address	Peer IP address
VC ID	VC's unique identifier
VC status	VC status, up or down
VC type	VC type
VC mode	VC mode, tagged or raw (only applies to the Ethernet access mode)
Group id	VC's local group ID
MTU	MTU of the locally configured VC

Field	Definition
Control Word	Whether the control word is supported
Output interface	Output interface on the public network used to transmit the VC process
imposed label stack	Added label stack
MPLS VC label	**Local** indicates the label locally allocated for the VC while **Remote** indicates the label allocated by the peer for the VC.

Configuring Kompella VPWS

Configuring the Public Network Tunnel

The LSP tunnel must be set up on the public network to carry the VC service. To run MPLS on the backbone network, LDP must be run on Ps and PEs to establish the public network tunnel. This includes configuring the label allocation protocol for MPLS devices and enabling the MPLS forwarding on each interface. The configuration procedure is as follows:

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie# **mpls ip**	Enables MPLS forwarding globally. ⚠ Caution This command is not applicable to switch chip forwarding.
Ruijie(config)# **mpls router ldp**	Enables LDP and enters LDP configuration mode.
Ruijie(config-mpls-router)# **ldp router-id interface loopback** *id* [**force**]	Configures LDP's router ID, which is usually the IP address of the loopback interface.
Ruijie(config-mpls-router)# **exit**	Exits LDP configuration mode.
Ruijie(config)# **interface** *type ID*	Enters public network interface configuration mode.
Ruijie(config-if-*type ID*)# **label-switching**	Enables the interface's MPLS forwarding function.
Ruijie(config-if-*type ID*)# **mpls ip**	Enables the interface's LDP function and MPLS forwarding function.
Ruijie(config-if-*type ID*)# **ip ref**	Enables the fast forwarding function for routers. You do not need to be enable the function for switches.
Ruijie(config-if-type ID)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves configuration.

# Configure the public network tunnel between PEs.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)# label-switching
Ruijie(config-if-GigabitEthernet 1/1)# mpls ip
Ruijie(config-if-GigabitEthernet 1/1)# ip ref
Ruijie(config-if-GigabitEthernet 1/1)# end
Ruijie# copy running-config startup-config
```

Caution

The LDP is a topology-driven protocol. To ensure the normal working of the LDP, enable IPv4 routing protocols and ensure their normal operations.

Configuring the L2VPN Address Family

Kompella VPWS uses MP-BGP4 as the signaling protocol to transmit layer-2 information and VC labels, realizing point-to-point VPN. In addition, the MP-BGP4 protocol can be used as the auto-discovery protocol and connect remote CEs. The procedure for enabling the L2VPN address family is as follows:

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router bg**p *asn-num*	Creates BGP and enters BGP configuration mode.
Ruijie(config)# **neighbor** *peer-address* remote-as *asn-number*	Sets up the IBGP session.
Ruijie(config)# **neighbor** *peer-adddress* **update-source** *interface-name*	Enables the IBGP session to use the address of the loopback interface as the session's source address.
Ruiije(config-router)# **address-family l2vpn vpws**	Enters the L2VPN VPWS address family.
Ruijie(config-router-af)# **neighbor** *ip-address* **activate**	Activates switching of L2VPN information on the BGP session.
Ruijie(config-router-af)# **neighbor** { *ip-address* | *peer-group-name* } **send-community** [**both | standard | extended**]	Specifies the extended community attribute to be sent to BGP neighbors.
Ruijie(config-router-af)# **end**	Returns from address family configuration mode to privileged mode.
Ruijie# **show bgp l2vpn vpws** { **all** [*id:offset* | **neighbor** *ip-address* **| summary**] }	Displays L2VPN address family information.

# Configure the L2VPN address family and enable VPWS information switching.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 10.10.10.1 remote-as 1
Ruijie(config-router)# neighbor 10.10.10.1 update-source loopback 0
Ruiije(config-router)# address-family l2vpn vpws
Ruijie(config-router-af)# neighbor 10.10.10.1 activate
Ruijie(config-router-af)# neighbor 10.10.10.1 send-community extended
Ruijie(config-router-af)# end
Ruijie# show bgp l2vpn vpws all
```

Configuring the Kompella VPWS Instance

The **l2 vfi** command can be used to create Kompella VPWS instances or enter Kompella VPWS configuration mode. The **no l2 vfi** command can be used to delete VFI instances. The unique local VFI instance name and the unique local device VPN ID must be specified when the instance is being created. The auto-discovery function must be enabled for the specified VFI instance. One VFI name must correspond to one VPN ID.

The **label-saving** command can be used to enable the label saving mode and allocate a label for the specified remote site. In label saving mode, **site range** does not take effect.

Command	**Function**
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **l2 vfi** *vpls-name* **vpnid** *vpn-id* **point-to-point**	Creates the Kompella VPWS instance and enters VPWS configuration mode.
Ruijie(config-vfi)# **rd** *rd_value*	Configures the RD value. Configure the RD first.
Ruijie(config-vfi)# **encapsulation mpls** [**ethernet** | **ethernetvlan | ppp | hdlc | ip-interworking**]	Specifies the encapsulation type of Kompella L2VPN PWs, which is Ethernet by default.
Ruijie(config-vfi)# r**oute-target** { **import | export | both** } *rt_value*	Configures RTs. Multiple RTs can be configured.
Ruijie(config-vfi)# **site-id** *id* [**site-range** *size*]	Configures the CE ID of a site and the site range. If the site range is not configured, the default value 16 will be adopted. Multiple site IDs can be configured for Kompella VPWS.
Ruijie(config-vfi-site)# **xconnect interface** *interface-type interface-number* **remote-ce-id** *id*	Binds the local interface and specifies the ID of the remote CE to be connected.
Ruijie(config-vfi-site)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves configuration.

# Configure a Kompella VPWS instance.

```
Ruijie#configure terminal
Ruijie(config)# l2 vfi vpls-1 vpnid 1 point-to-point
Ruijie(config-vfi)# rd 100:1
Ruijie(config-vfi)# encapsulation mpls ethernet
Ruijie(config-vfi)# route-target both 4500:2
Ruijie(config-vfi)# site-id 1
Ruijie(config-vfi-site)# xconnect interface gi 2/2 remote-ce-id 2
Ruijie(config-vfi-site)#end
Ruijie# copy running-config startup-config
```

Caution

The **point-to-point** keyword must be specified after the **l2 vfi** command to create a Kompella VPWS instance.

VFI instances of one VPN must be configured with the same ID to facilitate management.

Each site's ID is globally unique in VFI instances.

VFI instances of all PEs on one VPN must be configured with the same VPWS PW type. Otherwise, BGP signaling cannot be used to establish PWs.

We recommend specifying the PW type as Ethernet VLAN for VPWS connected through the sub-interface and as Ethernet for VPWS connected through the Ethernet. If the interface type is different from the specified PW type, although PWs can be established, two PW types adopt different ways to process tags of user packets, causing problems to communication between CEs. VLAN tags carried by user packets are processed as p-tags in Ethernet VLAN PWs while are transmitted transparently as c-tags in Ethernet PWs.

Configuring User Access VPWS

A created VFI instance takes effect only after the user configured with the VFI instance is connected with the link. Multiple point-to-point VCs can be configured in one VFI.

Switch VPWS access mode

Switches can provide only Ethernet VPWS services. The user access mode can be divided into the following modes according to whether packets carry VLAN tags:

83) Access interface access
84) Trunk interface access
85) VLAN tunnel interface access

⚠ Caution

Only the VLAN interface (SVI interface of switches) can provide the VPWS service. IP and VPWS services cannot be enabled concurrently on the VLAN interface at the same time.

One VLAN interface can bind only one VC instance and one VC instance cannot be bound on different VLAN interfaces.

When the port protection mode is enabled on the AC-end member port of L2VPN, the port protection mode does not take effect on the member port if the corresponding member port is not a Trunk interface.

These access modes are described in details as follows:

- VLAN access interface access

This mode applies when user packets transmitted on ACs are not encapsulated by 802.1Q (that is, the packets do not carry VLAN tags). Use the following commands to configure VLAN access interface access in privileged mode.

Command	**Function**
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters interface configuration mode.
Ruijie(config-if-*type ID*)# **switchport mode access**	Sets the interface in access mode.
Ruijie(config-if-*type ID*)# **switchport access vlan** *vlan-id*	Sets the interface as a member port of a VLAN port.
Ruijie(config-if-*type ID*)# **exit**	Exits interface configuration mode.
Ruijie(config)# **l2 vfi** *vfi_name* **vpnid** *vpn_id* **point-to-point**	Enters VFI configuration mode.
Ruijie(config-vfi)**#** **rd** *rd_value*	Defines the RD value of the Kompella VPWS instance.
Ruijie(config-vfi)# **route-target** { **import | export | both** } *rt_value*	Configures RT.
Ruijie(config-vfi)# **encapsulation mpls ethernet**	Configures the encapsulation method of VFI as Ethernet.
Ruijie(config-vfi)# **site-id** *id* [**site-range** *size*]	Configures site information of the VFI.

Command	Function
Ruijie(config-vfi-site)#**xconnect interface vlan** *vlan-id* **remote-ce-id** *id*	Connects the interface that binds VFI locally with the VFI's remote CEs.

Caution

In VLAN access interface access mode, we recommend setting the PW encapsulation mode to **ethernet**, and the encapsulation modes on two ends of a PW must be the same.

# Configure **gigabitethernet** *1/1* to be connected through the access interface and configure VPWS services under the corresponding VLAN interface.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/1
Ruijie(config-if-gigabitethernet 1/1)# switchport mode access
Ruijie(config-if-gigabitethernet 1/1)# switchport access vlan 2
Ruijie(config-if-gigabitethernet 1/1)# exit
Ruijie(config)# l2 vfi vfiA vpnid 1 point-to-point
Ruijie(config-vfi)# rd 2:2
Ruijie(config-vfi)# route-target both 2:2
Ruijie(config-vfi)# encapsulation mpls ethernet
Ruijie(config-vfi)# site-id 1
Ruijie(config-vfi-site)# xconnect interface vlan 2  remote-ce-id 2
```

- VLAN trunk interface access

This mode applies when several VPWS services for multiple users are transmitted on an AC. PE devices can match packets with VPWS services according to VLAN tags carried by the user packets to provide the multiplexing of access interfaces.

Use the following commands to configure VLAN trunk interface access in privileged mode.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters interface configuration mode.
Ruijie(config-if-*type ID*)# **switchport mode trunk**	Sets the interface in trunk working mode.
Ruijie(config-if-*type ID*)# **switchport trunk allow vlan add** *vlan-list*	Sets the VLAN flows allowed to be transmitted on the trunk link.
Ruijie(config-if-*type ID*)# **exit**	Exits interface configuration mode.
Ruijie(config)# **l2 vfi** *vfi_name* **vpnid** *vpn_id* **point-to-point**	Enters VFI configuration mode.
Ruijie(config-vfi)# **rd** *rd_value*	Defines the RD value of the Kompella VPWS instance.
Ruijie(config-vfi)# **route-target** { **import | export| both** } *rt_value*	Configures RT.
Ruijie(config-vfi)# **encapsulation mpls ethernetvlan**	Configures the encapsulation method of VFI as Ethernet VLAN.
Ruijie(config-vfi)# **site-id** *id* [**site-range** *size*]	Configures site information of the VFI.

Command	Function
Ruijie(config-vfi-site)#**xconnect interface vlan** *vlan-id* **remote-ce-id** *id*	Connects the interface that binds VFI locally with the VFI's remote CEs.

Caution

In trunk access interface access mode, we recommend setting the PW encapsulation mode to **ethernetvlan**, and the encapsulation modes on two ends of a PW must be the same.
The L2 VPN service cannot be bound to the Native VLAN of the Trunk interface.

# Configure **gigabitethernet** *1/1* to be connected through the trunk interface and configure VPWS under the corresponding VLAN interface.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/1
Ruijie(config-if-gigabitethernet 1/1)# switchport mode trunk
Ruijie(config-if-gigabitethernet 1/1)# switchport trunk allowed vlan add 2 3
Ruijie(config-if-gigabitethernet 1/1)# exit
Ruijie(config)# l2 vfi vfiA vpnid 1 point-to-point
Ruijie(config-vfi)# rd 2:2
Ruijie(config-vfi)# route-target both 2:2
Ruijie(config-vfi)# encapsulation mpls ethernetvlan
Ruijie(config-vfi)# site-id 1
Ruijie(config-vfi-site)# xconnect interface vlan 2  remote-ce-id 2
```

- VLAN tunnel interface access

This mode applies when user service packets transmitted on an AC carry private VLAN tags if users access the VPWS service. In this mode, all packets received by PEs from the interface are forwarded without any changes. This mode requires the VLAN member ports between PEs with CEs to work in tunnel mode.

Use the following commands to configure VLAN tunnel interface access in privileged mode.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters interface configuration mode.
Ruijie(config-if-*type ID*)# **switchport access** *vlan-id*	Sets the VLAN member port of the interface.
Ruijie(config-if-*type ID*)# **switchport mode dot1q-tunne**l	Sets the interface to work in tunnel mode.
Ruijie(config-if-*type ID*)**# exit**	Exits interface configuration mode.
Ruijie(config)# **l2 vfi** *vfi_name* **vpnid** *vpn_id* **point-to-point**	Enters VFI configuration mode.
Ruijie(config-vfi)# **rd** *rd_value*	Defines the RD value of the Kompella VPWS instance.
Ruijie(config-vfi)# **route-target** { **import | export | both** } *rt_value*	Configures RT.
Ruijie(config-vfi)# **encapsulation mpls ethernetvlan**	Configures the encapsulation method of VFI as Ethernet VLAN.
Ruijie(config-vfi)# **site-id** *id* [**site-range** *size*]	Configures site information of the VFI.

Command	Function
Ruijie(config-vfi-site)#**xconnect interface vlan** *vlan-id* **remote-ce-id** *id*	Connects the interface that binds VFI locally with the VFI's remote CEs.

Caution

In VLAN tunnel interface access mode, we recommend setting the PW encapsulation mode to **ethernet**, and the encapsulation modes on two ends of a PW must be the same.
For the VLAN tunnel interface access mode, only the basic QinQ is supported.

# Configure **gigabitethernet** *1/1* to be connected through the VLAN tunnel interface and configure VPWS under the corresponding VLAN interface.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/1
Ruijie(config-if-gigabitethernet 1/1)# switchport mode dot1q-tunnel
Ruijie(config-if-gigabitethernet 1/1)# switchport access 2
Ruijie(config-if-gigabitethernet 1/1)# exit
Ruijie(config)# l2 vfi vfiA vpnid 1 point-to-point
Ruijie(config-vfi)# rd 2:2
Ruijie(config-vfi)# route-target both 2:2
Ruijie(config-vfi)# encapsulation mpls ethernetvlan
Ruijie(config-vfi)# site-id 1
Ruijie(config-vfi-site)# xconnect interface vlan 2  remote-ce-id 2
```

Router VPWS access mode

There are several ways for users to connect to VPWS services provided by routers. Users can choose access modes according to actual application needs. Services provided by the VPWS depend on the link protocol adopted by the interface that connects the PE with the CE. Currently, the following four point-to-point L2VPN services are supported:

86) Simulative Ethernet line service
87) Simulative 802.1Q line service
88) Simulative PPP line service
89) Simulative PPP line service

- Ethernet interface access

This mode applies when user service packets transmitted on ACs carry private VLAN tags or do not carry VLAN tags in the case of VFI service access. In this mode, all packets received by PEs from the interface are forwarded without any changes and the private tags are considered part of the data.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters interface configuration mode.
Ruijie(config-if-*type ID*)# **ip ref**	Enables fast forwarding of the Ethernet interface.
Ruijie(config-if-*type ID*)# **exit**	Exits interface configuration mode.
Ruijie(config)# **l2 vfi** *vfi_name* **vpnid** *vpn_id* **point-to-point**	Enters VFI configuration mode.

Ruijie(config-vfi)# **rd** *rd_value*	Defines the RD value of the Kompella VPWS instance.
Ruijie(config-vfi)# **route-target** { **import | export | both** } *rt_value*	Configures RT.
Ruijie(config-vfi)# **encapsulation mpls ethernet**	Configures the encapsulation mode of VFI as Ethernet.
Ruijie(config-vfi)# **site-id** *id* [**site-range** *size*]	Configures site information of the VFI.
Ruijie(config-vfi-site)# **xconnect interface** *type ID* **remote-ce-id** *id*	Connects the interface that binds VFI locally with the VFI's remote CEs.

# Configure **gigabitethernet** *1/0* to provide the VPWS service of transparently transmitting Ethernet frames.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/0
Ruijie(config-if-gigabitethernet 1/0)# ip ref
Ruijie(config-if-gigabitethernet 1/0)# exit
Ruijie(config)# l2 vfi vfiA vpnid 1 point-to-point
Ruijie(config-vfi)# rd 2:2
Ruijie(config-vfi)# route-target both 2:2
Ruijie(config-vfi)# encapsulation mpls ethernet
Ruijie(config-vfi)# site-id 1
Ruijie(config-vfi-site)# xconnect interface gigabitethernet 1/0 remote-ce-id 2
```

Caution

In Ethernet interface access mode, we recommend setting the PW encapsulation mode to **ethernet**, and the encapsulation modes on two ends of a PW must be the same.

The remote CE ID must be specified to establish the Kompella VPWS.

- Ethernet sub-interface access

In this mode, the interface between a PE and a CE is encapsulated by the 802.1Q link protocol and provides VPWS services. The CE connects to the PE through the Ethernet sub-interface and requests Ethernet frame transmitted transparently by the PE. The Ethernet sub-interface access mode applies when several VPWS services for multiple users are transmitted on a physical access link. PE devices can match packets with VPWS services according to dot1q tags carried by the user packets to provide the multiplexing of access interfaces. In this mode, packets sent by the CE to the PE must carry VLAN tags.

Use the following commands to configure Ethernet sub-interface access in privileged mode.

Command	**Function**
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters sub-interface configuration mode.
Ruijie(config-if-*type ID*)# **encapsulation dot1Q** *vlan-id*	Configures the VLAN ID to be encapsulated.
Ruijie(config-if-*type ID*)# **exit**	Exits interface configuration mode.
Ruijie(config)# **l2 vfi** *vfi_name* **vpnid** *vpn_id* **point-to-point**	Enters VFI configuration mode.
Ruijie(config-vfi)# **rd** *rd_value*	Defines the RD value of the Kompella VPWS instance.
Ruijie(config-vfi)# **route-target** { **import | export | both** } *rt_value*	Configures RT.

Ruijie(config-vfi)# **encapsulation mpls ethernetvlan**	Configures the encapsulation mode of VFI as Ethernet VLAN.
Ruijie(config-vfi)# **site-id** *id* [**site-range** *size*]	Configures site information of the VFI.
Ruijie(config-vfi-site)# **xconnect interface** *type ID* **remote-ce-id** *id*	Connects the interface that binds VFI locally with the VFI's remote CEs.

# Configure **gigabitethernet** *1/0.100* to provide the VPWS service of transparently transmitting Ethernet frames.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/0
Ruijie(config-if-gigabitethernet 1/0)# ip ref
Ruijie(config-if-gigabitethernet 1/0)# exit
Ruijie(config)# interface gigabitethernet 1/0.100
Ruijie(config-if-serial 1/0.100)# encapsulation dot1q 100
Ruijie(config-if-serial 1/0.100)# exit
Ruijie(config)# l2 vfi vfiA vpnid 1 point-to-point
Ruijie(config-vfi)# rd 2:2
Ruijie(config-vfi)# route-target both 2:2
Ruijie(config-vfi)# encapsulation mpls ethernetvlan
Ruijie(config-vfi)# site-id 1
Ruijie(config-vfi-site)# xconnect interface gigabitethernet 1/0.100  remote-ce-id 2
```

Caution

In sub-interface access mode, we recommend setting the PW encapsulation mode to **ethernetvaln**, and the encapsulation modes on two ends of a PW must be the same.

The **ip ref** command must be used to enable the fast forwarding function on the master interface of the sub-interface.

- PPP access

In this mode, the interface between a PE and a CE encapsulates the PPP link protocol and provides VPWS services. The CE connects to the PE in PPP mode and requests the PPP frames transmitted transparently by the PE. The interface that encapsulates the PPP protocol is bound with the L2VPN service and its PE-end PPP protocol will be disabled. Therefore, the LCP and NCP of one CE will not interact with each other. The PE will transparently transmit the PPP negotiation control packet sent by the CE. The PPP negotiation will be conducted between CEs.

Use the following commands to configure PPP access in privileged mode.

Command	**Function**
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters interface configuration mode.
Ruijie(config-if-*type ID*)# **ip ref**	Enables fast forwarding of the sub-interface.
Ruijie(config-if-*type ID*)# **encapsulation ppp**	Configures the PPP encapsulation protocol.
Ruijie(config-if-*type ID*)# **exit**	Exits interface configuration mode.
Ruijie(config)# **l2 vfi** *vfi_name* **vpnid** *vpn_id* **point-to-point**	Enters VFI configuration mode.
Ruijie(config-vfi)# **rd** *rd_value*	Defines the RD value of the Kompella VPWS instance.

Ruijie(config-vfi)# **route-target** { **import | export | both** } *rt_value*	Configures RT.
Ruijie(config-vfi)# **encapsulation mpls ppp**	Configures the encapsulation mode of VFI as PPP.
Ruijie(config-vfi)# **site-id** *id* [**site-range** *size*]	Configures site information of the VFI.
Ruijie(config-vfi-site)# **xconnect interface** *type ID* **remote-ce-id** *id*	Connects the interface that binds VFI locally with the VFI's remote CEs.

# Configure **serial** *1/0* to provide the VPWS service of transparently transmitting PPP frames.

```
Ruijie# configure terminal
Ruijie(config)# interface serial 1/0
Ruijie(config-if-serial 1/0)# encapsulation ppp
Ruijie(config-if-serial 1/0)# ip ref
Ruijie(config-if-serial 1/0)# exit
Ruijie(config)# l2 vfi vfiA vpnid 1 point-to-point
Ruijie(config-vfi)# rd 2:2
Ruijie(config-vfi)# route-target both 2:2
Ruijie(config-vfi)# encapsulation mpls ppp
Ruijie(config-vfi)# site-id 1
Ruijie(config-vfi-site)# xconnect interface serial 1/0 remote-ce-id 2
```

- HDLC access

In this mode, the interface between a PE and a CE encapsulates the HDLC link protocol and provides VPWS services. The CE connects to the PE in HDLC mode and requests the HDLC frames transmitted transparently by the PE.

Use the following commands to configure HDLC access in privileged mode.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters interface configuration mode.
Ruijie(config-if-*type ID*)# **ip ref**	Enables fast forwarding of the sub-interface.
Ruijie(config-if-*type ID*)# **encapsulation hdlc**	Configures the HDLC encapsulation protocol.
Ruijie(config-if-*type ID*)# **exit**	Exits interface configuration mode.
Ruijie(config)# **l2 vfi** *vfi_name* **vpnid** *vpn_id* **point-to-point**	Enters VFI configuration mode.
Ruijie(config-vfi)# **rd** *rd_value*	Defines the RD value of the Kompella VPWS instance.
Ruijie(config-vfi)# **route-target** { **import | export | both** } *rt_value*	Configures RT.
Ruijie(config-vfi)# **encapsulation mpls hdlc**	Configures the encapsulation mode of VFI as PPP.
Ruijie(config-vfi)# **site-id** *id* [**site-range** *size*]	Configures site information of the VFI.
Ruijie(config-vfi-site)# **xconnect interface** *type ID* **remote-ce-id** *id*	Connects the interface that binds VFI locally with the VFI's remote CEs.

# Configure **serial** *1/0* to provide the VPWS service of transparently transmitting HDLC frames.

```
Ruijie# configure terminal
Ruijie(config)# interface serial 1/0
Ruijie(config-if-serial 1/0)# encapsulation hdlc
Ruijie(config-if-serial 1/0)# ip ref
Ruijie(config-if-serial 1/0)# exit
Ruijie(config)# l2 vfi vfiA vpnid 1 point-to-point
Ruijie(config-vfi)# rd 2:2
Ruijie(config-vfi)# route-target both 2:2
Ruijie(config-vfi)# encapsulation mpls hdlc
Ruijie(config-vfi)# site-id 1
Ruijie(config-vfi-site)# xconnect interface serial 1/0  remote-ce-id 2
```

Configuring Heterogeneous Media Communication VPWS

If CEs on two ends of the same L2VPN feature different link types, the L2VPN's feature of heterogeneous media intercommunication is needed. According to the suggestion of draft-kompella-ppvpn-l2vpn, the encapsulation type of the L2VPN interface of PEs needs to be ip-interworking during the establishment of L2VPN connection. Users' IP packets are transmitted on the MPLS network transparently. When the L2VPN's heterogeneous media communication function is used, VPWS service interfaces of PEs on both ends must encapsulate ip-interworking. After PW connection is set up, packets are processed as follows:

90) After a PE receives packets from a CE and decapsulates the link layer, the PE transmits IP packets to the MPLS network.
91) IP packets are transmitted transparently through the MPLS network to the peer PE.
92) The peer PE re-encapsulates the IP packets according to its link layer protocol type and sends them to the CE connected to it.
93) The link layer control packet (such PPP's IPCP) sent by the CE are processed by the PE without being transmitted on the MPLS network.
94) Non-IP packets (such as MPLS packets) are discarded and do not enter the MPLS network.

■ Among the Ethernet interfaces on the PE, the following L2VPN interfaces can be encapsulated in ip-interworking mode:

95) Ethernet interface or sub-interface
96) GigabitEthernet interface or sub-interface

Note the following points:

97) After being encapsulated as ip-interworking, the PE's Ethernet interface processes only ARP and IP packets received by the local CE and discards the others including IPv6 packets.
98) When the PE receives IP packets from the CE, the dynamic MAC is not updated;
99) If the VPWS inbound interface that encapsulates ip-interworking on the PE receives the CE's ARP request packets, the VPWS inbound interface uses the PE's MAC address to reply regardless of the destination IP address.
100) Each Ethernet interface or sub-interface of the PE can be connected to only one CE and cannot be connected to multiple CEs or other devices through a hub or a layer-2 switch. Otherwise, MAC addresses learned by the PE will be covered, obstructing the forwarding.

■ If a CE uses the PPP link protocol to access a PE, pay attention to the following points:

101) Unlike the negotiation that provides the homogeneous media L2VPN PPP simulative line service, the negotiation of PPP is conducted between the CE and the PE, rather than CEs; the address of the negotiation between PE and CE will not generate the corresponding route.
102) It supports PAP and CHAP authentication. The authentication method is the same as the common situation.
103) It does not support IPHC compression.
104) It supports transparent transmission of IP packets from the local CE to the peer CE and does not support transparent transmission though protocols such as MPLS and IPv6.

105) The **ppp ipcp address proxy** command must be used on the PE to specify the remote CE's IP address, which is the same as the IPCP proxy address of the PE as the remote CE. The address will not generate a route on the PE.

Caution

If both ends of the CE is configured with the address of the same network segment, they can be connected no matter which IP address is configured for the PE-end PPP proxy as the CE has a network segment route that leads to the peer CE and the next-hop output interface can be obtained.

If two ends of the CE are configured with addresses of different network segments, the PE-end PPP proxy must be specified as the peer CE address and a route that leads to the peer CE's network segment must be configured statically in the CE.

Use the following commands to configure the heterogeneous media communication VPWS access service in privileged mode.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **l2 vfi** *vpws-name* **vpnid** *vpn-id* point-to-point	Creates the Kompella VPWS instance and enters VPWS configuration mode.
Ruijie(config-vfi)# **rd** *rd_value*	Configures the RD value. Configure the RD first.
Ruijie(config-vfi)# **encapsulation mpls ip-interworking**	Specifies ip-interworking as the encapsulation type of Kompella L2VPN PW.
Ruijie(config-vfi)# **route-target** { **import | export | both** } *rt_value*	Configures RTs. Multiple RTs can be configured.
Ruijie(config-vfi-site)# **xconnect interface** *interface-type interface-number* **remote-ce-id** *id*	Configures the local interface to be bound and specifies the ID of the CE to be connected remotely.
Ruijie(config-vfi-site)# **local-ce mac** *mac*	Specifies the CE's static MAC address.
Ruijie(config-vfi-site)# **exit-site-mode**	Returns to VFI configuration mode.
Ruijie(config-vfi)# **exit**	Returns to global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters interface configuration mode.
Ruijie(config-if-*type ID*)# **ppp ipcp address proxy** *remote-ce-ip-addr*	(Optional) When the interface that connects the PE to the CE encapsulates the PPP link protocol, configure the remote CE's IP address on the PE as the proxy address for the remote CE to conduct IPCP negotiation with the local CE.
Ruijie(config-if-*type ID*)# **ip ref**	☑ For routers, the fast forwarding function of the interface must be enabled. You do not need to use this command on switches.
Ruijie(config-if-*type ID*)# **show running-config**	Displays the existing configuration information.

# Configure **serial** *1/0* to provide the heterogeneous media VPWS service of the PPP access mode.

```
Ruijie(config)# interface serial 1/0
Ruijie(config-if-serial 1/0)# encapsulation ppp
```

# Enable the fast forwarding function of the interface on routers. You do not need to use this command on switches.

```
Ruijie(config-if-serial 1/0)# ip ref
Ruijie(config-if-serial 1/0)# ppp ipcp address proxy 192.168.1.1
Ruijie(config-if-serial 1/0)# exit

Ruijie# configure terminal
Ruijie# l2 vfi vpws1 vpnid 1 point-to-point
Ruijie(config-vfi)# rd 100:1
Ruijie(config-vfi)# encapsulation mpls ip-interworking
Ruijie(config-vfi)# route-target both 100:1
Ruijie(config-vfi)# site-id 1
Ruijie(config-vfi-site)# xconnect interface serial 1/0 remote-ce-id 2
```

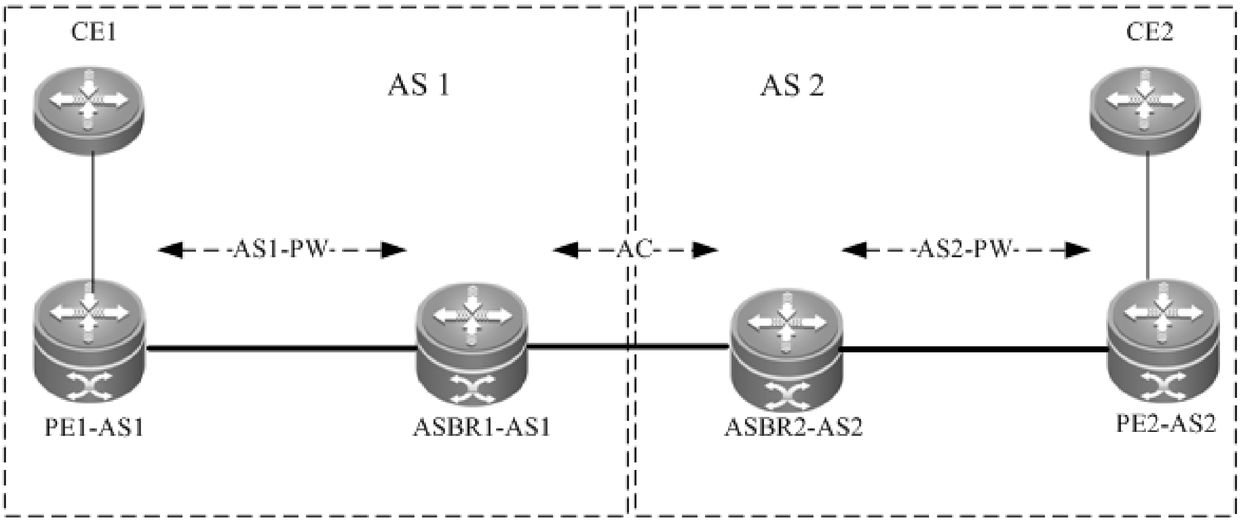
Configuring Inter-AS VPWS

In real application, multiple sites of a user's VPN may be connected to multiple SPs using different ASs or multiple ASs of an SP. The application mode in which the VPN crosses multiple ASs is called the inter-AS VPN. There are two solutions for configuring inter-AS VPWS:

- Inter-AS Option A: This solution is simple and can be adopted when the number of inter-AS L2VPNs on ASBR is small.
- Inter-AS Option C: You do not need to create or maintain any VCs on ASBR. When each AS has numerous inter-AS L2VPNs, this solution can be applied to solve the bottleneck of the ASBR's scalability.

Option A

Figure 51 Option A Inter-AS VPWS



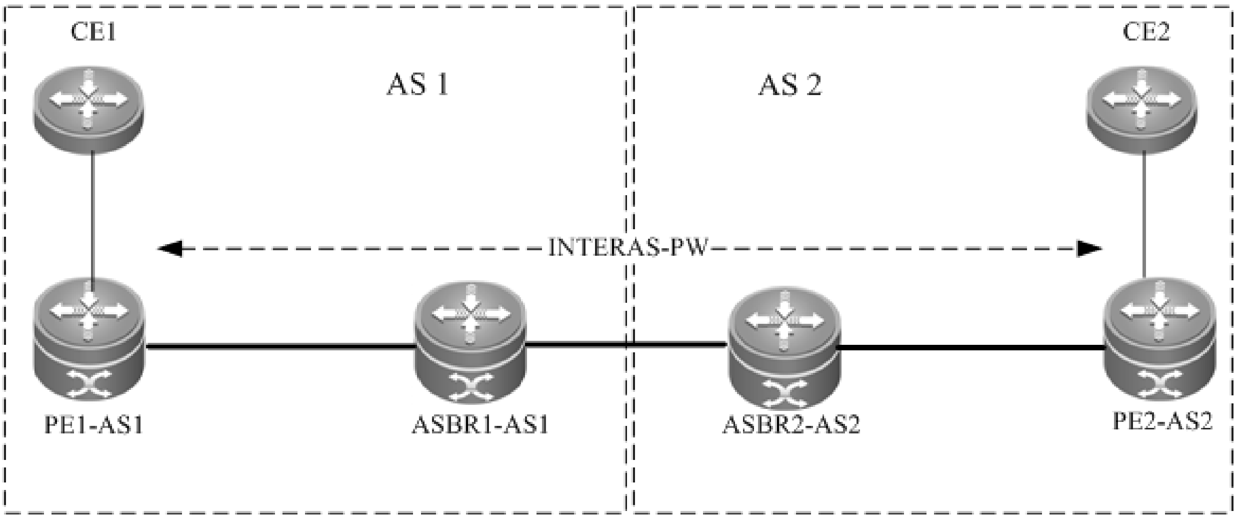
In the solution, ASBRs of two ASs are connected with each other and are PEs of their respective autonomous systems. Each ASBR considers the peer ASBR as its CE device. As shown in the preceding figure, for ASBR1-AS1 of AS1, ASBR2-AS2 of AS2 is only an accessed CE device; for ASBR2-AS2 of AS2, ASBR1-AS1 is also only an accessed CE device.

Option A is easy to implement. You do not need to especially configure two PEs that serve as ASBRs or configure an IP address for the interface between ASBRs. For each inter-AS L2VPN or each Inter-AS PW, a logical or physical link must be allocated between ASBRs of two ASs. When there are numerous inter-AS PWs, great pressure is caused to ASBRs, hindering the expansion.

The solution's configuration is similar to the aforementioned basic VPWS configuration.

Option C

Figure 52 Option C Inter-AS VPWS



As shown in the preceding figure, Option C is to set up an inter-AS PW on two ASs directly and switch PW labels. The principle is described as follows:

By sending tag IPv4 routes to the PE in respective ASs and sending tag IPv4 routes received by PEs in respective ASs to the ASBR peers of peer ASs, ASBRs connect the tunnel between two ASs and set up an LSP tunnel between the ingress PE and egress PE. Then, the Inter-AS LDP remote session are set up between PEs in different ASs and PW information are switched.

In the solution, ASBRs do not need to maintain inter-AS L2VPN information or prepare a physical or logical interface for the inter-AS L2VPN. However, it needs to provide an MPLS tunnel. The L2VPN information is directly switched between PEs, decreasing the pressure on ASBRs and facilitating the scalability.

The configuration procedure is as follows:

106) Configure MPLS signaling.
107) Configure PEs.
108) Configure ASBR.
109) Configure the L2VPN address family.
110) Configure a Kompella VPWS instance.
111) Configure the user access VPWS.
112) Check the configuration result.

- Configure MPLS signaling.

In each AS, enable the MPLS and LDP functions on PE and P devices and the interface that connects to the P or PE device in AS of the ABSR to set up a basic MPLS network. For the configuration procedures, see the chapter about basic MPLS configuration.

- Configuring PEs

Configure the PEs in ASs, set up an IBGP session between the PE and the AS, and exchange IPv4 routes that carry tags.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *asn-number*	Configures BGP and enters BGP configuration mode.
Ruijie(config-router)# **neighbor** *asbr-address* **remote-as** *asbr-asn-number*	Sets up IBGP sessions between the PE and ASBR.
Ruijie(config-router)# **neighbor** *asbr-adddress* **update-source** *interface-name*	Uses the loopback address as the source address of the BGP session set up between peers.
Ruijie(config-router)# **address-family ipv4**	Enters the IPv4 address family.
Ruijie(config-router-af)# **neighbor** *asbr-address* **send-label**	Enables IPv4 route tag switching.
Ruijie(config-router-af)# **show running-config**	Displays configuration information.

# Set up the IBGP session with the ASBR device 10.10.10.2 and enable the IPv4 route tag switching function.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 10.10.10.2 remote-as 1
Ruijie(config-router)# neighbor 10.10.10.2  update-source loopback 0
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 10.10.10.2 activate
Ruijie(config-router-af)# neighbor 10.10.10.2 send-label
Ruijie(config-router-af)# exit
```

- Configuring ASBRs

Configure ASBRs to set up the IBGP session with the PE in the same AS and with the ASBR in the other AS. Enable the IPv4 route tag switching function on both sessions and enable MPLS globally. Configure the PE address to be transmitted to another ASBR on the ASBR.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **mpls ip**	Enables the device to support MPLS forwarding. ⚠ Caution This command is not applicable to switch chip forwarding.
Ruijie(config)# **mpls router ldp**	Enables LDP protocol globally.
Ruijie(config-mpls-router)# **ldp router-id interface loopbac**k *id* **force**	Configures the IP address of the loopback interface as the router ID.
Ruijie(config-mpls-router)# **advertise-labels for bgp-routes**	Allocates labels for BGP's route.
Ruijie(config-mpls-router)# **exit**	Returns to config mode.
Ruijie(config)# **router bgp** *asn-number*	Configures BGP and enters BGP configuration mode.
Ruijie(config-router)# **neighbo**r *asbr-address* **remote-as** *asbr-asn-number*	Sets up EBGP session with ASBRs.
Ruijie(config-router)# **neighbo**r *pe-address* **remote-as** *asn-number*	Sets up EBGP session with PEs.

Ruijie(config-router)# **neighbor** *pe-adddress* **update-source loopback** *id*	Uses the loopback address as the source address of the BGP session set up between PE peer.
Ruijie(config-router)# **address-family ipv4**	Enters the IPv4 address family.
Ruijie(config-router-af)# **network** *pe-address* **mask** *mask-value*	(Optional) Uses the **network** command to import the PE route received to BGP. The IGP protocol can be re-distributed to import the route
Ruijie(config-router-af)# **neighbor** *asbr-address* **send-label**	Enables the IPv4 route label switching function on BGP that is set up with the ASBR in another AS.
Ruijie(config-router-af)# **neighbor** *pe-address* **send-label**	Enables the IPv4 route label switching function on BGP that is set up with the PE in the same AS.
Ruijie(config-router-af)# **neighbor** *asbr-ip-address* **route-map** *name* **out**	(Optional) Configures the route allocation policy. You can define route map rules (routemap) to control allocation of routes to neighbors and control whether these routes carry labels when they are sent.
Ruijie(config-router-af)# **neighbor** *asbr-ip-address* **route-ma**p *name* **in**	(Optional) Configures the route allocation policy. You can define route map rules (routemap) to control only routes that carry labels.
Ruijie(config-router-af)# **show running-config**	Displays configuration information.

# In the following example, the configured ASBR sets up an EBGP session with the ASBR in another AS (30.30.30.2) and the label switching function is enabled for IPv4 routes. The IBG neighbor is created between the ASBR and the PE in the same AS (10.10.10.1) and the label switching function is enabled for IPv4 routes.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# advertise-labels for bgp-routes
Ruijie(config-mpls-router)# exit
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 30.30.30.2 remote-as 2
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 30.30.30.2 activate
Ruijie(config-router-af)# neighbor 30.30.30.2 send-label
Ruijie(config-router-af)# exit
Ruijie(config-router)# neighbor 10.10.10.1 remote-as 1
Ruijie(config-router)# neighbor 10.10.10.1 update-source loopback 0
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 10.10.10.1 send-label
Ruijie(config-router-af)# exit
```

Caution

For the IBGP session set up between ASBR and the PE in the same AS, the **neighbor** *peer-address* **update-source** *loopback id* command must be used on the ASBR and PE to configure the address of the device's loopback interface as the source address of the session. Otherwise, the inter-AS LSP tunnel cannot be established.

The direct EBGP session established between ASBRs usually uses the direct connection interface's address as the source address of the BGP session to ensure that both ASBRs have routes that lead to each other. Therefore, you are not advised to use the **neighbor** *peer-address* **update-source** *loopback id* command on the EBGP session established based on direct connection to configure the address of the device's loopback interface as the source address of the session. If necessary, use the **neighbor ebgp-multihop** command to enable the multi-hop EBGP function, configure the static route on ASBR to ensure that the route can lead to the peer, and configure the static FTN to ensure that the inter-AS LSP's tunnel is available.

The **label-switching** command must be used on the interface between ASBRs to enable the interface's MPLS packet forwarding capability.

- Configuring the L2VPN address family

Configure L2VPN address families between PEs of ASs. For detailed configuration, see the Configuring L2VPN Address Family chapter.

- Configuring a Kompella VPWS instance

Configure L2VPN address families between PEs of ASs. For detailed configuration, see the Configuring Kompella VPWS Instance chapter.

- Configuring the user access VPWS

For detailed configuration, see the Configuring User Access VPWS chapter.

- Checking the configuration result

Command	**Function**
show bgp ipv4 unicast labels	Displays label information allocated by BGP for IPv4 routes.
show bgp l2vpn vpws all connections	Displays Kompella VPWS connection information.
show mpls l2transport vc [**detail**]	Displays VC status information.

# View route and label information on an ASBR or a PE.

```
Ruijie # show bgp ipv4 unicast labels
Network         Next Hop        In Label/Out Label
1.1.1.1/32      192.167.1.1     17/18
1.1.1.2/32      192.167.1.1     nolabel/19
```

Field	**Definition**
Network	Route prefix
Nexthop	Route's next-hop
In Label	Label (if any) allocated by the router
Out Label	Label (if any) learned from the next-hop router of the route

# View VC status information.

```
Ruijie # show mpls l2transport vc detail
Local interface : VLAN 2, AC state: up
Peer address: 192.168.0.1 ,VC ID: 2, VC status: up
```

```
VC type: vlan     VC mode:tagged
Group id: 0    MTU: 1500
Control Word not support
Output interface: VLAN 300 , imposed label stack {22 ,501 }
MPLS VC label:  local 22, remote 22
```

Field	**Definition**
Local interface	Local interface bound by VC
AC state	AC status, up or down
Peer address	VC's peer IP address
VC ID	VC's unique identifier
VC status	VC status, up or down
VC type	VC type
VC mode	VC mode, tagged or raw (only applies to the Ethernet access mode)
Group id	VC's local group ID
MTU	MTU of the locally configured VC
Control Word	Whether the control word is supported
Output interface	Output interface on the public network used to transmit the VC process
imposed label stack	Added label stack
MPLS VC label	Local and peer private labels bound for the VC

Other Parameters for Configuring Kompella VPWS

Configuring VPWS Instance Descriptors (Optional)

You can configure the descriptive information of each VPWS instance.

Command	**Function**
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **l2 vfi** *vfi-name*	Enters VFI configuration mode.
Ruijie(config-vfi)# **description** *vfi-description*	(Optional) Configures VFI's descriptive information.
Ruijie(config-vfi)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves configuration.

Configuring VPWS's Compatibility (Optional)

By default, the PW's mtu value provided by L2VPN is 1500 bytes. If the same PW's mtu values on two PEs are different, PW connection cannot be set up between the two PEs. Some manufacturers' devices do not support configuring mtu in L2VPN instances. When such devices perform Kompella communication with devices of other manufacturers, the **ingore match l2-extcommunity** command can be used to ignore received mtu and matching detection of **EncapsType** and **Control Flag**, ensuring that the VC link is UP.

Command	**Function**
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **l2 vfi** *vpls-name* **vpnid** *vpn-id* **autodiscovery**	Creates the Kompella VPWS instance and enters VPWS configuration mode.

Ruijie(config-vfi)# **ingore match l2-extcommunity**	Configures ignoring detection of L2VPN expanded community attribute members.
Ruijie# **copy running-config startup-config**	Saves configuration.

Caution

This command only takes effect on Kompella L2VPN.

Configuring mtu of a VPWS Instance (Optional)

You can configure each VFI instance's mtu value, which is **1500** by default. The mtu value of VFI indicates the length of the packet that can be transmitted by the PW, or the length of the user's layer-2 packet plus the length of the PW-encapsulated packet. By default, if the PW does not enable the control word, assuming that two labels are encapsulated, the length of an Ethernet packet that can be transmitted is 1492 bytes, of which 8 bytes are encapsulated by the PW (2 labels).

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **l2 vfi** *name*	Enters VFI configuration mode.
Ruijie(config-vfi)# **mtu** *mtu*	(Optional) Configures the mtu value of the VFI.
Ruijie(config-vfi)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves configuration.

Caution

The mtu values of one VFI instance on different PEs must be the same. Otherwise, the signaling protocol cannot establish PWs.

If the PW signaling protocol negotiation's mtu is modified, the mtu of the user access service interface must be adjusted (generally adjusted to the PW mtu length minus the encapsulated length); the PW's public-network-end output interface's mtu, MPLS mtu and PW mtu must be the same to ensure proper forwarding. The **mtu** command can be used on an interface to modify the interface's mtu. Use the **mpls mtu** command to modify the interface's MPLS mtu.

Configuring Static VC FTN and ILM Entries (Optional)

There are two methods to add VC FTN and ILM entries: by switching VC labels through the extended LDP and static configurations. These two methods cannot be applied to a VC instance at the same time. That is, if you add a VC FTN or ILM entry through the extended LDP, you cannot use the CLI command to add entries for the VC. Similarly, if you use the CLI command to add a VC FTN or ILM entry, you cannot add VC FTN or ILM entry by using the VPWS signaling protocol.

The procedure for configuring a VC FTN entry is as follows:

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **mpls static l2vc-ftn** *vc-id vc-peer-ip* **out-label** *out-label*	Configures an FTN entry for a static VC instance.
Ruijie(config)# **show running-config**	Displays all configuration information.

The procedure for configure a VC ILM entry is as follows:

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **mpls static ilm in-label** *in_label* **forward-action pop-l2vc-destport** *vc-id vc_peer_addr*	Configures an ILM entry for a static VC instance.
Ruijie(config)# **show running-config**	Displays all configuration information.

Caution

We do not recommend configuring static VC FTN and ILM when using the VPW dynamic signaling protocol to establish PW. For configured static VC forwarding table entries, the static public network LSP must be configured. VC is only effective when the corresponding public network LSP tunnel exists.
Static VC FTN and ILMF are not needed for heterogeneous media communication.
Static VC FTN and ILM do not take effect on a Kompella VPWS VC instance but only on a Martini VC instance. That is, they are generated by static forwarding table entries, not by LDP signaling.

Configuring Static PW (Optional)

When you can access the Martini VPWS via CLI configuration, you can specify the mode as the static mode, and then configure the outgoing label and incoming label of the VC manually instead of adding the FTN and ILM options of the VC through Label Distribution Protocol (LDP).

Run the following commands to configure a VPWS static PW:

Command	Function
Ruijie# **config terminal**	Enters the global configuration mode.
Ruijie(config)# **interface vlan** *vlan-id*	Configures and enters the VLAN interface configuration mode.
Ruijie(config-if-*type ID*)# **xconnect** *vc_peer vc_id* **encapsulation mpls ethernet raw manual**	Creates a VC and configures the raw encapsulation mode.
Ruijie(config-if-*type ID*)# **exit**	Exits the interface configuration mode.
Ruijie(config)# **mpls static-l2vc** *ipv4-address vc-id* **out-label** *out-label-value* **in-label** *in-label-value*	Configures the outgoing label and incoming label of the static PW.
Ruijie(config-vfi)# **end**	Returns to the privileged EXEC mode.
Ruijie# **copy running-config startup-config**	Saves the configuration.

Caution

The static PW does not apply to heterogeneous media interconnection.
The outgoing and incoming labels of the static PW do not take effect on the VC instances of the Kompella VPWS. They only apply to the VC instances of the Martini VPWS, that is, the static forwarding entry instead of LDP signaling is adopted.

Maintaining PW Connectivity of VPWS

Configuration Prerequisites

When using VCCV to check the PW connectivity of VPWS, you must ensure that the VPWS network is already correctly configured.

Checking PW Connectivity

Command	Function
Ruijie# **ping mpls pseudowire** { *ip-address vc-id* [**segment** *segment-number*] | **kompella** *vfi_name local_site_id remote_site_id* **rd** *remote_rd* } { **label-alert** | **ttl-expiry** } [**repeat** *repeat*] [**timeout** *timeout*] [**size** *size*] [**interval** *mseconds*] [**source** *ip-address*] [**destination** *ip-address*] [**pad** *pattern*] [**reply mode** { **ipv4** | **router-alert | control-channel** }] [**verbose**]	Checks the PW connectivity.

Example: Check the connectivity of the PW whose peer PE IPv4 address is 10.10.10.3 and PW ID is 100.

```
Ruijie#ping mpls pseudowire 10.10.10.3 100 label-alert

Sending 5, 112-byte MPLS Echoes on Pseudowire, peer address 10.10.10.3, VC ID 100,

    timeout is 2 seconds, send interval is 0 msec:

Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
  'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
  'P' - no rx intf label prot, 'p' - premature termination of LSP,
  'R' - transit router, 'I' - unknown upstream index,
  'X' - unknown return code, 'x' - return code 0

Press Ctrl+C to break.
!!!!!
Success rate is 100 percent(5/5),round-trip min/avg/max=20/36/60 ms
```

Locating Data Plane Fault of PW

Command	Function
Ruijie# **traceroute mpls pseudowire** { *ip-address vc-id* {**segment** *segment-number*} | **kompella** *vfi_name local_site_id remote_site_id* **rd** *remote_rd* } { **label-alert** | **ttl-expiry** } [**timeout** *timeout*] [**source** *ip-address*] [**destination** *ip-address*] [**reply mode** { **ipv4 | router-alert | control-channel** }] [**verbose**]	Traces the PW path.

Example: Track the path of the PW whose VFI name is vpn-1, local VE ID is 1, remote VE ID is 2, and remote RD is 200:1 to locate the fault.

```
Ruijie#traceroute mpls pseudowire kompella vpn-1 1 2 label-alert rd 200:1
```

```
Traceing Pseudowire Label Switched Path, VFI name vpn-1, local site id 1, remote site id 2,
timeout is 2 seconds.
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
  'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
  'P' - no rx intf label prot, 'p' - premature termination of LSP,
  'R' - transit router, 'I' - unknown upstream index,
  'X' - unknown return code, 'x' - return code 0

Press Ctrl+C to break.
  0 192.168.1.10    MRU 1500 [Labels: router-alert/1538 Exp: 0/0]
! 1 192.168.1.11    20 ms
```

Verifying VPWS Configuration

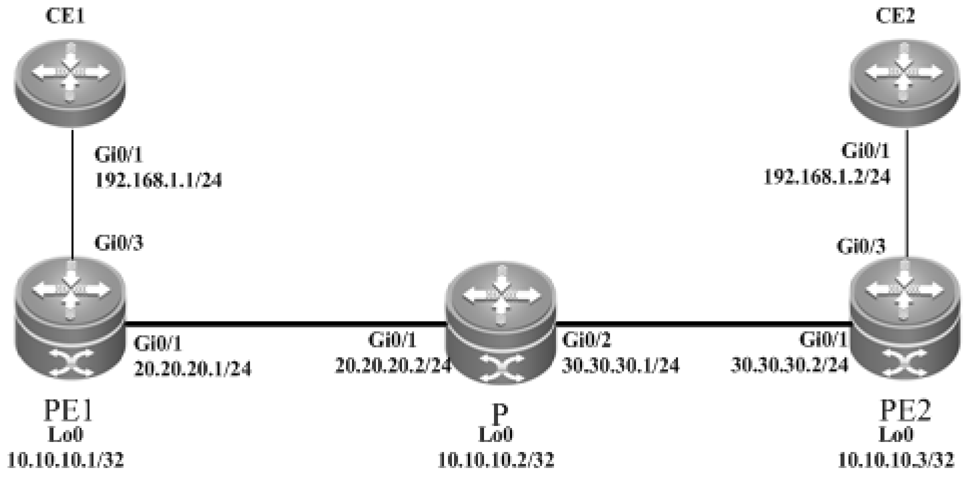
Command	Function
show bgp l2vpn vpws all	Displays NLRI information about all Kompella VPWS instances.
show bgp l2vpn vpws all connections	Displays Kompella VPWS signaling information.
show mpls l2transport vc [*vc_id* [*ip-address*]] | [**interface** *interface_name*] [**detail**]	Displays VC information established by VPWS.
show mpls vfi [*name*]	Displays VFI instance information of Kompella VPWS.
show mpls ldp vc	Displays VC signaling information of Martini VPWS.

Martini VPWS Router Configuration Instance

Connecting CEs to PEs Through Ethernet

As shown in the following network topology, the interface between PEs and CEs is an Ethernet interface. That is, CEs are connected to PEs through the Ethernet interface, through which L2VPN service is provided between CE1 and CE2.

Figure 53



The configuration procedure is as follows:

- Configuring CE1:

# Configure the interface that connects CE1 and PE1.

```
Ruijie(config)# interface gigabitethernet 0/1
Ruijie(config-if-Gigabitethernet 0/1)# ip address 192.168.1.1 255.255.255.0
```

# Enable the fast forwarding function of routers on the interface for routers. You do not need to use this command on switches.

```
Ruijie(config-if-gigabitethernet 0/1)# ip ref
Ruijie(config-if-Gigabitethernet 0/1)# end
```

- Configuring PE1:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 10.10.10.1 255.255.255.255
```

# Configure the public network LSP tunnel and remote LDP neighbor.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# neighbor 10.10.10.3
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 0/1
Ruijie(config-if-Gigabitethernet 0/1)# ip address 20.20.20.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 0/1)# mpls ip
```

# Enable the fast forwarding function of routers on the interface for routers. You do not need to use this command on switches.

```
Ruijie(config-if-gigabitethernet 0/1)# ip ref
Ruijie(config-if-Gigabitethernet 0/1)# exit
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# network 10.10.10.1 0.0.0.0 area 0
Ruijie(config-router)# end
```

# Configure the interface that connects PEs and CEs to enable the VPWS service.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 0/3
Ruijie(config-if-Gigabitethernet 0/3)# xconnect 10.10.10.3 2 encapsulation mpls ethernet raw
Ruijie(config-if-Gigabitethernet 0/3)# exit
```

- Configuring P:

# Configure the public network route protocol and LSP tunnel.

The configuration procedure is similar to the aforementioned MPLS basic function configuration instance.

- Configuring PE2:

The configuration is similar to that of PE1.

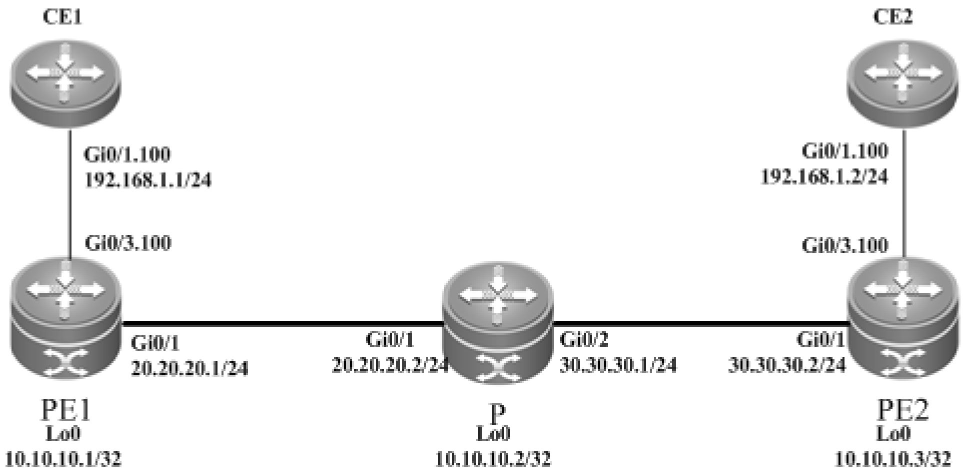
- Configuring CE2:

The configuration is similar to that of CE1.

Connecting CEs to PEs Through VLAN

As shown in the following network topology, the interface between PEs and CEs is an Ethernet sub-interface. That is, CEs are connected to PEs through the Ethernet sub-interface, through which L2VPN service is provided between CE1 and CE2.

Figure 54



The configuration procedure is as follows:

- Configuring CE1:

# Configure the interface that connects CE1 and PE2.

```
Ruijie(config)# interface gigabitethernet 0/1
```

# Enable the fast forwarding function of routers on the interface for routers. You do not need to use this command on switches.

```
Ruijie(config-if-gigabitethernet 0/1)# ip ref
Ruijie(config-if-gigabitethernet 0/1)# exit
Ruijie(config)# interface gigabitethernet 0/1.100
Ruijie(config-if-Gigabitethernet 0/1.100)# encapsulation dot1Q 100
Ruijie(config-if-Gigabitethernet 0/1.100)# ip address 192.168.1.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 0/1.100)# end
```

- Configuring PE1:

# Configure the loopback interface.

```
Ruijie# configure terminal
```

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 10.10.10.1 255.255.255.255
```

# Configure the public network LSP tunnel and remote LDP neighbor.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# neighbor 10.10.10.3
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 0/1
Ruijie(config-if-Gigabitethernet 0/1)# ip address 20.20.20.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 0/1)# mpls ip
Ruijie(config-if-Gigabitethernet 0/1)# label-switching
```

# Enable the fast forwarding function of routers on the interface for routers. You do not need to use this command on switches.

```
Ruijie(config-if-gigabitethernet 0/1)# ip ref
Ruijie(config-if-Gigabitethernet 0/1)# exit
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# network 10.10.10.1 0.0.0.0 area 0
Ruijie(config-router)# end
```

# Configure the interface that connects PEs and CEs to enable the VPWS service.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 0/3
Ruijie(config-if-Gigabitethernet 0/3)# ip ref
Ruijie(config-if-Gigabitethernet 0/3)# exit
Ruijie(config)# interface gigabitethernet 0/3.100
Ruijie(config-if-Gigabitethernet 0/3.100)# encapsulation dot1Q 100
Ruijie(config-if-Gigabitethernet 0/3.100)# xconnect 10.10.10.3 2 encapsulation mpls
ethernetvlan tagged
Ruijie(config-if-Gigabitethernet 0/3.100)# exit
```

- Configuring P:

# Configure the public network route protocol and LSP tunnel.

The configuration procedure is similar to the aforementioned MPLS basic function configuration instance.

- Configuring PE2:

The configuration is similar to that of PE1.

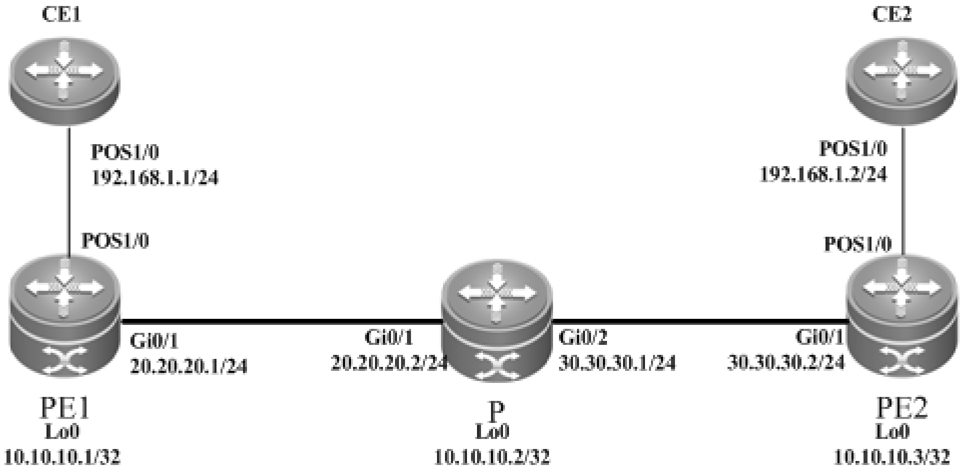
- Configuring CE2:

The configuration is similar to that of CE1.

Connecting CEs to PEs Through PPP

As shown in the following network topology, the interface between PEs and CEs is a POS interface. That is, the PPP link protocol is encapsulated and CEs are connected to PEs through PPP, through which L2VPN service is provided between CE1 and CE2.

Figure 55



The configuration procedure is as follows:

- Configuring CE1:

# Configure the interface that connects CE1 and PE2.

```
Ruijie(config)# interface pos 1/0
Ruijie(config-if-pos 1/0)# encapsulation ppp
Ruijie(config-if-pos 1/0)# ip address 192.168.1.1 255.255.255.0
Ruijie(config-if-pos 1/0)# clock internal
```

# Enable the fast forwarding function of routers on the interface for routers. You do not need to use this command on switches.

```
Ruijie(config-if-pos 1/0)# ip ref
Ruijie(config-if-pos 1/0)# end
```

- Configuring PE1:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 10.10.10.1 255.255.255.255
```

# Configure the public network LSP tunnel and remote LDP neighbor.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# neighbor 10.10.10.3
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 0/1
Ruijie(config-if-Gigabitethernet 0/1)# ip address 20.20.20.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 0/1)# mpls ip
Ruijie(config-if-Gigabitethernet 0/1)# label-switching
```

# Enable the fast forwarding function of routers on the interface for routers. You do not need to use this command on switches.

```
Ruijie(config-if-gigabitethernet 0/1)# ip ref
Ruijie(config-if-Gigabitethernet 0/1)# exit
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# network 10.10.10.1 0.0.0.0 area 0
Ruijie(config-router)# end
```

# Configure the interface that connects PEs and CEs to enable the VPWS service.

```
Ruijie(config)# interface pos 1/0
Ruijie(config-if-pos 1/0)# encapsulation ppp
Ruijie(config-if-pos 1/0)# clock internal
Ruijie(config-if-pos 1/0)# xconnect 10.10.10.3 2 encapsulation mpls ppp
Ruijie(config-if-pos 1/0)# end
```

- Configuring P:

# Configure the public network route protocol and LSP tunnel.

The configuration procedure is similar to the aforementioned MPLS basic function configuration instance.

- Configuring PE2:

The configuration is similar to that of PE1.

- Configuring CE2:

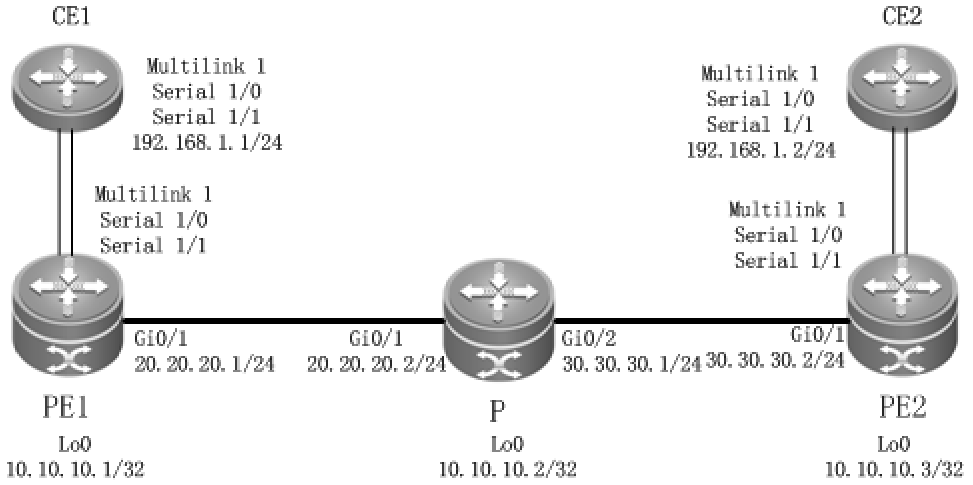
The configuration is similar to that of CE1.

Connecting CEs to PEs Through MultiPPP

As shown in the following network topology, PEs and CEs are connected through the Serial interface and the PPP protocol is encapsulated. PEs and CEs bind two Serial interfaces, which work in MultiPPP mode. Therefore, CEs are connected to PEs through MultiPPP to establish the L2VPN service between CE1 and CE2.

CEs are connected to PEs through MultiPPP by enabling the heterogeneous media access mode on the PE-end multilink interface. The mode does not support the homogeneous media access mode.

Figure 56



The configuration procedure is as follows:

- Configuring CE1:

# Configure the multilink interface that connects CE1 and PE2.

```
Ruijie(config)# interface mutilink 1
Ruijie(config-multilink 1)# ip address 192.168.1.1 255.255.255.0
```

# Enable the fast forwarding function of routers on the interface for routers. You do not use this command on switches.

```
Ruijie(config-multilink 1)# ip ref
Ruijie(config-multilink 1)# end
```

# Configure the serial interface bound with the multilink interface.

```
Ruijie(config)# interface serial 1/0
Ruijie(config-serial 1/0)# encapsulation ppp
Ruijie(config-serial 1/0)# ppp multilink
Ruijie(config-serial 1/0)# ppp multilink group 1
Ruijie(config-serial 1/0)# end
Ruijie(config)# interface serial 1/1
Ruijie(config-serial 1/1)# encapsulation ppp
Ruijie(config-serial 1/1)# ppp multilink
Ruijie(config-serial 1/1)# ppp multilink group 1
Ruijie(config-serial 1/1)# end
```

- Configuring PE1:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 10.10.10.1 255.255.255.255
```

# Configure the public network LSP tunnel and remote LDP neighbor.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# neighbor 10.10.10.3
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 0/1
Ruijie(config-if-Gigabitethernet 0/1)# ip address 20.20.20.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 0/1)# mpls ip
Ruijie(config-if-Gigabitethernet 0/1)# label-switching
```

# Enable the fast forwarding function of routers on the interface for routers. You do not use this command on switches.

```
Ruijie(config-if-gigabitethernet 0/1)# ip ref
Ruijie(config-if-Gigabitethernet 0/1)# exit
Ruijie(config)# router ospf 10

Ruijie(config-router)# network 10.10.10.1 0.0.0.0 area 0
Ruijie(config-router)# end
```

# Configure the interface that connects PEs and CEs to enable the VPWS service.

# Configure the multilink interface.

```
Ruijie(config)# interface mutilink 1
Ruijie(config-multilink 1)# ip ref
Ruijie(config-multilink 1)# xconnect 10.10.10.3 2 encapsulation mpls ip-interworking
Ruijie(config-multilink 1)# ppp ipcp address proxy 192.168.1.2
```

# Configure the serial interface bound with the multilink interface.

```
Ruijie(config)# interface serial 1/0
Ruijie(config-serial 1/0)# encapsulation ppp
Ruijie(config-serial 1/0)# ppp multilink
Ruijie(config-serial 1/0)# ppp multilink group 1
Ruijie(config-serial 1/0)# end
Ruijie(config)# interface serial 1/1
Ruijie(config-serial 1/1)# encapsulation ppp
Ruijie(config-serial 1/1)# ppp multilink
Ruijie(config-serial 1/1)# ppp multilink group 1
Ruijie(config-serial 1/1)# end
```

- Configuring P:

# Configure the public network route protocol and LSP tunnel.

The configuration procedure is similar to the aforementioned MPLS basic function configuration instance.

- Configuring PE2:

The configuration procedure is similar to that of PE1.

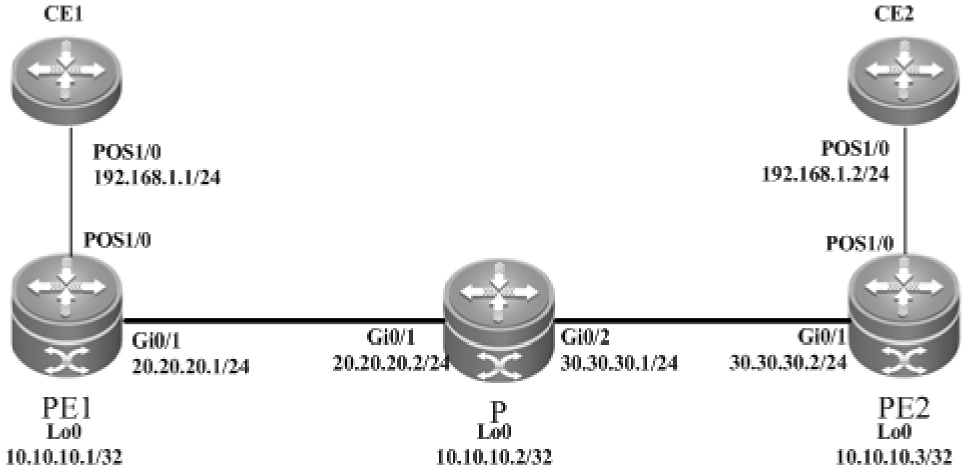
- Configuring CE2:

The configuration procedure is similar to that of CE1.

Connecting CEs to PEs Through HDLC

As shown in the following network topology, the interface that connects PEs and CEs is a POS interface and the HDLC link protocol is encapsulated. That is, CEs are connected to PEs through a HDLC interface, through which L2VPN service is provided between CE1 and CE2.

Figure 57



The configuration procedure is as follows:

- Configuring CE1:

# Configure the interface that connects CE1 and PE2.

```
Ruijie(config)# interface pos 1/0
Ruijie(config-if-pos 1/0)# encapsulation hdlc
Ruijie(config-if-pos 1/0)# ip address 192.168.1.1 255.255.255.0
Ruijie(config-if-pos 1/0)# clock internal
```

# Enable the fast forwarding function of routers on the interface for routers. You do not need to use this command on switches.

```
Ruijie(config-if-pos 1/0)# ip ref
Ruijie(config-if-pos 1/0)# end
```

- Configuring PE1:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 10.10.10.1 255.255.255.255
```

# Configure the public network LSP tunnel and remote LDP neighbor.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# neighbor 10.10.10.3
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 0/1
Ruijie(config-if-Gigabitethernet 0/1)# ip address 20.20.20.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 0/1)# mpls ip
Ruijie(config-if-Gigabitethernet 0/1)# label-switching
```

# Enable the fast forwarding function of routers on the interface for routers. You do not need to use this command on switches.

```
Ruijie(config-if-gigabitethernet 0/1)# ip ref
Ruijie(config-if-Gigabitethernet 0/1)# exit
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# network 10.10.10.1 0.0.0.0 area 0
Ruijie(config-router)# end
```

# Configure the interface that connects PEs and CEs to enable the VPWS service.

```
Ruijie(config)# interface pos 1/0
Ruijie(config-if-pos 1/0)# encapsulation hdlc
Ruijie(config-if-pos 1/0)# clock internal
Ruijie(config-if-pos 1/0)# xconnect 10.10.10.3 2 encapsulation mpls hdlc
Ruijie(config-if-pos 1/0)# end
```

- Configuring P:

# Configure the public network route protocol and LSP tunnel.

The configuration procedure is similar to the aforementioned MPLS basic function configuration instance.

- Configuring PE2:

The configuration is similar to that of PE1.

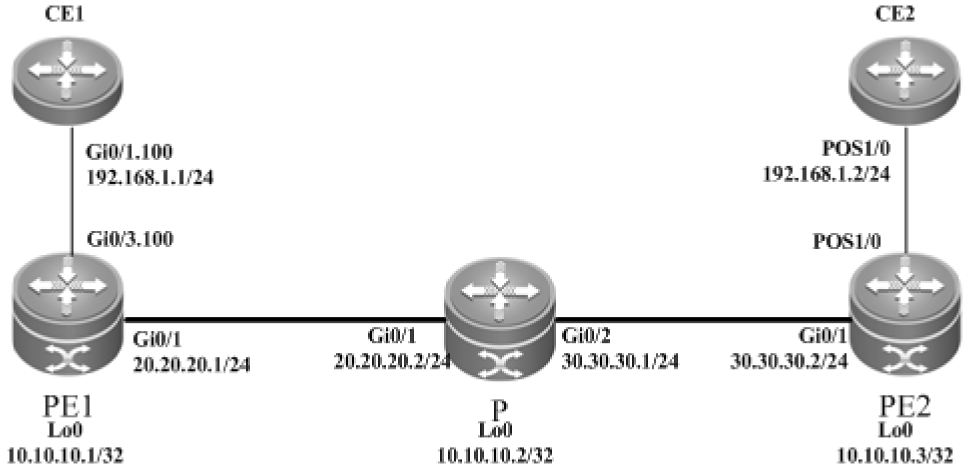
- Configuring CE2:

The configuration is similar to that of CE1.

VLAN and PPP Heterogeneous Media Communication

As shown in the following network topology, the interface that connects PE1 and CE1 is an Ethernet sub-interface and the encapsulated link protocol is 802.1Q. PE2 and CE2 are connected through the POS interface and the encapsulated link protocol is PPP, through which the L2VPN service is established between CE1 and CE2. VPWS provides the heterogeneous media communication L2VPN service.

Figure 58



The configuration procedure is as follows:

# Configure the interface that connects CE1 and PE1.

```
Ruijie(config)# interface gigabitethernet 0/1
```

# Enable the fast forwarding function of routers on the interface for routers. You do not need to use this command on switches.

```
Ruijie(config-if-gigabitethernet 0/1)# ip ref
Ruijie(config-if-gigabitethernet 0/1)# exit
Ruijie(config)# interface gigabitethernet 0/1.100
Ruijie(config-if-Gigabitethernet 0/1.100)# encapsulation dot1Q 100
Ruijie(config-if-Gigabitethernet 0/1.100)# ip address 192.168.1.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 0/1.100)# end
```

- Configuring PE1:

# Configure the loopback interface.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 10.10.10.1 255.255.255.255
```

# Configure the public network LSP tunnel and remote LDP neighbor.

```

```

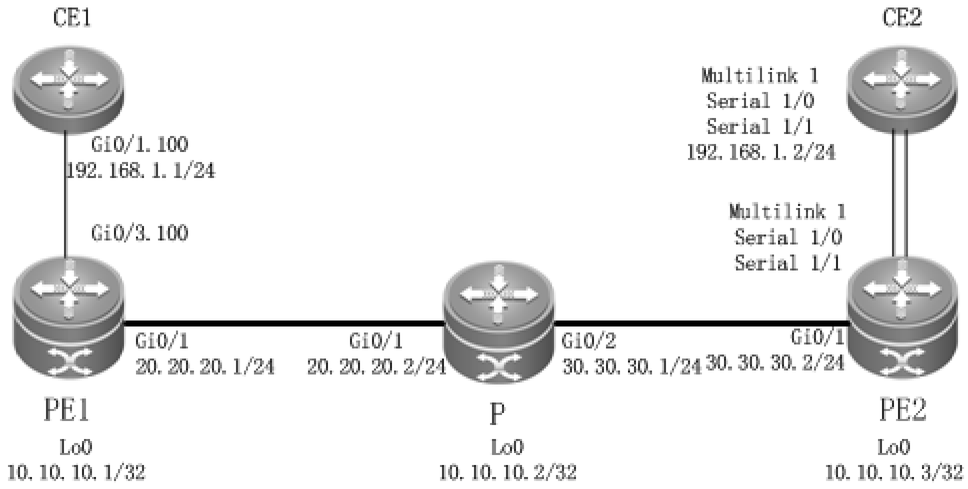
VLAN and MultiPPP Heterogeneous Media Communication

As shown in the following network topology, the interface that connects PE1 and CE1 is an Ethernet sub-interface and the encapsulated link protocol is 802.1Q. PE2 and CE2 are connected through the Serial interface and the encapsulated link protocol is PPP. PPP is bound by two physical lines in the MultiPPP working mode, through which the L2VPN service is established between CE1 and CE2. VPWS provides the heterogeneous media communication L2VPN service.

Figure 59



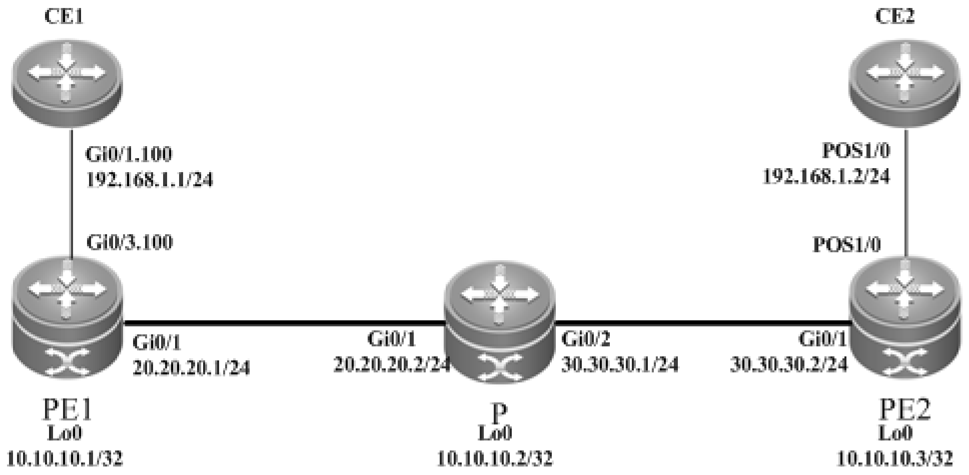
The configuration of CE1 and PE1 is generally the same as the configuration of VLAN and PPP heterogeneous media communication.

The configuration of CE2 and PE2 is generally the same as the configuration of a CE when it is connected to a PE through MultiPPP.

VLAN and HDLC Heterogeneous Media Communication

As shown in the following network topology, the interface between PE1 and CE1 is an Ethernet sub-interface and the encapsulated link protocol is 802.1Q. PE2 and CE2 are connected through the POS interface and the encapsulated link protocol is HDLC, through which the L2VPN service is established between CE1 and CE2. VPWS provides the heterogeneous media communication L2VPN service.

Figure 60



The configuration procedure is as follows:

# Configure the interface that connects CE1 and PE1.

```
Ruijie(config)# interface gigabitethernet 0/1
```

# Enable the fast forwarding function of routers on the interface for routers. You do not need to use this command on switches.

```

Ruijie(config-if-gigabitethernet 0/1)# ip ref
Ruijie(config-if-Gigabitethernet 0/1)# exit
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 30.30.30.0 0.0.0.255 area 0
Ruijie(config-router)# network 10.10.10.3 0.0.0.0 area 0
Ruijie(config-router)# end
```

# Configure the interface that connects PEs and CEs to enable the VPWS service.

```
Ruijie# configure terminal
Ruijie(config)# interface pos 1/0
Ruijie(config-if-pos 1/0)# ip ref
Ruijie(config-if-pos1/0)# encapsulation hdlc
Ruijie(config-if- pos1/0)# xconnect 10.10.10.3 2 encapsulation mpls ip-interworking
Ruijie(config-if-pos1/0)# exit
```

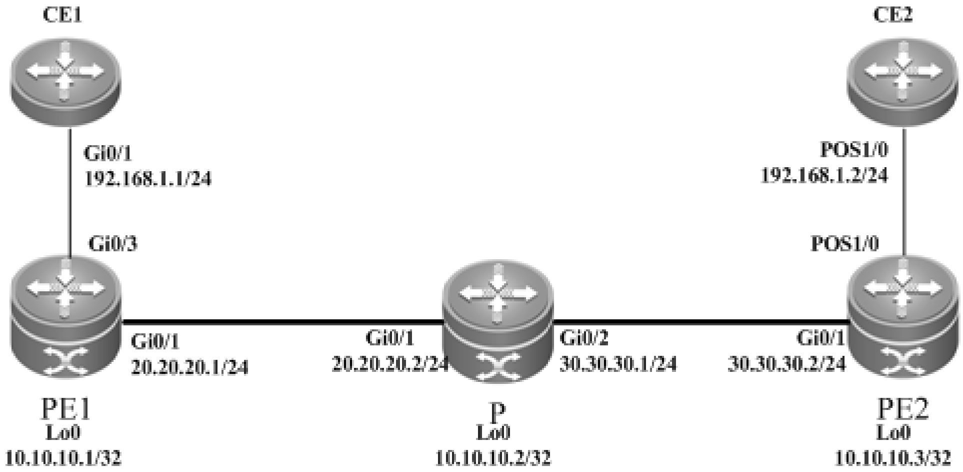
- Configuring CE2:

```
Ruijie(config)# interface pos 1/0
Ruijie(config-if-pos 1/0)# ip ref
Ruijie(config-if-pos 1/0)# encapsulation hdlc
Ruijie(config-if-pos 1/0)# ip address 192.168.1.2 255.255.255.0
Ruijie(config-if-pos 1/0)# clock internal
Ruijie(config-if-pos 1/0)# end
```

Ethernet and PPP Heterogeneous Media Communication

As shown in the following network topology, the interface between PE1 and CE1 is an Ethernet interface and the encapsulated link protocol is EthernetII. PE2 and CE2 are connected through the POS interface and the encapsulated link protocol is PPP, through which the L2VPN service is established between CE1 and CE2. VPWS provides the heterogeneous media communication L2VPN service.

Figure 61

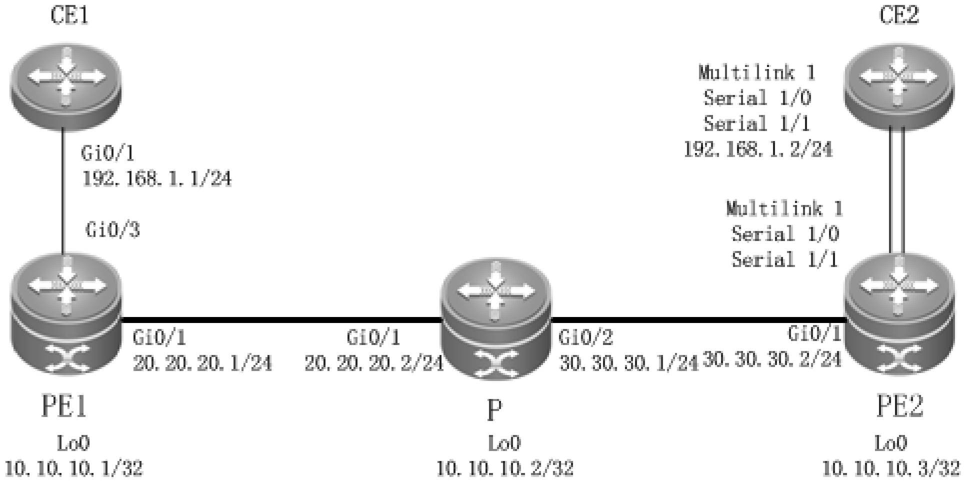


The configuration is generally the same as that for VLAN and PPP heterogeneous media communication, except the access modes of PE1 and CE1.

Ethernet and MultiPPP Heterogeneous Media Communication

As shown in the following network topology, the interface between PE1 and CE1 is an Ethernet interface and the encapsulated link protocol is EthernetII. PE2 and CE2 are connected through the Serial interface and the encapsulated link protocol is PPP. PPP is bound by two physical lines in the MultiPPP working mode, through which the L2VPN service is established between CE1 and CE2. VPWS provides the heterogeneous media communication L2VPN service.

Figure 62



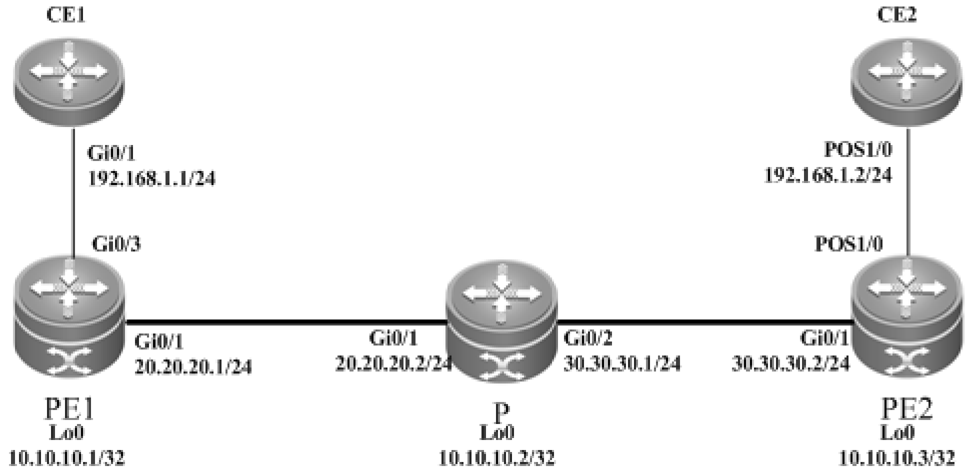
The configuration of CE1 and PE1 is generally the same as that for VLAN and PPP heterogeneous media communication, except the access mode of PE1 and CE1.

The configuration of CE2 and PE2 is generally the same as the configuration of a CE when it is connected to a PE through MultiPPP.

Ethernet and HDLC Heterogeneous Media Communication

As shown in the following network topology, the interface between PE1 and CE1 is an Ethernet interface and the encapsulated link protocol is EthernetII. PE2 and CE2 are connected through the POS interface and the encapsulated link protocol is HDLC, through which the L2VPN service is established between CE1 and CE2. VPWS provides the heterogeneous media communication L2VPN service.

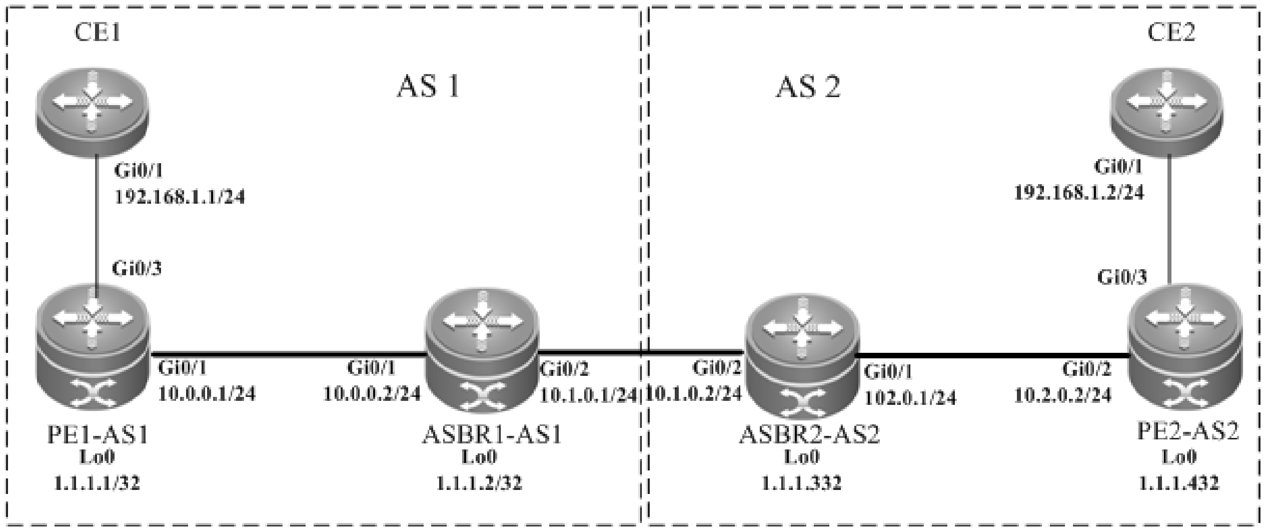
Figure 63



The configuration is generally the same as the configuration of VLAN and HDLC heterogeneous media communication, except the access modes of PE1 and CE1.

Option C Inter-AS VPWS

Figure 64 Option C: Inter-AS VPWS



The proceeding figure shows how to realize inter-AS VPWS by using the Option C solution. To set up a PW between PEs of different ASs, PW information is not maintained on ASBR and OSPF is used in each AS as IGP to realize inter-AS communication. Assuming that CE1 is connected to a PE through the master port, it is required to establish L2VPN communication between CE1 and CE2. Configuration of devices is described as follows (only configuration related to the function is included):

- Configuring CE1:

```
Ruijie# configure terminal
Ruijie(config)# interface GigabitEthernet 0/1
```

# The **no switchport** command is used on switches to switch the port mode to the Routed Port mode. It does not apply to routers and does not need to be used on routers.

```
Ruijie(config-if-GigabitEthernet 0/1)# no switchport
Ruijie(config-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0
```

# Enable the fast forwarding function of routers on the interface for routers. You do not need to use this command on switches.

```
Ruijie(config-if-gigabitethernet 0/1)# ip ref
Ruijie(config-if-GigabitEthernet 0/1)# end
```

The configuration of CE2 is similar to that of CE1.

- Configuring PE1-AS1:

# Configure the public network route protocol, MPLS signaling, and remote neighbors.

```
Ruijie# configure terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# neighbor 1.1.1.4
Ruijie(config-mpls-router)# exit
Ruijie(config)# router ospf 1
Ruijie(config-router)# network 10.0.0.0 0.0.0.255 area 0
Ruijie(config-router)# network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)# exit
Ruijie(config)# interface GigabitEthernet 0/1
```

# The **no switchport** command is used on switches to switch the port mode to the Routed Port mode. It does not apply to routers and does not need to be used on routers.

```
Ruijie(config-if-GigabitEthernet 0/1)# no switchport
```

# Enable the fast forwarding function of routers on the interface for routers. You do not need to use this command on switches.

```
Ruijie(config-if-gigabitethernet 0/1)# ip ref
Ruijie(config-if-GigabitEthernet 0/1)# ip address 10.0.0.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/1)# mpls ip
Ruijie(config-if-GigabitEthernet 0/1)# label-switching
Ruijie(config-if-GigabitEthernet 0/1)# end
```

# Configure BGP.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 1.1.1.2 remote-as 1
Ruijie(config-router)# neighbor 1.1.1.2 update-source loopback 0
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 1.1.1.2  activate
Ruijie(config-router-af)# neighbor 1.1.1.2  send-label
Ruijie(config-router-af)# end
```

# Configure the user access VPWS.

```
Ruijie# configure terminal
Ruijie(config)# interface GigabitEthernet 0/3
```

# Enable the fast forwarding function of routers on the interface for routers. You do not need to use this command on switches.

```
Ruijie(config-if-gigabitethernet 0/3)# ip ref
Ruijie(config-if-GigabitEthernet 0/3)# xconnect 1.1.1.1 1 encapsulation mpls ethernet
Ruijie(config-if-GigabitEthernet 0/3)# end
```

The configuration of PE2-AS2 is similar to that of PE1-AS1.

- Configuring ASBR1-AS1:

# Configure the loopback interface.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 1.1.1.2 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure the public network route protocol and MPLS signaling.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface GigabitEthernet 0/1
```

# The **no switchport** command is used on switches to switch the port mode to the Routed Port mode. It does not apply to routers and does not need to be used on routers.

```
Ruijie(config-if-GigabitEthernet 0/1)# no switchport
```

# Enable the fast forwarding function of routers on the interface for routers. You do not need to use this command on switches.

```
Ruijie(config-if-gigabitethernet 0/3)# ip ref
Ruijie(config-if-GigabitEthernet 0/1)# ip address 10.0.0.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/1)# mpls ip
Ruijie(config-if-GigabitEthernet 0/1)# label-switching
Ruijie(config-if-GigabitEthernet 0/1)# exit
Ruijie(config)# router ospf 1
Ruijie(config-router)# network 10.0.0.0 0.0.0.255 area 0
Ruijie(config-router)# network 1.1.1.2 0.0.0.0 area 0
Ruijie(config-router)# exit
```

# Configure the IP address of the interface connected to ASBR2.

```
Ruijie(config)# interface GigabitEthernet 0/2
```

# The **no switchport** command is used on switches to switch the port mode to the Routed Port mode. It does not apply to routers and does not need to be used on routers.

```
Ruijie(config-if-GigabitEthernet 0/2)# no switchport
```

# Enable the fast forwarding function of routers on the interface for routers. You do not need to use this command on switches.

```
Ruijie(config-if-gigabitethernet 0/2)# ip ref
Ruijie(config-if-GigabitEthernet 0/2)# ip address 10.1.0.1 255.255.255.0
```

# Enable the interface's label packet forwarding capability.

```
Ruijie(config-if-GigabitEthernet 0/2)# label-switching
Ruijie(config-if-GigabitEthernet 0/2)# exit
```

# Configure BGP.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 1.1.1.1 remote-as 1
Ruijie(config-router)# neighbor 1.1.1.1 update-source loopback 0
Ruijie(config-router)# neighbor 10.1.0.2 remote-as 2
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 1.1.1.1 activate
Ruijie(config-router-af)# neighbor 1.1.1.1 send-label
Ruijie(config-router-af)# neighbor 10.1.0.2 activate
Ruijie(config-router-af)# neighbor 10.1.0.2 send-label
Ruijie(config-router-af)# network 1.1.1.1 mask 255.255.255.255
Ruijie(config-router-af)# end
```

The configuration of ASBR2-AS2 is similar to that of ASBR1-AS1.

The configuration of PE2-AS2 is similar to that of PE1-AS1.

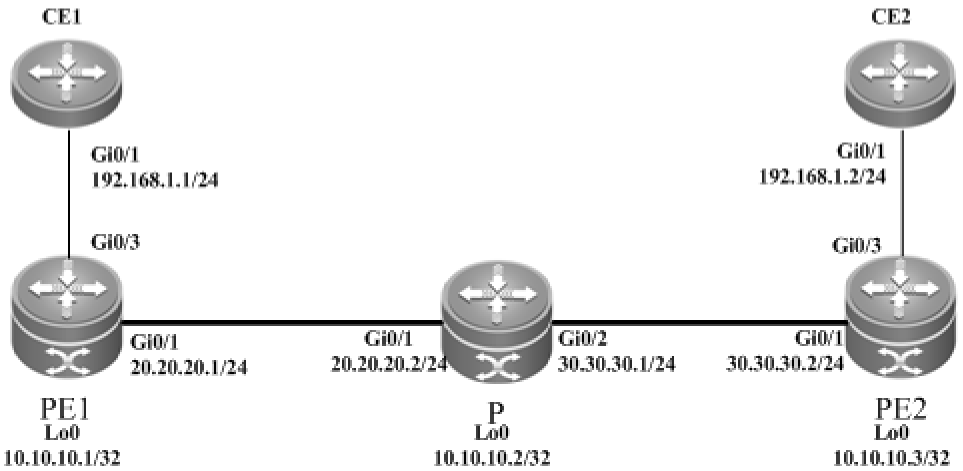
The configuration of CE2 is similar to that of CE1.

Kompella VPWS Router Configuration Instance

Connecting CEs to PEs Through Ethernet

As shown in the following network topology, the interface between PEs and CEs is an Ethernet interface. That is, CEs are connected to PEs through the Ethernet interface, through which the L2VPN service is provided between CE1 and CE2.

Figure 65



The configuration procedure is as follows:

Configuring CE1:

# Configure the interface between CE1 and PE1.

```
Ruijie(config)# interface gigabitethernet 0/1
Ruijie(config-if-Gigabitethernet 0/1)# ip address 192.168.1.1 255.255.255.0
```

# Enable the fast forwarding function of routers on the interface for routers. You do not need to use this command on switches.

```
Ruijie(config-if-gigabitethernet 0/1)# ip ref
Ruijie(config-if-Gigabitethernet 0/1)# end
```

Configuring PE1:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 10.10.10.1 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 10.10.10.1 0.0.0.0 area 0
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# exit
```

# Configure the public network tunnel between PEs.

```
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if-Gigabitethernet 0/1)# ip ref
Ruijie(config-if-Gigabitethernet 0/1)# ip address 20.20.20.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 0/1)# mpls ip
Ruijie(config-if-Gigabitethernet 0/1)# label-switching
Ruijie(config-if-Gigabitethernet 0/1)# exit
```

# Configure the L2VPN address family.

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 10.10.10.3 remote-as 100
Ruijie(config-router)# neighbor 10.10.10.3 update-source loopback 0
Ruiije(config-router)# address-family l2vpn vpws
Ruijie(config-router-af)# neighbor 10.10.10.3 activate
Ruijie(config-router-af)# neighbor 10.10.10.3 send-community extended
Ruijie(config-router-af)# exit
```

# Configure a VFI instance.

```
Ruijie# configure terminal
Ruijie(config)# l2 vfi vpws-1 vpnid 1 point-to-point
Ruijie(config-vfi)# rd 1:1
Ruijie(config-vfi)# encapsulation mpls ethernet
Ruijie(config-vfi)# route-target both 10000:1
Ruijie(config-vfi)# site-id 1
Ruijie(config-vfi-site)# xconnect interface gigabitEthernet 0/3 remote-ce-id 2
Ruijie(config-vfi-site)#exit-site-mode
Ruijie(config-vfi)#exit
```

# Enable the interface to connect to remote CEs.

```
Ruijie(config)# interface gigabitEthernet 0/3
Ruijie(config-if-GigabitEthernet 0/3)# ip ref
Ruijie(config-if-GigabitEthernet 0/3)# exit
```

Configuring P:

# Configure the public network route protocol and LSP tunnel.

The configuration is similar to the aforementioned MPLS basic function configuration instance.

Configuring PE2:

The configuration is similar to that of PE1.

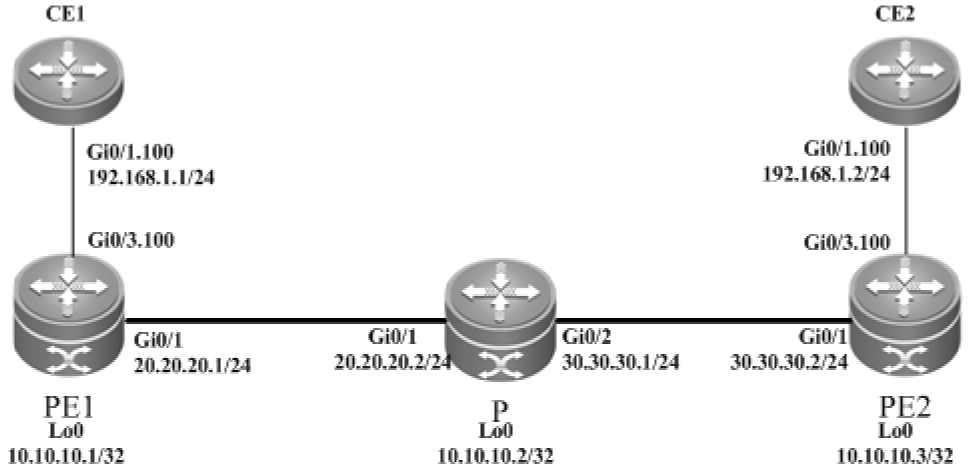
Configuring CE2:

The configuration is similar to that of CE1.

Connecting CEs to PEs Through VLAN

As shown in the following network topology, the interface that connects PEs and CEs is an Ethernet sub-interface. That is, CEs are connected to PEs through the Ethernet sub-interface, through which L2VPN service is provided between CE1 and CE2.

Figure 66



The configuration procedure is as follows:

Configuring CE1:

# Configure the interface between CE1 and PE1.

```
Ruijie(config)# interface gigabitethernet 0/1
```

# Enable the fast forwarding function of routers on the interface for routers. You do not need to use this command on switches.

```
Ruijie(config-if-gigabitethernet 0/1)# ip ref
Ruijie(config-if-gigabitethernet 0/1)# exit
Ruijie(config)# interface gigabitethernet 0/1.100
Ruijie(config-if-Gigabitethernet 0/1.100)# encapsulation dot1Q 100
Ruijie(config-if-Gigabitethernet 0/1.100)# ip address 192.168.1.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 0/1.100)# end
```

Configuring PE1:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 10.10.10.1 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 10.10.10.1 0.0.0.0 area 0
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
```

#Configure the public network tunnel between PEs.

```
Ruijie(config)# interface gigabitEthernet 0/1

Configuring P:

# Configure the public network route protocol and LSP tunnel.

The configuration is similar to the aforementioned MPLS basic function configuration instance.

Configuring PE2:

The configuration procedure is similar to that of PE1.

Configuring CE2:

The configuration procedure is similar to that of CE1.

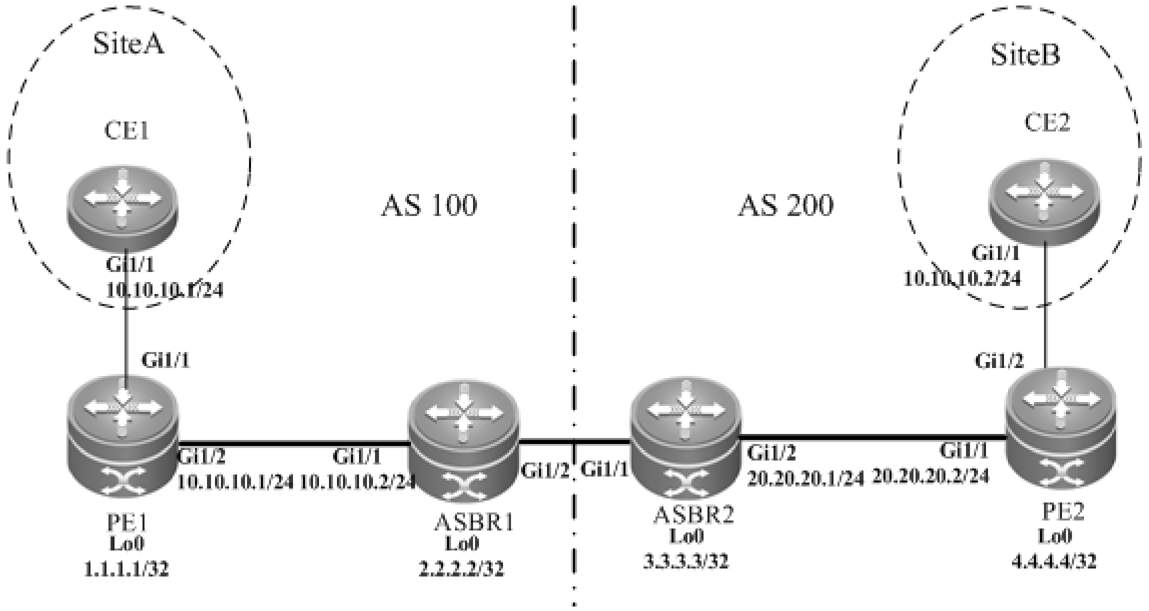
Option A Inter-AS VPWS

Networking Requirements

- CEs of customer S in site A and site B are connected with each other through the carrier's PE1 in AS 100 and PE2 in AS 200, realizing layer-2 point-to-point connection.
- PE1 and PE2 are in different autonomous ASs. ASBR1 and ASBR2 are considered CEs by each other, which means that the interface between ASBRs connects the AC to the VFI instance.

Networking Topology

Figure 67 Kompella VPWS inter-AS networking topology



The preceding figure shows the structure of the Kompella VPLS inter-AS networking topology in Option A. The intermediate interface is considered by ASBRs as AC access.

Configuration Tips

Before configuring Kompella VPWS, complete the following tasks:

- Run IGP in the carrier's network to realize connection between PE and ASBR devices.
- Establish the MP-IBGP peer relationship between PEs and intra-AS ASBRs.
- Obtain Kompella VPWS configuration information including VPWS instance descriptive information, RT value, CE ID, maximum planned site number, ID deviation, and interface information from the network administrator.

Configuration Steps

- Configuring CE1

See "Configuring CE1" in basic configuration examples.

- Configuring PE1

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes so that PEs can ping with ASBRs in the same AS.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)# network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
```

# Configure the public network tunnel between PEs.

```
Ruijie(config)# interface gigabitEthernet 1/2
Ruijie(config-if-Gigabitethernet 1/2)# ip ref
Ruijie(config-if-Gigabitethernet 1/2)# ip address 10.10.10.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 1/2)# mpls ip
Ruijie(config-if-Gigabitethernet 1/2)# label-switching
Ruijie(config-if-Gigabitethernet 1/2)# exit
```

# Configure the L2VPN address family.

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 2.2.2.2 remote-as 100
Ruijie(config-router)# neighbor 2.2.2.2 update-source loopback 0
Ruiije(config-router)# address-family l2vpn vpws
Ruijie(config-router-af)# neighbor 2.2.2.2 activate
Ruijie(config-router-af)# neighbor 2.2.2.2 send-community extended
Ruijie(config-router-af)# exit
```

# Configure a VFI instance.

```
Ruijie# configure terminal
Ruijie(config)# l2 vfi vpws-1 vpnid 1 point-to-point
Ruijie(config-vfi)# rd 100:1
Ruijie(config-vfi)# encapsulation mpls ethernet
Ruijie(config-vfi)# route-target both 10000:1
Ruijie(config-vfi)# site-id 1
Ruijie(config-vfi-site)# xconnect interface gigabitEthernet 1/1 remote-ce-id 2
Ruijie(config-vfi-site)#exit-site-mode
Ruijie(config-vfi)#exit
```

# Configure the interface between CEs and PEs and specify the remote CE ID.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)# ip ref
Ruijie(config-if-GigabitEthernet 1/1)# exit
```

- Configuring ASBR1:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 2.2.2.2 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF protocol, establish public network routes so that PEs can ping with ASBRs in the same domain.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 2.2.2.2 0.0.0.0 area 0
Ruijie(config-router)# network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# exit
```

# Configure the public network tunnel between PEs.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-Gigabitethernet 1/1)# ip ref
Ruijie(config-if-Gigabitethernet 1/1)# ip address 10.10.10.2 255.255.255.0
Ruijie(config-if-Gigabitethernet 1/1)# mpls ip
Ruijie(config-if-Gigabitethernet 1/1)# label-switching
Ruijie(config-if-Gigabitethernet 1/1)# exit
```

# Configure the L2VPN address family.

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 1.1.1.1 remote-as 100
Ruijie(config-router)# neighbor 1.1.1.1 update-source loopback 0
Ruiije(config-router)# address-family l2vpn vpws
Ruijie(config-router-af)# neighbor 1.1.1.1 activate
Ruijie(config-router-af)# exit
```

# Configure a VPWS instance.

```
Ruijie# configure terminal
Ruijie(config)# l2 vfi vpws-1 vpnid 2 point-to-point
Ruijie(config-vfi)# rd 100:1
Ruijie(config-vfi)# encapsulation mpls ethernet
Ruijie(config-vfi)# route-target both 10000:1
Ruijie(config-vfi)# site-id 2
Ruijie(config-vfi-site)# xconnect interface gigabitEthernet 1/2 remote-ce-id 1
Ruijie(config-vfi-site)#exit-site-mode
Ruijie(config-vfi)#exit
```

# Configure the interface between ASBR1 and ASBR2.

```
Ruijie(config)# interface gigabitEthernet 1/2
Ruijie(config-if-GigabitEthernet 1/2)# ip ref
Ruijie(config-if-GigabitEthernet 1/2)# exit
```

- Configure ASBR2:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 3.3.3.3 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF protocol, establish public network routes so that PEs can ping with ASBRs in the same domain.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 3.3.3.3 0.0.0.0 area 0
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
```

#Configure the public network tunnel between PEs.

```
Ruijie(config)# interface gigabitEthernet 1/2
Ruijie(config-if-Gigabitethernet 1/2)# ip ref
Ruijie(config-if-Gigabitethernet 1/2)# ip address 20.20.20.2 255.255.255.0

Ruijie(config-router-af)# neighbor 3.3.3.3 activate
Ruijie(config-router-af)# neighbor 3.3.3.3 send-community extended
Ruijie(config-router-af)# exit
```

# Configure a VPWS instance.

```
Ruijie# configure terminal
Ruijie(config)# l2 vfi vpws-1 vpnid 1 autodiscovery
Ruijie(config-vfi)# rd 200:1
Ruijie(config-vfi)# signal bgp
Ruijie(config-vfi)# encapsulation mpls ethernet
Ruijie(config-vfi)# route-target both 10000:1
Ruijie(config-vfi)# site-id 4
Ruijie(config-vfi-site)# xconnect interface gigabitEthernet 1/2 remote-ce-id 3
Ruijie(config-vfi-site)#exit-site-mode
Ruijie(config-vfi)#exit
```

# Configure the interface between PE2 and a CE.

```
Ruijie(config)# interface gigabitEthernet 1/2
Ruijie(config-if-GigabitEthernet 1/2)# ip ref
Ruijie(config-if-GigabitEthernet 1/2)# exit
```

- Configuring CE2:

See "Configuring CE2" in basic configuration examples.

Verification

After the configuration, CE1 can ping with CE2.

After completing the configuration of Kompella VPWS, use the following commands to check the operation of VPWS.

Command	Function
Ruijie# **show bgp l2vpn vpws all**	Displays all the VPWS information.
Ruijie# **show mpls l2transport vc** [*vc_id* [*ip-address*]] | [**interface** *interface_name*] [**detail**]	Displays information about the PW (including VPWS PW and VPLS PW).
Ruijie# **show bgp l2vpn** { **vpls | vpws** } **all connections** [**neighbor** *address*] | [**interface** *interface_name*] | [**site-i**d *id*] [**detail**]	Displays PW information.
Ruijie# **show mpls vfi** [*name*]	Displays all the configured or specified VFI information.

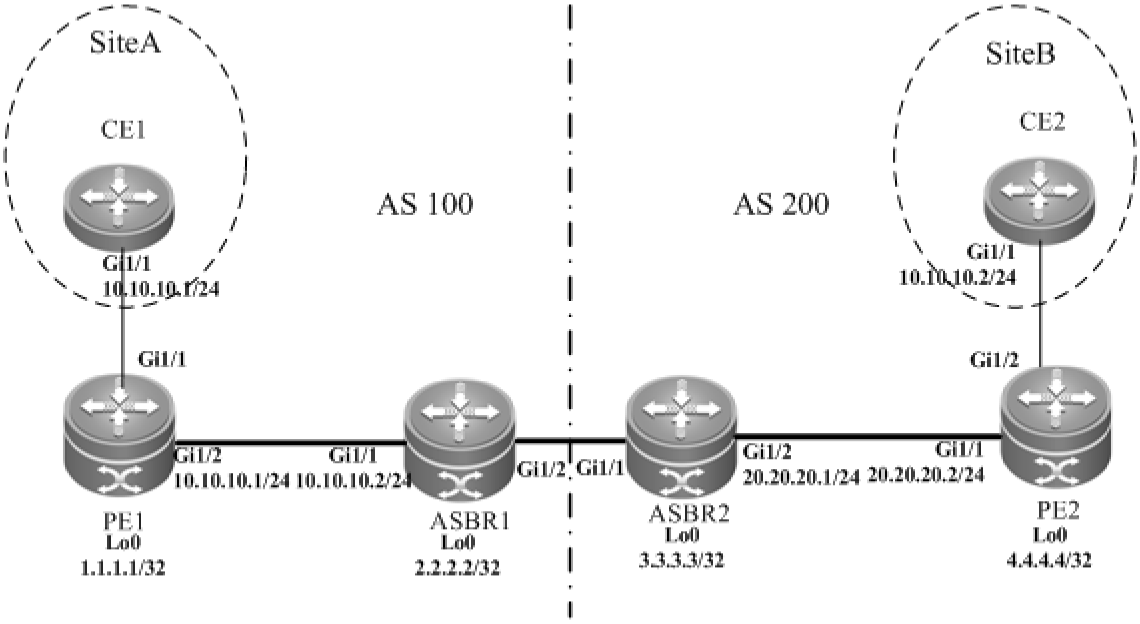
Option C Inter-AS VPWS

Networking Requirements

- CEs of customer S in site A and site B are connected with each other through the carrier's PE1 in AS 100 and PE2 in AS 200, realizing layer-2 point-to-point connection.
- PE1 and PE2 are in different ASs and can automatically detect PE devices involved in the VFI instance.
- ASBR is not responsible for maintaining VPWS label block messages.
- VPWS label block messages are directly switched between PEs.

Networking Topology

Figure 68 Kompella VPWS Option C inter-AS networking topology



The above figure shows the structure of Kompella VPWS Option C Inter-AS networking topology. Customer S's CE devices in Site A and Site B are connected to each other through PE1 in AS100 and PE2 in AS200, thus realizing layer-2 point-to-point connection.

Configuration Tips

Before configuring Kompella VPWS, complete the following tasks:

- Run IGP in the carrier's network to realize connection between PE and ASBR devices in the same AS.
- Establish a public network tunnel between PE and ASBR devices in the same AS and enable MPLS on the ASBR interface.
- Establish IBGP between PE and ASBR in the same AS.
- Establish EBGP between ASBR devices and enable send-label.
- Obtain Kompella VPWS configuration information including VPWS instance descriptive information, RT value, CE, planned site number, ID deviation, and interface information from the network administrator.

Configuration Steps

- Configuring CE1

See "Configuring CE1" in basic configuration examples.

- Configuring PE1

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255

- Configuring CE2

See "Configuring CE2" in basic configuration examples.

Verification

After the configuration, CE1 can ping with CE2.

After completing the configuration of Kompella VPLS, use the following commands to check the operation of VPWS:

Command	**Function**
Ruijie# **show bgp l2vpn vpws all**	Displays all the VPWS information.
Ruijie# **show mpls l2transport vc** [*vc_id* [*ip-address*]] | [**interface** *interface_name*] [**detail**]	Displays information about the PW (including VPWS PW and VPLS PW).
Ruijie# **show bgp l2vpn** { **vpls | vpws** } **all connections** [**neighbor** *address*] | [**interface** *interface_name*] | [**site-id** *id*] [**detail**]	Displays PW information.
Ruijie# **show mpls vfi** [*name*]	Displays all the configured or specified VFI information.

Examples of Maintaining PW Connectivity of VPWS

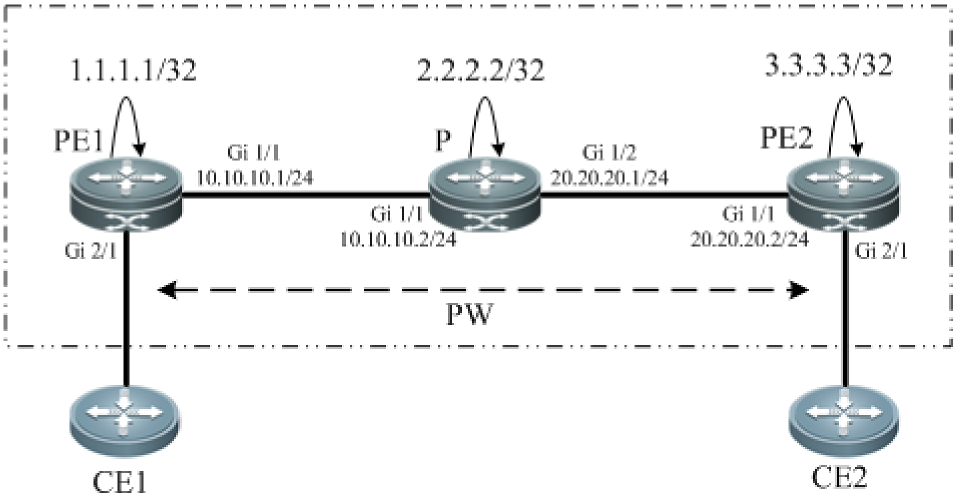
Verifying PW Connectivity and Fault of Martini VPWS

Networking Requirements

- The CE devices play the role of the customer network to connect to the PE devices via the AC.
- PE1 and PE2 establish a PW between them via LDP.
- PE1, P, and PE2 set up the public tunnel and LSP path via LDP.

Network Topology

Figure 33



Configuration Key Points

The configuration key points for PE1, P, and PE2 are as follows:

- Configure the IP address of the interface of each device and configure the Open Shortest Path First (OSPF) protocol.
- Configure the global MPLS capability and the interface MPLS capability of each device.
- Configure LDP to enable the network to forward MPLS traffic.
- Configure PWE3.
- Check the PW connectivity.
- Locate the PW fault.

Configuration Steps

(1) Configure the IP address of the interface of each node and configure the OSPF protocol.

#Configure PE1.

```
Ruijie(config)#interface loopback 0
Ruijie(config-if-Loopback 0)#ip address 1.1.1.1 255.255.255.255
Ruijie(config-if-Loopback 0)#exit
PE1 config-if-GigabitEthernet 1/1)#
Ruijie(config-if-GigabitEthernet 1/1)#ip address 10.10.10.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)#exit
Ruijie(config)#router ospf 10
Ruijie(config-router)#network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)#network 10.10.10.0 0.0.0.255 area 0
```

Ruijie(config-router)#exit#Configure P.

```
Ruijie(config)#interface loopback 0
Ruijie(config-if-Loopback 0)#ip address 2.2.2.2 255.255.255.255
Ruijie(config-if-Loopback 0)#exit
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#ip address 10.10.10.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)#exit
Ruijie(config)#interface gigabitEthernet 1/2
Ruijie(config-if-GigabitEthernet 1/2)#ip address 20.20.20.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/2)#exit
Ruijie(config)#router ospf 10
Ruijie(config-router)#network 2.2.2.2 0.0.0.0 area 0
Ruijie(config-router)#network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)#network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)#exit
```

#Configure PE2.

```
Ruijie(config)#interface loopback 0
Ruijie(config-if-Loopback 0)#ip address 3.3.3.3 255.255.255.255
Ruijie(config-if-Loopback 0)#exit
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#ip address 20.20.20.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)#exit
Ruijie(config)#router ospf 10
Ruijie(config-router)#network 3.3.3.3 0.0.0.0 area 0
Ruijie(config-router)#network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)#exit
```

(2) Configure the global MPLS capability and the interface MPLS capability of each node and enable the LDP function on the interfaces.

#Configure PE1.

```
Ruijie(config)#mpls ip
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)#neighbor 3.3.3.3.
Ruijie(config-mpls-router)#exit
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#mpls ip
Ruijie(config-if-GigabitEthernet 1/1)#label-switching
Ruijie(config-if-GigabitEthernet 1/1)#exit
```

#Configure P.

```
Ruijie(config)#mpls ip
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)#exit
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#mpls ip
Ruijie(config-if-GigabitEthernet 1/1)#label-switching
Ruijie(config-if-GigabitEthernet 1/1)#exit
Ruijie(config)#interface gigabitethernet 1/2
Ruijie(config-if-GigabitEthernet 1/2)#mpls ip
Ruijie(config-if-GigabitEthernet 1/2)#label-switching
Ruijie(config-if-GigabitEthernet 1/2)#exit
```

#Configure PE2.

```
Ruijie(config)#mpls ip
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)#neighbor 1.1.1.1
Ruijie(config-mpls-router)#exit
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#mpls ip
Ruijie(config-if-GigabitEthernet 1/1)#label-switching
Ruijie(config-if-GigabitEthernet 1/1)#exit
```

(3) Configure VPWS instances between PE1 and PE2 and enable CE1 and CE2 to access the VPWS.

#Configure PE1.

```
Ruijie(config)#interface gigabitethernet 2/1
Ruijie(config-if-Gigabitethernet 2/1)#xconnect 3.3.3.3 100  encapsulation mpls ethernet
Ruijie(config-if-Gigabitethernet 2/1)#exit
```

#Configure PE2.

```
Ruijie(config)#interface gigabitethernet 2/1
Ruijie(config-if-Gigabitethernet 2/1)#xconnect 1.1.1.1 100  encapsulation mpls ethernet
Ruijie(config-if-Gigabitethernet 2/1)#exit
```

(4) Verify the PW connectivity.

```
Ruijie#ping mpls pseudowire 3.3.3.3 100 label-alert
Sending 5, 112-byte MPLS Echoes on Pseudowire, peer address 3.3.3.3, VC ID 100,
    timeout is 2 seconds, send interval is 0 msec:

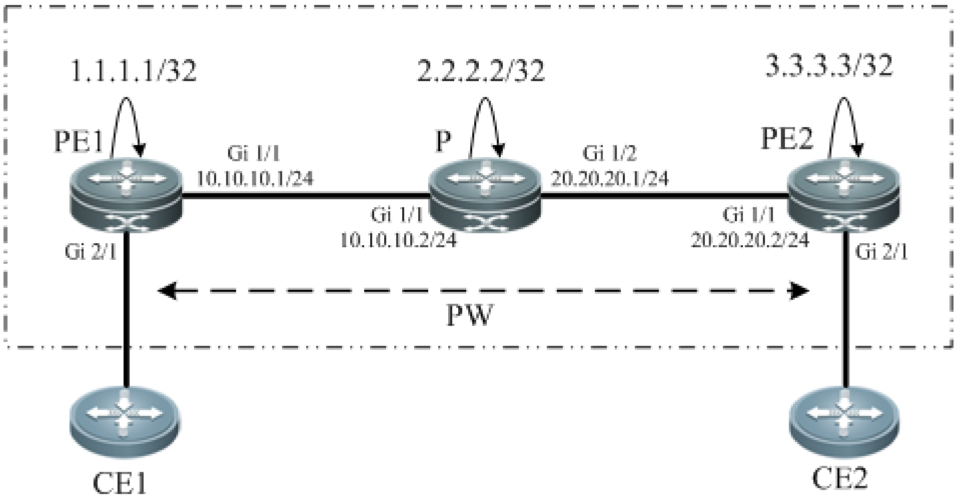
Verifying PW Connectivity of Kompella VPWS

Networking Requirements

As shown in Figure 3-25, PE1, P, and PE2 belong to the same MPLS domain, and CE1 and CE2 belong to the same VPN instance. PE1 and PE2 establish a PW between them and use the ping or traceroute command to check the PW connectivity to ensure services on the links.

Network Topology

Figure 34



Configuration Key Points

The configuration key points for each node are as follows:

(1). Configure the IP address of the interface of each node and configure the OSPF protocol.

(2). Configure the global MPLS capability and the interface MPLS capability of each node.

(3). Enable the L2VPN on PE1 and PE2 and create a VC connection.

(4). Check the PW connectivity.

(5). Locate the PW fault.

Configuration Steps

(1) Configure the IP address of the interface of each node and configure the OSPF protocol.

#Configure PE1.

```
Ruijie(config)#interface loopback 0
Ruijie(config-if-Loopback 0)#ip address 1.1.1.1 255.255.255.255
Ruijie(config-if-Loopback 0)#exit
Ruijie(config-if-GigabitEthernet 1/1)#ip address 10.10.10.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)#exit
Ruijie(config)#router ospf 10
Ruijie(config-router)#network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)#network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)#exit
```

#Configure P.

```
Ruijie(config)#interface loopback 0
Ruijie(config-if-Loopback 0)#ip address 2.2.2.2 255.255.255.255
Ruijie(config-if-Loopback 0)#exit
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#ip address 10.10.10.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)#exit
Ruijie(config)#interface gigabitEthernet 1/2
Ruijie(config-if-GigabitEthernet 1/2)#ip address 20.20.20.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/2)#exit
Ruijie(config)#router ospf 10
Ruijie(config-router)#network 2.2.2.2 0.0.0.0 area 0
Ruijie(config-router)#network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)#network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)#exit
```

#Configure PE2.

```
Ruijie(config)#interface loopback 0
Ruijie(config-if-Loopback 0)#ip address 3.3.3.3 255.255.255.255
Ruijie(config-if-Loopback 0)#exit
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#ip address 20.20.20.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)#exit
Ruijie(config)#router ospf 10
Ruijie(config-router)#network 3.3.3.3 0.0.0.0 area 0
Ruijie(config-router)#network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)#exit
```

(2) Configure the global MPLS capability and the interface MPLS capability of each node and enable the LDP function on the interfaces.

#Configure PE1.

```
Ruijie(config)#mpls ip
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)#exit
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#mpls ip
Ruijie(config-if-GigabitEthernet 1/1)#label-switching
Ruijie(config-if-GigabitEthernet 1/1)#exit
```

#Configure P.

```
Ruijie(config)#mpls ip
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)#exit
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#mpls ip
Ruijie(config-if-GigabitEthernet 1/1)#label-switching
Ruijie(config-if-GigabitEthernet 1/1)#exit
Ruijie(config)#interface gigabitEthernet 1/2
Ruijie(config-if-GigabitEthernet 1/2)#mpls ip
Ruijie(config-if-GigabitEthernet 1/2)#label-switching
Ruijie(config-if-GigabitEthernet 1/2)#exit
```

#Configure PE2.

```
Ruijie(config)#mpls ip
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)#exit
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#mpls ip
Ruijie(config-if-GigabitEthernet 1/1)#label-switching
Ruijie(config-if-GigabitEthernet 1/1)#exit
```

(3) Configure a L2VPN address family.

#Configure PE1.

```
Ruijie(config)#router bgp 100
Ruijie(config-router)#neighbor 3.3.3.3 remote-as 100
Ruijie(config-router)#neighbor 3.3.3.3 update-source loopback 0
Ruiije(config-router)#address-family l2vpn vpws
Ruijie(config-router-af)#neighbor 3.3.3.3 activate
Ruijie(config-router-af)#neighbor 3.3.3.3 send-community extended
Ruijie(config-router-af)#exit
```

#Configure PE2.

```
Ruijie(config)#router bgp 100
Ruijie(config-router)#neighbor 1.1.1.1 remote-as 100
Ruijie(config-router)#neighbor 1.1.1.1 update-source loopback 0
Ruiije(config-router)#address-family l2vpn vpws
Ruijie(config-router-af)#neighbor 1.1.1.1 activate
Ruijie(config-router-af)#neighbor 1.1.1.1 send-community extended
Ruijie(config-router-af)#exit
```

(4) Configure a VFI instance.

#Configure PE1.

```
Ruijie(config)#l2 vfi vpws-1 vpnid 1 point-to-point
Ruijie(config-vfi)#rd 1:1
Ruijie(config-vfi)#encapsulation mpls ethernet

VPLS

Introduction to VPLS

The Virtual Private LAN Service (VPLS) is a technology that provides virtual and dedicated Ethernet services on an IP/MPLS network. By using VPLS, you can set up PWs in full mesh mode between PEs to forward encapsulated Layer 2 Ethernet frames between the PEs on the MPLS network. In this manner, you can create a P2MP Ethernet VPN. With a VPLS VPN, the user Layer 2 devices are connected to each other across the IP/MPLS core network and the core network is like a virtual switch for the user.

Compared with VPWS, VPLS can provide P2MP solutions. Compared with L3VPN, VPLS has the advantages of L2VPN to provide better network scalability and maintenance.

The terms used in this document are as follows:

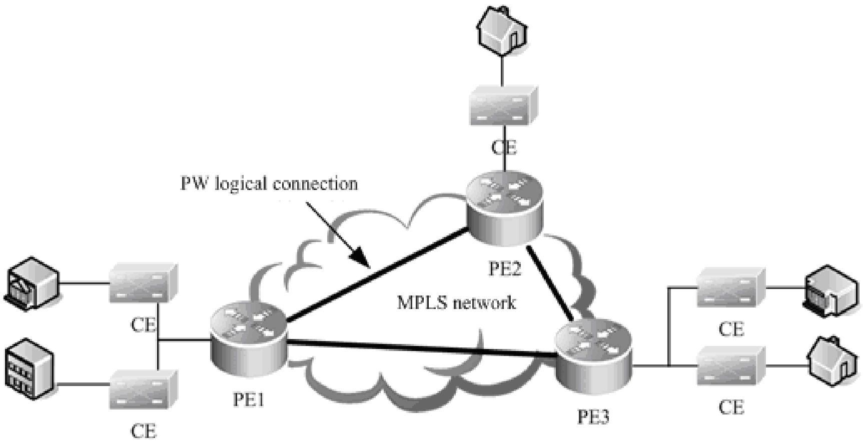
- PW: Pseudo Wire
- VPLS: Virtual Private LAN Service
- H-VPLS: Hierarchical VPLS
- MTU: Multi-Tenant Unit indicates corporate users at office buildings and business districts.
- As small edge devices at gathering places, the MTU is responsible for accessing corporate customers and aggregating users who require VPLS services to a PE through VCs.
- Spoke Connection: indicates the connection of a U-PE to an N-PE in H-VPLS. You can use a PW or QinQ.
- Spoke PW: indicates the Spoke connection between an N-PE and a U-PE when a PW is adopted, or the PW between a CE and PE when a user accesses the CE through PWs.

VPLS Network Structure

Basic VPLS

The following figure shows a typical VPLS model.

Figure 69



As shown in the VPLS networking in the preceding figure, PW logical connections are set up between PEs and the CEs are connected to the PEs enabled with VPLS. These VPLS PEs form P2MP services for the CEs. In this manner, the PEs are like a Layer 2 switch for the CEs to connect to.

The VPLS model in the dual-IGP instance has the following defects:

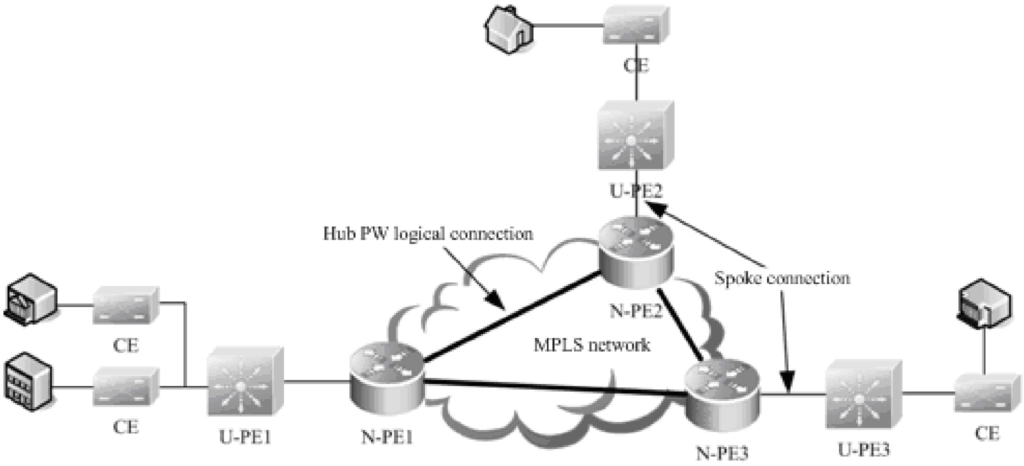
- Packets forwarded on the PWs between PEs are horizontally partitioned to avoid loops. That is, the packets received from a Hub PW are not forwarded to the Hub PW. Therefore, PWs must be set up between every two PEs. This incurs large system overheads and is not applicable to networks of large scales.
- The broadcast and multicast packets must be replicated at every PW, leading to low efficiency.

To address these problems, the hierarchical VPLS is introduced.

Hierarchical VPLS

The following figure shows a typical hierarchical VPLS (H-VPLS) model.

Figure 70



H-VPLS classifies the VPLS network into layers and sets up Hub PWs only between N-PEs on the core network. This addresses the problems on a common VPLS network. The Spoke connections between U-PEs and N-PEs are formed through PWs or QinQ tunnels. The U-PE can support VPWS or QinQ and is not required to support VPLS.

Using H-VPLS can reduce the burden on the VPLS core devices, decrease the overheads of the signaling protocol, reduce the number of packets that are replicated, and greatly strengthen the scalability of the VPLS network.

VPLS Signaling Protocol

VPLSs can be divided into Martini and Kompella VPLSs according to different VPLS signaling protocols. These two types of signaling are defined respectively in RFC4762 and RFC4761 of IETF. The Martini VPLS is based on the LDP signaling protocol and Kompella VPLS is based on the BGP signaling protocol. Given the BGP protocol's characteristics, such as the route reflector's characteristics, the Kompella VPLS can reduce the full inter-connection of BGP sessions, therefore facilitating the expansion of capacity. The Martini VPLS applies to small-sized and simple environment deployment.

VPLS Inter-AS

Both Martini and Kompella VPLSs can be inter-AS through Option A solution. In the inter-AS VPLS networking environment, the type of link between ASBRs must be the same as the type of VC. A sub-interface must be prepared for each inter-AS VC on ASBR. This solution can be adopted when the number of inter-AS VCs is small.

Option C is another solution to realize inter-AS VPLS. The SP network device only needs external tunnels on PEs in different ASs. ASBR does not maintain inter-AS VPLS information and does not need to prepare an interface for the inter-AS VPLS. VSI information of the VPLS can only be exchanged between PEs, reducing resource consumption without adding configuration tasks. The solution applies when the number of inter-AS VPLSs is large.

Configuring Martini VPLS

Configuring a Public Tunnel Between PEs

You must set up an LSP on the public network to carry VPLS services. To run MPLS on the backbone network, you must enable LDP on Ps and PEs at the same time to set up a public tunnel. This means that you have to configure LDP on MPLS devices and enable MPLS forwarding on each interface. The configuration procedure is as follows:

Command	**Function**
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **mpls ip**	Enables MPLS globally. ⚠ Caution This command is not applicable to switch chip forwarding.
Ruijie(config)# **mpls router ldp**	Enables LDP and enters LDP configuration mode.
Ruijie(config-mpls-router)# **ldp router-id interface loopback** *id* [**force**]	Configures the LDP router ID. The IP address of the loopback interface is generally used as the router ID.
Ruijie(config-mpls-router)# **exit**	Exits LDP configuration mode.
Ruijie(config)# **interface** *type ID*	Enters public network interface configuration mode.
Ruijie(config-if-*type ID*)# **label-switching**	Enables MPLS on the interface at the public network side.
Ruijie(config-if-*type ID*)# **mpls ip**	Enables LDP and MPLS forwarding for the interface.

Ruijie(config-if-type ID)# **ip ref**	The interface's fast forwarding function must be enabled for routers.
Ruijie(config-if-type ID)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves the configuration.

Caution

LDP is a topology-driven protocol. To ensure normal working of the LDP, enable IPv4 routing protocols and ensure their normal operations.

Configuring Remote LDP Peers

A PW is set up and maintained by the extended LDP. If other LSRs exist between two PEs, use the extended LDP discovery mechanism to set up a remote LDP session between the PEs and assign PW labels in the session. The procedures for configuring a remote LDP peer and setting up a remote LDP session are as follows:

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **mpls router ldp**	Enables LDP and enters LDP configuration mode.
Ruijie(config-mpls-router)# **neighbor** *ip_address*	Configures remote LDP peers.
Ruijie(config-mpls-router)# **exit**	Exits LDP configuration mode.
Ruijie(config)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves the configuration.

Caution

The PW label messages of the LDP are not affected by the LDP label distribution mode or label retention mode. The LDP is forced to work in DU and liberal label retention mode.

Martini VPLS Configuration Example

The **l2 vfi** command is used to create a VPLS instance and enter VPLS mode. The **no l2 vfi** command is used to delete a VPLS instance. When creating a VPLS instance, you must specify a name that is unique on the local device and specify a unique VPN ID. Each VPLS name corresponds to a VPN ID.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **l2 vfi** *vpls-name* **vpnid** *vpn-id*	Creates a VPLS instance and enters VPLS configuration mode.
Ruijie(config-vfi)# **neighbor** *ip-address* **encapsulation mpls** [**vc-id** *vc-id*] [**hub-vc** | **spoke-vc**] [**ethernet** | **ethernetvlan**]	Configures a VPLS peer. The default PW type is Ethernet. We recommend using the PW type for access interface access and VLAN tunnel interface access on switches and Ethernet interface access on routers. ☑ We recommend setting the PW type as Ethernet VLAN if switchers use Trunk interface access or routers use sub-interface access VPLS service.

Ruijie(config-vpls)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves the configuration.

⚠ Caution

The VPLS peer must be unique in the VPLS instance scope. To facilitate management, you must configure VPLS instances of one VPN with the same ID.

A PW's key is the PW ID and the VPLS peer's LSR ID. It must be unique globally, including VPWS PW.

Each configuration of the same peer by using the **neighbor** command will cover the previous one.

The **mtu** parameter and PW type of interfaces on two ends of a PW must be the same. The default PW type of the VPLS is Ethernet. PW IDs on two ends of PEs(that is, the VC IDs) must be the same.

When using the **neighbor** command to specify the address of the VC's peer neighbor, you must use the peer router ID as the peer address and the 32-bit address of the loopback interface as the peer router ID.

☑ For switches, DHCP packets cannot be transmitted transparently after **ip dhcp snooping** is enabled globally.

Configuring User Access VPLS

☑ For switches, each VPLS can bind only one interface. For routers, multiple interfaces can be bound.

Configuring VPLS access mode for switches

A VPLS instance takes effect only after the user of the VPLS instance accesses the VPLS. At present, there are three modes of user access VPLS services:

☑ For switches, a VPLS can bind only one SVI interface because VPLS is supported only by the SVI interface.

⚠ Caution

When the port protection mode is enabled on the AC-end member port of a L2VPN, the port protection mode does not take effect on the member port if the corresponding member port is not a trunk interface.

- VLAN access interface access

The VLAN access interface is applicable to the transmission of user packets that are not encapsulated through 802.1Q (that is, packets without VLAN tags) on VPLS ACs.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters interface mode of the specified physical interface.
Ruijie(config-if-*type ID*)# **switchport mode access**	Enables the interface to work in access mode.
Ruijie(config-if-*type ID*)# **switchport access** *vlan-id*	Sets the interface as a VLAN member interface.
Ruijie(config-if-*type ID*)# **exit**	Exits interface configuration mode.
Ruijie(config)# **interface vlan** *vlan-id*	Enters VLAN interface mode.
Ruijie(config-if-*type ID*)# **xconnect vfi** *vpls-name*	Binds the VLAN to a VPLS instance.
Ruijie(config-if-*type ID*)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves the configuration.

Caution

For the access interface access mode, we recommend setting the PW type to **ethernet**, and the two ends of PW must be set in the same type.

- VLAN trunk interface access

The VLAN trunk interface access is applicable to the transmission of multiple VPLS services on the same physical AC. Each VLAN corresponds to a VPLS instance. The PE determines the VPLS instance for user packets based on their VLAN tags to provide the multiplexing of access interfaces.

Command	**Function**
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters interface mode of the specified physical interface.
Ruijie(config-if-*type ID*)# **switchport mode trunk**	Enables the interface to work in trunk mode.
Ruijie(config-if-*type ID)#* **switchport trunk allow vlan** *vlan-list*	Enables the trunk link to allow VLAN traffic.
Ruijie(config-if-*type ID*)# **exit**	Exits interface configuration mode.
Ruijie(config)# **interface vlan** *vlan-id*	Enters VLAN interface mode.
Ruijie(config-if-*type ID*)# **xconnect vfi** *vpls-name*	Binds the VLAN to a VPLS instance.
Ruijie(config-if-*type ID*)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves the configuration.

Caution

For the Trunk interface access mode, we recommend setting the PW type as **ethernetvlan**, and the two ends of PW must be set in the same type.

The L2 VPN service cannot be bound to the Native VLAN of the Trunk interface.

- VLAN tunnel interface access

The VLAN tunnel interface access is applicable to the transmission of user service packets that carry private VLAN tags on the ACs when a user accesses VPLS services. In this mode, the PE forwards all packets received from the VLAN tunnel interface without any changes. This mode requires the VLAN member interfaces between PEs and CEs to work in tunnel mode.

Command	**Function**
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters interface mode of the specified physical interface.
Ruijie(config-if-*type ID*)# **switchport access** *vlan-id*	Sets the interface as a VLAN member interface.
Ruijie(config-if-*type ID*)# **switchport mode dot1q-tunnel**	Enables the interface to work in tunnel mode.
Ruijie(config-if-*type ID*)# **exit**	Exits interface configuration mode.
Ruijie(config)# **interface vlan** *vlan-id*	Enters VLAN interface mode.
Ruijie(config-if-*type ID*)# **xconnect vfi** *vpls-name*	Binds the VLAN to a VPLS instance.
Ruijie(config-if-*type ID*)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves the configuration.

Caution

For the VLAN tunnel interface access mode, we recommend setting the PW type as **Ethernet,** and the two ends of PW must be set in the same type.

For the VLAN tunnel interface access mode, only the basic QinQ is supported.

- PW access

The PW access is applicable to user access networks that are enabled with MPLS. In addition, the user is not directly connected to any VPLS PE link. In the H-VPLS model, the PW access mode can be used to access the N-PE if the U-PE has no bridging capability so that the VPLS access service can be provided on the U-PE for the user.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **l2 vfi** *name*	Enters VPLS configuration mode.
Ruijie(config-vpls)# **neighbor** *ip-address* **encapsulation mpls** [vc-id *vc-id*] **spoke-vc** [**ethernet** | **ethernetvlan**]	Configures a PW for user access.
Ruijie(config-vpls)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves the configuration.

For one VPLS instance, you can configure multiple PWs for user access.

Caution

When accessing VPLS services through PWs, you must specify the **spoke-vc** keyword in the **neighbor** command to configure PWs, enable the **label-switching** command on the Spoke PW access interface, and enable fast forwarding for routers.

Configuring VPLS access mode for routers

A created VPLS instance takes effect only after the user configured with the VPLS instance is connected with the link.

- Ethernet interface access

This mode applies when the user service packets transmitted on ACs carry private VLAN tags or do not carry VLAN tags in the case of VPLS service access. In this mode, all packets received by PEs from the interface are forwarded according to the destination MAC address and the private tags are considered part of the data. In such case, PEs provide port-based VPLS service. The address learning mode of the VPLS instance of the bound port is the free mode. MAC address overlapping in the user VLAN is not supported.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters the specified physical interface.
Ruijie(config-if-type ID)# **ip ref**	The interface's fast forwarding function must be enabled for routers.
Ruijie(config-if-*type ID*)# **xconnect vfi** *vpls-name*	Binds VLAN to the VPLS instance.
Ruijie(config-if-*type ID*)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves configuration.

Caution

For the VPLS service of the Ethernet interface access mode, we recommend setting the PW type to **ethernet**, and both ends of the PW in the same PW type.

The same VPLS instance can be bound to different interfaces to realize local connection.

If a VPLS instance is configured on different PEs with Ethernet interface and sub-interface access modes, we recommend setting all PWs of the VPLS instance to the **ethernetvlan** type.

- Sub-interface access

This mode applies when multiple VPLS services are transmitted on a physical AC. Each sub-interface corresponds to a VPLS instance. PE devices can match packets with VPLS instances according to VLAN tags carried by the user packets to provide the multiplexing of access interfaces.

Command	**Function**
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters the specified physical interface.
Ruijie(config-if-*type ID*)# **encapsulation dot1Q**	Sets the VIP encapsulated by the sub-interface.
Ruijie(config-if-type ID)# **ip ref**	The interface's fast forwarding function must be enabled for routers.
Ruijie(config-if-*type ID*)# **xconnect vfi** *vpls-name*	Binds VLAN to the VPLS instance.
Ruijie(config-if-*type ID*)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves configuration.

Caution

If a VPLS instance is used to transmit flows of multiple VLANs of the user, MAC address overlapping between VLANs of the user is not supported.

The same VPLS instance can be bound to different interfaces to realize local connection.

For the VPLS service of the sub-interface access mode, we recommend setting the PW type to **ethernetvlan**, and both ends of the PW in the same PW type.

- PW access

This mode applies when the user's access network is the MPLS network and no direct link is set up between the user and VPLS PEs. In the H-VPLS model, the PW access mode can be used to access the N-PE when the U-PE has no bridging capability so that the VPLS access service can be provided on the U-PE for the user.

Command	**Function**
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **l2 vfi** *name*	Enters VPLS configuration mode.
Ruijie(config-vfi)# **neighbor** *ip-address* **encapsulation mpls** [**vc-id** *vc-id*] **spoke-vc** [**ethernet | ethernetvlan**]	Configures the PW to be accessed by user.
Ruijie(config-vfi)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves configuration.

Caution

One VPLS instance can be configured with multiple PWs for user access.

When accessing VPLS services through PWs, you must specify the **spoke-vc** keyword in the **neighbor** command to configure PWs.

☑ For routers, the **label-switching** and **ip ref** commands must be enabled on the interface where Spoke PW is located.

Caution

If the Ethernet access mode is adopted, the PW type must be **ethernet**. If the Ethernet sub-interface access mode is adopted, the PW type must be **ethernetvlan**.

Verifying Martini VPLS Configuration

After completing the configuration of the VPLS, use the following commands to check the operation of VPLS.

Command	Function
Ruijie# **show mpls vfi**	Displays VPLS information.
Ruijie# **show mpls l2transport vc** [[*vc_id* [*ip-address*]] | [**interface** *interface-name*]] [**detail**]	Displays information about the PW (including VPWS PW and VPLS PW).
Ruijie# **show ip ref mpls forwarding-table vfi** [*vpls_name*] [**mac-address-table** [*H.H.H*] [**statistics**]	Displays all MAC addresses under the VPLS instance including static MAC addresses learned from PWs and ACs and configured by the user, and statistics of VPLS forwarding.
Ruijie# **show mpls forwarding-table**	Displays PW-related ILM and FTN forwarding table entries.
Ruijie# **show mpls ldp neighbor**	Displays all LDP neighbor information.
Ruijie# **show mpls ldp vc**	Displays all LDP VC information.

Configuring Kompella VPLS

Configuring the Public Network Tunnel Between PEs

You must set up an LSP tunnel must be set up on the public network to provide VPLS services. To run MPLS on the backbone network, you must enable LDP on Ps and PEs to establish a public network tunnel. This means that you have to configure LDP for MPLS devices and enable MPLS forwarding on each interface. The configuration procedure is as follows:

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie# **mpls ip**	Enables MPLS forwarding globally. Caution This command is not applicable to switch chip forwarding.
Ruijie(config)# **mpls router ldp**	Enables LDP and enters LDP configuration mode.

Command	Function
Ruijie(config-mpls-router)# **ldp router-id interface loopback** *id* [**force**]	Configures LDP's router ID, which is usually the IP address of the loopback interface.
Ruijie(config-mpls-router)# **exit**	Exits the LDP configuration mode.
Ruijie(config)# **interface** *type ID*	Enters public network interface configuration mode.
Ruijie(config-if-*type ID*)# **label-switching**	Enables the interface's MPLS forwarding function.
Ruijie(config-if-*type ID*)# **mpls ip**	Enables the interface's LDP function and MPLS forwarding function.
Ruijie(config-if-*type ID*)# **ip ref**	Enables the fast forwarding function for routers.
Ruijie(config-if-type ID)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves configuration.

# Configure the public network tunnel between PEs.

```
Ruijie# configure terminal
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0 force
Ruijie(config-mpls-router)# exit
Ruijie(config)# interface gigabitethernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)# label-switching
Ruijie(config-if-GigabitEthernet 1/1)# mpls ip
Ruijie(config-if-GigabitEthernet 1/1)# end
Ruijie# copy running-config startup-config
```

Caution

LDP is a topology-driven protocol. To ensure normal working of the LDP, enable IPv4 routing protocols and ensure their normal operations.

Configuring L2VPN VPLS Address Family

Kompella VPLS uses MP-BGP4 as signaling and auto-discovery mechanism. PE devices in one VPLS instance must exchange VPLS information through the L2VPN address family. By default, the L2VPN VPLS address family is not supported. The procedure for enabling the L2VPN address family is as follows:

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *asn-num*	Creates the BGP and enters BGP configuration mode.
Ruijie(config)# **neighbor** *peer-address* **remote-as** *asn-number*	Sets up an IBGP session.
Ruijie(config)# **neighbor** *peer-adddress* **update-source** **i***nterface-name*	Enables the IBGP session to use the address of the loopback interface as the session's source address.
Ruiije(config-router)# **address-family l2vpn vpls**	Enters the L2VPN VPLS address family.

Command	Function
Ruijie(config-router-af)# **neighbor** *ip-address* **activate**	Activates switching of VPLS information on the BGP session.
Ruijie(config-router-af)# **neighbor** { *ip-address* | *peer-group-name* } **send-community** [**both | standard | extended**]	Specifies the extended community attribute to be sent to BGP neighbors.
Ruijie(config-router-af)# **end**	Returns from address family configuration mode to privileged mode.
Ruijie# **show bgp l2vpn vpls** { **all** [**id:offset | neighbor ip-address | summary**] }	Displays L2VPN VPLS address family information.

# Configure the L2VPN address family and enable VPLS information switching.

```
Ruijie# configure terminal
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 10.10.10.1 remote-as 100
Ruijie(config-router)# neighbor 10.10.10.1 update-source loopback 0
Ruiije(config-router)# address-family l2vpn vpls
Ruijie(config-router-af)# neighbor 10.10.10.1 activate
Ruijie(config-router-af)# neighbor 10.10.10.1 send-community extended
Ruijie(config-router-af)# end
Ruijie# show bgp l2vpn vpls all
```

Configuring Kompella VPLS instance

The **l2 vfi** command can be used to create Kompella VPLS instances or enter Kompella VPLS configuration mode. The **no l2 vfi** command can be used to delete VPLS instances. The unique local VPLS instance name and the unique local device VPN ID must be specified when the instance is being created. The auto-discovery function must be enabled for the specified VPLS instance. Each VPLS name corresponds to a VPN ID. In auto-discovery mode, BGP is the default signaling.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **l2 vfi** *vpls-name* **vpnid** *vpn-id* **autodiscovery**	Creates the Kompella VPLS instance and enters VPLS configuration mode.
Ruijie(config-vfi)# **signal bgp**	Configures the VPLS instance signaling, which is BGP by default.
Ruijie(config-vfi)# **rd** *rd_value*	Configures the RD value. Configure the RD first.
Ruijie(config-vfi)# **encapsulation mpls** [**ethernet | ethernetvlan**]	Specifies the encapsulation mode of Kompella VPLS PWs, which is Ethernet (that is, raw mode) by default. If the sub-interface VPLS access mode is adopted, we recommend the **ethernetvlan** encapsulation mode (that is, tag mode).
Ruijie(config-vfi)# **route-target** { **import | export | both** } *rt_value*	Configures RTs. Multiple RTs can be configured.

Command	Function
Ruijie(config-vfi)# **site-id** *id* [**site-range** *size*]	Configures VE IDs of VPLS sites and the site range. If the site range is not configured, the default value 16 will be adopted.
Ruijie(config-vfi-site)# **xconnect interface** *interface-id*	Configures the interface bound by the site.
Ruijie(config-vfi-site)# **end**	Exits site configuration mode.
Ruijie# **copy running-config startup-config**	Saves configuration.

# Configure a Kompella VPLS instance.

```
Ruijie#configure terminal
Ruijie(config)# l2 vfi vpls-1 vpnid 1 autodiscovery
Ruijie(config-vfi)# signal bgp
Ruijie(config-vfi)# encapsulation mpls ethernet
Ruijie(config-vfi)# rd 100:1
Ruijie(config-vfi)# route-target both 4500:2
Ruijie(config-vfi)# site-id 1
Ruijie(config-vfi-site)# xconnect interface gigabitethernet 1/1
Ruijie(config-vfi-site)#end
Ruijie# copy running-config startup-config
```

⚠ Caution

The **autodiscovery** keyword must be specified after the **l2 vfi** command to create a Kompella VPLS instance.

The auto-discovery between PEs in a VPLS instance is based on MP-BGP. To configure the Kompella VPLS, specify the VPLS PW signaling protocol as BGP.

VPLS instances of one VPN must be configured with the same ID to facilitate management.

PEs on one VPLS must be configured with the same VPLS PW encapsulation mode. Otherwise, VPLS packets cannot be forwarded. Assuming that a VPLS-X exists, if the VPLS-X encapsulation mode on PE1 is **ethernet** (that is, raw mode), the VPLS encapsulation mode on PE2 must not be **ethernetvlan** (that is, tag mode).

☑ For switches, DHCP packets cannot be transmitted transparently after **ip dhcp snooping** is enabled globally.

Configuring User Access VPLS

Configuring VPLS Access Mode for Switches

A created VPLS instance takes effect only after the user configured with the VPLS instance is connected to the link. Currently, there are the following three ways for switch users to access VPLS services:

☑ For switches, a VPLS instance can bind only one SVI interface because VPLS is supported only by the SVI interface.

⚠ Caution

When the port protection mode is enabled on the AC-end member port of L2VPN, the port protection mode does not take effect on the member port if the corresponding member port is not a Trunk interface.

- VLAN access interface access

This mode applies when user packets transmitted on the VPLS AC are not encapsulated by 802.1Q (that is, the packets do not carry VLAN tags).

Command	**Function**
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters the specified physical interface.
Ruijie(config-if-*type ID*)# **switchport mode access**	Enables the interface to work in access mode.
Ruijie(config-if-*type ID*)# **switchport access** *vlan-id*	Sets the interface as a VLAN member port.
Ruijie(config-if-*type ID*)# **exit**	Exits interface configuration mode.
Ruijie(config)# **interface vlan** *vlan-id*	Enters VLAN interface mode.
Ruijie(config-if-*type ID*)# **exit**	Returns to global configuration mode.
Ruijie(config)# **l2 vfi** *vfi_name* **vpnid** *vpn_id* **autodiscovery**	Enters VFI configuration mode.
Ruijie(config-vfi)# **site-id i***d* [**site-range** *size*]	Configures site information of the VFI.
Ruijie(config-vfi-site)# **xconnect interface vlan** *id*	Configures the AC interface bound by the VPLS site.
Ruijie(config-vfi-site)# **end**	Returns to privileged configuration mode.
Ruijie# **copy running-config startup-config**	Saves configuration.

Caution

For the access interface access mode, we recommend setting the VPLS PW encapsulation mode to **ethernet** (that is, raw mode).

VLAN trunk interface access

This mode applies when multiple VPLS services are transmitted on a physical AC. Each VLAN corresponds to a VPLS instance. PE devices can match packets with VPLS instances according to VLAN tags carried by the user packets to provide the multiplexing of access interfaces.

Command	**Function**
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters the specified physical interface.
Ruijie(config-if-*type ID*)# **switchport mode trunk**	Enables the interface to work in trunk mode.
Ruijie(config-if-*type ID)#* **switchport trunk allow vlan add** *vlan-list*	Sets the VLAN flows allowed to be transmitted on the trunk link.
Ruijie(config-if-*type ID*)# **exit**	Exits interface configuration mode.
Ruijie(config)# **interface vlan** *vlan-id*	Enters VLAN interface mode.
Ruijie(config-if-*type ID*)# **exit**	Returns to global configuration mode.
Ruijie(config)# **l2 vfi** *vfi_name* **vpnid** *vpn_id* **autodiscovery**	Enters VFI configuration mode.
Ruijie(config-vfi)# **site-id** *id* [**site-range** *size*]	Configures site information of the VFI.
Ruijie(config-vfi-site)# **xconnect interface vlan** *id*	Configures the AC interface bound by the VPLS site.
Ruijie(config-vfi-site)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves configuration.

Caution

For the Trunk interface access mode, we recommend setting the VPLS PW encapsulation mode to **ethernetvlan** (that is, tag mode).

The L2 VPN service cannot be bound to the Native VLAN of the trunk interface.

- VLAN tunnel interface access

This mode applies when user service packets transmitted on ACs carry private VLAN tags if the user is connected to the VPLS service. In this mode, all packets received by PEs from the interface are forwarded without being processed. This mode requires the VLAN member port between PEs and CEs to work in tunnel mode.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters the specified physical interface.
Ruijie(config-if-*type ID*)# **switchport access** *vlan-id*	Sets the interface as a VLAN member port.
Ruijie(config-if-*type ID*)# **switchport mode dot1q-tunnel**	Enable the interface to work in tunnel mode.
Ruijie(config-if-*type ID*)# **exit**	Exits interface configuration mode.
Ruijie(config)# **interface vlan** *vlan-id*	Enters VLAN interface mode.
Ruijie(config-if-*type ID*)# **exit**	Returns to global configuration mode.
Ruijie(config)# **l2 vfi** *vfi_name* **vpnid** *vpn_id* **autodiscovery**	Enters VFI configuration mode.
Ruijie(config-vfi)# **site-id** *id* [**site-range** *size*]	Configures site information of the VFI.
Ruijie(config-vfi-site)# **xconnect interface vlan** *id*	Configures the AC interface bound by the VPLS site.
Ruijie(config-vfi-site)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves configuration.

Caution

For the VLAN tunnel interface access mode, we recommend setting the VPLS PW encapsulation mode to **ethernet** (that is, raw mode).

For the VLAN tunnel interface access mode, only the basic QinQ is supported.

Configuring VPLS Access Mode for Routers

A created VPLS instance takes effect only after the user configured with the VPLS instance is connected with the link.

There are the following two ways to access VPLS services:

- Ethernet interface access

This mode applies user service packets transmitted on ACs carry private VLAN tags or do not carry VLAN tags in the case of VPLS service access. In this mode, all packets received by PEs from the interface are forwarded according to the destination MAC address and the private tags are considered part of the data. In such case, PEs provide port-based VPLS services. The address learning mode of the VPLS instance of the bound port is the free mode. MAC address overlapping in the user VLAN is not supported.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters the specified physical interface.

Command	**Function**
Ruijie(config-if-*type ID*)# **ip ref**	Enables the fast forwarding function for routers.
Ruijie(config-if-*type ID*)# **end**	Returns to privileged mode.
Ruijie(config-if-*type ID*)# **exit**	Returns to global configuration mode.
Ruijie(config)# **l2 vfi** *vfi_name* **vpnid** *vpn_id* **autodiscovery**	Enters VFI configuration mode.
Ruijie(config-vfi)# **site-id** *id* [**site-range** *size*]	Configures site information of the VFI.
Ruijie(config-vfi-site)#**xconnect interface** *interface-id*	Configures the AC interface bound by the VPLS site.
Ruijie(config-vfi-site)#**end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves configuration.

# Configure Ethernet interface VPLS access.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/2
```

# Enable the fast forwarding function of the interface for routers.

```
Ruijie(config-if-GigabitEthernet 1/2)# ip ref
Ruijie(config-if-GigabitEthernet 1/2)# exit
Ruijie(config)# l2 vfi vfiA vpnid 1 autodiscovery
Ruijie(config-vfi)# rd 2:2
Ruijie(config-vfi)# route-target both 2:2
Ruijie(config-vfi)# encapsulation mpls ethernet
Ruijie(config-vfi)# site-id 1
Ruijie(config-vfi-site)# xconnect interface gigabitethernet 1/2
Ruijie(config-vfi-site)#end
Ruijie# copy running-config startup-config
```

Caution

For the Ethernet access mode, we recommend using the **encapsulation mpls ethernet** command to specify the Kompella VPLS PW encapsulation mode as **ethernet** (that is, raw mode). If the packets of imported PEs carry VLAN tags, the tags will be transmitted transparently as private tags.

☑ For routers, a VPLS instance can be configured with mixed access modes. For example, PEs in a VPLS instance are configured with both Ethernet and sub-interface access modes. In such case, we recommend setting the VPLS PW encapsulation mode on the PEs to **ethernetvlan** (that is, tag mode).

- Sub-interface access

PE devices can access a VPLS instance through sub-interfaces.

Command	**Function**
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters the specified physical interface.
Ruijie(config-if-*type ID*)# **ip ref**	For routers, the fast forwarding function must be enabled on the master interface of the sub-interface.
Ruijie(config-if-*type ID*)# **end**	Returns to privileged mode.
Ruijie(config-if-*type ID*)# e**xit**	Returns to global configuration mode.

Ruijie(config)# **l2 vfi** *vfi_name* **vpnid** *vpn_id* **autodiscovery**	Enters VFI configuration mode.
Ruijie(config-vfi)# **site-id** *id* [**site-range** *size*]	Configures site information of the VFI.
Ruijie(config-vfi-site)#**xconnect interface** *interface-id*	Configures the AC interface bound by the VPLS site.
Ruijie(config-vfi-site)#**end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves configuration.

# Configure sub-interface VPLS access.

```
Ruijie# configure terminal
```

# Enable the fast forwarding function of the sub-interface for routers.

```
Ruijie(config)# interface gigabitethernet 1/2
Ruijie(config-if-GigabitEthernet 1/2)# ip ref
Ruijie(config-if-GigabitEthernet 1/2)# exit
Ruijie(config)# interface gigabitethernet 1/2.10
Ruijie(config-if-GigabitEthernet 1/2.10)# encapsulation dot1Q 10
Ruijie(config-if-GigabitEthernet 1/2.10)#exit
Ruijie(config)# l2 vfi vfiA vpnid 1 autodiscovery
Ruijie(config-vfi)# rd 2:2
Ruijie(config-vfi)# route-target both 2:2
Ruijie(config-vfi)# encapsulation mpls ethernetvlan
Ruijie(config-vfi)# site-id 1
Ruijie(config-vfi-site)# xconnect interface gigabitethernet 1/2.10
Ruijie(config-vfi-site)#end
Ruijie# copy running-config startup-config
```

Caution

For the sub-interface access mode, we recommend using the **encapsulation mpls ethernetvlan** command to specify the Kompella VPLS PW encapsulation mode as **ethernetvlan** (that is, tag mode).

Configuring Kompella VPLS's Compatibility (Optional)

By default, the PW's mtu value provided by L2VPN is 1500 bytes. If the same PW's mtu values on two PEs are different, PW connection cannot be set up between the two PEs. Some manufacturers' devices do not support configuring mtu in L2VPN instances. When such devices perform Kompella communication with devices of other manufacturers, the **ingore match l2-extcommunity** command can be used to ignore received mtu and matching detection of **Control Flag**, ensuring that the VC link is UP.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **l2 vfi** *vpls-name* **vpnid** *vpn-id* **autodiscovery**	Creates the Kompella VPLS instance and enters VPLS configuration mode.
Ruijie(config-vfi)# **ingore match l2-extcommunity**	Configures ignoring detection of L2VPN expanded community attribute members.
Ruijie# **copy running-config startup-config**	Saves configuration.

Caution This command takes effect only on Kompella L2VPN.

Verifying Kompella VPLS Configuration

Command	Function
show bgp l2vpn vpls all	Displays NLRI information about all VPWS instances.
show bgp l2vpn vpls all connections	Displays all connection information of Kompella VPLS.
show mpls l2transport vc [*vc_id* [*ip-address*]] | [**interface** *interface_name*] [**detail**]	Displays VC information established by Kompella VPLS.
show mpls vfi [*name*]	Displays VPLS instance information.
Ruijie# **show ip ref mpls forwarding-table vfi** [*vpls_name*] [**mac-address-table** [*H.H.H*] **| statistics**]	Displays all MAC addresses under the VPLS instance including static MAC addresses learned from PWs and ACs and configured by the user, and statistics of VPLS forwarding.
Ruijie# **show mpls forwarding-table**	Displays PW-related ILM and FTN forwarding table entries.

Configuring Other VPLS Parameters

Configuring VPLS Instance Descriptors (Optional)

You can configure the descriptive information of each VPLS instance.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **l2 vfi** *vpls-name*	Enters VPLS configuration mode.
Ruijie(config-vfi)# **description** *vpls-description*	(Optional) Configures descriptive information of the VPLS.
Ruijie(config-vfi)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves configuration.

Configuring mtu of VPLS Instance (Optional)

You can configure each VPLS instance's mtu value, which is **1500** by default. The mtu value of VPLS indicates the length of the packet that can be transmitted by the PW, or the length of the user's layer-2 packet plus the length of the PW-encapsulated packet. By default, if the PW does not enable the control word, assuming that two labels are encapsulated, the length of an Ethernet packet that can be transmitted is 1492 bytes, of which 8 bytes are encapsulated by the PW (2 labels).

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **l2 vfi** *vpls-name*	Enters VPLS configuration mode.
Ruijie(config-vfi)# **mtu** *mtu*	(Optional) Configures the mtu value of the VPLS.
Ruijie(config-vfi)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves configuration.

Caution

The mtu values of one VPLS instance on different PEs must be the same. Otherwise, the signaling protocol cannot establish PWs.

Currently, transmission of VPLS fragments is not supported. If the PW signaling protocol negotiation's mtu is modified, the mtu of the user access service interface must be adjusted (generally adjusted to the PW mtu length minus the encapsulated length); the PW's public-network-end output interface's mtu, MPLS mtu and PW mtu must be the same to ensure proper forwarding. The **mtu** command can be used on an interface to modify the interface's mtu. Use the **mpls mtu** command to modify MPLS mtu of the interface.

Configuring VPLS Transparent Transmission Bridge Protocol Control Packet (Optional)

You can control whether the VPLS interface transparently transmits bridge protocol control packets to meet application needs.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type ID*	Enters specified interface mode.
Ruijie(config-if-*type ID*)# **l2 vfi tunnel-protocol stp**	Enables the interface to transparently transmit STP packets.
Ruijie(config-if-*type ID*)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves configuration.

Caution

Generally, BPDU packets do not carry VLAN Tag. If CEs access PEs through a trunk interface or sub-interface and the BPDU transparent transmission function is enabled on the access interface, the BPDU packets sent by CEs must carry corresponding VLAN tags so that the BPDU packets can be identified by the corresponding VPLS instances and transmitted transparently in the VPLS instances.

Configuring MAC Address Aging Time (Optional)

You can configure each VPLS instance's address aging time, which is 300 seconds by default.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **l2 vfi** *vpls-name*	Enters VPLS configuration mode.
Ruijie(config-vfi)# **mac-address aging-time** *interval*	(Optional) Configures the address aging time of the VPLS.
Ruijie(config-vfi)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves configuration.

Caution

If the aging time of MAC addresses is changed, all the MAC addresses will be aged according to the new aging time. If the aging time is set to *m*, MACs that have not performed communication will be aged after *m*. Configuring MAC Address Capacity Volume Limit (Optional)

You can configure each VPLS instance's MAC address capacity limit and behavior to be performed when the limit is exceeded.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **l2 vfi** *vpls-name*	Enters VPLS configuration mode.
Ruijie(config-vfi)# **mac-limit** { **action** { **discard | forward** } **|** **alarm** { **disable | enable** } **| maximum** *count*	(Optional) Configures each VPLS instance's MAC address capacity limit and behavior to be performed when the limit is exceeded.
Ruijie(config-vfi)# **end**	Returns to privileged mode.
Ruijie# **copy running-config startup-config**	Saves configuration.

Caution

By default, the message warning of exceeding the capacity is disabled. If it is enabled, the Log message will be displayed when the MAC capacity of the VPLS instance is exceeded for the first time. The Log message will be displayed again when the VPLS MAC capacity drops to below the limit.

Configuring Static MAC Addresses (Optional)

You can configure static MAC addresses for VPLS instances. When conflicts exist in static MAC addresses and dynamically learned ones, dynamically learned MAC addresses are overwritten.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie(config)# **mpls static vfi** *vpls-name* **mac-address** *H.H.H* **neighbor** *ip-address*	Configures MAC addresses for a VPLS instance.
Ruijie(config)# **end**	Returns to the privileged mode.
Ruijie# **copy running-config startup-config**	Saves the configuration.

Caution

Static MAC addresses configured through configuration of relate PWs of neighbor addresses can work properly only in the following scenario: The L2VPN instance has only a PW for the neighbor configured. If the L2VPN instance is configured with multiple PWs for the neighbor, the configured static MAC address will bind with a PW randomly, leading to incorrect forwarding.

Clearing Dynamic MAC Addresses (Optional)

A VPLS instance can dynamically learn MAC addresses from ACs and PWs. You can clear the MAC addresses learned dynamically by VPLS instances, including the local and remote VPLS instances.

Command	Function
Ruijie# **config terminal**	Enters global configuration mode.
Ruijie# **clear l2 vfi** *vpls-name* mac-**address local**	Clears the MAC addresses learned dynamically by the local (local PE) VPLS instance.
Ruijie# **clear l2 vfi** *vpls-name* mac-address **remote**	Clears the MAC addresses learned dynamically by the remote (another PE) VPLS instance.

Caution

Clearing MAC addresses of remote PEs is effective for Martini VPLS only.

Applying Tunnel Policy (Optional)

Configuring Tunnel Policy

For details, see Section 3.2.2.6.

Applying Tunnel Policy to Martini VPLS

Command	Function
Ruijie# **config terminal**	Enters the global configuration mode.
Ruijie(config)# **l2 vfi** *vpls-name* **vpnid** *vpn-id*	Creates a VPLS instance and enters the VPLS configuration mode.
Ruijie(config-vfi)# **neighbor** *ip-address* **encapsulation mpls** [**vc-id** *vc-id*] [**hub-vc** | **spoke-vc**] [**ethernet** | **ethernetvlan**] [**tnl-policy** *policy-name*]	Configures a VPLS peer and applies the tunnel policy.

#Example: Apply the tunnel policy to the Martini VPLS.

```
Ruijie# configure terminal
Ruijie(config)# l2 vfi vpls-1 vpnid 1
Ruijie(config-vfi)# neighbor 2.2.2.2 encapsulation mpls vc-id 1 tnl-policy pol
Ruijie(config-vfi)# exit
```

Applying Tunnel Policy to Kompella VPLS

Command	Function
Ruijie# **config terminal**	Enters the global configuration mode.
Ruijie(config)# **l2 vfi** *vpls-name* **vpnid** *vpn-id* **autodiscovery**	Creates a Kompella VPLS instance and enters the VPLS configuration mode.
Ruijie(config-vfi)# **neighbor** *peer-address* **tnl-policy** *policy-name*	Applies the tunnel policy to the VFI.

#Example: Apply the tunnel policy to the Kompella VPLS.

```
Ruijie# configure terminal
Ruijie(config)# l2 vfi vpls-2 vpnid 2 autodiscovery
Ruijie(config-vfi)# rd 2:2
Ruijie(config-vfi)# neighbor 2.2.2.2 tnl-policy pol
Ruijie(config-vfi)# exit
```

Configuring PW Class (Optional)

Configure the PW class instance to be referenced by the VPLS. Use the **pw-class** command to create a PW template instance and enter the PW template instance. Use the **no** form of this command to delete the PW template instance. You must specify a locally unique name for the PW template instance when you create it.

Command	Function
Ruijie# **configure terminal**	Enters the global configuration mode.
Ruijie(config)#**pw-class** *pwc1*	Creates a PW class instance and enters the PW class configuration mode.
Ruijie(config-pw-class)#**backup neighbor** *ip-address* [**vc-id** *vc_id*] [**manual**]	Configures the IP address and VC identifier of the remote neighbor of the backup PW. If no VC identifier is configured, reuse the VC identifier of the primary PW. The other attributes of the standby PW also use the attributes of the primary PW.
Ruijie(config-pw-class)# **vccv bfd** [**primary** | **backup**] **enable**	Enables the PW connectivity check. The PW connectivity check is enabled on the primary and backup PWs by default. The PW connectivity check in BFD mode is supported.
Ruijie(config-pw-class)# **fast-reroute** [**delay** *delay-time* | **immediately** | **never**]	Configures the switchback policy for switching from the backup PW back to primary PW. The switchback to the primary PW is delayed for 300s by default.
Ruijie(config-pw-class)# **end**	Returns to the privileged EXEC mode.
Ruijie# **copy running-config startup-config**	Saves the configuration.

Configuring VPLS Referencing PW Class (Optional)

Run the following commands to enable the VPLS to reference the PW class instance.

Command	Function
Ruijie# **config terminal**	Enters the global configuration mode.
Ruijie(config)# **l2 vfi** *vpls-name* **vpnid** *vpn-id*	Creates a VPLS instance and enters the VPLS configuration mode.
Ruijie(config-vfi)# **neighbor** *ip-address* **encapsulation mpls** [**vc-id** *vc-id*] [**hub-vc** | **spoke-vc**] [**ethernet** | **ethernetvlan**] [**manual**] [**tnl-policy** *policy-name*] [**pw-class** *class-name*]	Configures a VPLS peer and reference the PW class instance.
Ruijie(config-vfi)# **end**	Returns to the privileged EXEC mode.
Ruijie# **copy running-config startup-config**	Saves the configuration.

Caution

You must create a PW class instance before it can be referenced.

#Example: Enable the Martini VPLS to reference the PW class instance.

```
Ruijie# configure terminal
Ruijie(config)# l2 vfi vfi_frr vpnid 1
Ruijie(config-vfi)# neighbor 2.2.2.2 encapsulation mpls pw-class pwc1
Ruijie(config-vfi)# exit
```

Configuring MAC Address Learning of VPLS (Optional)

The VPLS can dynamically learn the MAC addresses of the AC and the PW. You can control the MAC address learning function on the VPLS, including enabling or disabling learning of the AC MAC address and learning of the PW MAC address.

Command	Function
Ruijie# **config terminal**	Enters the global configuration mode.
Ruijie(config)# **l2 vfi** *name* **vpnid** *vpn-id*	Creates a VPLS instance and enters the VPLS configuration mode.
Ruijie(config-vfi)# **mac-learning** [**ac|pw**] **disable**	Controls MAC address learning. The MAC addresses of the AC and the PW are learned concurrently by default.
Ruijie(config-vfi)# **end**	Returns to the privileged EXEC mode.
Ruijie# **copy running-config startup-config**	Saves the configuration.

Caution This command is available to both the Martini VPLS and the Kompella VPLS.

Configuring MAC Address Withdrawal of VPLS (Optional)

You can withdraw the remote MAC address dynamically learned by the VPLS and forward the MAC address withdrawal message to other PE devices.

Command	Function
Ruijie# **config terminal**	Enters the global configuration mode.
Ruijie(config)# **l2 vfi** *name* **vpnid** *vpn-id*	Creates a VPLS instance and enters the VPLS configuration mode.
Ruijie(config-vfi)# **mac-withdraw enable**	Enables the MAC address withdrawal message sending function. If this function is disabled, the local spoke PW is invalid or the AC is invalid. In this case, no MAC address withdrawal message is sent to the remote peer. Upon receiving the MAC address withdrawal message from the hub PW, the PE device withdraws the MAC address and sends the MAC address withdrawal message other PEs.
Ruijie(config-vfi)# **end**	Returns to the privileged EXEC mode.
Ruijie# **copy running-config startup-config**	Saves the configuration.

Caution Withdrawing the MAC address of the remote PE is available to the Martini VPLS only.

Configuring Action on Unknown Unicast Packets Received by VPLS Instance (Optional)

Run the following commands to configure the forwarding action on the unknown unicast packets received by the VPLS instance.

Command	Function
Ruijie# **config terminal**	Enters the global configuration mode.
Ruijie(config)# **l2 vfi** *name* **vpnid** *vpn-id*	Creates a VPLS instance and enters the VPLS configuration mode.
Ruijie(config-vfi)# **unknown-frame unicast** [**ac-ac |ac-pw** | **pw-ac**] **discard**	Configures the forwarding action on the unknown unicast and broadcast packets.
Ruijie(config-vfi)# **end**	Returns to the privileged EXEC mode.
Ruijie# **copy running-config startup-config**	Saves the configuration.

Maintaining PW Connectivity of VPLS

Configuration Prerequisites

When using VCCV to detect the PW connectivity of the VPLS, you must ensure that the PWE3 network is already correctly configured.

Checking PW Connectivity

Command	Function
Ruijie#**ping mpls pseudowire** { *ip-address vc-id* [**segment** *segment-number*] | **kompella** *vfi_name local_site_id remote_site_id* **rd** *remote_rd* } { **label-alert** | **ttl-expiry** } [**repeat** *repeat*] [**timeout** *timeout*] [**size** *size*] [**interval** *mseconds*] [**source** *ip-address*] [**destination** *ip-address*] [**pad** *pattern*] [**reply mode** { **ipv4** | **router-alert | control-channel** }] [**verbose**]	Checks the PW connectivity.

Example: Check the connectivity of the PW whose peer PE IPv4 address is 10.10.10.10 and PW ID is 100.

```
Ruijie#ping mpls pseudowire 10.10.10.3 100 label-alert
Sending 5, 112-byte MPLS Echoes on Pseudowire, peer address 10.10.10.3, VC ID 100,
     timeout is 2 seconds, send interval is 0 msec:

Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
  'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
  'P' - no rx intf label prot, 'p' - premature termination of LSP,
  'R' - transit router, 'I' - unknown upstream index,
  'X' - unknown return code, 'x' - return code 0
```

```
Press Ctrl+C to break.
!!!!!
Success rate is 100 percent(5/5),round-trip min/avg/max=20/36/60 ms
```

Locating Data Plane Fault of PW

Command	Function
Ruijie#**traceroute mpls pseudowire** { *ip-address vc-id* {**segment** *segment-number*} | **kompella** *vfi_name local_site_id remote_site_id* **rd** *remote_rd* } { **label-alert** | **ttl-expiry** } [**repeat** *repeat*] [**timeout** *timeout*] [**size** *size*] [**interval** *mseconds*] [**source** *ip-address*] [**destination** *ip-address*] [**pad** *pattern*] [**reply mode** { **ipv4** | **router-alert** }] [**verbose**]	Tracks the PW path to locate the connectivity fault.

Example: Track the path of the PW whose VFI name is vpn-1, local VE ID is 1, remote VE ID is 2, and remote RD is 200:1 to locate the fault.

```
Ruijie#traceroute mpls pseudowire kompella vpn-1 1 2 rd 200:1 label-alert
Traceing Pseudowire Label Switched Path, VFI name vpn-1, local site id 1, remote site id 2,
timeout is 2 seconds.
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
  'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
  'P' - no rx intf label prot, 'p' - premature termination of LSP,
  'R' - transit router, 'I' - unknown upstream index,
  'X' - unknown return code, 'x' - return code 0

Press Ctrl+C to break.
  0 192.168.1.10   MRU 1500 [Labels: router-alert/1538 Exp: 0/0]

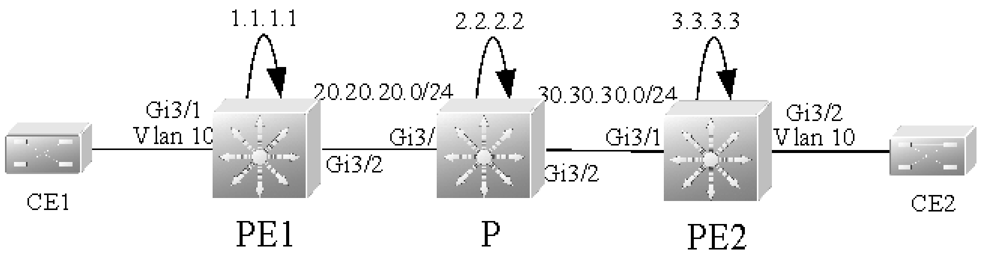
```

Typical Examples of Martini VPLS Configuration for Switches

Basic VPLS

As shown in the following figure, CE1 and CE2 access the same VPLS network through PE1 and PE2. PE1, P, and PE2 form a public MPLS network that provides VPLS services. On PE1 and PE2, bind VLAN 10 to the VPLS instance.

Figure 71



The configuration procedure is as follows:

Configuring PE1:

# Configure the loopback interface.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# neighbor 3.3.3.3
Ruijie(config-mpls-router)# exit
```

# Enable LDP and MPLS on the public network interface.

```
Ruijie(config)# interface gigabitEthernet 3/2
Ruijie(config-if-Gigabitethernet 3/2)# no switchport
Ruijie(config-if-Gigabitethernet 3/2)# ip address 20.20.20.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 3/2)# mpls ip
Ruijie(config-if-Gigabitethernet 3/2)# label-switching
Ruijie(config-if-Gigabitethernet 3/2)# exit
```

# Configure a VPLS instance and specify the peer PE.

```
Ruijie(config)# l2 vfi vfi_a vpnid 1
Ruijie(config-vpls)# neighbor 3.3.3.3 encapsulation mpls
Ruijie(config-vpls)# exit
```

# Bind the VLAN interface to the VPLS instance.

```
Ruijie(config)# vlan 10
Ruijie(config-vlan)# exit
Ruijie(config)# interface vlan 10
Ruijie(config-if-Vlan 10)# xconnect vfi vfi_a
Ruijie(config-if-Vlan 10)# exit
```

# Configure the interface between PEs and CEs.

```
Ruijie(config)# interface gigabitEthernet 3/1
Ruijie(config-if-GigabitEthernet 3/1)# switchport access vlan 10
Ruijie(config-if-GigabitEthernet 3/1)# exit
```

Configuring P:

# Configure the loopback interface.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 2.2.2.2 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 2.2.2.2 0.0.0.0 area 0
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# network 30.30.30.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# exit
```

# Enable LDP and MPLS on an interface.

```
Ruijie(config)# interface gigabitEthernet 3/1
Ruijie(config-if-Gigabitethernet 3/1)# no switchport
Ruijie(config-if-Gigabitethernet 3/1)# ip address 20.20.20.2 255.255.255.0
Ruijie(config-if-Gigabitethernet 3/1)# mpls ip
Ruijie(config-if-Gigabitethernet 3/1)# label-switching
Ruijie(config-if-Gigabitethernet 3/1)# exit
Ruijie(config)# interface gigabitEthernet 3/2
Ruijie(config-if-Gigabitethernet 3/2)# no switchport
Ruijie(config-if-Gigabitethernet 3/2)# ip address 30.30.30.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 3/2)# mpls ip
Ruijie(config-if-Gigabitethernet 3/2)# label-switching
Ruijie(config-if-Gigabitethernet 3/2)# exit
```

Configuring PE2:

# Configure the loopback interface.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 3.3.3.3 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 3.3.3.3 0.0.0.0 area 0
Ruijie(config-router)# network 30.30.30.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# neighbor 1.1.1.1
Ruijie(config-mpls-router)# exit
```

# Enable LDP and MPLS on the public network interface.

```
Ruijie(config)# interface gigabitEthernet 3/1
Ruijie(config-if-Gigabitethernet 3/1)# no switchport
Ruijie(config-if-Gigabitethernet 3/1)# ip address 30.30.30.2 255.255.255.0
Ruijie(config-if-Gigabitethernet 3/1)# mpls ip
Ruijie(config-if-Gigabitethernet 3/1)# label-switching
Ruijie(config-if-Gigabitethernet 3/1)# exit
```

# Configure a VPLS instance and specify the peer PE.

```
Ruijie(config)# l2 vfi vfi_a vpnid 1
Ruijie(config-vpls)# neighbor 1.1.1.1 encapsulation mpls
Ruijie(config-vpls)# exit
```

# Bind the VLAN interface to the VPLS instance.

```
Ruijie(config)# vlan 10
Ruijie(config-vlan)# exit
Ruijie(config)# interface vlan 10
Ruijie(config-if-Vlan 10)# xconnect vfi vfi_a
Ruijie(config-if-Vlan 10)# exit
```

# Configure the interface between PEs and CEs.

```
Ruijie(config)# interface gigabitEthernet 3/2
Ruijie(config-if-Gigabitethernet 3/2)#  switchport access vlan 10
Ruijie(config-if-Gigabitethernet 3/2)# exit
```

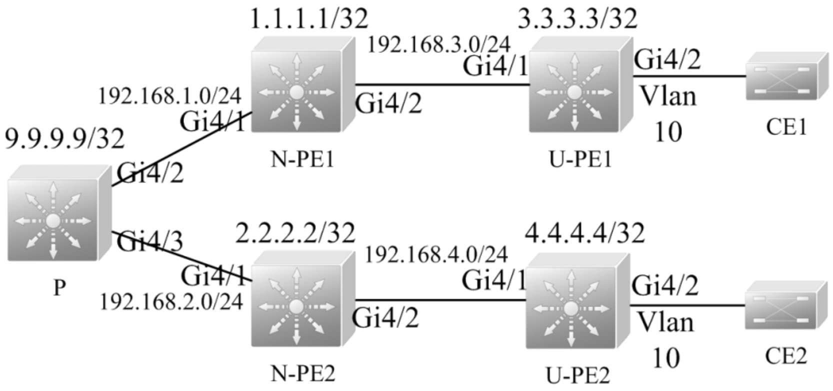
H-VPLS (PW Access)

Figure 72



As shown in the preceding figure, CE1 and CE2 access the same H-VPLS network through U-PE1 and U-PE2, which are connected to N-PE1 and N-PE2 respectively. The N-PEs and U-PEs are connected through PWs. All U-PEs and N-PEs belong to the MPLS network and work together to provide VPLS services.

When setting up PWs between N-PEs and U-PEs, you must specify the PW of the N-PEs with the U-PEs as a Spoke PW. On the U-PE end, the PW type is not restricted. If U-PEs support VPLS, the PW between U-PEs and N-PEs can be either a Hub PW or a Spoke PW. If the U-PEs do not support VPLS, the VPWS PW can also be configured.

In this example, U-PE1 and N-PE1 are connected through a Hub PW whereas U-PE2 and N-PE2 are connected through a VPWS PW.

- Configuring U-PE1:

# Configure the loopback interface.

```
Ruijie(config)# interface loopback 0

Ruijie(config-if-GigabitEthernet 4/2)# switchport access vlan 10
Ruijie(config-if-GigabitEthernet 4/2)# exit
```

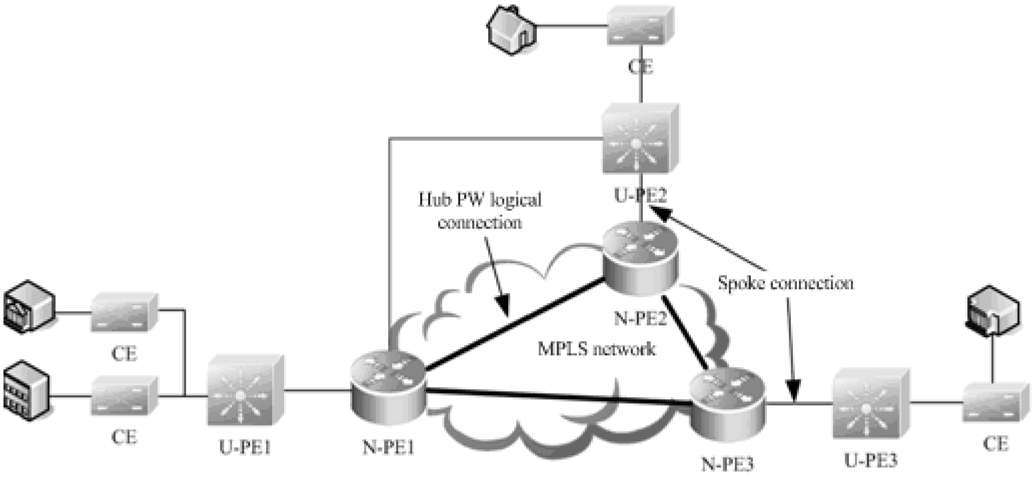
H-VPLS (QinQ Access and Dual-Homed)

If the U-PE and N-PE are connected through only one Spoke, the U-PE communication with the external network is discontinued if the Spoke connection fails. To solve this problem, you can connect the U-PE to N-PEs in dual-homed mode. In this mode, the U-PE is connected to different N-PEs, which belong to the same VPLS network, through two (or more) Spoke connections. In normal situations, only one of the Spoke connections is working. It is called the active connection and the others are backup ones. If the active connection fails, one backup connection is chosen to take over the task.

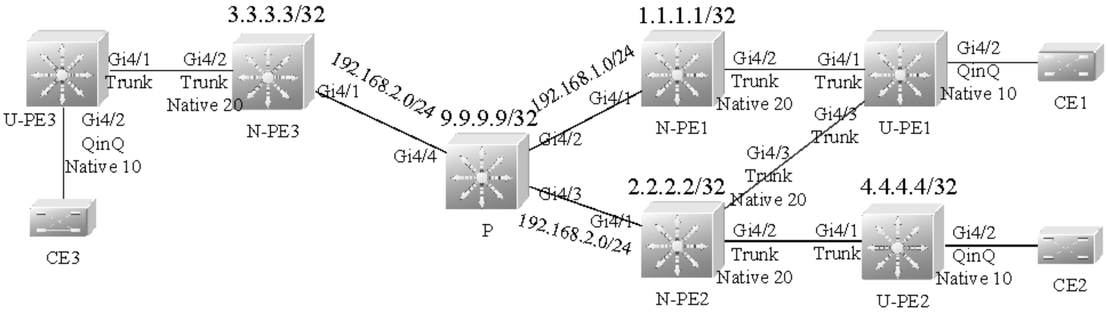
The following shows a schematic diagram of an H-VPLS network in dual-homed mode.

Figure 73



On an H-VPLS network in QinQ and dual-homed access mode, you can use the STP to switch over the active and standby connections. The STP, however, does not belong to users and is transmitted only over the carrier's network (U-PEs and N-PEs). To avoid the impact of STP protocol packets (BPDUs) on user packets, you must create a special VPLS instance on the N-PE to transparently transmit BPDU packets in dual-homed mode.

Figure 40



The preceding figure shows an H-VPLS topology in dual-homed mode. The CE is connected to U-PEs on the same H-VPLS network and the U-PEs are connected to N-PEs through the QinQ tunnel. The N-PEs belong to the MPLS network and the U-PEs do not run MPLS, but the N-PEs and U-PEs work together to provide VPLS services. The upstream interface on the U-PE works in trunk mode and allows the traffic of the VLAN to which the U-PE interface connected to the CE belongs to pass through. Enable QinQ on the interfaces that connect U-PEs and CEs. This QinQ native LVAN cannot be the same as the native VLAN on the U-PE1 interface connected to the N-PE or the native VLAN on the N-PE interface connected to the U-PE. This is because the QinQ native VLAN on the interfaces that connect U-PEs and CEs is used to identify VPLS instances provided for a user whereas the native VLAN on the N-PE trunk interface connected to the U-PE is used to identify the VPLS instance for transparently transmitting BPDU packets in dual-homed mode. Set up Hub PWs between N-PEs. Enable dual-homed mode on U-PE1 and you can find that U-PE1 is connected to both N-PE1 and N-PE2.

As shown in Figure 1-27, only one VPLS instance is provided for the user. You are required to create a special VPLS instance to transparently transmit BPDU packets in dual-homed mode. You only need to enable this VPLS instance on the N-PEs to which the U-PE is connected.

Configuring U-PE1:

# Configure a Spoke connection to the peer N-PE1.

```
Ruijie(config)# interface gigabitEthernet 4/1
Ruijie(config-if-GigabitEthernet 4/1)# switchport mode trunk
Ruijie(config-if-GigabitEthernet 4/1)# exit
```

# Configure a Spoke connection to the peer N-PE2.

```
Ruijie(config)# interface gigabitEthernet 4/3
Ruijie(config-if-GigabitEthernet 4/3)# switchport mode trunk
Ruijie(config-if-GigabitEthernet 4/3)# exit
```

# Configure the interface between PEs and CEs.

```
Ruijie(config)# interface gigabitEthernet 4/2
Ruijie(config-if-GigabitEthernet 4/2)# switchport access vlan 10
Ruijie(config-if-GigabitEthernet 4/2)# switchport mode dot1q-tunnel
Ruijie(config-if-GigabitEthernet 4/2)# exit
```

# Enable STP only on the U-PEs that adopt the dual-homed access mode.

```
Ruijie(config)# spanning-tree
```

Configuring N-PE1:

# Configure the loopback interface.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)# network 192.168.1.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# neighbor 2.2.2.2
Ruijie(config-mpls-router)# neighbor 3.3.3.3
Ruijie(config-mpls-router)# exit
```

# Enable LDP and MPLS on the public network interface.

```
Ruijie(config)# interface gigabitEthernet 4/1
Ruijie(config-if-GigabitEthernet 4/1)# no switchport
Ruijie(config-if-GigabitEthernet 4/1)# ip address 192.168.1.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 4/1)# mpls ip
Ruijie(config-if-GigabitEthernet 4/1)# label-switching
Ruijie(config-if-GigabitEthernet 4/1)# exit
```

# Configure the N-PE interface connected to the U-PE.

```
Ruijie(config)# interface gigabitEthernet 4/2
Ruijie(config-if-GigabitEthernet 4/2)# switchport mode trunk
Ruijie(config-if-GigabitEthernet 4/2)# switchport trunk native vlan 20
Ruijie(config-if-GigabitEthernet 4/2)# exit
```

# Configure a VPLS instance for the user and enable Hub PWs to connect the N-PEs in the same VPLS instance.

```
Ruijie(config)# l2 vfi vfi_a vpnid 1
Ruijie(config-vpls)# neighbor 2.2.2.2 encapsulation mpls
Ruijie(config-vpls)# neighbor 3.3.3.3 encapsulation mpls
Ruijie(config-vpls)# exit
```

# Bind the QinQ VLAN interface to the VPLS instance.

```
Ruijie(config)# vlan 10
Ruijie(config-vlan)# exit
Ruijie(config)# interface vlan 10
Ruijie(config-if-Vlan 10)# xconnect vfi vfi_a
Ruijie(config-if-Vlan 10)# exit
```

# Configure the VPLS instance to transparently transmit BPDU packets and enable Hub PWs to connect other N-PEs in dual-homed mode.

```
Ruijie(config)# l2 vfi vfi_bpdu vpnid 100
Ruijie(config-vpls)# neighbor 2.2.2.2 encapsulation mpls
Ruijie(config-vpls)# exit
```

# Bind the native VLAN interface, which is used to transparently transmit BPDUs, to the VPLS instance.

```
Ruijie(config)# vlan 20
Ruijie(config-vlan)# exit
Ruijie(config)# interface vlan 20
Ruijie(config-if-Vlan 20)# xconnect vfi vfi_bpdu
Ruijie(config-if-Vlan 20)# l2 vfi tunnel-protocol stp
Ruijie(config-if-Vlan 20)# exit
```

Configuring P:

# Configure the loopback interface.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 9.9.9.9 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 9.9.9.9 0.0.0.0 area 0
Ruijie(config-router)# network 192.168.1.0 0.0.0.255  area 0
Ruijie(config-router)# network 192.168.2.0 0.0.0.255  area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# exit
```

# Enable LDP and MPLS on an interface.

```
Ruijie(config)# interface gigabitEthernet 4/2
Ruijie(config-if-GigabitEthernet 4/2)#  no switchport
Ruijie(config-if-GigabitEthernet 4/2)#  ip address 192.168.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 4/2)#  mpls ip
Ruijie(config-if-GigabitEthernet 4/2)#  label-switching
Ruijie(config-if-GigabitEthernet 4/2)#  exit
Ruijie(config)# interface gigabitEthernet 4/3
Ruijie(config-if-GigabitEthernet 4/3)#  no switchport
Ruijie(config-if-GigabitEthernet 4/3)#  ip address 192.168.2.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 4/3)#  mpls ip
Ruijie(config-if-GigabitEthernet 4/3)#  label-switching
Ruijie(config-if-GigabitEthernet 4/3)# exit
```

Configuring N-PE2:

# Configure the loopback interface.

```
Ruijie(config)#  interface loopback 0
Ruijie(config-if-Loopback 0)# # ip address 2.2.2.2 255.255.255.255
Ruijie(config-if-Loopback 0)#  exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 2.2.2.2 0.0.0.0  area 0
Ruijie(config-router)# network 192.168.2.0 0.0.0.255  area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# neighbor 1.1.1.1
Ruijie(config-mpls-router)# neighbor 3.3.3.3
Ruijie(config-mpls-router)# exit
```

# Enable LDP and MPLS on the public network interface.

```
Ruijie(config)# interface gigabitEthernet 4/1
Ruijie(config-if-GigabitEthernet 4/1)# no switchport
Ruijie(config-if-GigabitEthernet 4/1)# ip address 192.168.2.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 4/1)# mpls ip
Ruijie(config-if-GigabitEthernet 4/1)# label-switching
Ruijie(config-if-GigabitEthernet 4/1)# exit
```

# Configure the N-PE interface connected to U-PEs (to two U-PEs at the same time).

```
Ruijie(config)# interface gigabitEthernet 4/2
Ruijie(config-if-GigabitEthernet 4/2)# switchport mode trunk
Ruijie(config-if-GigabitEthernet 4/2)# switchport trunk native vlan 20
Ruijie(config-if-GigabitEthernet 4/2)# exit
Ruijie(config)# interface gigabitEthernet 4/3
Ruijie(config-if-GigabitEthernet 4/3)# switchport mode trunk
Ruijie(config-if-GigabitEthernet 4/3)#  switchport trunk native vlan 20
Ruijie(config-if-GigabitEthernet 4/3)#  exit
```

# Configure a VPLS instance for the user and enable Hub PWs to connect the N-PEs in the same VPLS instance.

```
Ruijie(config)# l2 vfi vfi_a vpnid 1
Ruijie(config-vpls)#  neighbor 1.1.1.1 encapsulation mpls
Ruijie(config-vpls)# neighbor 3.3.3.3 encapsulation mpls
Ruijie(config-vpls)# exit
```

# Bind the QinQ VLAN interface to the VPLS instance.

```
Ruijie(config)# vlan 10
Ruijie(config-vlan)# exit
Ruijie(config)# interface vlan 10
Ruijie(config-if-Vlan 10)# xconnect vfi vfi_a
Ruijie(config-if-Vlan 10)# exit
```

# Enable the VPLS instance to transparently transmit BPDU packets and enable Hub PWs to connect other N-PEs in dual-homed mode.

```
Ruijie(config)# l2 vfi vfi_bpdu vpnid 100
Ruijie(config-vpls)# neighbor 1.1.1.1 encapsulation mpls
Ruijie(config-vpls)# exit
```

# Bind the native VLAN interface, which is used to transparently transmit BPDU packets, to the VPLS instance.

```
Ruijie(config)# vlan 20
Ruijie(config-vlan)# exit
Ruijie(config)# interface vlan 20
Ruijie(config-if-Vlan 20)# xconnect vfi vfi_bpdu
Ruijie(config-if-Vlan 20)# l2 vfi tunnel-protocol stp
Ruijie(config-if-Vlan 20)# exit
```

Configuring U-PE2:

# Refer to U-PE1. Since U-PE2 is connected to only one N-PE, STP is not required.

Configuring U-PE3:

# Refer to U-PE2.

Configuring N-PE3:

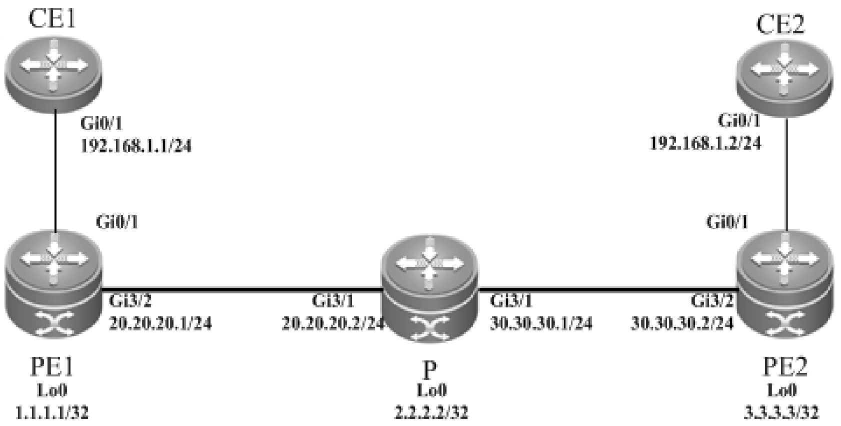
# Refer to N-PE1.

Typical Examples of Martini VPLS Configuration for Routers

Basic VPLS (Ethernet Interface Access)

As shown in the following figure, CE1 and CE2 access the same VPLS network through PE1 and PE2. PE1, P, and PE2 form a public MPLS network to provide VPLS services. Gi0/1 is bound on PE1 and PE2 to the VPLS instance.

Figure 41



The configuration procedure is as follows:

Configuring PE1:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# neighbor 3.3.3.3
Ruijie(config-mpls-router)# exit
```

# Enable LDP and MPLS on the public network interface.

```
Ruijie(config)# interface gigabitEthernet 3/2
Ruijie(config-if-Gigabitethernet 3/2)# ip ref
Ruijie(config-if-Gigabitethernet 3/2)# ip address 20.20.20.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 3/2)# mpls ip
Ruijie(config-if-Gigabitethernet 3/2)# label-switching
Ruijie(config-if-Gigabitethernet 3/2)# exit
```

# Configure a VPLS instance and specify the peer PE.

```
Ruijie(config)# l2 vfi vfi_a vpnid 1
Ruijie(config-vpls)# neighbor 3.3.3.3 encapsulation mpls ethernet
Ruijie(config-vpls)# exit
```

# Configure the interface that connects PEs and CEs to bind the VPLS instance.

```
Ruijie(config)# interface gigabitethernet 0/1
Ruijie(config-if-Gigabitethernet 0/1)# ip ref
Ruijie(config-if-Gigabitethernet 0/1)# xconnect vfi vfi_a
Ruijie(config-if-Gigabitethernet 0/1)# exit
```

Configuring P:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 2.2.2.2 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 2.2.2.2 0.0.0.0 area 0
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# network 30.30.30.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# exit
```

# Enable LDP and MPLS on an interface.

```
Ruijie(config)# interface gigabitEthernet 3/1
Ruijie(config-if-Gigabitethernet 3/1)# ip ref
Ruijie(config-if-Gigabitethernet 3/1)# ip address 20.20.20.2 255.255.255.0
Ruijie(config-if-Gigabitethernet 3/1)# mpls ip
Ruijie(config-if-Gigabitethernet 3/1)# label-switching
Ruijie(config-if-Gigabitethernet 3/1)# exit
Ruijie(config)# interface gigabitEthernet 3/2
Ruijie(config-if-Gigabitethernet 3/2)# ip ref
Ruijie(config-if-Gigabitethernet 3/2)# ip address 30.30.30.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 3/2)# mpls ip
Ruijie(config-if-Gigabitethernet 3/2)# label-switching
Ruijie(config-if-Gigabitethernet 3/2)# exit
```

Configuring PE2:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 3.3.3.3 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 3.3.3.3 0.0.0.0 area 0
Ruijie(config-router)# network 30.30.30.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# neighbor 1.1.1.1
Ruijie(config-mpls-router)# exit
```

# Enable LDP and MPLS on the public network interface.

```
Ruijie(config)# interface gigabitEthernet 3/1
Ruijie(config-if-Gigabitethernet 3/1)# ip ref
Ruijie(config-if-Gigabitethernet 3/1)# ip address 30.30.30.2 255.255.255.0
Ruijie(config-if-Gigabitethernet 3/1)# mpls ip
Ruijie(config-if-Gigabitethernet 3/1)# label-switching
Ruijie(config-if-Gigabitethernet 3/1)# exit
```

# Configure a VPLS instance and specify the peer PE.

```
Ruijie(config)# l2 vfi vfi_a vpnid 1
Ruijie(config-vpls)# neighbor 1.1.1.1 encapsulation mpls ethernet
Ruijie(config-vpls)# exit
```

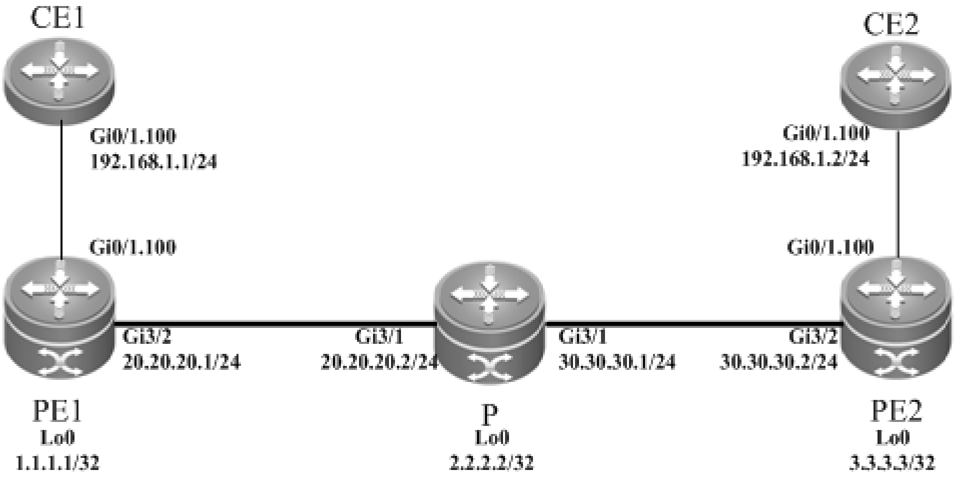
# Configure the interface that connects PEs and CEs to bind the VPLS instance.

```
Ruijie(config)# interface gigabitethernet 0/1
Ruijie(config-if-Gigabitethernet 0/1)# ip ref
Ruijie(config-if-Gigabitethernet 0/1)# xconnect vfi vfi_a
Ruijie(config-if-Gigabitethernet 0/1)# exit
```

Basic VPLS (Ethernet Sub-interface Access)

As shown in the following figure, CE1 and CE2 access the same VPLS network through PE1 and PE2. PE1, P, and PE2 form a public MPLS network to provide VPLS services. VLAN 10 is bound on PE1 and PE2 to the VPLS instance.

Figure 74



The configuration procedure is as follows:

Configuring PE1:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# neighbor 3.3.3.3
Ruijie(config-mpls-router)# exit
```

# Enable LDP and MPLS on the public network interface.

```
Ruijie(config)# interface gigabitEthernet 3/2
Ruijie(config-if-Gigabitethernet 3/2)# ip ref
Ruijie(config-if-Gigabitethernet 3/2)# ip address 20.20.20.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 3/2)# mpls ip
Ruijie(config-if-Gigabitethernet 3/2)# label-switching
Ruijie(config-if-Gigabitethernet 3/2)# exit
```

# Configure a VPLS instance and specify the peer PE.

```
Ruijie(config)# l2 vfi vfi_a vpnid 1
Ruijie(config-vpls)# neighbor 3.3.3.3 encapsulation mpls ethernetvlan
Ruijie(config-vpls)# exit
```

# Configure the interface that connects PEs and CEs to bind the VPLS instance.

```
Ruijie(config)# interface gigabitethernet 0/1
Ruijie(config-if-Gigabitethernet 0/1)# ip ref
Ruijie(config-if-Gigabitethernet 0/1)# exit
Ruijie(config)# interface gigabitethernet 0/1.100
Ruijie(config-if-Gigabitethernet 0/1.100)# encapsulation dot1Q 100
Ruijie(config-if-Gigabitethernet 0/1.100)# xconnect vfi vfi_a
Ruijie(config-if-Gigabitethernet 0/1.100)# exit
```

Configuring P:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 2.2.2.2 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 2.2.2.2 0.0.0.0 area 0
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# network 30.30.30.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# exit
```

# Enable LDP and MPLS on an interface.

```
Ruijie(config)# interface gigabitEthernet 3/1
Ruijie(config-if-Gigabitethernet 3/1)# ip ref
Ruijie(config-if-Gigabitethernet 3/1)# ip address 20.20.20.2 255.255.255.0
Ruijie(config-if-Gigabitethernet 3/1)# mpls ip
Ruijie(config-if-Gigabitethernet 3/1)# label-switching
Ruijie(config-if-Gigabitethernet 3/1)# exit
Ruijie(config)# interface gigabitEthernet 3/2
Ruijie(config-if-Gigabitethernet 3/2)# ip ref
Ruijie(config-if-Gigabitethernet 3/2)# ip address 30.30.30.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 3/2)# mpls ip
Ruijie(config-if-Gigabitethernet 3/2)# label-switching
Ruijie(config-if-Gigabitethernet 3/2)# exit
```

Configuring PE2:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 3.3.3.3 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 3.3.3.3 0.0.0.0 area 0
Ruijie(config-router)# network 30.30.30.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# neighbor 1.1.1.1
Ruijie(config-mpls-router)# exit
```

# Enable LDP and MPLS on the public network interface.

```
Ruijie(config)# interface gigabitEthernet 3/1
Ruijie(config-if-Gigabitethernet 3/1)# ip ref
Ruijie(config-if-Gigabitethernet 3/1)# ip address 30.30.30.2 255.255.255.0
Ruijie(config-if-Gigabitethernet 3/1)# mpls ip
Ruijie(config-if-Gigabitethernet 3/1)# label-switching
Ruijie(config-if-Gigabitethernet 3/1)# exit
```

# Configure a VPLS instance and specify the peer PE.

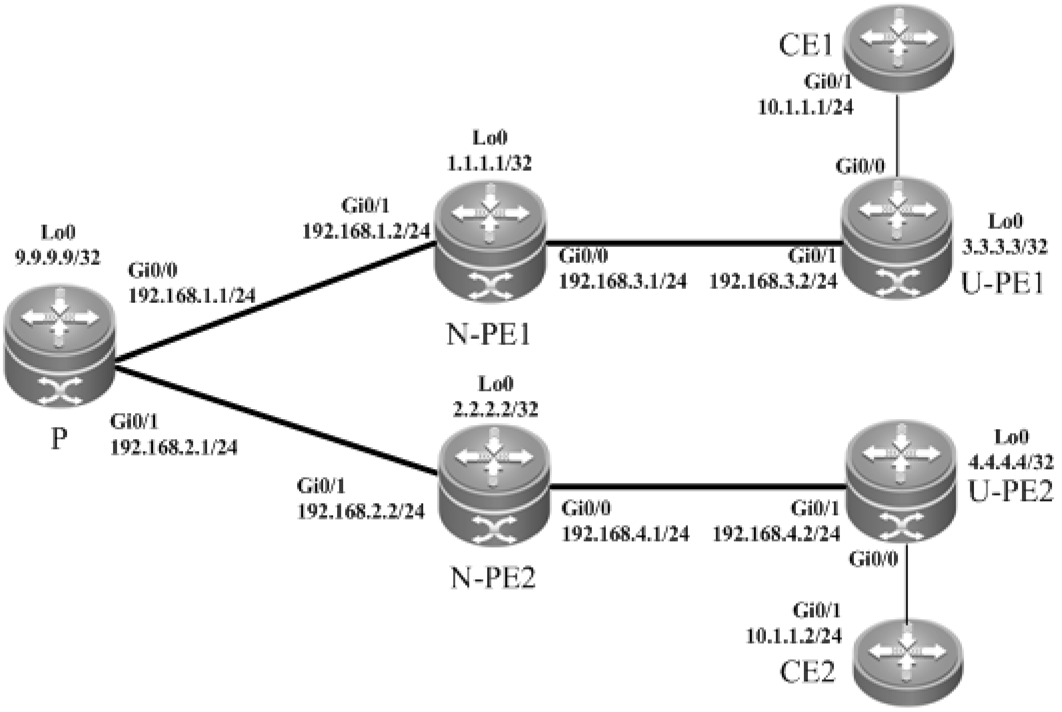
```
Ruijie(config)# l2 vfi vfi_a vpnid 1
Ruijie(config-vpls)# neighbor 1.1.1.1 encapsulation mpls ethernetvlan
Ruijie(config-vpls)# exit
```

# Configure the interface that connects PEs and CEs to bind the VPLS instance.

```
Ruijie(config)# interface gigabitethernet 0/1
Ruijie(config-if-Gigabitethernet 0/1)# ip ref
Ruijie(config-if-Gigabitethernet 0/1)# exit
Ruijie(config)# interface gigabitethernet 0/1.100
Ruijie(config-if-Gigabitethernet 0/1.100)# encapsulation dot1Q 100
Ruijie(config-if-Gigabitethernet 0/1.100)# xconnect vfi vfi_a
Ruijie(config-if-Gigabitethernet 0/1.100)# exit
```

H-VPLS (PW Access)

Figure 75



As shown in the preceding figure, CE1 and CE2 access the same H-VPLS network through U-PE1 and U-PE2, which are connected to N-PE1 and N-PE2 respectively. The N-PEs and U-PEs are connected through PWs. All U-PEs and N-PEs belong to the MPLS network and work together to provide VPLS services.

When setting up PWs between N-PEs and U-PEs, you must specify the PW of the N-PEs with the U-PEs as a Spoke PW. On the U-PE end, the PW type is not restricted. If U-PEs support VPLS, the PW between U-PEs and N-PEs can be either a Hub PW or a Spoke PW. If the U-PEs do not support VPLS, the VPWS PW can also be configured.

In this example, U-PE1 and N-PE1 are connected through a Hub PW whereas U-PE2 and N-PE2 are connected through a VPWS PW.

Configuring U-PE1:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 3.3.3.3 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 3.3.3.3 0.0.0.0 area 0
Ruijie(config-router)# network 192.168.3.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# neighbor 1.1.1.1
Ruijie(config-mpls-router)# exit
```

# Enable LDP and MPLS on the public network interface.

```
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ip ref
Ruijie(config-if-GigabitEthernet 0/1)# ip address 192.168.3.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/1)# mpls ip
Ruijie(config-if-GigabitEthernet 0/1)# label-switching
Ruijie(config-if-GigabitEthernet 0/1)# exit
```

# Configure a VPLS instance and enable PWs to connect to the peer N-PE

```
Ruijie(config)# l2 vfi vfi_a vpnid 1
Ruijie(config-vpls)# neighbor 1.1.1.1 encapsulation mpls
Ruijie(config-vpls)# exit
```

# Configure the interface that connects PEs and CEs to bind the VPLS instance.

```
Ruijie(config)# interface gigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)# ip ref
Ruijie(config-if-GigabitEthernet 0/0)# exit
```

Configuring N-PE1:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)# network 192.168.1.0 0.0.0.255 area 0
Ruijie(config-router)# network 192.168.3.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# neighbor 2.2.2.2
Ruijie(config-mpls-router)# neighbor 3.3.3.3
Ruijie(config-mpls-router)# exit
```

# Enable LDP and MPLS on the public network interface.

```
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ip ref
Ruijie(config-if-GigabitEthernet 0/1)# ip address 192.168.1.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/1)# mpls ip
Ruijie(config-if-GigabitEthernet 0/1)# label-switching
Ruijie(config-if-GigabitEthernet 0/1)# exit
Ruijie(config)# interface gigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)# ip ref
Ruijie(config-if-GigabitEthernet 0/0)# ip address 192.168.3.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/0)# mpls ip
Ruijie(config-if-GigabitEthernet 0/0)# label-switching
Ruijie(config-if-GigabitEthernet 0/0)# exit
```

# Configure a VPLS instance, enable a Hub PW to connect another N-PE, and enable a Spoke PW to connect the peer U-PE.

```
Ruijie(config)# l2 vfi vfi_a vpnid 1
Ruijie(config-vpls)# neighbor 2.2.2.2 encapsulation mpls
Ruijie(config-vpls)# neighbor 3.3.3.3 encapsulation mpls spoke-vc
Ruijie(config-vpls)# exit
```

Configuring P:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 9.9.9.9 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 9.9.9.9 0.0.0.0 area 0
Ruijie(config-router)# network 192.168.1.0 0.0.0.255 area 0
Ruijie(config-router)# network 192.168.2.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# exit
```

# Enable LDP and MPLS on an interface.

```
Ruijie(config)# interface gigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)# ip ref
Ruijie(config-if-GigabitEthernet 0/0)# ip address 192.168.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/0)# mpls ip
Ruijie(config-if-GigabitEthernet 0/0)# label-switching
Ruijie(config-if-GigabitEthernet 0/0)# exit
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ip ref
Ruijie(config-if-GigabitEthernet 0/1)# ip address 192.168.2.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/1)# mpls ip
Ruijie(config-if-GigabitEthernet 0/1)# label-switching
Ruijie(config-if-GigabitEthernet 0/1)# exit
```

Configuring N-PE2:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 2.2.2.2 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 2.2.2.2 0.0.0.0 area 0
Ruijie(config-router)# network 192.168.2.0 0.0.0.255 area 0

Ruijie(config-if-GigabitEthernet 0/1)#  exit
```

# Configure the interface that connects PEs and CEs to enable VPWS.

```
Ruijie(config)# interface gigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)# ip ref
Ruijie(config-if-GigabitEthernet 0/0)# xconnect 2.2.2.2 1 encapsulation mpls ethernet
Ruijie(config-if-GigabitEthernet 0/0)# exit
```

Typical Examples of Kompella VPLS Configuration for Switches

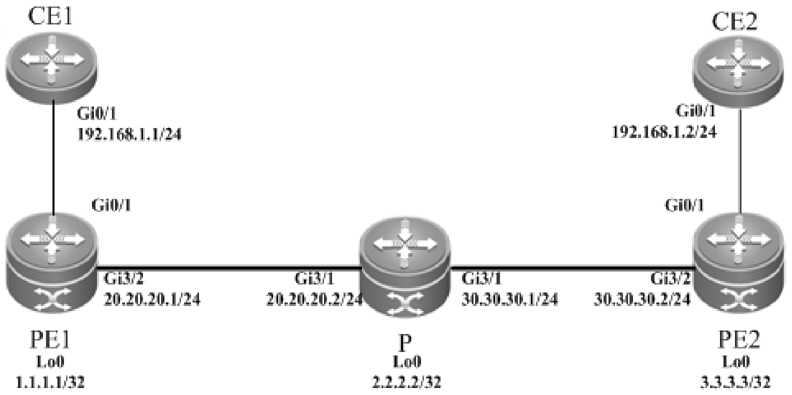
Basic VPLS

Networking Requirements

- CE1 and CE2 access the same VPLS network through PE1 and PE2.
- PE1, P and PE2 form the public MPLS network.
- VLAN 10 is bound on PE1 and PE2 to the VPLS instance.

Networking Topology

Figure 76



Configuration Tips

Before configuring Kompella VPLS, complete the following tasks:

- Run IGP in the carrier's network to realize connection between PE1 and PE2.
- Obtain Kompella VPLS configuration information including VPLS instance descriptive information, RT value, VE ID, maximum planned site number, VE ID deviation, and interface information from the network administrator.

Configuration Steps

Configuring PE1:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# neighbor 3.3.3.3
Ruijie(config-mpls-router)# exit
```

# Enable LDP and MPLS on the public network interface.

```
Ruijie(config)# interface gigabitEthernet 3/2
Ruijie(config-if-Gigabitethernet 3/2)# no switchport
Ruijie(config-if-Gigabitethernet 3/2)# ip address 20.20.20.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 3/2)# mpls ip
Ruijie(config-if-Gigabitethernet 3/2)# label-switching
Ruijie(config-if-Gigabitethernet 3/2)# exit
```

# Configure a VLAN interface.

```
Ruijie(config)# vlan 10
Ruijie(config-vlan)# exit
```

# Configure the L2VPN address family.

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 3.3.3.3 remote-as 100
Ruijie(config-router)# neighbor 3.3.3.3 update-source loopback 0
Ruiije(config-router)# address-family l2vpn vpls
Ruijie(config-router-af)# neighbor 3.3.3.3 activate
Ruijie(config-router-af)# neighbor 3.3.3.3 send-community extended
Ruijie(config-router-af)# exit
```

# Configure the interface that connects PEs and CEs.

```
Ruijie(config)# interface gigabitEthernet 3/1
Ruijie(config-if-GigabitEthernet 3/1)# switchport access vlan 10
Ruijie(config-if-GigabitEthernet 3/1)# exit
```

# Configure a VPLS instance.

```
Ruijie# configure terminal
Ruijie(config)# l2 vfi vpls-1 vpnid 1 autodiscovery
Ruijie(config-vfi)# rd 1:1

Ruijie(config-vfi-site)# xconnect interface vlan 10
Ruijie(config-vfi-site)# exit-site-mode
Ruijie(config-vfi)# exit
```

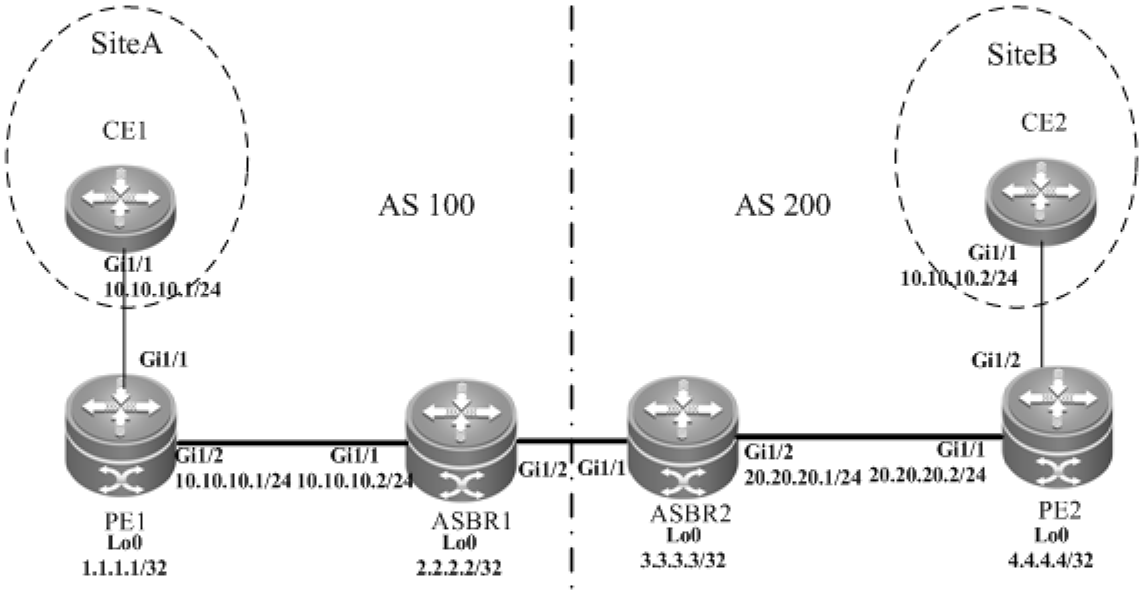
Inter-AS Configuration Examples – Option A Solution

Networking Requirements

- LAN segments of customer S in site A and site B are connected with each other through the carrier's PE1 in AS100 and PE2 in AS 200, forming a virtual and simulative LAN service, or VPLS service.
- PE1 and PE2 are in different ASs. ASBR1 and ASBR2 are considered CE devices by each other, which means that the interface between ASBRs connects the AC to the VPLS instance;

Networking Topology

Figure 77 Kompella VPLS inter-AS networking topology



The preceding figure shows the structure of the Kompella VPLS inter-AS networking topology in Option A. The intermediate interface is considered by ASBRs as AC connection.

Configuration Tips

Before configuring Kompella VPLS, complete the following tasks:

- Run IGP in the carrier's network to realize connection between PE and ASBR devices.
- Establish the MP-IBGP peer relationship between PEs and intra-AS ASBRs.
- Obtain Kompella VPLS configuration information including VPLS instance descriptive information, RT value, VE ID, maximum planned site number, VE ID deviation, and interface information from the network administrator.

Configuration Steps

- Configuring CE1

See "Configuring CE1" in basic configuration examples.

- Configuring PE1:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes so that PEs can ping with ASBRs in the same AS.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)# network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# exit
```

# Configure the public network tunnel between PEs.

```
Ruijie(config)# interface gigabitEthernet 1/2
Ruijie(config-if-Gigabitethernet 1/2)# ip address 10.10.10.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 1/2)# mpls ip
Ruijie(config-if-Gigabitethernet 1/2)# label-switching
Ruijie(config-if-Gigabitethernet 1/2)# exit
```

# Configure the L2VPN address family.

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 2.2.2.2 remote-as 100
Ruijie(config-router)# neighbor 2.2.2.2 update-source loopback 0
Ruiije(config-router)# address-family l2vpn vpls
Ruijie(config-router-af)# neighbor 2.2.2.2 activate
Ruijie(config-router-af)# neighbor 2.2.2.2 send-community extended
Ruijie(config-router-af)# exit
```

# Configure a VLAN interface.

```
Ruijie(config)# vlan 10
Ruijie(config-vlan)# exit
```

# Configure the interface between CEs and PEs.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)# switchport access vlan 10
Ruijie(config-if-GigabitEthernet 1/1)# exit
```

# Configure a VPLS instance.

```
Ruijie# configure terminal
Ruijie(config)# l2 vfi vpls-1 vpnid 1 autodiscovery
Ruijie(config-vfi)# rd 100:1
Ruijie(config-vfi)# signal bgp
Ruijie(config-vfi)# encapsulation mpls ethernet
Ruijie(config-vfi)# route-target both 10000:1
Ruijie(config-vfi)# site-id 1
Ruijie(config-vfi-site)# xconnect interface vlan 10
Ruijie(config-vfi-site)#exit-site-mode
```

- Configuring ASBR1:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 2.2.2.2 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF protocol and establish public network routes so that PEs can ping with ASBRs in the same AS.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 2.2.2.2 0.0.0.0 area 0
Ruijie(config-router)# network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# exit
```

#Configure the public network tunnel between PEs.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-Gigabitethernet 1/1)# ip address 10.10.10.2 255.255.255.0
Ruijie(config-if-Gigabitethernet 1/1)# mpls ip
Ruijie(config-if-Gigabitethernet 1/1)# label-switching
Ruijie(config-if-Gigabitethernet 1/1)# exit
```

# Configure the L2VPN address family.

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 1.1.1.1 remote-as 100
Ruijie(config-router)# neighbor 1.1.1.1 update-source loopback 0
Ruiije(config-router)# address-family l2vpn vpls
Ruijie(config-router-af)# neighbor 1.1.1.1 activate
Ruijie(config-router-af)# neighbor 1.1.1.1 send-community extended
Ruijie(config-router-af)# exit
```

# Configure a VLAN interface.

```
Ruijie(config)# vlan 10
Ruijie(config-vlan)# exit
```

# Configure the interface between ASBR1 and ASBR2.

```
Ruijie(config)# interface gigabitEthernet 1/2
Ruijie(config-if-GigabitEthernet 1/2)# switchport access vlan 10
Ruijie(config-if-GigabitEthernet 1/2)# exit
```

# Configure a VPLS instance.

```
Ruijie# configure terminal
Ruijie(config)# l2 vfi vpls-1 vpnid 1 autodiscovery
Ruijie(config-vfi)# rd 100:1
Ruijie(config-vfi)# signal bgp
Ruijie(config-vfi)# encapsulation mpls ethernet
Ruijie(config-vfi)# route-target both 10000:1
Ruijie(config-vfi)# mtu 1500
Ruijie(config-vfi)# site-id 2
Ruijie(config-vfi-site)# xconnect interface vlan 10
Ruijie(config-vfi-site)#exit-site-mode
Ruijie(config-vfi)#exit
```

- Configuring ASBR2:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 3.3.3.3 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes so that PEs can ping with ASBRs in the same AS.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 3.3.3.3 0.0.0.0 area 0
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# exit
```

# Configure the public network tunnel between PEs.

```
Ruijie(config)# interface gigabitEthernet 1/2
Ruijie(config-if-Gigabitethernet 1/2)# ip address 20.20.20.2 255.255.255.0
Ruijie(config-if-Gigabitethernet 1/2)# mpls ip
Ruijie(config-if-Gigabitethernet 1/2)# label-switching
Ruijie(config-if-Gigabitethernet 1/2)# exit
```

# Configure the L2VPN address family.

```
Ruijie(config)# router bgp 200
Ruijie(config-router)# neighbor 4.4.4.4 remote-as 200
Ruijie(config-router)# neighbor 4.4.4.4 update-source loopback 0
Ruiije(config-router)# address-family l2vpn vpls
Ruijie(config-router-af)# neighbor 4.4.4.4 activate
Ruijie(config-router-af)# neighbor 4.4.4.4 send-community extended
Ruijie(config-router-af)# exit
```

# Configure a VLAN interface.

```
Ruijie(config)# vlan 10
Ruijie(config-vlan)# exit
```

# Configure the interface between ASBR1 and ASBR2.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#  switchport access vlan 10
Ruijie(config-if-GigabitEthernet 1/1)# exit
```

# Configure a VPLS instance.

```
Ruijie# configure terminal
Ruijie(config)# l2 vfi vpls-1 vpnid 1 autodiscovery
Ruijie(config-vfi)# rd 200:1
Ruijie(config-vfi)# signal bgp
Ruijie(config-vfi)# encapsulation mpls ethernet
Ruijie(config-vfi)# route-target both 10000:1
Ruijie(config-vfi)# site-id 3
Ruijie(config-vfi-site)# xconnect interface vlan 10
Ruijie(config-vfi-site)#exit-site-mode
Ruijie(config-vfi)#exit
```

- Configuring PE2:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 4.4.4.4 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes so that PEs can ping with ASBRs in the same AS.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 4.4.4.4 0.0.0.0 area 0
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# exit
```

# Configure the public network tunnel between PEs.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-Gigabitethernet 1/1)# ip address 20.20.20.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 1/1)# mpls ip
Ruijie(config-if-Gigabitethernet 1/1)# label-switching
Ruijie(config-if-Gigabitethernet 1/1)# exit
```

# Configure the L2VPN address family.

```
Ruijie(config)# router bgp 200
Ruijie(config-router)# neighbor 3.3.3.3 remote-as 200
Ruijie(config-router)# neighbor 3.3.3.3 update-source loopback 0
Ruiije(config-router)# address-family l2vpn vpls
Ruijie(config-router-af)# neighbor 3.3.3.3 activate
Ruijie(config-router-af)# neighbor 3.3.3.3 send-community extended
Ruijie(config-router-af)# exit
```

# Configure a VLAN interface.

```
Ruijie(config)# vlan 10
Ruijie(config-vlan)# exit
```

# Configure the interface that connects PE2 and a CE.

```
Ruijie(config)# interface gigabitEthernet 1/2
Ruijie(config-if-GigabitEthernet 1/2)# switchport access vlan 10
Ruijie(config-if-GigabitEthernet 1/2)# exit
```

# Configure a VPLS instance.

```
Ruijie# configure terminal
Ruijie(config)# l2 vfi vpls-1 vpnid 1 autodiscovery
Ruijie(config-vfi)# rd 200:1
Ruijie(config-vfi)# signal bgp
Ruijie(config-vfi)# encapsulation mpls ethernet
Ruijie(config-vfi)# route-target both 10000:1
Ruijie(config-vfi)# site-id 4
Ruijie(config-vfi-site)# xconnect interface vlan 10
Ruijie(config-vfi-site)#exit-site-mode
Ruijie(config-vfi)#exit
```

- Configuring CE2:

See "Configuring CE2" in basic configuration examples.

Verification

After the configuration, CE1 can ping with CE2.

After completing the configuration of Kompella VPLS, use the following commands to check the operation of VPLS.

Command	Function
Ruijie# **show bgp l2vpn vpls all**	Displays all the VPLS information.
Ruijie# **show mpls l2transport vc** [*vc_id* [*ip-address*]] | [**interface** *interface_name*] [**detail**]	Displays information about the PW (including VPWS PW and VPLS PW).
Ruijie# **show bgp l2vpn** { **vpls | vpws** } **all connections** [**neighbor** *address*] | [**interface** *interface_name*] | [**site-id** *id*] [**detail**]	Displays VPLS PW information.
Ruijie# **show mpls vfi** [*name*]	Displays all the configured or specified VFI information.

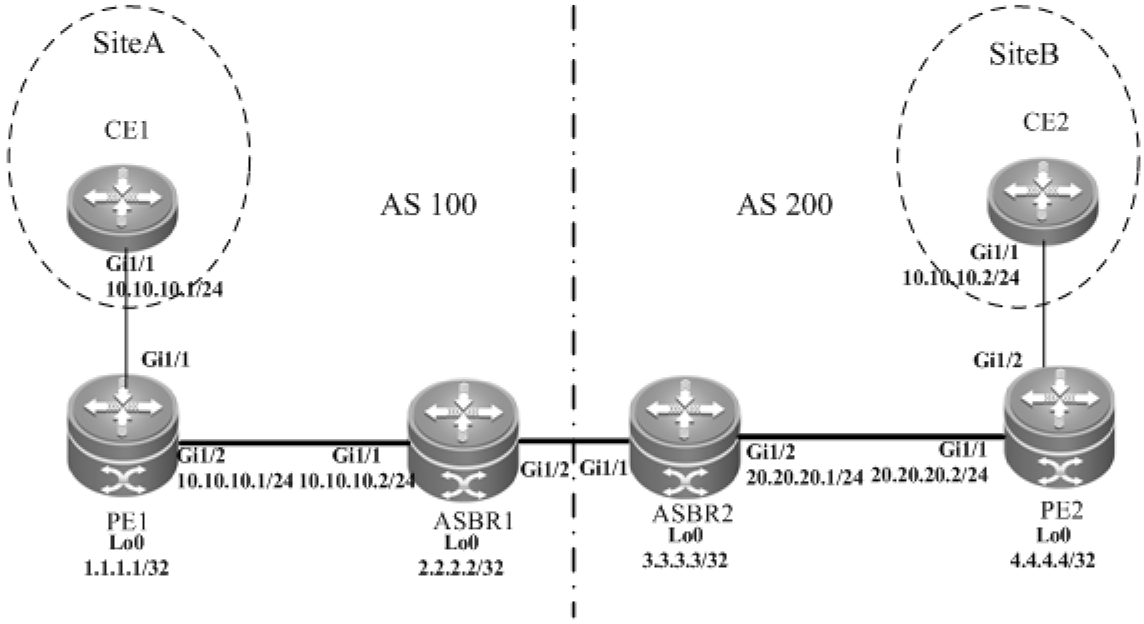
Inter-AS Configuration Examples – Option C Solution

Networking Requirements

- LAN segments of customer S in site A and site B are connected with each other through the carrier's PE1 in AS 1 and PE2 in AS 2, forming a virtual and simulative LAN service or VPLS service.
- PE1 and PE2 are in different ASs and can automatically detect PE devices involved in the VPLS instance.
- ASBR is not responsible for maintaining VPLS label block messages.
- VPLS label block messages are directly exchanged between PEs.

Networking Topology

Figure 78 Kompella VPLS Option C inter-AS networking topology



The preceding figure shows the structure of Kompella VPLS Option C inter-AS networking topology. Customer S's LAN segments in site A and site B are connected to each other through PE1 in AS 100 and PE2 in AS200 as one LAN.

Configuration Tips

Before configuring Kompella VPLS, complete the following tasks:

- Run IGP in the carrier's network to realize connection between VPLS-PE and ASBR devices in the same AS.
- Establish a public network tunnel between PE and ASBR devices in the same AS and enable MPLS on the ASBR interface.
- Establish IBGP between PE and ASBR in the same AS.
- Establish EBGP between ASBR devices and enable send-label.
- Obtain Kompella VPLS configuration information including VPLS instance descriptive information, RT value, VE ID, planned site number, VE ID deviation, and interface information from the network administrator.

Caution

When Option C (multihop MP-EBGP) is applied to realize inter-AC Kompella L2VPN applications, the next hop will be changed to itself by default when such information is sent to the peer EBGP if the MP-EBGP connection is set up by the route reflector between ASs to switch NLRI information of L2VPN. To realize the Kompella L2VPN through Option C solution, the **neighbor next-hop-unchanged** command must be configured on the route reflector so that the reflector does not change the next hop when NLRI information is sent. Otherwise, the inter-AS forwarding fails.

Configuration Steps

- Configuring CE1:

See "Configuring CE1" in basic configuration examples.

- Configuring PE1:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)# network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# exit
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# exit
```

# Configure the public network tunnel between PEs.

```
Ruijie(config)# interface gigabitEthernet 1/2
Ruijie(config-if-Gigabitethernet 1/2)# ip address 10.10.10.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 1/2)# mpls ip
Ruijie(config-if-Gigabitethernet 1/2)# label-switching
Ruijie(config-if-Gigabitethernet 1/2)# exit
```

# Configure the L2VPN address family.

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 4.4.4.4 remote-as 200
Ruijie(config-router)# neighbor 4.4.4.4 update-source loopback 0
Ruijie(config-router)# neighbor 4.4.4.4  ebgp-multihop
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# no neighbor 4.4.4.4  activate
Ruijie(config-router-af)# exit
Ruiije(config-router)# address-family l2vpn vpls
Ruijie(config-router-af)# neighbor 4.4.4.4 activate
Ruijie(config-router-af)# neighbor 4.4.4.4 send-community extended
Ruijie(config-router-af)# exit
```

# Configure a VLAN interface.

```
Ruijie(config)# vlan 10
Ruijie(config-vlan)# exit
```

# Configure the interface that connects CEs.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)# switchport access vlan 10
Ruijie(config-if-GigabitEthernet 1/1)# exit
```

# Configure a VPLS instance.

```
Ruijie# configure terminal
Ruijie(config)# l2 vfi vpls-1 vpnid 1 autodiscovery
Ruijie(config-vfi)# rd 100:1
Ruijie(config-vfi)# signal bgp
Ruijie(config-vfi)# encapsulation mpls ethernet
Ruijie(config-vfi)# route-target both 10000:1
Ruijie(config-vfi)# site-id 1
Ruijie(config-vfi-site)# xconnect interface vlan 10
Ruijie(config-vfi-site)#exit-site-mode
Ruijie(config-vfi)#exit
```

- Configuring ASBR1:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 2.2.2.2 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# redistribute bgp subnets
Ruijie(config-router)# network 2.2.2.2 0.0.0.0 area 0
Ruijie(config-router)# network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# advertise-labels for bgp-routes
Ruijie(config-mpls-router)# exit
```

#Configure the public network tunnel between PEs.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-Gigabitethernet 1/1)# ip address 10.10.10.2 255.255.255.0
Ruijie(config-if-Gigabitethernet 1/1)# mpls ip
Ruijie(config-if-Gigabitethernet 1/1)# label-switching
Ruijie(config-if-Gigabitethernet 1/1)# exit
```

# Configure the interface that connects ASBRs.

```
Ruijie(config)# interface gigabitEthernet 1/2
Ruijie(config-if-Gigabitethernet 1/2)# ip address 192.168.1.1 255.255.255.252
Ruijie(config-if-Gigabitethernet 1/2)# label-switching
Ruijie(config-if-Gigabitethernet 1/2)# exit
```

# Enable ASBRs to allocate labels for PEs' routes.

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 192.168.1.2 remote-as 200
Ruijie(config-router)# address-family ipv4

```

- Configuring ASBR2:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 3.3.3.3 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 20
Ruijie(config-router)# redistribute bgp subnets
Ruijie(config-router)# network 3.3.3.3 0.0.0.0 area 0
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# advertise-labels for bgp-routes
Ruijie(config-mpls-router)# exit
```

# Configure the public network tunnel between PEs.

```
Ruijie(config)# interface gigabitEthernet 1/2
Ruijie(config-if-Gigabitethernet 1/2)# ip address 20.20.20.2 255.255.255.0
Ruijie(config-if-Gigabitethernet 1/2)# mpls ip
Ruijie(config-if-Gigabitethernet 1/2)# label-switching
Ruijie(config-if-Gigabitethernet 1/2)# exit
```

# Configure the interface that connects ASBRs.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-Gigabitethernet 1/1)# ip address 192.168.1.1 255.255.255.252
Ruijie(config-if-Gigabitethernet 1/1)# label-switching
Ruijie(config-if-Gigabitethernet 1/1)# exit
```

# Enable ASBRs to allocate labels for PEs' routes.

```
Ruijie(config)# router bgp 200
Ruijie(config-router)# neighbor 192.168.1.1 remote-as 100
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 192.168.1.1  send-label
Ruijie(config-router-af)# network 4.4.4.4 mask 255.255.255.255
Ruijie(config-router-af)# end
```

- Configuring PE2:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 4.4.4.4 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 20
Ruijie(config-router)# network 4.4.4.4 0.0.0.0 area 0
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# exit
```

# Configure the public network tunnel between PEs.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-Gigabitethernet 1/1)# ip address 20.20.20.1 255.255.255.0

Ruijie(config-vfi-site)#exit-site-mode
Ruijie(config-vfi)#exit
```

- Configuring CE2:

See "Configuring CE2" in basic configuration examples.

Verification

After the configuration, CE1 can ping with CE2.

After completing the configuration of Kompella VPLS, use the following commands to check the operation of VPLS.

Command	Function
Ruijie# **show bgp l2vpn vpls all**	Displays all the VPLS information.
Ruijie# **show mpls l2transport vc** [*vc_id* [*ip-address*]] | [**interface** *interface_name*] [**detail**]	Displays information about the PW (including VPWS PW and VPLS PW)
Ruijie# **show bgp l2vpn** { **vpls | vpws** } **all connection**s [**neighbor** *address*] | [**interface** *interface_name*] | [**site-id** *id*] [**detail**]	Displays VPLS PW information.
Ruijie# s**how mpls vfi** [*name*]	Displays all the configured or specified VFI information.

Typical Examples of Kompella VPLS Configuration for Routers

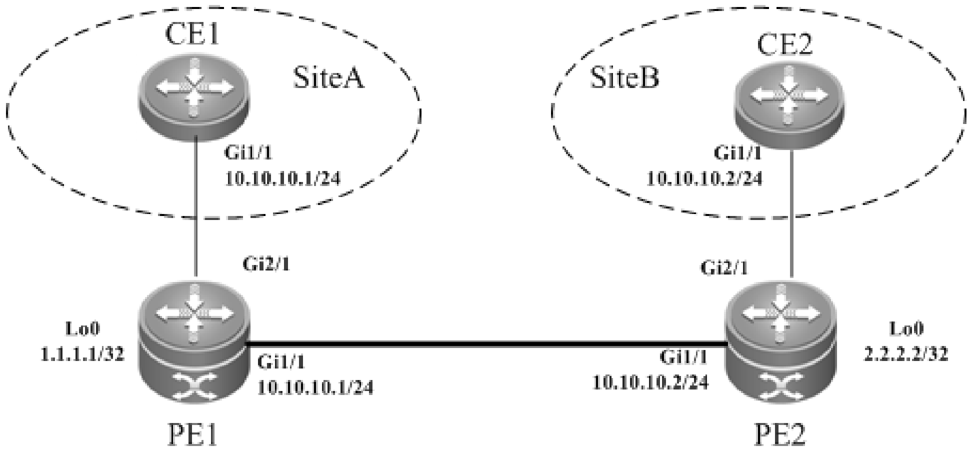
Basic Configuration Examples (Ethernet Access)

Networking Requirements

- LAN segments of customer S in site A and site B are connected with each other through the carrier's network devices, PE1 and PE2, forming a virtual and simulative LAN service or VPLS service.
- PE1 and PE2 are in the same AS and can automatically detect PE devices involved in the VPLS instance.
- Customer S's long-term network deployment plan is to connect LANs in five sites at most.
- The signaling protocol adopted by the carrier is the MP-BGP4 protocol.
- PEs are connected to CEs through the Ethernet interface.

Networking Topology

Figure 79 Basic Kompella VPLS configuration networking topology



Configuration Tips

Before configuring Kompella VPLS, complete the following tasks:

- Configure the public network tunnel that transmits data frames between VPLS PEs.
- Enable the L2VPN address family on PEs.
- Obtain Kompella VPLS configuration information including VPLS instance descriptive information, RT value, VE ID, planned site number, VE ID deviation, and interface information from the network administrator, and configure the Kompella VPLS instance.
- Configure the user access VPLS.

Configuration Steps

- Configuring CE1:

# Configure OSPF.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure the interface between CEs and PEs.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-Gigabitethernet 1/1)# ip ref
Ruijie(config-if-Gigabitethernet 1/1)# ip address 10.10.10.1 255.255.255.0
Ruijie(config-router)# exit
```

- Configuring PE1

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)# network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# exit
```

# Configure the public network tunnel between PEs.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-Gigabitethernet 1/1)# ip ref
Ruijie(config-if-Gigabitethernet 1/1)# ip address 10.10.10.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 1/1)# mpls ip
Ruijie(config-if-Gigabitethernet 1/1)# label-switching
Ruijie(config-if-Gigabitethernet 1/1)# exit
```

# Configure the L2VPN address family.

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 2.2.2.2 remote-as 100
Ruijie(config-router)# neighbor 2.2.2.2 update-source loopback 0

Ruijie(config-router-af)# neighbor 2.2.2.2 activate
Ruijie(config-router-af)# neighbor 2.2.2.2 send-community extended
Ruijie(config-router-af)# exit
```

# Configure a VPLS instance.

```
Ruijie# configure terminal
Ruijie(config)# l2 vfi vpls-1 vpnid 1 autodiscovery
Ruijie(config-vfi)# rd 1:1
Ruijie(config-vfi)# signal bgp
Ruijie(config-vfi)# encapsulation mpls ethernet
Ruijie(config-vfi)# route-target both 10000:1
Ruijie(config-vfi)# site-id 1
Ruijie(config-vfi-site)# xconnect interface gigabitEthernet 2/1
Ruijie(config-vfi-site)#exit-site-id
Ruijie(config-vfi)# exit
```

# Configure the interface.

```
Ruijie(config)# interface gigabitEthernet 2/1
Ruijie(config-if-GigabitEthernet 2/1)# ip ref
Ruijie(config-if-GigabitEthernet 2/1)# exit
```

- Configuring PE2:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 2.2.2.2 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 2.2.2.2 0.0.0.0 area 0
Ruijie(config-router)# network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# exit
```

# Configure the public network tunnel between PEs.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-Gigabitethernet 1/1)# ip ref
Ruijie(config-if-Gigabitethernet 1/1)# ip address 10.10.10.2 255.255.255.0
Ruijie(config-if-Gigabitethernet 1/1)# mpls ip
Ruijie(config-if-Gigabitethernet 1/1)# label-switching
Ruijie(config-if-Gigabitethernet 1/1)# exit
```

# Configure the L2VPN address family.

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 1.1.1.1 remote-as 100
Ruijie(config-router)# neighbor 1.1.1.1 update-source loopback 0

Ruijie(config-vfi-site)#exit-site-id
Ruijie(config-vfi)#exit
```

# Configure the interface.

```
Ruijie(config)# interface gigabitEthernet 2/1
Ruijie(config-if-GigabitEthernet 2/1)# ip ref
Ruijie(config-if-GigabitEthernet 2/1)# exit
```

- Configuring CE2:

# Configure OSPF.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure the interface between CEs and PEs.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-Gigabitethernet 1/1)# ip ref
Ruijie(config-if-Gigabitethernet 1/1)# ip address 10.10.10.2 255.255.255.0
Ruijie(config-router)# exit
```

Verification

After the configuration, CE1 can ping with CE2.

After completing the configuration of Kompella VPLS, use the following commands to check the operation of VPLS.

Command	Function
Ruijie# **show bgp l2vpn vpls all**	Displays all the VPLS information.
Ruijie# **show mpls l2transport vc** [*vc_id* [*ip-address*]] | [**interface** *interface_name*] [**detail**]	Displays information about PW (including VPWS PW and VPLS PW)
Ruijie# **show bgp l2vpn** { **vpls | vpws** } **all connections** [**neighbor** *address*] | [**interface** *interface_name*] | [**site-id** *id*] [**detail**]	Displays VPLS PW information.
Ruijie# **show mpls vfi** [*name*]	Displays all the configured or specified VFI information.

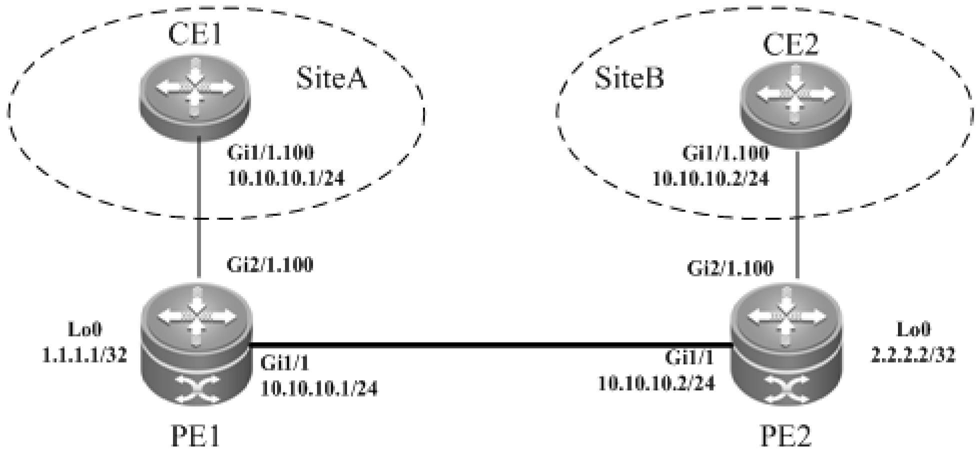
Basic Configuration Examples (Ethernet Sub-interface Access)

Networking Requirements

- LAN segments of customer S in site A and site B are connected with each other through the carrier's network devices, PE1 and PE2, forming a virtual and simulative LAN service or VPLS service.
- PE1 and PE2 are in the same AS and can automatically detect PE devices involved in the VPLS instance.
- Customer S's long-term network deployment plan is to connect LANs in five sites at most.
- The signaling protocol adopted by the carrier is the MP-BGP4 protocol.
- PEs are connected to CEs through the Ethernet sub-interface.

Networking Topology

Figure 80 Basic Kompella VPLS configuration networking topology



Configuration Tips

Before configuring Kompella VPLS, complete the following tasks:

- Configure the public network tunnel that transmits data frames between VPLS PEs.
- Enable the L2VPN address family on PEs.
- Obtain Kompella VPLS configuration information including VPLS instance descriptive information, RT value, VE ID, planned site number, VE ID deviation, and interface information from the network administrator, and configure the Kompella VPLS instance.
- Configure the user access VPLS.

Configuration Steps

- Configuring CE1:

# Configure OSPF.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure the interface between CEs and PEs.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-Gigabitethernet 1/1)# ip ref
Ruijie(config-if-Gigabitethernet 1/1)# exit
Ruijie(config)# interface gigabitEthernet 1/1.100
Ruijie(config-if-Gigabitethernet 1/1.100)# encapsulation dot1Q 100

- Configuring CE2:

# Configure OSPF.

```
Ruijie# configure terminal
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure the interface between CEs and PEs.

```
Ruijie(config)# interface gigabitEthernet 1/1.100
Ruijie(config-if-Gigabitethernet 1/1.100)# encapsulation dot1Q 100
Ruijie(config-if-Gigabitethernet 1/1.100)# ip ref
Ruijie(config-if-Gigabitethernet 1/1.100)# ip address 10.10.10.2 255.255.255.0
Ruijie(config-router)# exit
```

Verification

After the configuration, CE1 can ping with CE2.

After completing the configuration of Kompella VPLS, use the following commands to check the operation of VPLS.

Command	Function
Ruijie# **show bgp l2vpn vpls all**	Displays all the VPLS information.
Ruijie# **show mpls l2transport vc** [*vc_id* [*ip-address*]] | [**interface** *interface_name*] [**detail**]	Displays information about the PW (including VPWS PW and VPLS PW).
Ruijie# **show bgp l2vpn** { **vpls | vpws** } **all connections** [**neighbor** *address*] | [**interface** *interface_name*] | [**site-id** *id*] [**detail**]	Displays VPLS PW information.
Ruijie# s**how mpls vfi** [*name*]	Displays all the configured or specified VFI information.

Inter-AS Configuration Examples – Option A Solution

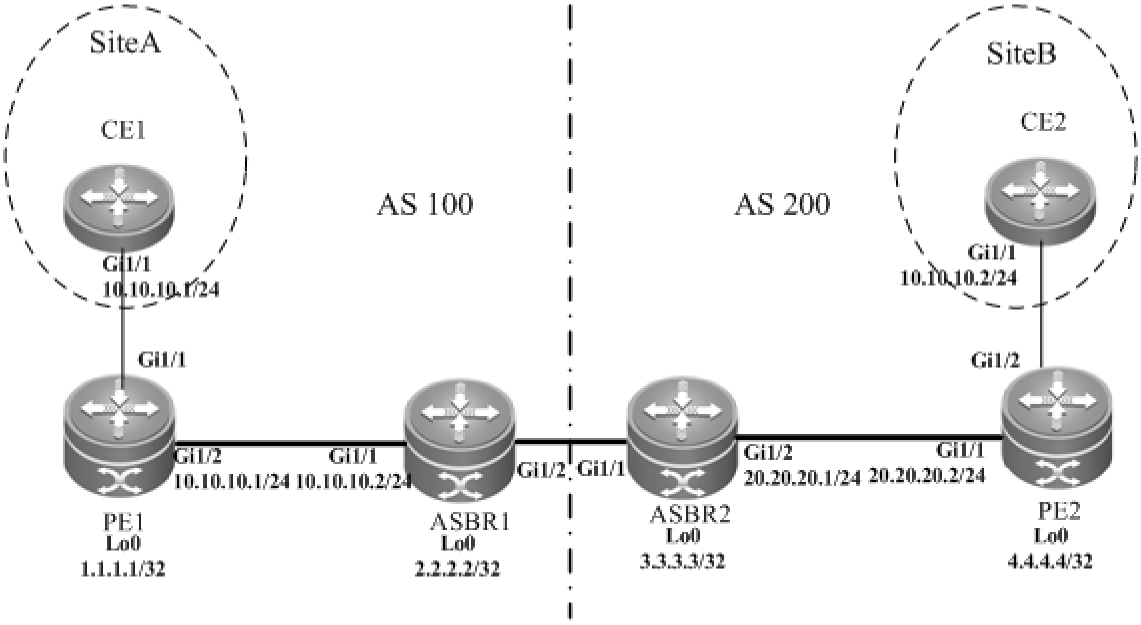
Networking Requirements

- LAN segments of customer S in site A and site B are connected with each other through the carrier's PE1 in AS 100 and PE2 in AS 200, forming a virtual and simulative LAN service or VPLS service;

- PE1 and PE2 are in different ASs. ASBR1 and ASBR2 are considered CE devices by each other, which means that the interface between ASBRs connects the AC to the VPLS instance.

Networking Topology

Figure 81 Kompella VPLS inter-AS networking topology



The preceding figure shows the structure of the Kompella VPLS inter-AS networking topology in Option A. The intermediate interface is considered by ASBRs as AC connection.

Configuration Tips

Before configuring Kompella VPLS, complete the following tasks:

- Run IGP in the carrier's network to realize connection between PE and ASBR devices.
- Establish the MP-IBGP peer relationship between PEs and intra-domain ASBRs in the domain.
- Obtain Kompella VPLS configuration information including VPLS instance descriptive information, RT value, VE ID, maximum planned site number, VE ID deviation, and interface information from the network administrator.

Configuration Steps

- Configuring CE1:

See "Configuring CE1" in basic configuration examples.

- Configuring PE1:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes so that PEs can ping with ASBRs in the same AS.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 1.1.1.1 0.0.0.0 area 0

Ruijie(config-vfi)# route-target both 10000:1
Ruijie(config-vfi)# site-id 4
Ruijie(config-vfi-site)# xconnect interface gigabitEthernet 1/2
Ruijie(config-vfi-site)#exit-site-mode
Ruijie(config-vfi)#exit
```

- Configuring CE2:

See "Configuring CE2" in basic configuration examples.

Verification

After the configuration, CE1 can ping with CE2.

After completing the configuration of Kompella VPLS, use the following commands to check the operation of VPLS.

Command	**Function**
Ruijie# **show bgp l2vpn vpls all**	Displays all the VPLS information.
Ruijie# **show mpls l2transport vc** [*vc_id* [*ip-address*]] | [**interface** *interface_name*] [**detail**]	Displays information about PW (including VPWS PW and VPLS PW)
Ruijie# **show bgp l2vpn** { **vpls | vpws** } **all connections** [**neighbor** *address*] | [**interface** *interface_name*] | [**site-id** *id*] [**detail**]	Displays VPLS PW information.
Ruijie# **show mpls vfi** [*name*]	Displays all the configured or specified VFI information.

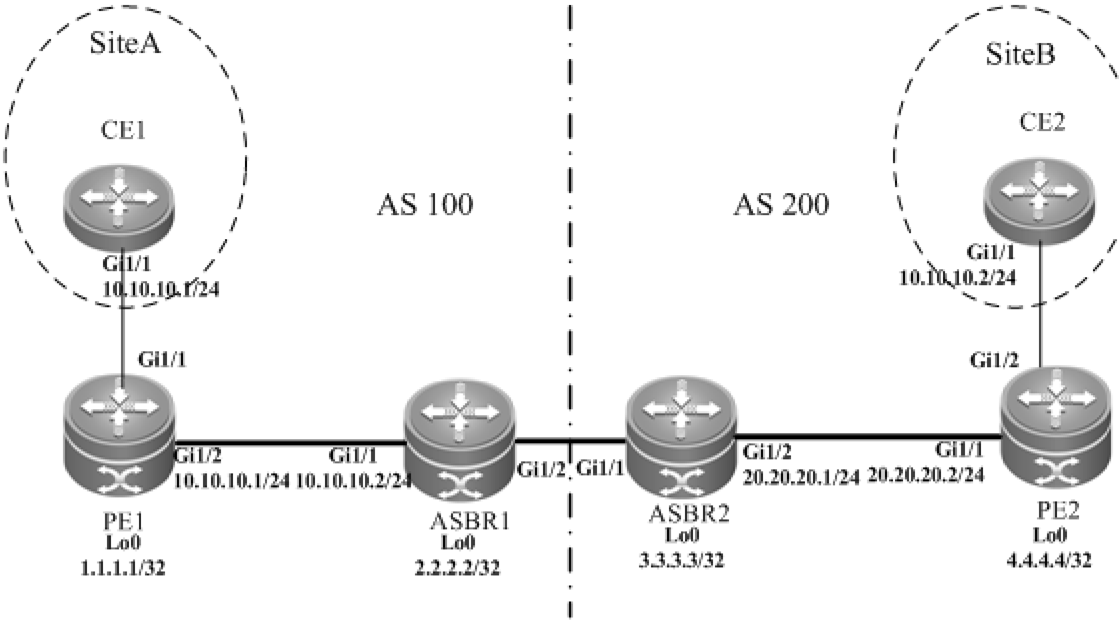
Inter-AS Configuration Examples – Option C Solution

Networking Requirements

- LAN segments of customer S in site A and site B are connected with each other through the carrier's PE1 in AS 1 and PE2 in AS 2, forming a virtual and simulative LAN service or VPLS service.
- PE1 and PE2 are in different ASs and can automatically detect PE devices involved in the VPLS instance.
- ASBR is not responsible for maintaining VPLS label block messages.
- VPLS label block messages are directly exchanged between PEs.

Networking Topology

Figure 50 Kompella VPLS Option C inter-AS networking topology



The preceding figure shows the structure of Kompella VPLS Option C inter-AS networking topology. Customer S's LAN segments in site A and site B are connected to each other through PE1 in AS 100 and PE2 in AS 200 as one LAN.

Configuration Tips

Before configuring Kompella VPLS, complete the following tasks:

- Run IGP in the carrier's network to realize connection between VPLS-PE and ASBR devices in the same AS.
- Establish a public network tunnel between PE and ASBR devices in the same AS and enable MPLS on the ASBR interface.
- Establish IBGP between PE and ASBR devices in the same AS.
- Establish EBGP between ASBR devices and enable send-label.
- Obtain Kompella VPLS configuration information including VPLS instance descriptive information, RT value, VE ID, planned site number, VE ID deviation, and interface information from the network administrator.

⚠ Caution

When Option C (multihop MP-EBGP) is applied to realize Inter-AC Kompella L2VPN applications, the next hop will be changed to itself by default when such information is sent to the peer EBGP if the MP-EBGP connection is set up by the route reflector between ASs to switch NLRI information of L2VPN. To realize the Kompella L2VPN through Option C solution, the **neighbor next-hop-unchanged** command must be configured on the route reflector so that the reflector does not change the next hop when NLRI information is sent. Otherwise, inter-AS forwarding fails.

Configuration Steps

- Configuring CE1:

See "Configuring CE1" in basic configuration examples.

- Configuring PE1:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)# network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# exit
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# exit
```

# Configure the public network tunnel between PEs.

```
Ruijie(config)# interface gigabitEthernet 1/2
Ruijie(config-if-Gigabitethernet 1/2)# ip ref
Ruijie(config-if-Gigabitethernet 1/2)# ip address 10.10.10.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 1/2)# mpls ip
Ruijie(config-if-Gigabitethernet 1/2)# label-switching
Ruijie(config-if-Gigabitethernet 1/2)# exit
```

# Configure the L2VPN address family.

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 4.4.4.4 remote-as 200
Ruijie(config-router)# neighbor 4.4.4.4 update-source loopback 0
Ruijie(config-router)# neighbor 4.4.4.4  ebgp-multihop
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# no neighbor 4.4.4.4  activate
Ruijie(config-router-af)# exit
Ruiije(config-router)# address-family l2vpn vpls
Ruijie(config-router-af)# neighbor 4.4.4.4 activate
Ruijie(config-router-af)# neighbor 4.4.4.4 send-community extended
Ruijie(config-router-af)# exit
```

# Configure the interface that connects CEs.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)# ip ref
Ruijie(config-if-GigabitEthernet 1/1)# exit
```

# Configure a VPLS instance.

```
Ruijie# configure terminal
Ruijie(config)# l2 vfi vpls-1 vpnid 1 autodiscovery
Ruijie(config-vfi)# rd 100:1
Ruijie(config-vfi)# signal bgp
Ruijie(config-vfi)# encapsulation mpls ethernet
Ruijie(config-vfi)# route-target both 10000:1
Ruijie(config-vfi)# site-id 1
Ruijie(config-vfi-site)# xconnect interface gigabitEthernet 1/1
Ruijie(config-vfi-site)#exit-site-mode
Ruijie(config-vfi)#exit
```

- Configuring ASBR1:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 2.2.2.2 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 10
Ruijie(config-router)# redistribute bgp subnets
Ruijie(config-router)# network 2.2.2.2 0.0.0.0 area 0
Ruijie(config-router)# network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# advertise-labels for bgp-routes
Ruijie(config-mpls-router)# exit
```

#Configure the public network tunnel between PEs.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-Gigabitethernet 1/1)# ip ref
Ruijie(config-if-Gigabitethernet 1/1)# ip address 10.10.10.2 255.255.255.0
Ruijie(config-if-Gigabitethernet 1/1)# mpls ip
Ruijie(config-if-Gigabitethernet 1/1)# label-switching
Ruijie(config-if-Gigabitethernet 1/1)# exit
```

# Configure the interface that connects ASBRs.

```
Ruijie(config)# interface gigabitEthernet 1/2
Ruijie(config-if-Gigabitethernet 1/2)# ip ref
Ruijie(config-if-Gigabitethernet 1/2)# ip address 192.168.1.1 255.255.255.252
Ruijie(config-if-Gigabitethernet 1/2)# label-switching
Ruijie(config-if-Gigabitethernet 1/2)# exit
```

# Enable ASBRs to allocate labels for PEs' routes.

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 192.168.1.2 remote-as 200
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 192.168.1.2 send-label
Ruijie(config-router-af)# network 1.1.1.1 mask 255.255.255.255
Ruijie(config-router-af)# end
```

- Configuring ASBR2:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 3.3.3.3 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 20
Ruijie(config-router)# redistribute bgp subnets
Ruijie(config-router)# network 3.3.3.3 0.0.0.0 area 0
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# advertise-labels for bgp-routes
Ruijie(config-mpls-router)# exit
```

# Configure the public network tunnel between PEs.

```
Ruijie(config)# interface gigabitEthernet 1/2
Ruijie(config-if-Gigabitethernet 1/2)# ip ref
Ruijie(config-if-Gigabitethernet 1/2)# ip address 20.20.20.2 255.255.255.0
Ruijie(config-if-Gigabitethernet 1/2)# mpls ip
Ruijie(config-if-Gigabitethernet 1/2)# label-switching
Ruijie(config-if-Gigabitethernet 1/2)# exit
```

# Configure the interface that connects ASBRs.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-Gigabitethernet 1/1)# ip ref
Ruijie(config-if-Gigabitethernet 1/1)# ip address 192.168.1.1 255.255.255.252
Ruijie(config-if-Gigabitethernet 1/1)# label-switching
Ruijie(config-if-Gigabitethernet 1/1)# exit
```

# Enable ASBRs to allocate labels for PEs' routes.

```
Ruijie(config)# router bgp 200
Ruijie(config-router)# neighbor 192.168.1.1 remote-as 100
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# neighbor 192.168.1.1  send-label
Ruijie(config-router-af)# network 4.4.4.4 mask 255.255.255.255
Ruijie(config-router-af)# end
```

- Configuring PE2:

# Configure the loopback interface address.

```
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 4.4.4.4 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

# Configure OSPF and establish public network routes.

```
Ruijie(config)# router ospf 20
Ruijie(config-router)# network 4.4.4.4 0.0.0.0 area 0
Ruijie(config-router)# network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)# exit
```

# Configure LDP and globally enable MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)# exit
```

# Configure the public network tunnel between PEs.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-Gigabitethernet 1/1)# ip ref
Ruijie(config-if-Gigabitethernet 1/1)# ip address 20.20.20.1 255.255.255.0
Ruijie(config-if-Gigabitethernet 1/1)# mpls ip
Ruijie(config-if-Gigabitethernet 1/1)# label-switching
Ruijie(config-if-Gigabitethernet 1/1)# exit
```

# Configure the L2VPN address family.

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 1.1.1.1 remote-as 200
Ruijie(config-router)# neighbor 1.1.1.1 update-source loopback 0
Ruijie(config-router)# neighbor  1.1.1.1  ebgp-multihop
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# no neighbor  1.1.1.1 activate
Ruijie(config-router-af)# exit
Ruiije(config-router)# address-family l2vpn vpls
Ruijie(config-router-af)# neighbor 1.1.1.1 activate
Ruijie(config-router-af)# neighbor 1.1.1.1 send-community extended
Ruijie(config-router-af)# exit
```

# Enable the interface that connects PEs and CEs to bind the VPLS instance.

```
Ruijie(config)# interface gigabitEthernet 1/2
Ruijie(config-if-GigabitEthernet 1/2)# ip ref
Ruijie(config-if-GigabitEthernet 1/2)# exit
```

# Configure a VPLS instance.

```
Ruijie# configure terminal
Ruijie(config)# l2 vfi vpls-1 vpnid 1 autodiscovery
Ruijie(config-vfi)# rd 200:1
Ruijie(config-vfi)# signal bgp
Ruijie(config-vfi)# encapsulation mpls ethernet
Ruijie(config-vfi)# route-target both 10000:1
Ruijie(config-vfi)# mtu 1500
Ruijie(config-vfi)# site-id 2
Ruijie(config-vfi-site)# xconnect interface gigabitEthernet 1/2
Ruijie(config-vfi-site)#exit-site-mode
Ruijie(config-vfi)#exit
```

- Configuring CE2:

See "Configuring CE2" in basic configuration examples.

Verification

After the configuration, CE1 can ping with CE2.

After completing the configuration of Kompella VPLS, use the following commands to check the operation of VPLS.

Command	Function
Ruijie# **show bgp l2vpn vpls all**	Displays all the VPLS information.
Ruijie# **show mpls l2transport vc** [*vc_id* [*ip-address*]] | [**interface** *interface_name*] [**detail**]	Displays information about the PW (including VPWS PW and VPLS PW)
Ruijie# **show bgp l2vpn** { **vpls | vpws** } **all connections** [**neighbor** *address*] | [**interface** *interface_name*] | [**site-id** *id*] [**detail**]	Displays VPLS PW information.
Ruijie# **show mpls vfi** [*name*]	Displays all the configured or specified VFI information.

Examples of Maintaining PW Connectivity of VPLS

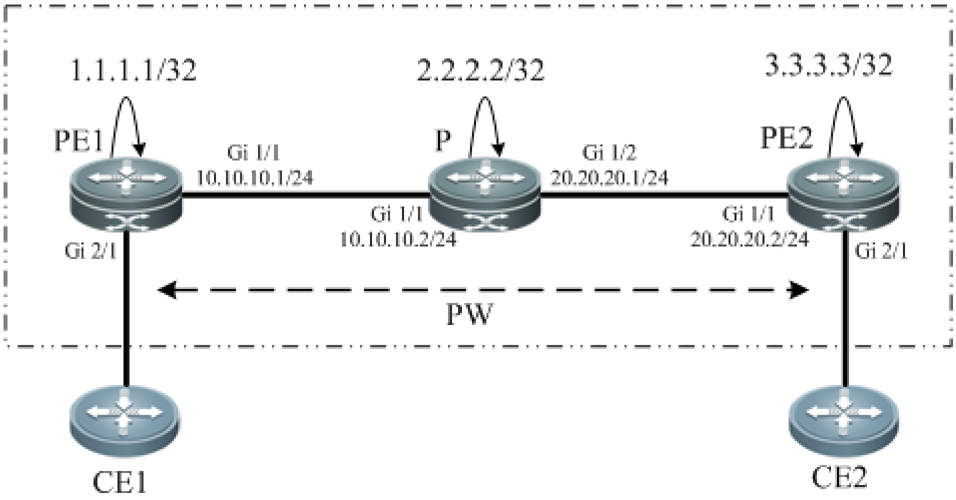
Verifying PW Connectivity and Fault of Martini VPLS

Networking Requirements

- The CE devices play the role of the customer network to connect to the PE devices via the AC.
- PE1 and PE2 establish a PW between them via LDP.
- PE1, P, and PE2 set up the public tunnel and LSP path via LDP.

Network Topology

Figure 51



Configuration Key Points

The configuration key points for PE1, P, and PE2 are as follows:

- Configure the IP address of the interface of each device and configure the OSPF protocol.
- Configure the global MPLS capability and the interface MPLS capability of each device.
- Configure LDP to enable the network to forward MPLS traffic.
- Configure the VPLS.
- Check the PW connectivity.
- Locate the PW fault.

Configuration Steps

(1) Configure the IP address of the interface of each node and configure the OSPF protocol.

#Configure PE1.

```
Ruijie(config)#interface loopback 0
Ruijie(config-if-Loopback 0)#ip address 1.1.1.1 255.255.255.255
Ruijie(config-if-Loopback 0)#exit
Ruijie(config-if-GigabitEthernet 1/1)#ip address 10.10.10.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)#exit
Ruijie(config)#router ospf 10
Ruijie(config-router)#network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)#network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)#exit
```

#Configure P.

```
Ruijie(config)#interface loopback 0
Ruijie(config-if-Loopback 0)#ip address 2.2.2.2 255.255.255.255
Ruijie(config-if-Loopback 0)#exit
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#ip address 10.10.10.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)#exit
Ruijie(config)#interface gigabitEthernet 1/2
Ruijie(config-if-GigabitEthernet 1/2)#ip address 20.20.20.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/2)#exit
Ruijie(config)#router ospf 10
Ruijie(config-router)#network 2.2.2.2 0.0.0.0 area 0
Ruijie(config-router)#network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)#network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)#exit
```

#Configure PE2.

```
Ruijie(config)#interface loopback 0
Ruijie(config-if-Loopback 0)#ip address 3.3.3.3 255.255.255.255
Ruijie(config-if-Loopback 0)#exit
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#ip address 20.20.20.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)#exit
Ruijie(config)#router ospf 10
Ruijie(config-router)#network 3.3.3.3 0.0.0.0 area 0
Ruijie(config-router)#network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)#exit
```

(2) Configure the global MPLS capability and the interface MPLS capability of each node and enable the LDP function on the interfaces.

#Configure PE1.

```
Ruijie(config)#mpls ip
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)#neighbor 3.3.3.3
Ruijie(config-mpls-router)#exit
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#mpls ip
Ruijie(config-if-GigabitEthernet 1/1)#label-switching
Ruijie(config-if-GigabitEthernet 1/1)#exit
```

#Configure P.

```
Ruijie(config)#mpls ip
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)#exit
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#mpls ip
Ruijie(config-if-GigabitEthernet 1/1)#label-switching
Ruijie(config-if-GigabitEthernet 1/1)#exit
Ruijie(config)#interface gigabitethernet 1/2
Ruijie(config-if-GigabitEthernet 1/2)#mpls ip
Ruijie(config-if-GigabitEthernet 1/2)#label-switching
Ruijie(config-if-GigabitEthernet 1/2)#exit
```

#Configure PE2.

```
Ruijie(config)#mpls ip
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)#neighbor 1.1.1.1
Ruijie(config-mpls-router)#exit
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#mpls ip
Ruijie(config-if-GigabitEthernet 1/1)#label-switching
Ruijie(config-if-GigabitEthernet 1/1)#exit
```

(3) Configure VPLS instances between PE1 and PE2 and enable CE1 and CE2 to access the VPLS.

#Configure PE1.

```
Ruijie(config)# l2 vfi vfi-a vpnid 1
Ruijie(config-vfi)# neighbor 1.1.1.1 vc-id 100 encapsulation mpls
Ruijie(config-vfi)# exit
Ruijie(config)# vlan 10
Ruijie(config-vlan)# exit
Ruijie(config)# interface vlan 10
Ruijie(config-if-Vlan 10)# xconnect vfi vfi-a
Ruijie(config-if-Vlan 10)# exit
Ruijie(config)# interface gigabitEthernet 3/2
Ruijie(config-if-Gigabitethernet 3/2)#  switchport access vlan 10
Ruijie(config-if-Gigabitethernet 3/2)# exit
```

#Configure PE2.

```
Ruijie(config)# l2 vfi vfi-a vpnid 1
Ruijie(config-vfi)# neighbor 3.3.3.3 vc-id 100 encapsulation mpls
Ruijie(config-vfi)# exit
Ruijie(config)# vlan 10
Ruijie(config-vlan)# exit
Ruijie(config)# interface vlan 10
Ruijie(config-if-Vlan 10)# xconnect vfi vfi-a
Ruijie(config-if-Vlan 10)# exit
Ruijie(config)# interface gigabitEthernet 1/3
Ruijie(config-if-Gigabitethernet 1/3)#  switchport access vlan 10
Ruijie(config-if-Gigabitethernet 1/3)# exit
```

(4) Verify the PW connectivity.

```
Ruijie#ping mpls pseudowire 3.3.3.3 100 label-alert
Sending 5, 112-byte MPLS Echoes on Pseudowire, peer address 3.3.3.3, VC ID 100,

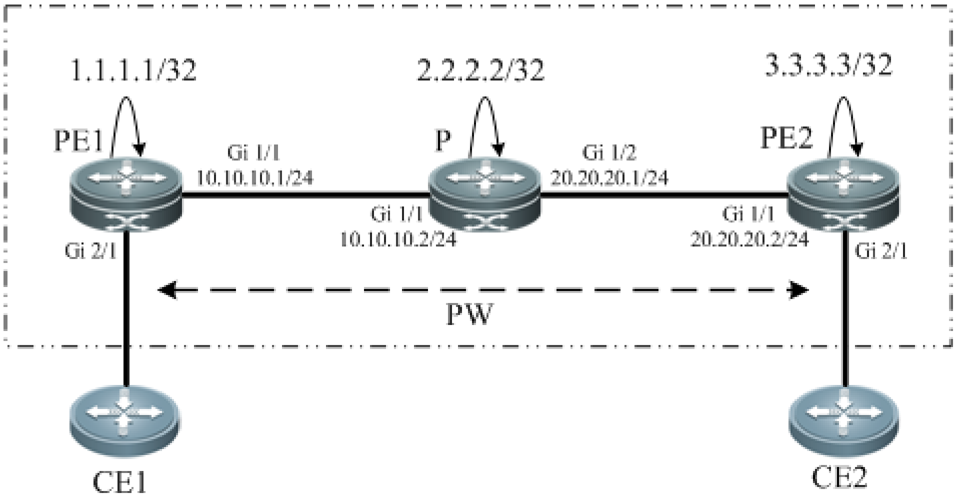
Verifying PW Connectivity of Kompella VPLS

Networking Requirements

As shown in Figure 3-36, PE1, P, and PE2 belong to the same MPLS domain, and CE1 and CE2 belong to the same VPN instance. PE1 and PE2 establish a PW between them and use the ping or traceroute command to check the PW connectivity to ensure services on the links.

Network Topology

Figure 52 错误!未指定顺序。



Configuration Key Points

The configuration key points for each node are as follows:

- Configure the IP address of the interface of each node and configure the OSPF protocol.
- Configure the global MPLS capability and the interface MPLS capability of each node.
- Enable the L2VPN on PE1 and PE2 and create a VC connection.
- Check the PW connectivity.
- Locate the PW fault.

Configuration Steps

(1) Configure the IP address of the interface of each node and configure the OSPF protocol.

#Configure PE1.

```
Ruijie(config)#interface loopback 0
Ruijie(config-if-Loopback 0)#ip address 1.1.1.1 255.255.255.255
Ruijie(config-if-Loopback 0)#exit
Ruijie(config-if-GigabitEthernet 1/1)#ip address 10.10.10.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)#exit
Ruijie(config)#router ospf 10
Ruijie(config-router)#network 1.1.1.1 0.0.0.0 area 0
Ruijie(config-router)#network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)#exit
```

#Configure P.

```
Ruijie(config)#interface loopback 0
Ruijie(config-if-Loopback 0)#ip address 2.2.2.2 255.255.255.255
Ruijie(config-if-Loopback 0)#exit
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#ip address 10.10.10.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)#exit
Ruijie(config)#interface gigabitEthernet 1/2
Ruijie(config-if-GigabitEthernet 1/2)#ip address 20.20.20.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/2)#exit
Ruijie(config)#router ospf 10
Ruijie(config-router)#network 2.2.2.2 0.0.0.0 area 0
Ruijie(config-router)#network 10.10.10.0 0.0.0.255 area 0
Ruijie(config-router)#network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)#exit
```

#Configure PE2.

```
Ruijie(config)#interface loopback 0
Ruijie(config-if-Loopback 0)#ip address 3.3.3.3 255.255.255.255
Ruijie(config-if-Loopback 0)#exit
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#ip address 20.20.20.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)#exit
Ruijie(config)#router ospf 10
Ruijie(config-router)#network 3.3.3.3 0.0.0.0 area 0
Ruijie(config-router)#network 20.20.20.0 0.0.0.255 area 0
Ruijie(config-router)#exit
```

(2) Configure the global MPLS capability and the interface MPLS capability of each node and enable the LDP function on the interfaces.

#Configure PE1.

```
Ruijie(config)#mpls ip
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)#exit
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#mpls ip
Ruijie(config-if-GigabitEthernet 1/1)#label-switching
Ruijie(config-if-GigabitEthernet 1/1)#exit
```

#Configure P.

```
Ruijie(config)#mpls ip
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)#exit
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#mpls ip
Ruijie(config-if-GigabitEthernet 1/1)#label-switching
Ruijie(config-if-GigabitEthernet 1/1)#exit
Ruijie(config)#interface gigabitEthernet 1/2
Ruijie(config-if-GigabitEthernet 1/2)#mpls ip
Ruijie(config-if-GigabitEthernet 1/2)#label-switching
Ruijie(config-if-GigabitEthernet 1/2)#exit
```

#Configure PE2.

```
Ruijie(config)#mpls ip
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0  force
Ruijie(config-mpls-router)#exit
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#mpls ip
Ruijie(config-if-GigabitEthernet 1/1)#label-switching
Ruijie(config-if-GigabitEthernet 1/1)#exit
```

(3) Configure a L2VPN address family.

#Configure PE1.

```
Ruijie(config)#router bgp 100
Ruijie(config-router)#neighbor 3.3.3.3 remote-as 100
Ruijie(config-router)#neighbor 3.3.3.3 update-source loopback 0
Ruiije(config-router)#address-family l2vpn vpws
Ruijie(config-router-af)#neighbor 3.3.3.3 activate
Ruijie(config-router-af)#neighbor 3.3.3.3 send-community extended
Ruijie(config-router-af)#exit
```

#Configure PE2.

```
Ruijie(config)#router bgp 100
Ruijie(config-router)#neighbor 1.1.1.1 remote-as 100
Ruijie(config-router)#neighbor 1.1.1.1 update-source loopback 0
Ruiije(config-router)#address-family l2vpn vpws
Ruijie(config-router-af)#neighbor 1.1.1.1 activate
Ruijie(config-router-af)#neighbor 1.1.1.1 send-community extended
Ruijie(config-router-af)#exit
```

(4) Configure a VFI instance.

#Configure PE1.

```
Ruijie(config)# vlan 10
Ruijie(config-vlan)# exit
Ruijie(config)# interface gigabitEthernet 3/2
Ruijie(config-if-Gigabitethernet 3/2)#  switchport access vlan 10
Ruijie(config-if-Gigabitethernet 3/2)# exit
Ruijie(config)# l2 vfi vpls-1 vpnid 1 autodiscovery

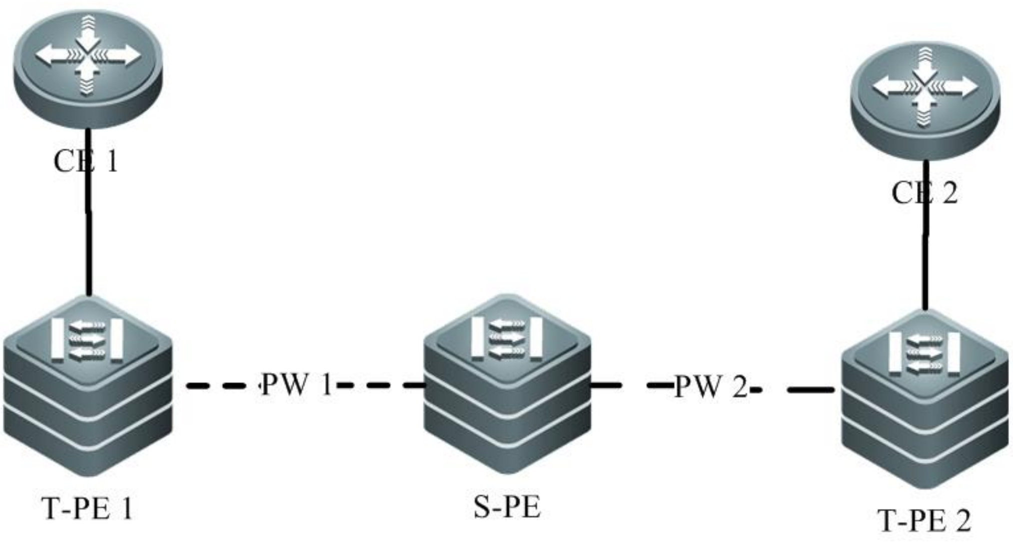
MS-PW

Introduction

MS-PW is an intra-domain or cross-domain end-to-end pseudo wire in the IP/MPLS network, and is set up between two user-oriented T-PE devices of the operator and passes through one or more PE devices (switches). It is used to simulate Layer 2 point-to-point services. The MS-PW allows you to carry the specific services from the AC across domains on the paths or tunnels between the ingress and egress of the PW and to manage the information such as the service-related signaling, statuses, and alarms on the border of the PW.

Overview

Figure 53 Basic MS-PW Topology



Involved devices are as follows:

- CE (customer edge): the device directly connected to the user network and operator network. It can be a router, a bridge device, or a host. The customer edge is the start point and end point of the simulation service. It does not participate in the establishment and maintenance of the PW. Therefore, it cannot perceive whether the end-to-end PW exists.

- T-PE (PW terminating provider edge): the device connected to the customer edge via the access circuit. This type of device mainly processes the data from the CE devices and forwards it to the peer PE devices. In addition, T-PE needs to process the simulation data from the peer end-to-end PW of the PW.

- S-PE (switching provider edge): a key device in the establishment of a MS-PW. It serves as the joint of the control plane and data plane of the MS-PW between two T-PEs and connects the adjacent segments of the MS-PW based on the PW identifier. On the data plane, the S-PE handles the multiplex layer of the PW and exchanges PW packets between adjacent PW segments. On the control plane, the S-PE participates in the establishment and maintenance of the PW. In addition, it participates in the VCCV and operation, administration, and management (OAM). You can also pre-configure the PW segments on the S-PE and bind the two PW segments on both sides of the S-PE.

Working Principle

The connection of multiple PW segments is not directly set up between two T-PE devices, but via an S-PE. For example, as shown in Figure 3-38, T-PE1 and T-PE2 set up a connection with the S-PE separately. The S-PE is responsible for connecting the PW segments on both sides of it. During establishment signaling negotiation, one of the T-PE devices sends a mapping packet that carries parameters to the S-PE, and the S-PE processes the packet and then forwards the processed packet to the other T-PE. After the parameters of both T-PE devices are negotiated, the PW is established. Same with the mapping packets, the release, withdrawal, and notification packets are also transmitted segment by segment.

Figure 54 MS-PW Signaling Interworking

(2) Label mapping message
Capability negotiation succeeds
(3) Label mapping message
(4) Label mapping message
AC down
(5) Label withdrawal message
(6) Label withdrawal message
(8) Label release message
(7) Label release message

Implementation of the MS-PW solution is described in detail as follows:

- A PW segment connecting T-PE1 with the S-PE and a PW segment connecting T-PE2 with the S-PE are configured. During the signaling connection, T-PE1 and T-PE2 play the active role and the S-PE plays the passive role. However, if the S-PE is configured in static mode, it serves as the T-PE.

- The S-PE connects the two PW segments. During the signaling negotiation, the parameters of T-PE1 and T-PE2 are negotiated through the S-PE. If the parameters of both ends are consistent, the PW is established via the S-PE. Otherwise, the S-PE does not send label mapping messages to the downstream devices.

- Same with the mapping packets, the release, withdrawal, and notification packets are also transmitted segment by segment, so that the packets can be forwarded to each segment or one of the MS-PW segments can be removed without affecting others.

The figure above shows that T-PE1 initiates a delete or reset message. However, any PE device (T-PE or S-PE) on the MS-PW can possibly initiate the delete or reset message for certain reasons, causing the removal of the MS-PW. Similarly, the PE devices only need to send related messages to each PW segment of the MS-PW.

Protocols and Standards

- RFC5254: Requirements for Multi-Segment Pseudo-wire Emulation Edge-to-Edge (PWE3)

- RFC 6073: Segmented Pseudowire

- RFC 5659: An Architecture for Multi-Segment Pseudowire Emulation Edge-to-Edge

- RFC 5085: Pseudowire Virtual Circuit Connectivity Verification (VCCV): A Control Channel for Pseudowire

Defaults

The default PW value of the T-PE is the same as that of a common Martini VPWS and static VPWS. For the S-PE, when the PW is dynamically established, the related PW attributes of the default PW value are obtained via negotiation with the T-PE.

Configuring MS-PW

Perform the following steps to configure a MS-PW:

- (Mandatory) Configure the MPLS.
- (Mandatory) Configure PW segments.
- (Mandatory) Configure the PW switching point.
- Display the configuration.

Configuring MPLS

Enable the MPLS on the T-PEs and S-PE. The configuration is similar to the configuration of public network tunnels described in Section 3.2 "VPWS".

Configuring PW Segments

Configure the PW segments on both T-PE devices. The configuration is the same as that of the Martini VPWS and static VPWS. For details, see related sections.

Configuring PW Switching Point

Run the following commands to configure the PW switching point on S-PE:

Command	Function
Ruijie# **config terminal**	Enters the global configuration mode.
Ruijie(config)# **l2 vfi** *name* **switching**	Creates a switching VFI instance.
Ruijie(config-vfi)# **neighbor** *ip-address vc-id* **encapsulation mpls** [**manual**] [**no-switching-tlv**] [**tnl-policy** *policy-name*]	Joins the PWs located on both sides of the VFI.
Ruijie(config-vfi)# **end**	Returns to the privileged EXEC mode.
Ruijie# **copy running-config startup-config**	Saves the configuration.

Caution

The MS-PW can be established only after the PWs are configured successfully on both sides of S-PE.

Displaying Configuration

After the configuration is completed, run the following commands to display the information of the switching VFI:

Command	Function
Ruijie#**show mpls switching vfi** [*name*]	Displays the information of the switching VFI.

Ruijie#**show mpls l2transport switching vfi** [*name*]	Displays the switching information of the switching VFI.

Examples of Configuring MS-PW

Configuring Static MS-PW

Networking Requirements

You need to connect CE1 on Site A and CE2 on Site B to T-PE1 and T-PE2 respectively. The requirements are as follows:

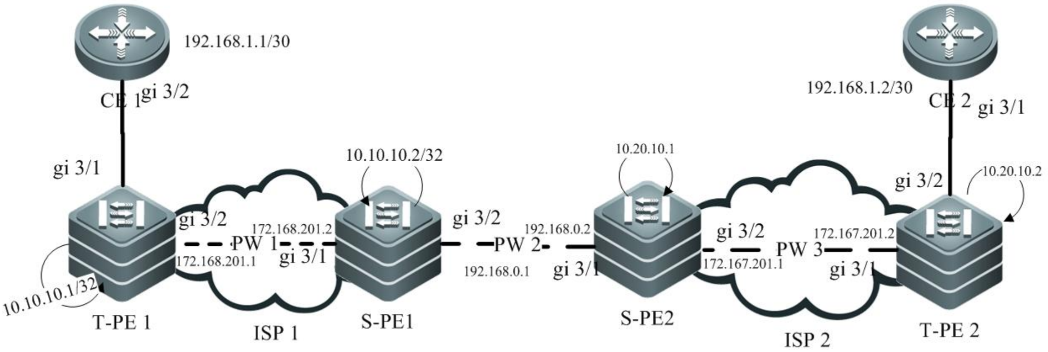
(1) T-PE1 and S-PE1 establish PW1.

(2) S-PE2 and T-PE2 establish PW3.

(3) Join PW1 and PW2 (from S-PE1 to S-PE2) on the switching node S-PE1 and join PW2 and PW3 (from S-PE1 to S-PE2) on the switching node S-PE2 to establish a cross-domain MS-PW.

Network Topology

Figure 55 Cross-domain MS-PW



Configuration Key Points

The configuration key points are as follows:

- The CE device is connected to the PE device through an Ethernet interface. The PW operates in Ethernet mode.
- The MPLS is configured on the backbone network to establish a label switched path (LSP) statically.
- PW segments are configured between T-PE1 and S-PE1 and between T-PE2 and S-PE2 separately.
- The PWs on both sides of the two switching node device are statically jointed to form a MS-PW.

Configuration Steps

- Configure CE-1.

#Configure the IP address.

```
Ruijie# config terminal
Ruijie(config)# interface gigabitethernet 3/2
Ruijie(config-if-GigabitEthernet 3/2)# ip address 192.168.1.1 255.255.255.252
Ruijie(config-if-GigabitEthernet 3/2)# exit
```

- Configure CE-2.
- The configuration of CE-2 is similar to that of CE-1.Configure T-PE1.

#Configure the IP address.

```
Ruijie# config terminal
Ruijie(config)# interface loopback 0
Ruijie(config-if-Loopback 0)# ip address 10.10.10.1 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
Ruijie(config)# interface gigabitEthernet 3/2
Ruijie(config-if-GigabitEthernet 3/2)# ip address 172.168.201.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 3/2) # exit
```

Ruijie(config)##Configure the routing protocol.

```
Ruijie(config)# router ospf 1
Ruijie(config-router)# network 10.10.10.1 0.0.0.0 area 0
Ruijie(config-router)# network 172.168.201.0 0.0.0.255 area 0
Ruijie(config-router)# exit
Ruijie(config)#
```

#Configure the MPLS.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp

```

Configuring MPLS GR

Note

Routers and router icons contained in this chapter refer to routers and layer-3 switches with the routing protocol enabled.

LDP GR

Overview

The Internet Engineering Task Force (IETF) has extended the Label Distribution Protocol (LDP), which is a signaling protocol of Multiprotocol Label Switching (MPLS), so that a device may instruct neighbors to keep related MPLS forwarding entries and set an "old" flag for these MPLS forwarding entries when the LDP is restarted on the device. After the LDP is restarted, neighbors assist the device to implement information synchronization so that the device is restored to the status before the LDP restart within the shortest possible time. The packet forwarding path does not change and data forwarding is not interrupted in the system throughout the LDP restart, guaranteeing the high reliability of MPLS application services.

Basic Concepts

GR Routers Classified by Capability

GR routers are classified by capability into GR-capable routers, GR-aware routers, and GR-unaware routers.

- GR-Capable Router

A GR-capable router is a router that has GR capability. In general, a GR-capable router is equipped with two management boards which work in 1+1 master/slave mode. The GR-capable router can send an advertisement packet to neighboring routers during master/slave switchover of the management boards, so that neighboring routers keep forwarding entries related to the GR-capable router. After master/slave switchover, routing tables are re-established without causing route flapping or changing the packet forwarding path, guaranteeing uninterrupted data forwarding in the system.

- GR-Aware Router

A GR-aware router is a router that has GR detection capability. It may be not equipped with two management boards but can detect that its neighbors are experiencing GR and can assist its neighbors to complete GR.

- GR-Unaware Router

A GR-unaware router is a router that does not have GR detection capability. It cannot detect that its neighbors are experiencing GR, cannot assist its neighbors to complete GR, and does not have GR capability. Generally, if a router has no awareness capability, it is because the system software does not provide the GR feature or the GR feature is disabled.

GR Routers Classified by Role

GR routers are classified by role during router restart into GR restarters and GR helpers.

- GR Restarter

The GR restarter has GR capability and its restart is triggered by administrators or faults.

- GR Helper

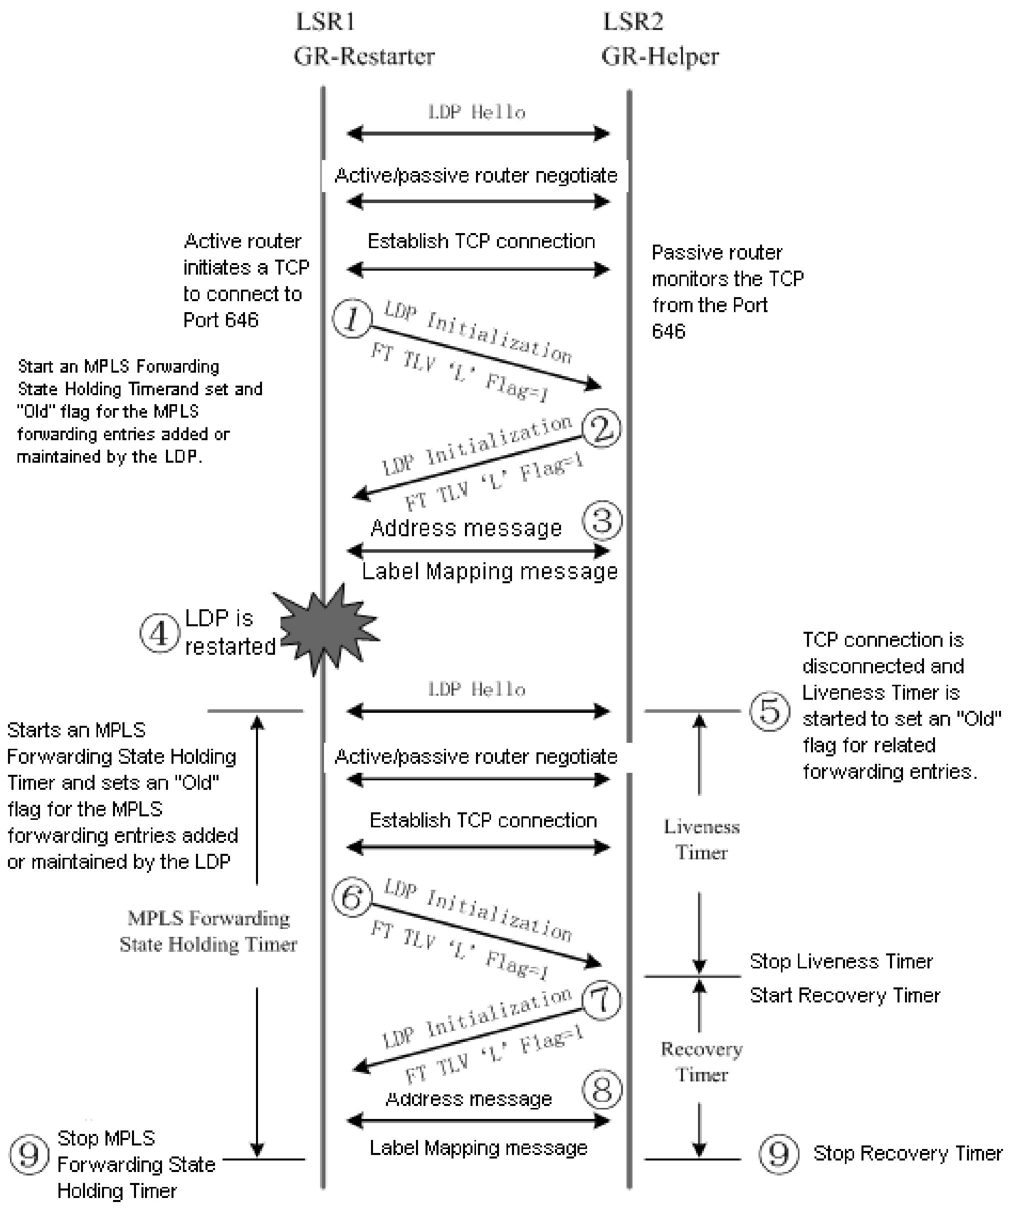
The GR helper is a neighbor of the GR restarter. It must be at least a GR-aware router.

Working Principle

The LDP GR function must be enabled on and supported by two routers in order to establish a GR-capable LDP session between them. If not, only a common LDP session can be established. If the initiator supports LDP GR and LDP GR is enabled on it during LDP session establishment, the initiator sends an Initialization message that carries an FT Session TLV.

If the passive router receives an Initialization message that carries an FT Session TLV during session establishment, it may choose to add or not add the FT Session TLV to the Initialization message to be sent to the initiator depending on its LDP GR capability. If the passive router supports LDP GR and LDP GR is enabled on it, the Initialization message will carry the FT Session TLV to establish a GR-capable LDP session. Otherwise, the Initialization message will not carry the FT Session TLV to establish a common GR-incapable LDP session LDP session. If the passive router receives an Initialization message that does not carry the FT Session TLV, a common GR-incapable LDP session is established, no matter whether the passive router adds the FT Session TLV to the Initialization message to be sent. Figure 1-1 shows the process of LDP session establishment between two Label Switching Routers (LSRs) with LDP GR capability.

Figure 1-1 LDP GR session establishment process



LSR1
GR-Restarter
LSR2
GR-Helper

Start Recovery Timer
7
LDP Initialization
FT TLV 'L' Flag=1
Recovery Timer
8
Address message
Label Mapping message
9
Stop MPLS Forwarding State Holding Timer
9
Stop Recovery Timer

LSR 1 initiates an Initialization message that carries an optional FT Session TLV, indicating that LSR 1 itself supports LDP GR.

After LSR 2 that supports LDP GR receives the Initialization message that carries the FT Session TLV, it returns an Initialization message that also carries the FT Session TLV to LSR 1. When LSR 1 receives the Initialization message from LSR 2, a GR-capable LDP session is established.

LSR 1 and LSR 2 exchange LDP Address messages and Label Mapping messages with each other.

The LDP on LSR 1 is restarted for a certain reason. LSR 1 keeps all MPLS forwarding entries added or maintained by the LDP, sets an "old" flag for these forwarding entries, and starts an MPLS Forwarding State Holding Timer.

After LSR 2 with LDP GR capability detects that the GR-capable LDP session with LSR 1 is disconnected, LSR 2 keeps the MPLS forwarding entries related to this session and sets an "old" flag for these forwarding entries. At the same time, LSR 2 selects a smaller value of its Liveness Timer and the FT Reconnect Timeout in the received FT Session TLV to start a Liveness Timer, and keeps these "old" forwarding entries before the Liveness Timer is triggered.

To re-establish a session with LSR 2, LSR 1 sets the Recovery Time in the FT Session TLV of the Initialization message to the remaining value of the MPLS Forwarding State Holding Timer.

After receiving the Initialization message that carries the FT Session TLV from LSR 1, LSR 2 detects that Recovery Time is not 0, LSR 2 continues to keep the "old" forwarding entries, stops the Liveness Timer, selects a smaller value of the its Recovery Time and the Recovery Time in the received FT Session TLV to start a Recovery Timer, and keeps these "old" forwarding entries before the Recovery Timer is triggered.

LSR 1 and LSR 2 exchange LDP Address and Label Mapping messages with each other, and keep or remove the "old" flag set for MPLS forwarding entries.

The GR process ends. LSR 1 and LSR 2 delete the MPLS forwarding entries with the "old" flag from themselves respectively.

Protocols and Specifications

The protocols or specifications involved are as follows:

- RFC 3036: LDP Specification
- RFC 3037: LDP Applicability
- RFC 3215: LDP State Machine
- RFC 3478: Graceful Restart Mechanism for LDP
- RFC 3479: Fault Tolerance for LDP

Configuring LDP GR

Network Environment

The GR function of the MPLS LDP is configured to maintain the neighborhood and sessions between routers and recover sessions and label information when faults occur on MPLS devices.

Prerequisites

Complete the following tasks before configuring MPLS LDP GR:

- Configure IGP GR.
- Configure MPLS LDP session information.

Data Preparations

Prepare the following data before configuring MPLS LDP GR:

- LDP session re-connection time
- LDP neighbor keep-alive time
- LDP session recovery time

Configuring the LDP GR

By default, the LDP GR function is disabled on a device. To enable the LDP GR function on a device, enter privileged user mode and run the following commands:

Command	Function
Ruijie#**configure terminal**	Enters global configuration mode.

Ruijie(config)#**mpls ip**	Enables global MPLS forwarding. Caution This command is not applicable to forwarding on switch chips.
Ruijie(config)#**interface type ID**	Enters interface configuration mode.
Ruijie(config-if-type ID)#**no switchport**	Sets ports to L3 ports (Switch configuration).
Ruijie(config-if-type ID)#**mpls ip**	Enables LDP forwarding on interfaces.
Or:	
Ruijie(config-if-type ID)#**mpls ip**	Enables LDP forwarding on interfaces (Router configuration).
Ruijie(config-if-type ID)#**ip ref**	Enables fast forwarding on interfaces.
Ruijie(config-if-type ID)#**label-switching**	Enables MPLS packet processing on interfaces.
Ruijie(config)#**mpls router ldp**	Enters LDP configuration mode.
Ruijie(config-mpls-router)#l**dp router-id** *Loopback ID* **force**	Sets the router ID to a loopback ID (The settings immediately take effect).
Ruijie(config-mpls-router)#**graceful-restart**	Enables LDP GR. By default, LDP GR is disabled.
Ruijie(config-mpls-router)#**end**	Exits LDP configuration mode.
Ruijie#s**how mpls ldp graceful-restart**	Displays LDP GR sessions and session parameters.

To disable LDP GR, run the **no graceful-restart** command.

Note The existing LDP session is not affected when LDP GR is enabled. For example, the LDP session does not restart. The LDP GR takes effect only after the LDP session restarts..

Configuring Parameters Related to LDP GR (Optional)

Enter LDP configuration mode and run the following commands:

Command	**Function**
Ruijie#**configure terminal**	Enters global configuration mode.
Ruijie(config)#**mpls router ldp**	Enables the LDP and enters LDP configuration mode.
Ruijie(config-mpls-router)**#graceful-restart timer reconnect** *seconds*	Sets the LDP session re-connection time. By default, the LDP session reconnection time is 300 seconds.
Ruijie(config-mpls-router)#**graceful-restart timer neighbor-liveness** *seconds*	Sets the LDP neighbor keep-alive time. By default, the LDP neighbor keep-alive time is 120 seconds.
Ruijie(config-mpls-router)#**graceful-restart timer recovery** *seconds*	Sets the LDP session recovery time. By default, the LDP session recovery time is 120 seconds.
Ruijie(config-mpls-router)#**end**	Exits LDP configuration mode.
Ruijie#**show mpls ldp graceful-restart**	Displays LDP GR sessions and session parameters.

To restore the default settings of parameters related to LDP GR, run the **no graceful-restart timer reconnect, no graceful-restart timer neighbor-liveness**, and **no graceful-restart timer recovery** commands.

Verification

To display LDP GR configuration and running information, run the following commands.

Command	Function
show mpls ldp graceful-restart	Displays LDP GR sessions and session parameters.
show mpls ldp bindings [all | **vrf** *vrf-name*] [*ip-address/mask*|label *label*] **[remote | local**]	Displays the mapping between Forwarding Equivalence Classes (FECs) and labels.
show mpls ldp neighbor [all | **vrf** *vrf-name*] [*ip-address*] [**detail]**	Displays the status of LDP neighbors.

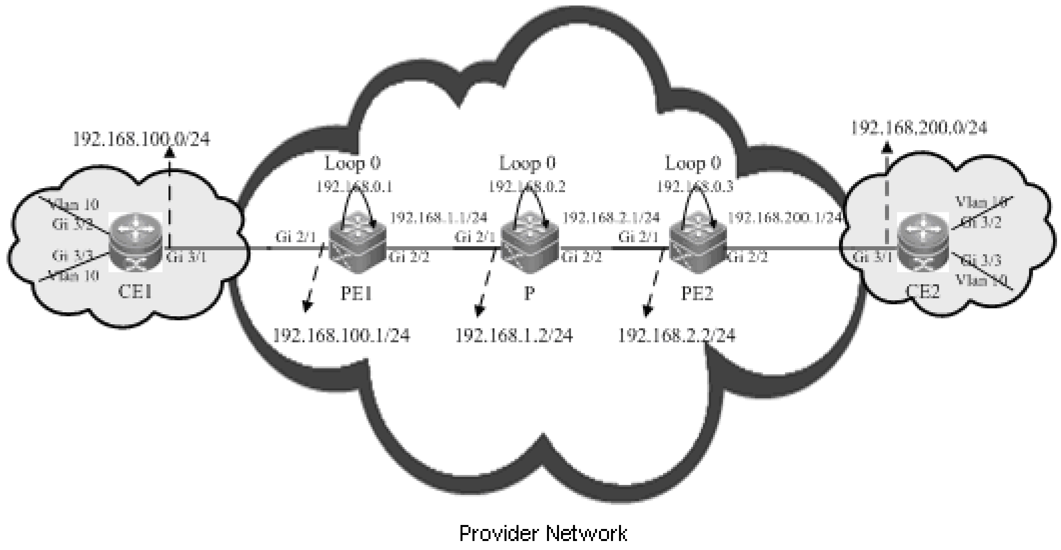
Configuration Examples

Networking Requirements

- An MPLS network consists of Provider Edge (PE) and Provider (P) devices.
- PE and P devices support the LDP and are capable of GR.
- This following describes how to configure LDP GR on PE 1 and a P device. PE 1 is a GR-capable router and the GR restarter. The P device is a GR-aware router and the GR helper.

Networking Topology

Figure 1-2 Networking topology for configuring LDP GR



Configuration Tips

Configure PE 1 and the P device as follows:

- Configure interface IP addresses and the Open Shortest Path First (OSPF) protocol.
- Enable global MPLS packet forwarding on devices, MPLS forwarding, and the LDP on interfaces.
- Configure the LDP to enable the network to forward MPLS traffic.
- Enable the LDP GR protocol.

- Configure parameters related to LDP GR.
- Restart the LDP session for the configurations to take effect.

Configuration Steps

- Configure interface IP addresses and the OSPF protocol.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

## The **no switchport** command is used on a switch to switch to Routed Port mode. It is not applicable to routers, and therefore you do not need to run this command on routers.

```
Ruijie(config)#interface gigabitEthernet 2/1
Ruijie(config-if-GigabitEthernet 2/1)#no switchport
Ruijie(config-if-GigabitEthernet 2/1)#ip address 192.168.100.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 2/1)#exit
```

## The **no switchport** command runs on a switch to switch to Routed Port mode. It is not applicable to routers, and therefore you do not need to run this command on routers.

```
Ruijie(config)#interface gigabitEthernet 2/2
Ruijie(config-if-GigabitEthernet 2/2)#no switchport
Ruijie(config-if-GigabitEthernet 2/2)#ip address 192.168.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 2/2)#exit
Ruijie(config)#interface loopback 0
Ruijie(config-Loopback 0)#ip address 192.168.0.1 255.255.255.255
Ruijie(config-Loopback 0)#exit
Ruijie(config)#router ospf 1
Router(config-router)#network 192.168.100.1 255.255.255.0 area 0
Router(config-router)#network 192.168.1.1 255.255.255.0 area 0
Router(config-router)#network 192.168.0.1 255.255.255.255 area 0
Router(config-router)#exit
```

# Configure the P device by running the same commands as those on PE 1.

- Enable global MPLS forwarding on devices, MPLS packet forwarding, and the LDP on interfaces.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls ip
```

## The **ip ref** command is used on a router to enable MPLS fast forwarding on the router. You do not need to run this command on switches.

```
Ruijie(config)#interface gigabitEthernet 2/2
Ruijie(config-if-GigabitEthernet 2/2)#label-switching
Ruijie(config-if-GigabitEthernet 2/2)#mpls ip
Ruijie(config-if-GigabitEthernet 2/2)#ip ref
```

```
Router(config-if-GigabitEthernet 2/2)#exit
```

# Configure the P device.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls ip
```

## The **ip ref** command is used on a router to enable MPLS fast forwarding on the router. You do not need to run this command on switches.

```
Ruijie(config)#interface gigabitEthernet 2/1
Ruijie(config-if-GigabitEthernet 2/1)#label-switching
Ruijie(config-if-GigabitEthernet 2/1)#mpls ip
Ruijie(config-if-GigabitEthernet 2/1)#ip ref
Router(config-if-GigabitEthernet 2/1)#exit
```

## The **ip ref** command is used on a router to enable MPLS fast forwarding on the router. You do not need to run this command on switches.

```
Ruijie(config)#interface gigabitEthernet 2/2
Ruijie(config-if-GigabitEthernet 2/2)#label-switching
Ruijie(config-if-GigabitEthernet 2/2)#mpls ip
Ruijie(config-if-GigabitEthernet 2/2)#ip ref
Router(config-if-GigabitEthernet 2/2)#exit
```

- Configure the LDP to enable the network to forward MPLS traffic.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0 force
```

# Configure the P device.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0 force
```

- Enable the LDP GR protocol.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#graceful-restart
```

# Configure the P device.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

```
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#graceful-restart
```

- Configure parameters related to LDP GR.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls router ldp
```

## Set the LDP reconnection time to 300 seconds, LDP neighbor keep-alive time to 120 seconds, and LDP recovery time to 120 seconds.

```
Ruijie(config-mpls-router)#graceful-restart timer reconnect 300
Ruijie(config-mpls-router)#graceful-restart timer neighbor-liveness 120
Ruijie(config-mpls-router)#graceful-restart timer recovery 120
Ruijie(config-mpls-router)#exit
```

# Configure the P device.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls router ldp
```

## Set the LDP reconnection time to 300 seconds, LDP neighbor keep-alive time to 120 seconds, and LDP recovery time to 120 seconds.

```
Ruijie(config-mpls-router)#graceful-restart timer reconnect 300
Ruijie(config-mpls-router)#graceful-restart timer neighbor-liveness 120
Ruijie(config-mpls-router)#graceful-restart timer recovery 120
Ruijie(config-mpls-router)#exit
```

- Restart the LDP session for the configurations to take effect.

# Restart the LDP session on PE 1.

```
Ruijie#clear mpls ldp neighbor all
```

# Restart the LDP session on the PE device.

```
Ruijie#clear mpls ldp neighbor all
```

Verification

Run the following commands to view configurations on PE 1:

# View LDP GR information on PE 1.

```
Ruijie#show mpls ldp graceful-restart
Default VRF:
  LDP Graceful Restart is enabled
  Neighbor Liveness Timer: 120 seconds
  Max Recovery Time: 120 seconds
  Forwarding State Holding Time: 300 seconds
  Down Neighbor Database (1 records):

```

L3VPN GR

Overview

L3 VPN GR (VPN GR) implements uninterrupted forwarding of Virtual Private Network (VPN) services. It ensures that the data of VPN services can be normally forwarded when the control plane on a device fails, protecting VPN services on the network.

The following prerequisites must be met for VPN GR:

- Devices support 1+1 management board redundancy.
- Devices support uninterrupted forwarding of routing protocols.
- Devices support the BGP/MPLS GR protocol.
- Devices support the LDP GR protocol.

The objectives of VPN GR are to:

- Minimize routing protocol flapping during master/slave management board switchover.

- Minimize the impact on VPN services.
- Minimize Single-Point Failures (SPFs) on access devices and improve VPN network reliability.
- Minimize the packet loss rate of VPN traffic.

Note

GR must be supported in unicast routing to implement uninterrupted forwarding of routing protocols. In other words, the device must support OSPF GR, IS-IS GR, or BGP GR.

Basic Concepts

GR Routers Classified by Capability

GR routers are classified by capability into GR-capable routers, GR-aware routers, and GR-unaware routers.

- GR-Capable Router

A GR-capable router is a router that has GR capability. In general, a GR-capable router is equipped with two management boards which work in 1+1 master/slave mode. The GR-capable router can send an advertisement packet to neighboring routers during master/slave switchover of the management boards, so that neighboring routers keep forwarding entries related to the GR-capable router. After master/slave switchover, routing tables are re-established without causing route flapping or changing the packet forwarding path, guaranteeing uninterrupted data forwarding in the system.

- GR-Aware Router

A GR-aware router is a router that has GR detection capability. It may be not equipped with two management boards but can detect that its neighbors are experiencing GR and can assist its neighbors to complete GR.

- GR-Unaware Router

A GR-unaware router is a router that does not have GR detection capability. It cannot detect that its neighbors are experiencing GR, cannot assist its neighbors to complete GR, and does not have GR capability. Generally, if a router has no awareness capability, it is because the system software does not provide the GR feature or the GR feature is disabled.

GR Routers Classified by Role

GR routers are classified by role during router restart into GR restarters and GR helpers.

- GR Restarter

The GR restarter has GR capability and its restart is triggered by administrators or faults.

- GR Helper

The GR helper is a neighbor of the GR restarter. It must be at least a GR-aware router.

Working Principle

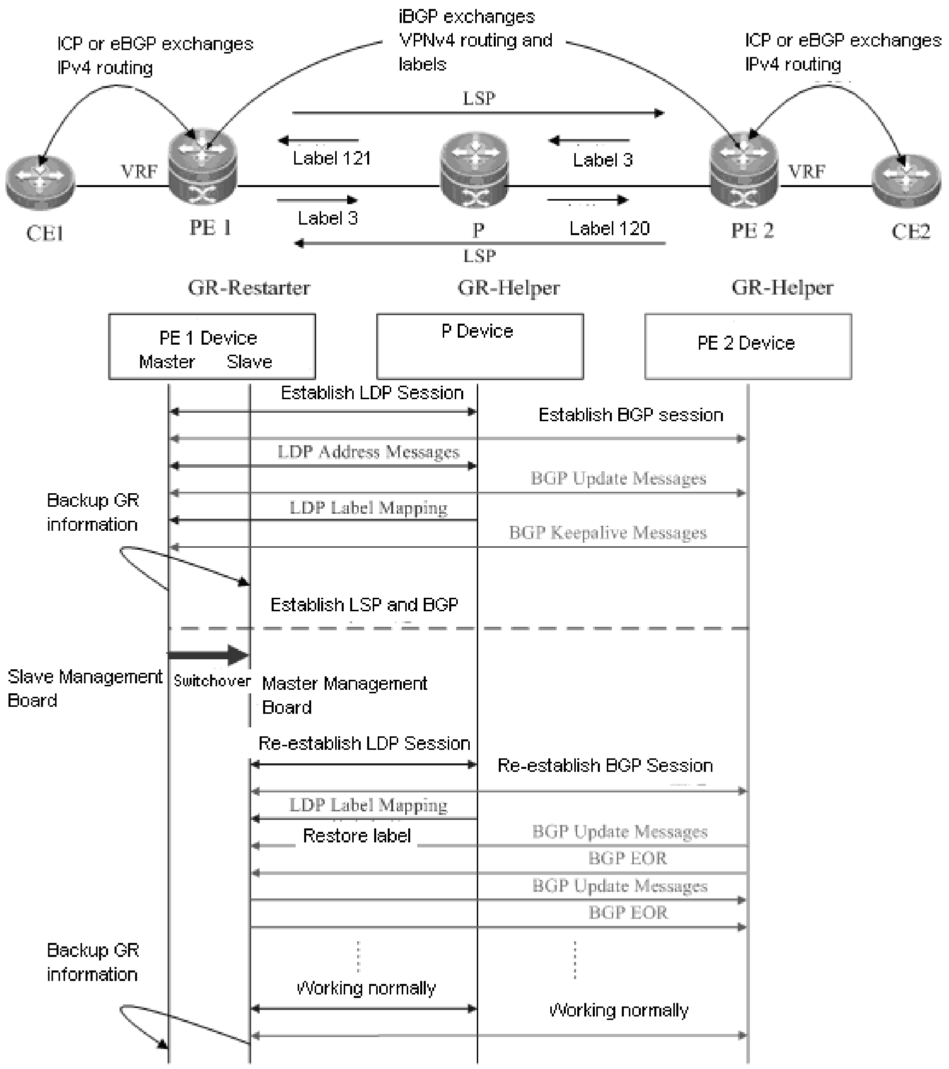
Both the control plane and the forwarding plane on a traditional device are implemented by the same processor which simultaneously maintains a routing table and a forwarding table. To improve forwarding performance and reliability of devices, a multi-processor architecture is used on high-end and mid-range devices. The processors of control modules such as the routing protocol module are located on a master management board and data forwarding processors are located on line cards. In this manner,, the control plane and the forwarding plane are separated from each other so that data forwarding on line cards is not affected when the control plane is restarted. This technology provides a prerequisite for implementing GR. The GR-capable routers mentioned in this document are such routers where the control plane and the forwarding plane are separated from each other.

The VPN network shown in Figure 1-3 has the following features:

- Customer Edge (CE) devices represent a customer network. The Interior Gateway Protocol (IGP) or Exterior Border Gateway Protocol (eBGP) runs on the CE devices.
- PE and P devices form a provider network. The IGP runs on these devices.
- Public network tunnels and Label Switching Paths (LSPs) are established using the LDP between PE 1, PE 2, and the P device.
- Private network tunnels are established using the Interior Border Gateway Protocol (iBGP) between PE 1 and PE 2.
- The IGP, BGP, and LDP have GR capability.
- PE devices are GR-capable routers, and the P device is a GR-aware router.

Note For details about IGP GR, BGP GR, and LDP GR, see related sections in *OSPF*, *BGP*, and *LDP GR*.

Figure 1-3 VPN networking topology



The following describes the GR process of the access device PE 1 of a provider network. Master/slave management board switchover occurs on PE 1. PE 1 works as a GR restarter and PE 2 and the P device works as GR helpers.. The process of master/slave management board switchover is as follows:

- Before master/slave management board switchover

PE 1 performs IGP GR or eBGP GR negotiation with the connected CE device, IGP GR and LDP GR negotiation with the P device, and iBGP GR negotiation with PE 2.

PE 1 sends an Initialization message that carries the optional FT Session TLV to the P device to establish a GR-capable LDP session. After the LDP session is established, they exchange LDP Address messages and Label Mapping messages with each other. In this manner, GR-capable LSPs are established for data forwarding.

PE 1 sends an Open message to PE 2 to establish a GR-capable iBGP session. The Open message carries GR capability parameters <AFI=IPv4, SAFI=Unicast> and <AFI=IPv4, SAFI=VPNv4>.

When the master management board works, the GR information is backed up to the slave management board. In this manner, the GR backup enables the system to access these original data during GR protocol restart and apply the data to the protocol GR process after master/slave management board switchover.

- During master/slave management board switchover

After the GR information on PE 1 is backed up to the slave management board,, the master/slave management board switchover is performed.

After detecting that the Transfer Control Protocol (TCP) session is down, the P device sets an "old" flag for the respective LSPs and starts a forwarding entry aging timer to continue to forward data before this aging timer expires.

After detecting that the TCP connection is broken, PE 2 immediately marks the route learned from PE 1 as "old" and starts a restart timer for PE 1. If PE 2 does not receive an Open message within the restart timer, it deletes the "old" flag for the route. If PE 2 receives an Open message, it deletes the restart timer. In this period of time, PE 1 and PE 2 continue to forward traffic along the original route.

- After master/slave management board switchover

The slave management board on PE 1 becomes the new master management board, and the original master management board becomes the new slave management board. The new master management board checks the GR information backed up and determines whether forwarding entries before the restart are retained. Then the Command Line Interface (CLI) configuration initialization process and the GR process continue. During IGP GR, BGP GR, and LDP GR, all the devices send notification messages to all IGP, BGP, and LDP neighbors for connection re-establishment.

113) IGP convergence

PE 1 sends an Initialization message that carries the FT Session TLV to the P device, and re-establishes a session upon receiving a response to obtain topology and routing information. PE 1 re-computes the routing table and deletes the "old" routes. The IGP convergence is completed.

114) BGP processing

PE 1 and CE 1 exchange routing information with each other. PE 1 updates its routing table and forwarding entries based on the new routing and forwarding information, substitutes invalid routes. The BGP convergence is completed.

PE 1 and PE 2 start to re-establish a BGP session with each other. PE 1 sends an Open message to PE 2. The Open message carries GR capability parameters. PE 1 receives and processes an Update message from PE 2. These messages carry IP prefix information. PE 1 does not start BGP route preference until receiving an EOR flag from PE2. PE 1 sends an Update message that carries prefix information to PE 2. After sending the Update message, PE 1 sends the EOR flag to PE 2. After receiving the EOR flag, PE 2 starts BGP route preference. The network convergence is completed.

115) LDP processing

PE 1 sends an Initialization message that carries the FT Session TLV to the neighboring P device. A GR-capable LDP session is established after the P device receives the Initialization message. Then PE 1 and the P device exchange LDP Address and Label Mapping messages again with each other, and keep or remove the "old" flag set for MPLS forwarding entries. When the GR process ends, both devices delete their "old" MPLS forwarding entries respectively.

Note The preceding IGP GR, BGP GR, and LDP GR processes do not follow a strict priority sequence. In terms of route convergence, unicast routes converge first and converged routes are advertised to the LDP.

Before all protocols complete the GR process, only Routing Information Base (RIB) information on the master management board is updated. The Forwarding Information Base (FIB) information on interface boards is not updated.

The FIB information on interface boards is updated only after all protocols complete the GR process.

Protocols and Specifications

The protocols or specifications involved are as follows:

- RFC 4724: Graceful Restart Mechanism for BGP
- RFC 4781: Graceful Restart Mechanism for BGP with MPLS

Configuring L3VPN GR

Network Environment

On an MPLS network, L3VPN GR is required for the devices carrying L3VPN services. In this manner, data forwarding is not interrupted during master/slave management board switchover on devices, guaranteeing traffic continuity.

Note The GR capability does not guarantee traffic continuity when master/slave management board switchover also occurs on neighboring devices.

Prerequisites

Complete the following tasks before configuring L3VPN GR:

- Build an L3VPN environment and configure L3VPN.
- Ensure that devices support management board redundancy.
- Ensure that the IGP has GR capability.
- Ensure that the BGP has GR capability.
- Ensure that the LDP has GR capability.

Note For details about L3VPN configuration, see related sections in *BGP/MPLS VPN Configuration*.

Data Preparations

Prepare the following data before configuring L3VPN GR:

- IGP GR parameters
- BGP GR parameters
- LDP GR parameters

Configuring IGP GR

Note For details about IGP GR configuration, see related sections in *OSPF*.

Configuring BGP GR

Note For details about BGP GR configuration, see related sections in *BGP*.

Configuring LDP GR

Note For details about LDP GR configuration, see the "LDP GR" section in this document.

Verification

To display L3VPN GR configuration and running information, run the following commands:

Command	Function
show ip vrf [*vrf_name*]	Displays VRF configuration information.
show ip bgp vpnv4 {**all** | **rd** *route-distinguish* | **vrf** *vrf_name*} [*network-address*] **[summary**] [**neighbor] [label]**	Displays VPN routing information.
show ip bgp summary	Displays the status of all BGP connections.
show ip route vrf *vrf_name* [**A.B.C.D** | **bgp** | c**onnected | isis | ospf | rip | static | weight]**	Displays VRF routing information.
show mpls ldp graceful-restart [all | vrf *vrf-name***]**	Displays LDP GR sessions and session parameters.

Note All the preceding commands can be configured in any mode except for user mode.

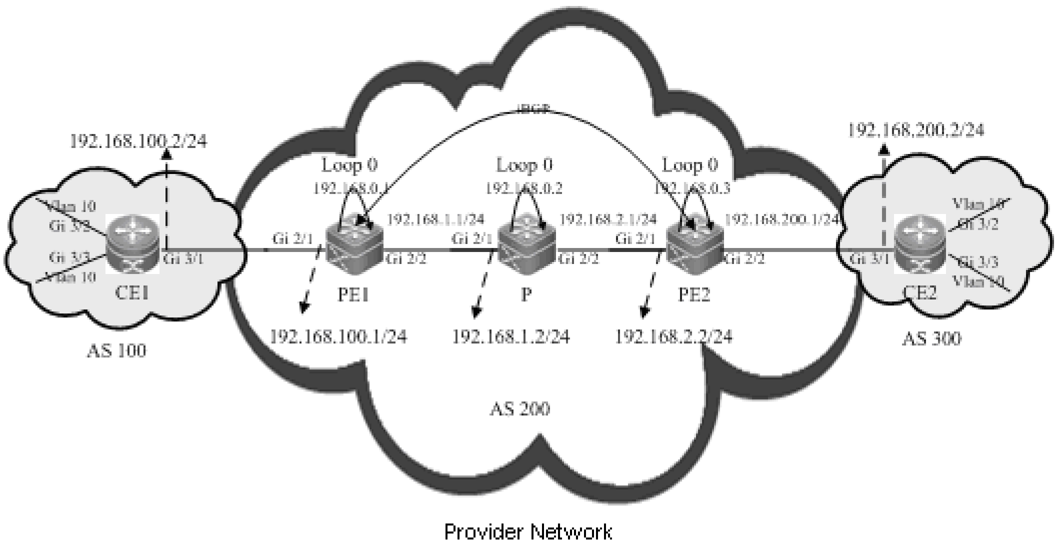
Configuration Examples

Networking Requirements

- CE devices represent a customer network. The IGP or eBGP runs on the CE devices.
- PE and P devices form a provider network. The IGP runs on these devices.
- Public network tunnels and LSPs are established using the LDP between PE 1, PE 2, and the P device.
- Private network tunnels are established using the iBGP between PE 1 and PE 2.
- The IGP, BGP, and LDP have GR capability.
- PE devices are GR-capable routers, and the P device is a GR-aware router.

Networking Topology

Figure 1-4 Networking topology for configuring L3VPN GR



Configuration Tips

Configure PE 1, PE 2, and the P device as follows:

- Configure VRF.
- Configure interface IP addresses and the OSPF protocol.
- Enable global MPLS forwarding on devices, MPLS packet forwarding, and the LDP on interfaces.
- Configure the LDP to enable the network to forward MPLS traffic.
- Enable the LDP GR protocol and configure parameters related to LDP GR.
- Configure L3VPN.
- Enable the BGP GR protocol.
- Restart the LDP session for the configurations to take effect.

Configuration Steps

- Configure VRF.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

## Define VRF.

```
Ruijie(config)#ip vrf 10
Ruijie(config-vrf)#rd 1:100
Ruijie(config-vrf)#route-target both 1:100
Ruijie(config-vrf)#exit
```

# Configure the P device. VRF configuration is not required on the P device.

# Configure PE 2 by running the same commands as those on PE 1.

- Configure interface IP addresses and the OSPF protocol.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

## The **no switchport** command is used on a switch to switch to Routed Port mode. It is not applicable to routers and therefore you do not need to run the command on routers.

```
Ruijie(config)#interface gigabitEthernet 2/1
Ruijie(config-if-GigabitEthernet 2/1)#no switchport
Ruijie(config-if-GigabitEthernet 2/1)#ip vrf forwarding 10
Ruijie(config-if-GigabitEthernet 2/1)#ip address 192.168.100.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 2/1)#exit
```

## The **no switchport** command is used on a switch to switch to Routed Port mode. It is not applicable to routers and therefore you do not need to run the command on routers.

```
Ruijie(config)#interface gigabitEthernet 2/2
Ruijie(config-if-GigabitEthernet 2/2)#no switchport
Ruijie(config-if-GigabitEthernet 2/2)#ip address 192.168.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 2/2)#exit
```

## Configure the loopback interface **loopback 0**.

```
Ruijie(config)#interface loopback 0
Ruijie(config-Loopback 0)#ip address 192.168.0.1 255.255.255.255
Ruijie(config-Loopback 0)#exit
```

## Activate the OSPF protocol and enter OSPF mode.

```
Ruijie(config)#router ospf 10
Ruijie(config-router)#network 192.168.0.1 255.255.255.255 area 0
Ruijie(config-router)#network 192.168.1.0 255.255.255.0 area 0
Ruijie(config-router)#end
```

# Configure the P device.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

## The **no switchport** command is used on a switch to switch to Routed Port mode. It is not applicable to routers and therefore you do not need to run the command on routers.

```
Ruijie(config)#interface gigabitEthernet 2/1
Ruijie(config-if-GigabitEthernet 2/1)#no switchport
Ruijie(config-if-GigabitEthernet 2/1)#ip address 192.168.1.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 2/1)#exit
```

## The **no switchport** command is used on a switch to switch to Routed Port mode. It is not applicable to routers and therefore you do not need to run the command on routers.

```
Ruijie(config)#interface gigabitEthernet 2/2
Ruijie(config-if-GigabitEthernet 2/2)#no switchport
Ruijie(config-if-GigabitEthernet 2/2)#ip address 192.168.2.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 2/2)#exit
```

## Configure the loopback interface **loopback 0**.

```
Ruijie(config)#interface loopback 0
Ruijie(config-Loopback 0)#ip address 192.168.0.2 255.255.255.255
Ruijie(config-Loopback 0)#exit
```

## Activate the OSPF protocol and enter OSPF mode.

```
Ruijie(config)#router ospf 10
Ruijie(config-router)#network 192.168.1.0 255.255.255.0 area 0
Ruijie(config-router)#network 192.168.2.0 255.255.255.0 area 0
Ruijie(config-router)#network 192.168.0.2 255.255.255.255 area 0
Ruijie(config-router)#end
```

# Configure PE 2 by running the same commands as those on PE 1.

- Enable global MPLS forwarding on devices, MPLS packet forwarding, and the LDP on interfaces.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls ip
```

## The **ip ref** command is used on a router to enable MPLS fast forwarding on the router. You do not need to run this command on switches.

```
Ruijie(config)#interface gigabitEthernet 2/2
Ruijie(config-if-GigabitEthernet 2/2)#label-switching
Ruijie(config-if-GigabitEthernet 2/2)#mpls ip
Ruijie(config-if-GigabitEthernet 2/2)#ip ref
Router(config-if-GigabitEthernet 2/2)#exit
```

# Configure the P device.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

```
Ruijie(config)#mpls ip
```

## The **ip ref** command is used on routers to enable MPLS fast forwarding on the router. You do not need to run this command on switches.

```
Ruijie(config)#interface gigabitEthernet 2/1
Ruijie(config-if-GigabitEthernet 2/1)#label-switching
Ruijie(config-if-GigabitEthernet 2/1)#mpls ip
Ruijie(config-if-GigabitEthernet 2/1)#ip ref
Router(config-if-GigabitEthernet 2/1)#exit
```

## The **ip ref** command is used on a router to enable MPLS fast forwarding on the router. You do not run this command on switches.

```
Ruijie(config)#interface gigabitEthernet 2/2
Ruijie(config-if-GigabitEthernet 2/2)#label-switching
Ruijie(config-if-GigabitEthernet 2/2)#mpls ip
Ruijie(config-if-GigabitEthernet 2/2)#ip ref
Router(config-if-GigabitEthernet 2/2)#exit
```

# Configure PE 2 by running the same commands as those on PE 1.

- Configure the LDP to enable the network to forward MPLS traffic.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0 force
```

# Configure the P device.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0 force
```

# Configure PE 2.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0 force
```

Enable the LDP GR protocol, and configure parameters related to LDP GR.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#graceful-restart
```

## Set the LDP reconnection time to 300 seconds, LDP neighbor keep-alive time to 120 seconds, and LDP recovery time to 120 seconds.

```
Ruijie(config-mpls-router)#graceful-restart timer reconnect 300
Ruijie(config-mpls-router)#graceful-restart timer neighbor-liveness 120
Ruijie(config-mpls-router)#graceful-restart timer recovery 120
Ruijie(config-mpls-router)#exit
```

# Configure the P device.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#graceful-restart
```

## Set the LDP reconnection time to 300 seconds, LDP neighbor keep-alive time to 120 seconds, and LDP recovery time to 120 seconds.

```
Ruijie(config-mpls-router)#graceful-restart timer reconnect 300
Ruijie(config-mpls-router)#graceful-restart timer neighbor-liveness 120
Ruijie(config-mpls-router)#graceful-restart timer recovery 120
Ruijie(config-mpls-router)#exit
```

# Configure PE 2 by running the same commands as those on PE 1.

- Configure L3VPN.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

## Configure the eBGP peer CE.

```
Ruijie(config)#router bgp 200
Ruijie(config-router)#address-family ipv4 vrf 10
Ruijie(config-router-af)#neighbor 192.168.100.2 remote-as 100
Ruijie(config-router-af)#neighbor 192.168.100.2 update-source GigabitEthernet 2/1
Ruijie(config-router-af)#neighbor 192.168.200.2 activate
Ruijie(config-router-af)#exit-address-family
Ruijie(config-router)#exit
```

## Configure the iBGP peer PE 2.

```
Ruijie(config-router)#address-family ipv4
Ruijie(config-router-af)#neighbor 192.168.0.3 remote-as 200
Ruijie(config-router-af)#neighbor 192.168.0.3 update-source loopback 0
Ruijie(config-router-af)#neighbor 192.168.0.3 activate
Ruijie(config-router-af)#exit-address-family
Ruijie(config-router)#address-family vpnv4 unicast
Ruijie(config-router-af)#neighbor 192.168.0.3 activate
Ruijie(config-router-af)#exit-address-family
Ruijie(config-router)#exit
```

# Configure the P device. L3VPN configuration is not required on the P device.

# Configure PE 2 by running the same commands as those on PE 1.

- Enable the BGP GR protocol.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

## Enable the BGP and enter BPG configuration mode.

```
Ruijie(config)#router bgp 200
```

## Enable BGP GR.

```
Ruijie(config-router)#bgp graceful-restart
```

# Configure the P device. BGP GR does not need to be enabled on the P device.

# Configure PE 2 by running the same commands as those on PE 1.

Restart the LDP session for the configurations to take effect.

# Restart the LDP session on PE 1.

```
Ruijie#clear mpls ldp neighbor all
```

# Restart the LDP session on the PE device.

```
Ruijie#clear mpls ldp neighbor all
```

# Restart the LDP session on PE 1.

```
Ruijie#clear mpls ldp neighbor all
```

Verification

Run the following commands to view configurations on PE 1:

# View LDP GR information on PE 1.

```
Ruijie#show mpls ldp graceful-restart
Default VRF:
  LDP Graceful Restart is enabled
  Neighbor Liveness Timer: 120 seconds
  Max Recovery Time: 120 seconds
  Forwarding State Holding Time: 300 seconds
  Down Neighbor Database (1 records):
    Peer LDP Ident: 192.168.0.2:0; Local LDP Ident: 192.168.0.1:0
        Status: recovering (86 seconds left)
        Address list contains 3 addresses:
          192.168.0.2    192.168.1.2    192.168.2.1
  Graceful Restart-enabled Sessions:
   Peer LDP Ident: 192.168.0.2:0, State: estab
```

# View BGP GR information on PE 1.

```
Ruijie#show bgp vpnv4 unicast all neighbor
BGP neighbor is 192.168.0.3, remote AS 200, internal link
BGP version 4, remote router ID 192.168.0.3
BGP state = Established, up for 02:49:47
Last read 00:00:47, hold time is 180, keepalive interval is 60 seconds
Neighbor capabilities:
Route refresh: advertised and received(new)
Address family VPNv4 Unicast: advertised and received
Graceful Restart Capability: advertised and received
Remote Restart timer is 120 seconds
Address families preserved by peer:
VPNv4 Unicast
```

L2VPN GR

Note

L2VPN GR described in this section indicates GR for Virtual Pseudo Wire Service (VPWS) and Virtual Private LAN Service (VPLS).

Overview

For VPWS and VPLS services, public network tunnels are established based on basic MPLS network services. In addition, the extended LDP is used to distribute VC labels for the establishment of virtual lines. Therefore, extended LDP GR must be implemented to ensure uninterrupted forwarding of VPWS and VPLS services. Extended LDP GR is implemented based on the same working principles as basic LDP GR, except that the MPLS forwarding entries to be backed up are different. Therefore, extended LDP GR and basic LDP GR can be uniformly implemented.

Note

For details about LDP GR and configuration methods, see the "LDP GR" section in this document.
The working principles of VPWS GR are described in the following text. That of VPLS GR is not described in this document.

VPWS GR implements uninterrupted forwarding of VPWS services. It ensures that the data of VPWS services can be forwarded when the control plane on a device fails, protecting VPWS services on the network. The following prerequisites must be met for VPWS GR:

- Devices support 1+1 management board redundancy.
- Devices support uninterrupted forwarding of routing protocols.
- Devices support the LDP GR protocol.

The objectives of VPWS GR are to:

- Minimize routing protocol flapping during master/slave management board switchover.

- Minimize the impact on VPWS services.
- Minimize SPFs on access devices and improve VPWS network reliability.
- Minimize the packet loss rate of VPWS traffic.

Note

GR must be supported in unicast routing to implement uninterrupted forwarding of routing protocols. In other words, the device must support OSPF GR, IS-IS GR, or BGP GR.

Basic Concepts

GR Routers Classified by Capability

GR routers are classified by capability into GR-capable routers, GR-aware routers, and GR-unaware routers.

- GR-Capable Router

A GR-capable router is a router that has GR capability. In general, a GR-capable router is equipped with two management boards which work in 1+1 master/slave mode. The GR-capable router can send an advertisement packet to neighboring routers during master/slave switchover of the management boards, so that neighboring routers keep forwarding entries related to the GR-capable router. After master/slave switchover, routing tables are re-established without causing route flapping or changing the packet forwarding path, guaranteeing uninterrupted data forwarding in the system.

- GR-Aware Router

A GR-aware router is a router that has GR detection capability. It may be not equipped with two management boards but can detect that its neighbors are experiencing GR and can assist its neighbors to complete GR.

- GR-Unaware Router

A GR-unaware router is a router that does not have GR detection capability. It cannot detect that its neighbors are experiencing GR, cannot assist its neighbors to complete GR, and does not have GR capability. Generally, if a router has no awareness capability, it is because the system software does not provide the GR feature or the GR feature is disabled.

GR Routers Classified by Role

GR routers are classified by role during router restart into GR restarters and GR helpers.

- GR Restarter

The GR restarter has GR capability and its restart is triggered by administrators or faults.

- GR Helper

The GR helper is a neighbor of the GR restarter. It must be at least a GR-aware router.

Working Principle

Both the control plane and the forwarding plane on a traditional device are implemented by the same processor which simultaneously maintains a routing table and a forwarding table. To improve forwarding performance and reliability of devices, a multi-processor architecture is used on high-end and mid-range devices. The processors of control modules such as the routing protocol module are located on a master management board and data forwarding processors are located on line cards. In this manner,, the control plane and the forwarding plane are separated from each other so that data forwarding on line cards is not affected when the control plane is restarted. This technology provides a prerequisite for implementing GR. The GR-capable routers mentioned in this document are such routers where the control plane and the forwarding plane are separated from each other.

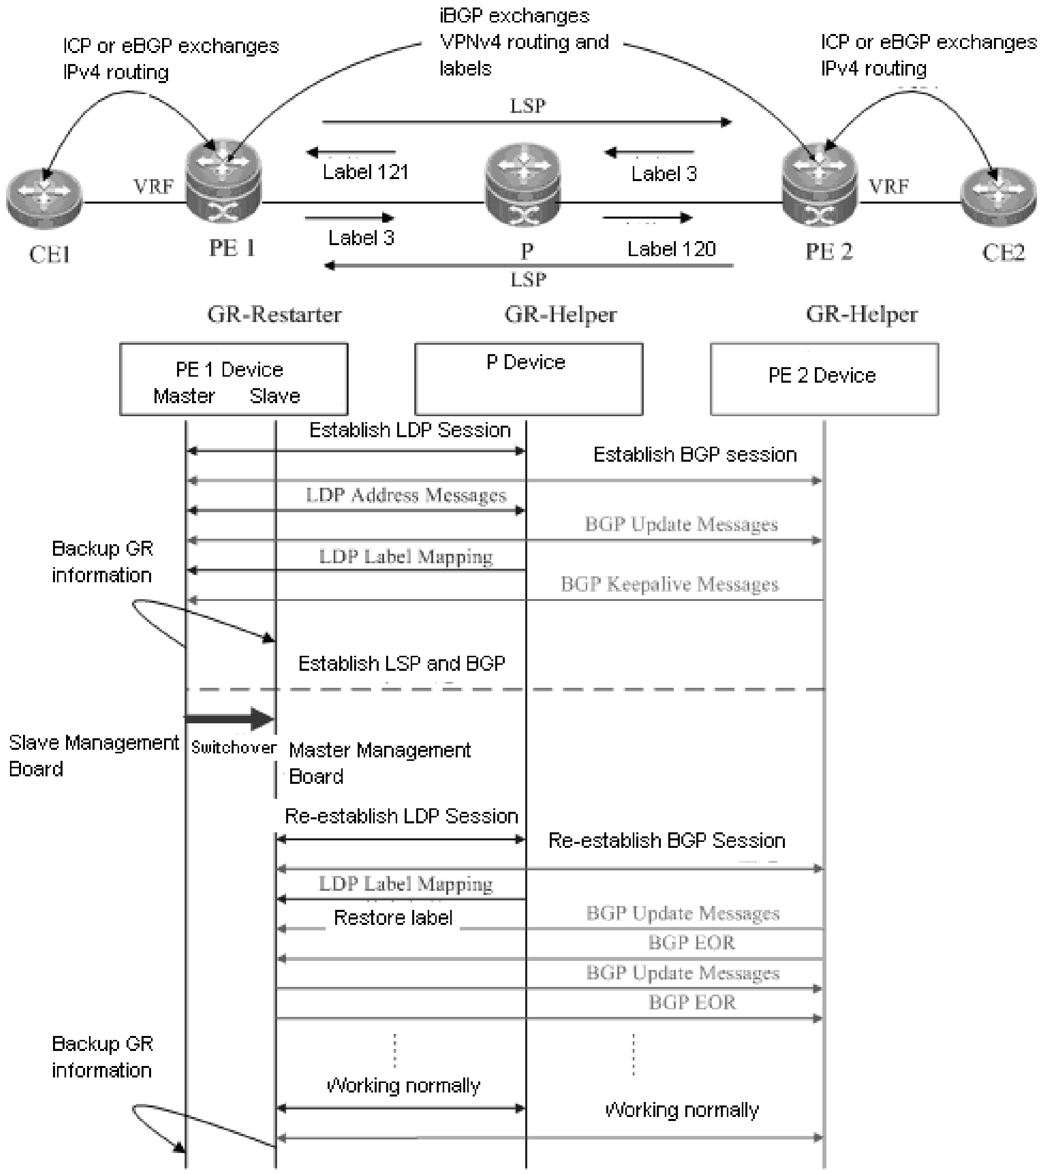
The VPWS network shown in Figure 1-5 has the following features:

- CE devices represent a customer network. The IGP runs on the CE devices.
- PE and P devices form a provider network. The IGP and LDP run on these devices.
- Public network tunnels and LSPs are established using the LDP between PE 1, PE 2, and the P device.
- Private network tunnels are established using the LDP between PE 1 and PE 2.
- The IGP and LDP have GR capability.
- PE devices are GR-capable routers, and the P device is a GR-aware router.

Note

For details about IGP GR and LDP GR, see related sections in *OSPF* and *LDP GR*.

Figure 1-5 VPWS networking topology



The following describes the GR process of the access device PE 1 of a provider network. Master/slave management board switchover occurs on PE 1. PE 1 works as a GR restarter, whereas PE 2 and the P device work as GR helpers. When master/slave management board switchover occurs on PE 1, a certain procedure applies. The procedure consists of the following three phases:

Before Master/Slave Management Board Switchover

PE 1 performs LDP GR and IGP GR negotiation with the P device, IGP GR negotiation with the connected CE device, and extended LDP GR negotiation with PE 2. PE 1 sends an Initialization message that carries the optional FT Session TLV to the P device and PE 2 to establish a GR-capable LDP session.

After the LDP session is established, they exchange LDP Address and Label Mapping messages with each other. In this manner, GR-capable LSPs are established for data forwarding.

When the master management board works normally, it must back up GR information to the slave management board to support GR.

During Master/Slave Management Board Switchover

GR information on PE 1 has been backed up to the slave management board. The major task of PE 1 in this phase is to perform master/slave management board switchover.

The P device and PE 2 detect that the TCP session is down, and therefore set an "old" flag for the respective LSPs. They also start a forwarding entry aging timer and continue to forward data before this aging timer expires. The working process on CEs is similar, except that it is an IGP GR process.

After Master/Slave Management Board Switchover

The slave management board on PE 1 becomes the new master management board, and the original master management board becomes the new slave management board. The new master management board starts to check the GR information previously backed up and determines whether forwarding entries before the restart are retained. Then the CLI configuration initialization process and the GR process continue. During LDP GR and IGP GR, all the devices send notification messages to all IGP and LDP neighbors for connection re-establishment.

- IGP convergence
- PE 1 sends an Initialization message that carries the FT Session TLV to the P device, and re-establishes a session upon receiving a response to obtain topology and routing information. Then PE 1 re-computes the routing table, deletes the "old" routes, and therefore completes IGP convergence.
- LDP processing
- PE 1 sends an Initialization message that carries the FT Session TLV to the neighboring P device and PE 2. A GR-capable LDP session is established after the P device and PE 2 receive the Initialization message. Then the devices exchange LDP Address and Label Mapping messages again with each other, and keep or remove the "old" flag set for MPLS forwarding entries. When the GR process ends, the P device, PE 1, and PE 2 delete the "old" MPLS forwarding entries from themselves respectively.

Note

The preceding IGP GR and LDP GR processes do not follow a strict priority sequence. In terms of route convergence, IGP routes converge first and converged routes are advertised to the LDP.

Before all protocols complete the GR process, only RIB information on the master management board is updated. The FIB information on interface boards do not be updated.

The FIB information on interface boards is updated only after all protocols complete the GR process.

Protocols and Specifications

The following protocols or specifications involved are as follows:

- RFC 3036: LDP Specification
- RFC 3037: LDP Applicability
- RFC 3215: LDP State Machine
- RFC 3478: Graceful Restart Mechanism for LDP
- RFC 3479: Fault Tolerance for LDP

Configuring VPWS GR

Network Environment

VPWS GR is required for VPWS applications on service bearing devices on an MPLS network. In this manner, data forwarding is not interrupted during master/slave management board switchover on devices, guaranteeing traffic continuity.

Note The GR capability does not guarantee traffic continuity when master/slave management board switchover also occurs on neighboring devices.

Prerequisites

Complete the following tasks before configuring VPWS GR:

- Build a VPWS environment and configure VPWS.
- Ensure that the IGP has GR capability.
- Ensure that the LDP has GR capability.

Note For details about VPWS configuration, see the "Configuring VPWS" section in *MPLS*.

Data Preparations

Prepare the following data before configuring VPWS GR:

- IGP GR parameters
- LDP GR parameters

Configuring IGP GR

Note For details about IGP GR configuration, see related sections in *OSPF*.

Configuring LDP GR

Note For details about LDP GR configuration, see the "LDP GR" section in this document.

Verification

To display VPWS GR configuration and running information, run the following commands:

Command	Function
show mpls ldp graceful-restart [all | vrf *vrf-name*]	Displays LDP GR sessions and session parameters.
show mpls ldp vc [all | vpws | hub | spoke] [*vc-id*]	Displays LDP Pseudo Wire (PW) information.

Note All the preceding commands can be configured in any mode except for the user mode.

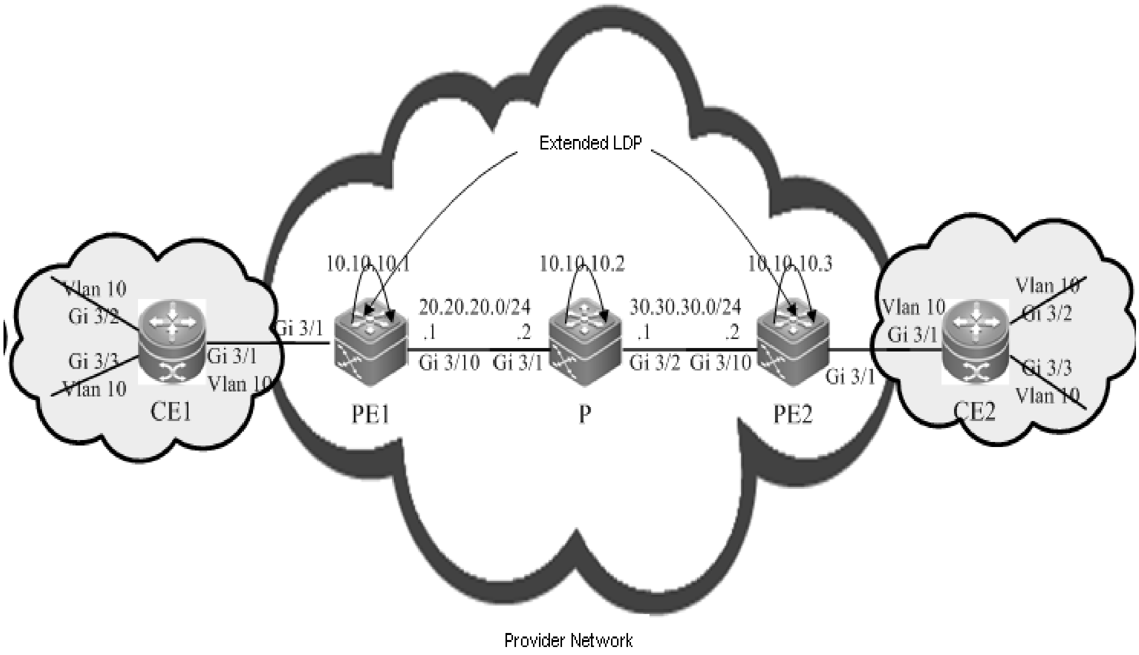
Configuration Examples

Networking Requirements

- Interconnection ports between PE and CE devices work in access mode, so that each CE device is connected to the respective PE device through an access link. The respective PE device establishes PW services for the Virtual Local Area Network (VLAN) to which the access port belongs. Since the Ethernet mode is applied, frames transmitted on the PW between PE 1 and PE 2 do not carry the VLAN 10 tag.
- CE, PE, and P devices support the LDP and are capable of GR.
- PE and P devices support the LDP and are capable of GR.
- PE and P devices form a provider network.
- PE devices are GR-capable routers, and the P device is a GR-aware router.

Networking Topology

Figure 1-6 Networking topology for configuring L2VPN GR



Configuration Tips

Configure PE 1, PE 2, and the P device as follows:

- Configure interface IP addresses and the OSPF protocol.
- Enable global MPLS forwarding on devices, MPLS packet forwarding, and the LDP on interfaces.
- Configure the LDP to enable the network to forward MPLS traffic.
- Configure VPWS.
- Enable the LDP GR protocol, and configure parameters related to LDP GR.
- Restart the LDP session for the configurations to take effect.

Configuration Steps

- Configure interface IP addresses and the OSPF protocol.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

## The **no switchport** command is used on a switch to switch to the Routed Port mode. It is not applicable to routers and therefore you do not need to run the command on routers.

```
Ruijie(config)#interface gigabitEthernet 3/10
Ruijie(config-if-GigabitEthernet 3/10)#no switchport
Ruijie(config-if-GigabitEthernet 3/10)#ip address 20.20.20.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 3/10)#exit
Ruijie(config)#interface loopback 0
Ruijie(config-Loopback 0)#ip address 10.10.10.1 255.255.255.255
Ruijie(config-Loopback 0)#exit
```

## Activate the OSPF protocol and enter OSPF mode.

```
Ruijie(config)#router ospf 10
Ruijie(config-router)#network 20.20.20.0 255.255.255.0 area 0
Ruijie(config-router)#network 10.10.10.1 255.255.255.255 area 0
Ruijie(config-router)#end
```

# Configure the P device.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

## The **no switchport** command is used on a switch to switch to Routed Port mode. It is not applicable to routers and therefore you do not need to run the command on routers.

```
Ruijie(config)#interface gigabitEthernet 3/1
Ruijie(config-if-GigabitEthernet 3/1)#no switchport
Ruijie(config-if-GigabitEthernet 3/1)#ip address 20.20.20.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 3/1)#exit
```

## The **no switchport** command is used on a switch to switch to Routed Port mode. It is not applicable to routers and therefore you do not need to run the command on routers.

```
Ruijie(config)#interface gigabitEthernet 3/2
Ruijie(config-if-GigabitEthernet 3/2)#no switchport
Ruijie(config-if-GigabitEthernet 3/2)#ip address 30.30.30.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 3/2)#exit
```

## Configure the loopback interface **loopback 0**.

```
Ruijie(config)#interface loopback 0
Ruijie(config-Loopback 0)#ip address 10.10.10.1 255.255.255.255
Ruijie(config-Loopback 0)#exit
```

## Activate the OSPF protocol and enter OSPF mode.

```
Ruijie(config)#router ospf 10
Ruijie(config-router)#network 20.20.20.0 255.255.255.0 area 0
Ruijie(config-router)#network 30.30.30.0 255.255.255.0 area 0
Ruijie(config-router)#network 10.10.10.2 255.255.255.255 area 0
Ruijie(config-router)#end
```

# Configure PE 2.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

## The **no switchport** command is used on a switch to switch to Routed Port mode. It is not applicable to routers and therefore you do not need to run the command on routers.

```
Ruijie(config)#interface gigabitEthernet 3/10
Ruijie(config-if-GigabitEthernet 3/10)#no switchport
Ruijie(config-if-GigabitEthernet 3/10)#ip address 30.30.30.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 3/10)#exit
```

## Configure the loopback interface **loopback 0**.

```
Ruijie(config)#interface loopback 0
Ruijie(config-Loopback 0)#ip address 10.10.10.3 255.255.255.255
Ruijie(config-Loopback 0)#exit
```

## Activate the OSPF protocol and enter OSPF mode.

```
Ruijie(config)#router ospf 10
Ruijie(config-router)#network 30.30.30.0 255.255.255.0 area 0
Ruijie(config-router)#network 10.10.10.3 255.255.255.255 area 0
Ruijie(config-router)#end
```

- Enable global MPLS forwarding on devices, MPLS packet forwarding, and the LDP on interfaces.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls ip
```

## The **ip ref** command is used on a router to enable MPLS fast forwarding on the router. You do not need to run the command on switches.

```
Ruijie(config)#interface gigabitEthernet 3/10
Ruijie(config-if-GigabitEthernet 3/10)#label-switching
Ruijie(config-if-GigabitEthernet 3/10)#mpls ip
Ruijie(config-if-GigabitEthernet 3/10)#ip ref
Router(config-if-GigabitEthernet 3/10)#exit
```

# Configure the P device.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls ip
```

## The **ip ref** command is used on a router to enable MPLS fast forwarding on the router. You do not need to run the command on switches.

```
Ruijie(config)#interface gigabitEthernet 3/1
Ruijie(config-if-GigabitEthernet 3/1)#label-switching
Ruijie(config-if-GigabitEthernet 3/1)#mpls ip
Ruijie(config-if-GigabitEthernet 3/1)#ip ref
Router(config-if-GigabitEthernet 3/1)#exit
```

## The **ip ref** command is run a router to enable MPLS fast forwarding on the router. You do not need to run this command on switches.

```
Ruijie(config)#interface gigabitEthernet 3/2
Ruijie(config-if-GigabitEthernet 3/2)#label-switching
Ruijie(config-if-GigabitEthernet 3/2)#mpls ip
Ruijie(config-if-GigabitEthernet 3/2)#ip ref
Router(config-if-GigabitEthernet 3/2)#exit
```

# Configure PE 2 by running the same commands as those on PE 1.

- Configure the LDP to enable the network to forward MPLS traffic.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0 force
```

## Configure a remote LDP neighbor.

```
Ruijie(config-mpls-router)#neighbor 10.10.10.3
Ruijie(config-mpls-router)#exit
```

# Configure the P device.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0 force
```

# Configure PE 2.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0 force
```

## Configure a remote LDP neighbor.

```
Ruijie(config-mpls-router)#neighbor 10.10.10.1
Ruijie(config-mpls-router)#exit
```

- Configure VPWS.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

## Switch configurations

### Configure access ports between PE 1 and CE 1.

```
Ruijie(config)#interface gigabitEthernet 3/1
Ruijie(config-if-GigabitEthernet 3/1)#switchport mode access
Ruijie(config-if-GigabitEthernet 3/1)#switchport access vlan 10
Ruijie(config-if-GigabitEthernet 3/1)#exit
```

### Configure PW services for VLAN 10 on PE 1.

```
Ruijie(config)#interface vlan 10
Ruijie(config-if-VLAN 10)#xconnect 10.10.10.3 2 encapsulation mpls ethernet
Ruijie(config-if-VLAN 10)#exit
```

## Router configurations

### Configure PW services for the GE interface 3/1 on PE 1.

```
Ruijie(config)#interface gigabitEthernet 3/1
Ruijie(config-if-GigabitEthernet 3/1)#ip ref
Ruijie(config-if-GigabitEthernet 3/1)#xconnect 10.10.10.3 2 encapsulation mpls ethernet
Ruijie(config-if-GigabitEthernet 3/1)#exit
```

# Configure PE 2.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

## Switch configurations

### Configure access ports between PE 2 and CE 2.

```
Ruijie(config)#interface gigabitEthernet 3/1
Ruijie(config-if-GigabitEthernet 3/1)#switchport mode access
Ruijie(config-if-GigabitEthernet 3/1)#switchport access vlan 10
Ruijie(config-if-GigabitEthernet 3/1)#exit
```

### Configure PW services for VLAN 10 on PE 2.

```
Ruijie(config-if-VLAN 10)#interface vlan 10
Ruijie(config-if-VLAN 10)#xconnect 10.10.10.1 2 encapsulation mpls ethernet
Ruijie(config-if-VLAN 10)#exit
```

## Router configurations

### Configure PW services for the GE interface 3/1 on PE 2.

```
Ruijie(config)#interface gigabitEthernet 3/1
Ruijie(config-if-GigabitEthernet 3/1)#ip ref
Ruijie(config-if-GigabitEthernet 3/1)#xconnect 10.10.10.1 2 encapsulation mpls ethernet
Ruijie(config-if-GigabitEthernet 3/1)#exit
```

- Enable the LDP GR protocol, and configure parameters related to LDP GR.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#graceful-restart
```

## Set the LDP reconnection time to 300 seconds, LDP neighbor keep-alive time to 120 seconds, and LDP recovery time to 120 seconds.

```
Ruijie(config-mpls-router)#graceful-restart timer reconnect 300
Ruijie(config-mpls-router)#graceful-restart timer neighbor-liveness 120
Ruijie(config-mpls-router)#graceful-restart timer recovery 120
Ruijie(config-mpls-router)#exit
```

# Configure the P device.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#graceful-restart
```

## Set the LDP reconnection time to 300 seconds, LDP neighbor keep-alive time to 120 seconds, and LDP recovery time to 120 seconds.

```
Ruijie(config-mpls-router)#graceful-restart timer reconnect 300
Ruijie(config-mpls-router)#graceful-restart timer neighbor-liveness 120
Ruijie(config-mpls-router)#graceful-restart timer recovery 120
Ruijie(config-mpls-router)#exit
```

# Configure PE 2 by running the same commands as those on PE 1.

- Restart the LDP session for the configurations to take effect.

# Restart the LDP session on PE 1.

```
Ruijie#clear mpls ldp neighbor all
```

# Restart the LDP session on the PE device.

```
Ruijie#clear mpls ldp neighbor all
```

# Restart the LDP session on PE 1.

```
Ruijie#clear mpls ldp neighbor all
```

Verification

Run the following commands to view configurations on PE 1:

# View LDP GR information on PE 1.

```
Ruijie#show mpls ldp graceful-restart
Default VRF:
  LDP Graceful Restart is enabled
  Neighbor Liveness Timer: 120 seconds
  Max Recovery Time: 120 seconds
  Forwarding State Holding Time: 300 seconds
  Down Neighbor Database (1 records):
    Peer LDP Ident: 10.10.10.2:0; Local LDP Ident: 10.10.10.1:0
        Status: recovering (86 seconds left)
        Address list contains 3 addresses:
          10.10.10.2   20.20.20.2   30.30.30.1

```

Configuring MPLS BFD

Note The routers or router icons involved in this chapter represent common routers or L3 switches where routing protocols are running.

Overview

Note MPLS Bidirectional Forwarding Detection (BFD) is implemented in accordance with *BFD For MPLS LSPs* as defined by IETF. As a component of BFD applications, MPLS BFD describes a method for detecting MPLS LSPs. For details about BFD, see related sections in *BFD*.

In general, the following methods are used to detect LSP faults on an MPLS network:

- MPLS OAM mechanism. It can effectively detect, confirm, and locate internal defects or faults on an MPLS network. Currently, the standardization for MPLS OAM is still under way and various OAM mechanisms are in a starting-off phase in terms of practical network applications. Therefore, not all devices on a network can support the OAM.
- Hello packet mechanism of the MPLS signaling protocol. It takes a long time for the mechanism to detect a fault. In general, the detection time is a matter of seconds. Therefore, plenty of traffic is lost if the hello mechanism is applied.

MPLS BFD can resolve all the preceding problems. It has the following features:

- MPLS BFD supports interworking and provides a unified detection mechanism for the entire network.
- MPLS BFD provides fast detection. It makes possible lightly-loaded fast detection to quicken the start of a backup forwarding path and therefore improves MPLS network reliability.
- MPLS BFD can detect MPLS LSP faults on the data plane. BFD uses a fixed packet format which facilitates hardware implementation and firewall transversal.

EFD Session Establishment

BFD uses a local discriminator My Discriminator and a remote discriminator Your Discriminator to differentiate BFD sessions between a pair of systems. The discriminators can be configured in either manual or auto mode.

- Manual configuration: The local discriminator and the remote discriminator are manually configured for BFD. In this manner, the LSP Ping Echo packet to be sent before BFD session establishment does not need to carry any discriminator to perform negotiation and learn the remote discriminator. Instead, a BFD session is directly established.

- Auto configuration: The LSP Ping Echo packet to be sent before BFD session establishment carries a discriminator to perform negotiation and learn the remote discriminator before a BFD session is established.

At the initial stage of BFD session establishment, the roles of devices at both ends are classified into initiators and passive LSRs. Whether the ingress/egress LSR is an initiator or a passive LSR depends on specific applications, but at least one of them must be the initiator. Therefore, the following two scenarios may exist at the initial stage:

Both Are Initiators

If both the ingress LSR and the egress LSR are initiators, LSPs are unidirectional. Therefore, this scenario can be further divided into the following two cases:

- BFD is applied to detect both LSPs from the ingress LSR to the egress LSR and from the egress LSR to the ingress LSR

The ingress LSR sends an LSP Ping echo request that carries a local discriminator to the egress LSR. When the egress LSR receives the echo request, it obtains a remote discriminator from the echo request, so that the egress LSR owns both a local discriminator generated by itself and a remote discriminator. Then the egress LSR sends a BFD control packet to the ingress LSR. When the ingress LSR receives the BFD control packet, it obtains a remote discriminator from the received BFD control packet. Therefore, the ingress LSR also owns a local discriminator generated by itself and a remote discriminator, and then sends a BFD control packet to the egress LSR. Till now, both LSRs proceed to the initial stage of BFD session establishment.

You must noted that the egress LSR may return or not return an echo reply upon receipt of the echo request. If the egress LSR returns an echo reply, the echo reply must carry a local discriminator generated by the egress LSR itself. In this manner, the ingress LSR can obtain a remote discriminator from either the BFD control packet or the echo reply.

Note The working process on the egress LSR is similar to that on the ingress LSR.

- BFD is applied to detect the LSP from the ingress LSR to the egress LSR, and detect IP addresses (in a multi-hop situation) from the egress LSR to the ingress LSR

In this case, discriminators are manually configured on the ingress LSR and the egress LSR to establish a BFD session. In other words, the BFD session is established without experiencing automatic discriminator negotiation but the session establishment process directly starts after discriminators are manually configured on the two LSRs.

One Is the Initiator and the Other Is a Passive LSR

The initiator sends an LSP Ping echo request that carries a local discriminator to the passive LSR. When the passive LSR receives the echo request, it obtains a remote discriminator from the echo request, so that it owns both a local discriminator generated by itself and a remote discriminator. Then the passive LSR sends a BFD control packet to the initiator. When the initiator receives the BFD control packet, it obtains a remote discriminator from the received BFD control packet. Therefore, the initiator also owns a local discriminator generated by itself and a remote discriminator, and then sends a BFD control packet to the passive LSR. Till now, both LSRs proceed to the initial stage of BFD session establishment.

You must noted that the passive LSR may return or not return an echo reply upon receipt of the echo request. If the passive LSR returns an echo reply, the echo reply must carry a local discriminator generated by the passive LSR itself. In this manner, the initiator can obtain a remote discriminator from either the BFD control packet or the echo reply.

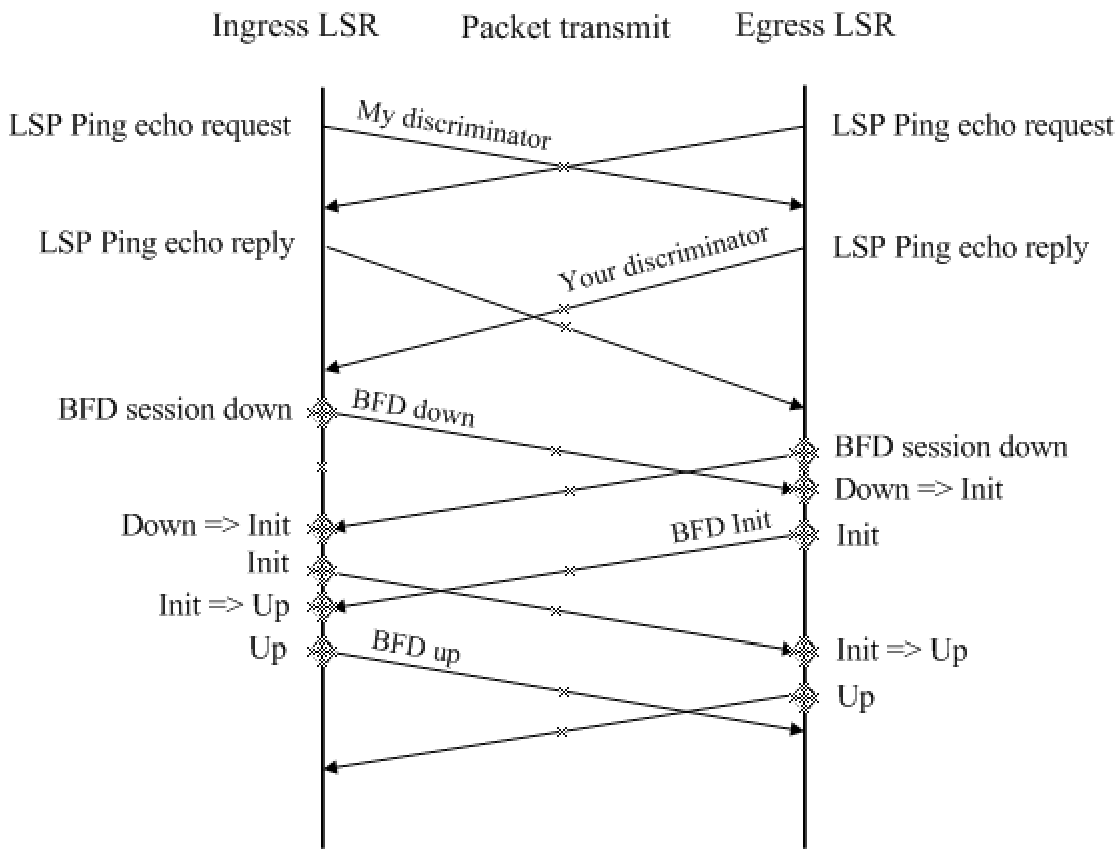
The passive LSR does not send any BFD control packet to the initiator unless it has received the echo request from the initiator.

Note Currently, only the first case is supported for BFD+LSP. That is, both LSRs must be initiators.

Example

This section describes the BFD session establishment process when both LSRs are initiators and BFD is applied to detect both LSPs from the ingress LSR to the egress LSR and from the egress LSR to the ingress LSR.

Figure 2-1 BFD session establishment process



- Before the ingress LSR and the egress LSR start BFD, they must learn the remote discriminator from each other and ensure that the LSPs are up. As shown in Figure 2-1, the ingress LSR sends an LSP Ping echo request that carries a local discriminator to the egress LSR. Upon receipt of the echo request, the egress LSR returns an echo reply that carries the local discriminator generated by the egress LSR itself to the ingress LSR. This is the same for the egress LSR. You must note that an LSR needs to learn the remote discriminator from the LSP Ping echo request if discriminators are not manually specified on both LSRs. If both the local discriminator and the remote discriminator are specified on both LSRs, this step does not apply during BFD session establishment but the next step directly continues. For details about discriminator configuration, see the "BFD+LSP" section in this document.

- The ingress LSR and the egress LSR start the BFD mechanism. The initial BFD status is Down on both LSRs. Each LSR sends a BFD packet that carries the Down status.
- Upon receipt of the BFD packet that carries the Down status, the egress LSR transits its local BFD status to "Init" and sends a BFD packet that carries the Init status.
- The egress LSR no longer processes any received BFD packet that carries the Down status after its local BFD status changes to the Init state.
- The same BFD status transition process applies on the ingress LSR.
- When receiving a BFD packet that carries the Init status, the egress LSR changes its local BFD status to the Up status.
- The same BFD status transition process applies on the ingress LSR.
- The status of the local BFD session status is Up, indicating that a BFD session has been successfully established.

BFD Modes

Before two LSRs exchange BFD control packets, a BFD session must be established on the condition that the control plane and the data plane take the same path. The following two modes exist for BFD session operations:

- Asynchronous mode
- Inquiry mode

In addition to the two operation modes, an echo function is defined for BFD. The echo function can be applied to both the asynchronous mode and the inquiry mode.

Note

Currently, only the asynchronous mode is supported for BFD+LSP. The inquiry mode and the echo function are not supported in the BFD+LSP scenario.

BFD+LSP

A BFD session is identified by a local discriminator My Discriminator and a remote discriminator Your Discriminator. The following two configuration modes can be applied to BFD+LSP based on the way by which the local discriminator and the remote discriminator are specified:

- Manual configuration
- In manual configuration mode, the local discriminator and remote discriminator are manually configured for BFD, so that the LSP Ping Echo packet to be sent before BFD session establishment does not need to carry any discriminator to perform negotiation and learn the remote discriminator. Instead, a BFD session is directly established.
- Auto configuration
- In automatic configuration mode, the LSP Ping Echo packet to be sent before BFD session establishment carries a discriminator to perform negotiation and learn the remote discriminator before a BFD session is established.

Currently, BFD+LSP is classified into BFD for static LSPs and BFD for LDP LSPs based on LSP type.

BFD for Static LSPs

BFD for static LSPs can be configured in manual or automatic mode. Since LSPs are unidirectional links but BFD is a bidirectional mechanism, reverse link detection can be performed based on one of the following detection methods when BFD is used to detect static LSPs:

- IP address mode for reverse link detection
- Static LSP mode for reverse link detection

BFD for LDP LSPs

BFD for static LSPs can be configured in manual or automatic mode. Since LSPs are unidirectional links but BFD is a bidirectional mechanism, reverse link detection can be performed based on one of the following detection methods when BFD is used to detect LDP LSPs:

- IP address mode for reverse link detection
- LDP LSP mode for reverse link detection

LDP LSPs bear basic VPN/PW public network services, so BFD for LDP LSPs is a mechanism for detecting faults of basic VPN/PW public network services. It provides fast detection for MPLS-based applications, such as VPN FRR and PW FRR, to protect services and guarantee MPLS network reliability.

Default Settings

Feature	Default
BFD session establishment mode	Active mode. Both LSRs must be initiators during BFD+LSP applications.
BFD mode	Asynchronous mode. Currently, only the asynchronous mode is supported for BFD+LSP. The inquiry mode and the echo function are not supported in the BFD+LSP scenario.
BFD session parameters	No default values are available. The BFD session parameters must be configured.
BFD authentication mode	Disabled. BFD authentication is not supported.

Protocols and Specifications

The following protocols or specifications involved are as follows:

- draft-ietf-bfd-base-09: Bidirectional Forwarding Detection
- draft-ietf-bfd-generic-05: Generic Application of BFD
- draft-ietf-bfd-mib-06: Bidirectional Forwarding Detection Management Information Base
- draft-ietf-bfd-v4v6-1hop-09: BFD for IPv4 and IPv6 (Single Hop)
- draft-ietf-bfd-multihop-07: BFD for IPv4 and IPv6 (Multihop)
- draft-ietf-bfd-mpls-07: BFD For MPLS LSPs

Configuring MPLS BFD

Configuring BFD for Static LSPs

Network Environment

BFD can be used to detect the continuity of static LSPs. When BFD is used for static LSPs, a static LSP that is down is not selected as the forwarding path of a private network route.

Prerequisites

Complete the following tasks before configuring BFD for static LSPs:

- Enable MPLS.
- Configure static LSPs.

Data Preparations

Prepare the following data before configuring BFD for static LSPs:

- My Discriminator and Your Discriminator of the BFD session
- Selection of the reverse link detection method
- BFD session parameters: BFD control packet sending interval, BFD control packet receiving interval, and the detection multiplier of BFD control packets

Configuring BFD on the Ingress LSR

By default, BFD for static LSPs is disabled on a device. To enable BFD for static LSPs on a device, enter privileged user mode to run the following commands:

Command	**Function**
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface type ID**	Enters the interface configuration mode.
Ruijie(config-if-type ID)# **bfd interval** *milliseconds* min_rx *milliseconds* multiplier *multiplier-value*	Sets BFD session parameters.
Ruijie(config-if-type ID)# **exit**	Exits interface configuration mode.
Ruijie(config)# **bfd bind static-lsp peer-ip** *ip-address* s**ource-ip** *ip-address* [**local-discriminator** *discr-value* **remote-discriminato**r *discr-value*] [**process-state**]	Sets BFD for static LSPs along with BFD session status handling. If manual configuration is applied on the ingress LSR, manual configuration must also be applied on the egress LSR. In other words, the configuration modes on both LSRs must be symmetrical.

To disable BFD for static LSPs, run the **no bfd bind static-lsp peer-ip** *ip-address* command.

Caution

Only static LSPs established by host route triggering are supported in BFD for static LSPs.

The *process-state* parameter must be specified for applications using BFD for fault detection, for example, when BFD is combined with LSP.

If discriminators are manually configured, the local and remote discriminators configured on the ingress LSR must match with those configured on the egress LSR.

Configuring BFD on the Egress LSR

By default, BFD for static LSPs is disabled on a device. To enable BFD for static LSPs on a device, enter privileged user mode to run the following commands:

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface type ID**	Enters interface configuration mode.
Ruijie(config-if-type ID)# **bfd interval** *milliseconds* min_rx *milliseconds* **multiplier** *multiplier-value*	Sets BFD session parameters.
Ruijie(config-if- type ID)# exit	Exits interface configuration mode.
Ruijie(config)# **bfd bind static-lsp peer-ip** *ip-address* **source-ip** *ip-address* [**local-discriminator** *discr-value* re**mote-discriminator** *discr-value*] **[process-state]**	Sets BFD for static LSPs without BFD session status handling. If manual configuration is applied on the ingress LSR, manual configuration must also be applied on the egress LSR. In other words, the configuration modes on both LSRs must be symmetrical.
Or:	
bfd bind backward-lsp-with-ip peer-ip *ip-address* **[vrf** *vrf-name*] **interface** *interface-type interface-number* **[source-ip** *ip-address*] {**local-discriminator** *discr-valu***e remote-discriminator** *discr-value*}	Sets the IP address mode for reverse link detection in BFD for LSPs. If the IP mode is applied for LSP reverse link detection during configuration, a local discriminator and a remote discriminator must be manually specified for the forward LSP.
Ruijie(config)# **exit**	Exits global configuration mode.

To disable BFD for static LSPs, run the **no bfd bind static-lsp peer-ip** *ip-address* or no bfd bind **backward-lsp-with-ip peer-ip** *ip-address* [**vrf** *vrf-name*] command.

Caution

Only static LSPs established by host route triggering are supported in BFD for static LSPs.

The IP detection mode can be applied on the reverse link during BFD for LSPs.

If discriminators are manually configured, the local and remote discriminators configured on the egress LSR must match with those configured on the ingress LSR.

Verification

To display configuration and running information about BFD for static LSPs, run the following commands:

Command	Function
show bfd neighbors [vrf *vrf-name*] [i**pv4** *ip-address* [**details] | client {static-lsp | backward-lsp-with-**ip} **[ipv4** *ip-address* [**details] | [details**]]	Displays BFD session information.

Configuring BFD for LDP LSPs

Network Environment

BFD can be used to detect the continuity of LDP LSPs. When BFD is used with LDP LSPs, an LDP LSP that is Down is not selected as the forwarding path of a private network route.

Prerequisites

Complete the following tasks before configuring BFD for LDP LSPs:

- Enable MPLS.
- Enable LDP.

Data Preparations

Prepare the following data before configuring BFD for LDP LSPs:

- My Discriminator and Your Discriminator of the BFD session
- Selection of the reverse link detection method
- BFD session parameters: BFD control packet sending interval, BFD control packet receiving interval, and the detection multiplier of BFD control packets

Configuring BFD on the Ingress LSR

By default, BFD for LDP LSPs is disabled on a device. To enable BFD for LDP LSPs on a device, enter privileged user mode to run the following commands:

Command	Function
Ruijie# **configure terminal**	Enters the global configuration mode
Ruijie(config)# **interface type ID**	Enters interface configuration mode.
Ruijie(config-if-type ID)# **bfd interval** *milliseconds* min_rx *milliseconds* **multiplier** *multiplier-value*	Sets BFD session parameters.
Ruijie(config-if-type ID)# **exit**	Exits interface configuration mode.
Ruijie(config)**#mpls router ldp**	Enters LDP configuration mode.
Ruijie(config-mpls-router)# **bfd bind ldp-lsp peer-ip** *ip-address* **nexthop** *ip-address* **[interface** *interface-type interface-number*] **source-ip** *ip-address* **[local-discriminator** *discr-value* **remote-discriminato**r *discr-value*] [**process-state**]	Sets BFD for LDP LSPs along with BFD session status handling. If manual configuration is applied on the ingress LSR, manual configuration must also be applied on the egress LSR. In other words, the configuration modes on both LSRs must be symmetrical.

To disable BFD for LDP LSPs, run the **no bfd bind ldp-lsp peer-ip** *ip-address* command.

Caution

Only LDP LSP established by host route triggering is supported in BFD for LDP LSPs.
One LSP can be bound to only one BFD session.
BFD binding can be performed only on the ingress LSR of the LDP LSP.
The *process-state* parameter must be specified for applications using BFD for fault detection, for example, when BFD is combined with LSP.
If discriminators are manually configured, the local and remote discriminators configured on the ingress LSR must match with those configured on the egress LSR.

Configuring BFD on the Egress LSR

By default, BFD for LDP LSPs is disabled on a device. To enable BFD for LDP LSPs on a device, enter the privileged user mode to run the following commands:

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface type ID**	Enters interface configuration mode.
Ruijie(config-if-type ID)# **bfd interval** *milliseconds* min_rx *millisecond*s **multiplier** *multiplier-value*	Sets BFD session parameters.
Ruijie(config-if-type ID)# **exit**	Exits interface configuration mode.
Ruijie(config)# **bfd bind backward-lsp-with-ip peer-ip** *ip-address* [**vrf** *vrf-name*] **interface** *interface-type interface-number* **[source-ip** *ip-address*] l**ocal-discriminator** *discr-value* **remote-discriminato**r *discr-value*	Sets the IP address mode for reverse link detection in BFD for LSPs. If the IP mode is applied for LSP reverse link detection during configuration, a local discriminator and a remote discriminator must be manually specified for the forward LSP.
Or:	
Ruijie(config)#**mpls router ldp**	Enters LDP configuration mode.
Ruijie(config-mpls-router)# **bfd bind ldp-lsp peer-i**p *ip-address* **nexthop** *ip-address* [**interface** *interface-type interface-number*] **source-ip** *ip-address* **[local-discriminator** *discr-value* **remote-discriminato**r *discr-value*] [**process-state**]	Sets BFD for LDP LSPs without BFD session status handling. If manual configuration is applied on the ingress LSR, manual configuration must also be applied on the egress LSR. In other words, the configuration modes on both LSRs must be symmetrical.
Ruijie(config-bfd-router)# **exit**	Exits the LDP configuration mode.

To disable BFD for LDP LSPs, run the **no bfd bind backward-lsp-with-ip peer-ip** *ip-address* [**vrf** *vrf-name*] or **no bfd bind ldp-lsp peer-ip** *ip-address* command.

Caution

The IP detection mode can be applied on the reverse link during BFD for LSPs.
Or BFD can be configured to detect the other LSP.
1. Only LDP LSPs established by host route triggering are supported in BFD for LDP LSPs.
2. One LSP can be bound to only one BFD session.

3. BFD binding can be performed only on the ingress LSR of the LDP LSP.

If discriminators are manually configured, the local and remote discriminators configured on the egress LSR must match with those configured on the ingress LSR.

Verification

To display configuration and running information about BFD for LDP LSPs, run the following commands:

Command	Function
show bfd neighbors [**vrf** *vrf-name*] [**ipv4** *ip-address* [**details] | client {ldp-lsp | backward-lsp-with-**ip} [**ipv4** *ip-address* [**details] | [details]**]	Displays BFD session information.

Configuration Examples

Configuring BFD for Static LSPs

Networking Requirements

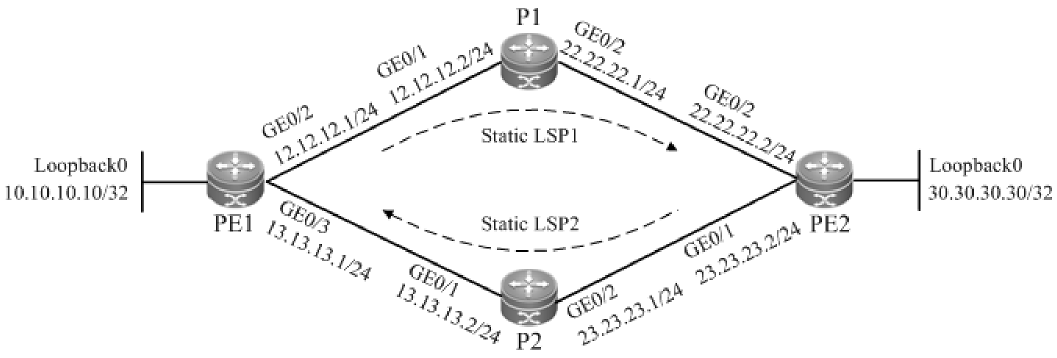
BFD can be configured to detect the continuity of static LSPs. Two links exist between PE 1 and PE 2, as shown in Figure 2-2.

- PE 1, PE 2, P1, and P2 form an MPLS network.
- A static LSP (LSP 1) exists and spans PE 1, P1 and PE 2 in turn. BFD is configured to detect this static LSP.
- A static LSP (LSP 2) exists and spans PE 2, P2 and PE 1 in turn. BFD is configured to detect this static LSP and notify faults if any to PE 1. This static LSP is used on the reverse link.

If LSP 1 fails, PE 1 can quickly receive a fault notification and handle the fault by deleting respective static MPLS routes.

Networking Topology

Figure 2-2 Networking topology for configuring BFD for static LSPs



Configuration Tips

Configure all devices as follows:

- Configure interface IP addresses and the OSPF protocol on devices.

- Enable global MPLS forwarding on all devices, and MPLS packet forwarding on interfaces.
- Configure static MPLS routes on the devices to enable the network to forward MPLS traffic.
- Configure BFD on PE 1 to detect static LSP 1.
- Configure BFD on PE 2 to detect static LSP 2, which is used as the LSP on the reverse link.

Configuration Steps

Configure interface IP addresses and the OSPF protocol on devices.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#interface gigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)#no switchport
Ruijie(config-if-GigabitEthernet 0/2)#ip address 12.12.12.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/2)#exit
Ruijie(config)#interface gigabitEthernet 0/3
Ruijie(config-if-GigabitEthernet 0/3)#no switchport
Ruijie(config-if-GigabitEthernet 0/3)#ip address 13.13.13.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/3)#exit
Ruijie(config)#interface loopback 0
Ruijie(config-Loopback 0)#ip address 10.10.10.10 255.255.255.255
Ruijie(config-Loopback 0)#exit
Ruijie(config)#router ospf 1
Router(config-router)#network 12.12.12.1 255.255.255.0 area 0
Router(config-router)#network 13.13.13.1 255.255.255.0 area 0
Router(config-router)#network 10.10.10.10 255.255.255.255 area 0
Router(config-router)#exit
```

# Configure the other devices by running the same commands as those on PE 1.

Enable global MPLS forwarding on all devices, and MPLS packet forwarding on interfaces.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls ip
Ruijie(config)#interface gigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)#label-switching
Ruijie(config-if-GigabitEthernet 0/2)#mpls ip
Router(config-if-GigabitEthernet 0/2)#exit
Ruijie(config)#interface gigabitEthernet 0/3
Ruijie(config-if-GigabitEthernet 0/3)#label-switching
Ruijie(config-if-GigabitEthernet 0/3)#mpls ip
Router(config-if-GigabitEthernet 0/3)#exit
```

# Configure the other devices by running the same commands as those on PE 1.

Configure static MPLS routes on the devices to enable the network to forward MPLS traffic.

# Configure static LSP 1: PE1->P1->PE2.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls static ftn 30.30.30.30/32 out-label 16 nexthop gigabitEthernet 0/2
12.12.12.2
```

# Configure P1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls static ilm in-label 16 forward-action swap-label 3 nexthop
gigabitEthernet 0/2 22.22.22.2 fec 30.30.30.30/32
```

## Run the **ping mpls ipv4** *30.30.30.30* command on PE 1 after the preceding configurations are complete. Ensure that the ping operation is successful.

# Configure static LSP 2: PE2->P2->PE1.

# Configure PE 2.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls static ftn 10.10.10.10/32 out-label 16 nexthop gigabitEthernet 0/1
23.23.23.1
```

# Configure P2.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls static ilm in-label 16 forward-action swap-label 3 nexthop
gigabitEthernet 0/1 13.13.13.1 fec 10.10.10.10/32
```

## Run the **ping mpls ipv4** *10.10.10.10* command on PE 2 after the preceding configurations are complete. Ensure that the ping operation is successful.

Configure BFD on PE 1 to detect LSP 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#interface gigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)#bfd interval 50 min_rx 50 multiplier 3
Ruijie(config-if-GigabitEthernet 0/2)#exit
Ruijie(config)#bfd bind static-lsp peer-ip 30.30.30.30 source-ip 10.10.10.10
local-discriminator 1 remote-discriminator 2 process-state
Ruijie(config)#exit
```

Configure BFD on PE 2 to detect LSP 2, which is used as the LSP on the reverse link.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)#bfd interval 50 min_rx 50 multiplier 3
Ruijie(config-if-GigabitEthernet 0/1)#exit
Ruijie(config)#bfd bind static-lsp peer-ip 10.10.10.10 source-ip 30.30.30.30
local-discriminator 2 remote-discriminator 1
Ruijie(config)#exit
```

Configuring BFD for LDP LSPs

Networking Requirements

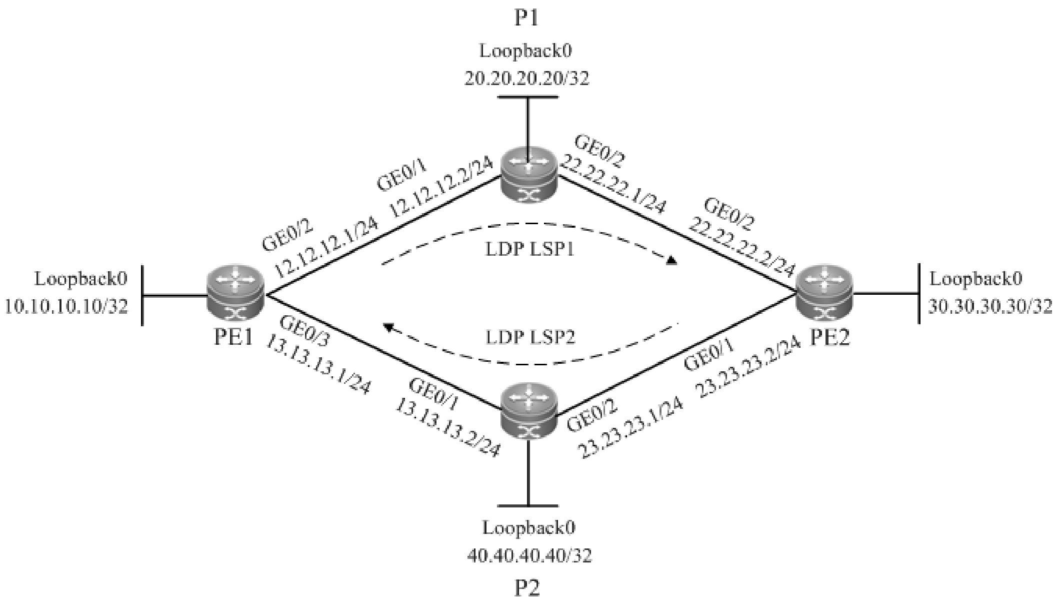
BFD can be configured to detect the continuity of LDP LSPs. Two links exist between PE 1 and PE 2, as shown in Figure 2-3.

- PE 1, PE 2, P1, and P2 form an MPLS network.
- Costs are configured for the interfaces on PE 1 and PE 2, so that two LSPs can be established between PE 1 and PE 2, as shown in Figure 2-3.
- An LDP LSP (LDP LSP 1) exists and spans PE 1, P1 and PE 2 in turn. BFD is configured to detect this LDP LSP.
- An LDP LSP (LDP LSP 2) exists and spans PE 2, P2 and PE 1 in turn. BFD is configured to detect this LDP LSP and notify faults if any to PE 1. This LDP LSP is used on the reverse link.

If LDP LSP 1 fails, PE 1 can quickly receive a fault notification and handle the fault by deleting respective MPLS routes.

Networking Topology

Figure 2-3 Networking topology for configuring BFD for LDP LSPs



Configuration Tips

Configure all devices as follows:

- Configure interface IP addresses and the OSPF protocol on devices.

- Enable global MPLS forwarding on devices, MPLS packet forwarding, and the LDP on interfaces.
- Configure the LDP to enable the network to forward MPLS traffic.
- Configure BFD on PE 1 to detect LDP LSP 1.
- Configure BFD on PE 2 to detect LDP LSP 2, which is used as the LSP on the reverse link.

Configuration Steps

Configure interface IP addresses and the OSPF protocol on devices.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
```

## The **no switchport** command is used on a switch to switch to Routed Port mode. It is not applicable to routers, and therefore you do not need to run this command on routers.

```
Ruijie(config)#interface gigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)#no switchport
Ruijie(config-if-GigabitEthernet 0/2)#ip address 12.12.12.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/2)#exit
```

## The **no switchport** command is used on a switch to switch to Routed Port mode. It is not applicable to routers, and therefore you do not need to run this command on routers.

```
Ruijie(config)#interface gigabitEthernet 0/3
Ruijie(config-if-GigabitEthernet 0/3)#no switchport
Ruijie(config-if-GigabitEthernet 0/3)#ip address 13.13.13.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/3)#exit
Ruijie(config)#interface loopback 0
Ruijie(config-Loopback 0)#ip address 10.10.10.10 255.255.255.255
Ruijie(config-Loopback 0)#exit
Ruijie(config)#router ospf 1
Router(config-router)#network 12.12.12.1 255.255.255.0 area 0
Router(config-router)#network 13.13.13.1 255.255.255.0 area 0
Router(config-router)#network 10.10.10.10 255.255.255.255 area 0
Router(config-router)#exit
```

# Configure the other devices by running the same commands as those on PE 1.

Enable global MPLS forwarding on devices, MPLS packet forwarding, and the LDP on interfaces.

## Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#mpls ip
```

## The **ip ref** command is run a router to enable MPLS fast forwarding on the router. You do not need to run this command on switches..

```
Ruijie(config)#interface gigabitEthernet 0/3
Ruijie(config-if-GigabitEthernet 0/3)#label-switching
Ruijie(config-if-GigabitEthernet 0/3)#mpls ip
Ruijie(config-if-GigabitEthernet 0/3)#ip ref
Router(config-if-GigabitEthernet 0/3)#exit
```

## The **ip ref** command is run a router to enable MPLS fast forwarding on the router. You do not need to run this command on switches.

```
Ruijie(config)#interface gigabitEthernet 0/3
Ruijie(config-if-GigabitEthernet 0/3)#label-switching
Ruijie(config-if-GigabitEthernet 0/3)#mpls ip
Ruijie(config-if-GigabitEthernet 0/3)#ip ref
Router(config-if-GigabitEthernet 0/3)#exit
```

# Configure P1.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#mpls ip
```

## The **ip ref** command is run a router to enable MPLS fast forwarding on the router. You do not need to run this command on switches.

```
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)#label-switching
Ruijie(config-if-GigabitEthernet 0/1)#mpls ip
Ruijie(config-if-GigabitEthernet 0/1)#ip ref
Router(config-if-GigabitEthernet 0/1)#exit
```

## The **ip ref** command is run a router to enable MPLS fast forwarding on the router. You do not need to run this command on switches..

```
Ruijie(config)#interface gigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)#label-switching
Ruijie(config-if-GigabitEthernet 0/2)#mpls ip
Ruijie(config-if-GigabitEthernet 0/2)#ip ref
Router(config-if-GigabitEthernet 0/2)#exit
```

# Configure the other devices by running the same commands as those on PE 1.

Enable global MPLS forwarding on devices, MPLS packet forwarding, and the LDP on interfaces.

# Configure PE1

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0 force
```

# Configure P1.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0 force
```

# Configure the other devices by running the same commands as those on PE 1.

Configure BFD on PE 1 to detect LDP LSP 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface gigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)#bfd interval 50 min_rx 50 multiplier 3
Ruijie(config-if-GigabitEthernet 0/2)#exit
Ruijie(config)#mpls router ldp

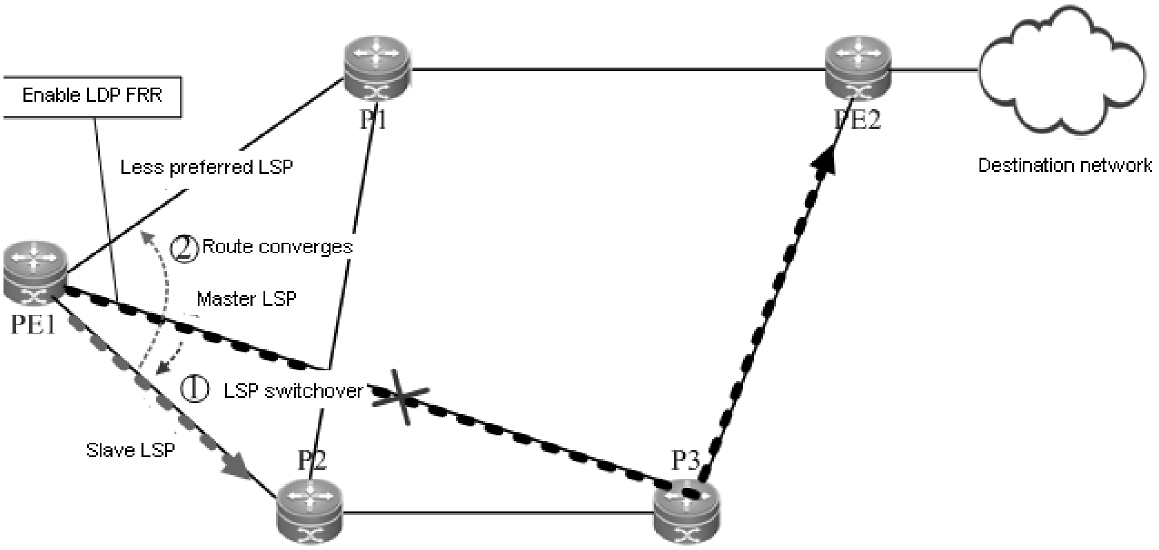
Configuring LDP FRR

Note The routers or router icons involved in this chapter represent common routers or L3 switches where routing protocols are running.

Overview

LDP Fast Rerouting (FRR) ensures that traffic can switch over from a master LSP to a backup LSP within a very short time when the master LSP fails and that traffic switches back to a new LSP from the backup LSP during route convergence. In this manner, traffic is not interrupted in the short time before network convergence, improving MPLS network reliability and protecting key services on the MPLS network.

Figure 3-1 Working principles of LDP FRR



LDP FRR is an extension of the LDP. The LDP works in free label retention mode. LDP FRR backs up retained labels (i.e. LSPs). When a link fails, the system can quickly detect the failure of the master LSP using a fast link failure detection technology such as BFD. While the LDP regenerates a new LSP, traffic on the master LSP switches back to the backup LSP to implement uninterrupted traffic forwarding. After the new LSP is generated, traffic is forwarded on the new LSP.

As shown in Figure 3-1. LDP FRR involves three types of LSPs: master LSP, less preferred LSP, and backup LSP. The master LSP is the optimal LSP along which traffic is forwarded when the network is stable and routes are converged. The less preferred LSP is one that has a cost value larger than the cost value of the master LSP. When the master LSP fails, routes converge on the less preferred LSP. The backup LSP is a backup LSP with a specified next hop. The three LSPs have different cost values.

In the LDP FRR solution, the next hop of the backup LSP interface is specified on the master LSP interface and BFD is configured on the master link to quickly detect faults of the master link. If the master link fails suddenly and a long time is required for routes to converge on the less preferred LSP, the quick link fault detection mechanism detects that the master link fails and therefore immediately switches traffic from the master LSP to the backup LSP, so that traffic is not discarded. In this manner, traffic to the destination network is forwarded by the backup LSP before routes converge on the less preferred LSP.

In the following several seconds, the master link fault is detected by the routing protocol and rerouting is performed through information exchange between routers. Finally, a notification message is sent to the LDP. The LDP regenerates a less preferred LSP based on the new next hop carried in the notification, and changes the path of the traffic to the destination network to the less preferred LSP, so that traffic smoothly switches over to the less preferred LSP from the backup LSP. If the less preferred LSP is just the backup LSP, traffic does not need to switch back to the less preferred LSP from the backup LSP. Even so, traffic still experiences the backup LSP phase and the less preferred LSP phase after route convergence, except that traffic just passes the same link in the two phases.

Configuring LDP FRR

Network Environment

When the LDP cannot effectively protect traffic on an MPLS network, LDP FRR can be configured on ports to protect the traffic and avoid traffic loss.

Prerequisites

Complete the following tasks before configuring LDP FRR:

- Enable MPLS.
- Configure MPLS LDP.

Data Preparations

Prepare the following data before configuring LDP FRR:

- Interface of the backup LSP, which is also the master interface
- Next-hop IP address of the backup LSP
- Name of the access control list (ACL)
- Priority of the backup LSP
- Length of the LDP FRR protection timer (optional)
- BRD single-hop detection parameters (optional)

Configuring the LDP FRR

By default, LDP FRR is disabled on a device. To enable the LDP FRR function on a device, enter the privileged user mode to run the following commands:

Command	**Function**
Ruijie#**configure terminal**	Enters global configuration mode.

Ruijie(config)#**mpls ip**	Enables MPLS forwarding. Caution This command is not applicable to forwarding on switch chips.
Ruijie(config)**#interface type ID**	Enters interface configuration mode.
Ruijie(config-if-type ID)#**mpls ip**	Enables LDP forwarding on interfaces (router configuration).
Ruijie(config-if-type ID)**#ip ref**	Enables fast forwarding on interfaces.
Ruijie(config-if-type ID)#**label-switching**	Enables MPLS packet processing on interfaces.
Ruijie(config-if-type ID)#**exit**	Exits the interface configuration mode.
Ruijie(config)**#mpls router ldp**	Enters the LDP configuration mode.
Ruijie(config-mpls-router)#**ldp router-id** *Loopback ID* **force**	Sets the router ID to a loopback ID (the settings immediately take effect).
Ruijie(config-mpls-router)#**exit**	Exits LDP configuration mode.
Ruijie(config)**#interface type ID**	Enters interface configuration mode.
Ruijie(config-if-type ID)# **mpls ldp frr nexthop** *nexthop-address* [**interface** *interface-type interface-number*] [**acl** *acl-name*] [**priority** *priority*]	Enables LDP FRR on interfaces.

To disable LDP FRR, run the **no mpls ldp frr** [**nexthop** *nexthop-address*] [**acl** *acl-name*] [**priority** *priority*] command.

Note Do not enable or disable LDP FRR during LDP GR.

Caution You must specify labels to work in free retention mode during LDP FRR configuration.

Configuring the LDP FRR Protection Timer (Optional)

If the master LSP link is recovered within the LDP FRR protection timer, traffic switches over to the master LSP link only after the LDP FRR protection timer expires. To configure the LDP FRR protection timer, enter the interface configuration mode to run the following commands in turn:

Command	**Function**
Ruijie**#configure terminal**	Enters global configuration mode.
Ruijie(config)**#mpls ip**	Enables MPLS forwarding. This command is not applicable to forwarding on switch chips.
Ruijie(config)#**interface type ID**	Enters the interface configuration mode.
Ruijie(config-if-type ID)**#mpls ip**	Enables LDP forwarding on interfaces.
Ruijie(config-if-type ID)#**ip ref**	Enables fast forwarding on interfaces.

Command	Function
Ruijie(config-if-type ID)#**label-switching**	Enables MPLS packet processing on interfaces.
Ruijie(config-if-type ID)#**exit**	Exits the interface configuration mode.
Ruijie(config)#**mpls router ldp**	Enters the LDP configuration mode.
Ruijie(config-mpls-router)#**ldp router-id** *Loopback ID* **force**	Sets the router ID to a loopback ID (the settings immediately take effect).
Ruijie(config-mpls-router)#**exit**	Exits the LDP configuration mode.
Ruijie(config)#**interface type ID**	Enters the interface configuration mode.
Ruijie(config-if-type ID)# **mpls ldp frr nexth**op *nexthop-address* [**acl** *acl-name*] [**priority** *priority*]	Enables LDP FRR on interfaces.
Ruijie(config-if-type ID)# **mpls ldp frr timer protect-time {infinity** | *seconds*}	Sets the LDP FRR protection timer on interfaces.

To enable the LDP FRR protection timer, run the **no mpls ldp frr timer protect-time** command.

Configuring Single-Hop BFD (Optional)

Run the **bfd bind peer-ip** command to configure single-hop BFD. After single-hop BFD is configured, the status of a BFD session is indicated in interface status information. Then LDP FRR detects the interface status and perform switchover. By default, single-hop BFD is disabled on a device. You can run the **no bfd bind peer-ip** command to disable single-hop BFD if necessary.

Note

Single-hop BFD is optional during LDP FRR configuration. For details about single-hop BFD configuration, see related sections in *BFD Configuration*.

Configuring DLDP (Optional)

Run the **dldp ip** command to configure the Device Link Detection Protocol (DLDP) function on a device. By default, probes are tried three times every 100 milliseconds. You can run the **no dldp ip** command to restore the default DLDP settings.

Note

For details about DLDP and configuration methods, see related sections in *DLDP*.

Verification

After configuring LDP FRR, run the following command to show LSP information:

Command	Function
show mpls rib	Displays MPLS routing information.

Configuration Examples

Networking Requirements

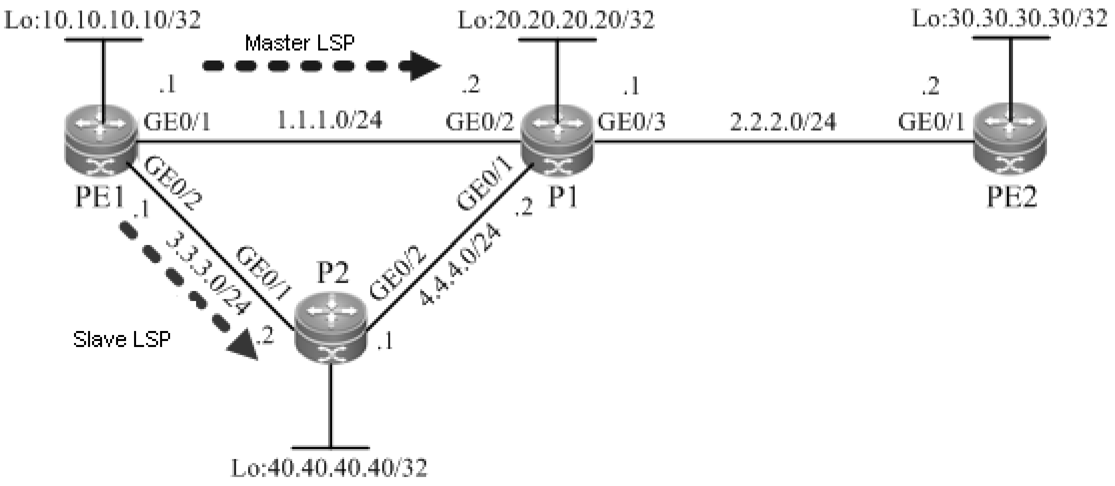
At least two links to the destination network are required when the LDP FRR is configured. Two links exist between PE 1 and PE 2, as shown in Figure 3-2.

- The PE1->P1->PE2 link is the master LSP.
- The PE1->P2->P1->PE2 link is the backup LSP.

LDP FRR can be configured on PE 1 and P1 to protect links between PE 1 and P1 and therefore avoid traffic loss.

Networking Topology

Figure 3-2 Networking topology for configuring LDP FRR



Configuration Tips

Configure all devices as follows:

- Configure interface IP addresses and the OSPF protocol on devices.
- Enable global MPLS forwarding on devices, MPLS packet forwarding, and the LDP on interfaces.
- Configure the LDP to enable the network to forward MPLS traffic.
- Configure LDP FRR.

116) Enable LDP FRR on the interfaces of PE 1 and P1 to generate the backup LSP.
117) Configure the LDP FRR protection timer on the interfaces of PE 1 and P1.
118) Configure single-hop BFD on the interfaces of PE 1 and P1.

Configuration Steps

- Configure interface IP addresses and the OSPF protocol on devices.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)#no switchport
Ruijie(config-if-GigabitEthernet 0/1)#ip address 1.1.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/1)#exit
Ruijie(config)#interface gigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)#no switchport
Ruijie(config-if-GigabitEthernet 0/2)#ip address 3.3.3.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/2)#exit
Ruijie(config)#interface loopback 0
Ruijie(config-Loopback 0)#ip address 10.10.10.10 255.255.255.255
Ruijie(config-Loopback 0)#exit
Ruijie(config)#router ospf 1
Router(config-router)#network 1.1.1.1 255.255.255.0 area 0
Router(config-router)#network 3.3.3.1 255.255.255.0 area 0
Router(config-router)#network 10.10.10.10 255.255.255.255 area 0
Router(config-router)#exit
```

# Configure the other devices by running the same commands as those on PE 1.

- Enable global MPLS forwarding on devices, MPLS packet forwarding, and the LDP on interfaces.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls ip
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)#label-switching
Ruijie(config-if-GigabitEthernet 0/1)#mpls ip
Router(config-if-GigabitEthernet 0/1)#exit
Ruijie(config)#interface gigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)#label-switching
Ruijie(config-if-GigabitEthernet 0/2)#mpls ip
Router(config-if-GigabitEthernet 0/2)#exit
```

# Configure the other devices by running the same commands as those on PE 1.

- Configure the LDP so that the network can forward MPLS traffic.

# Configure PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0 force
```

# Configure the other devices by running the same commands as those on PE 1.

- Configure LDP FRR.

# Configure PE 1.

## Enable LDP FRR on the interface of PE 1 to generate the backup LSP.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)#mpls ldp frr nexthop 3.3.3.2
Ruijie(config-if-GigabitEthernet 0/1)#exit
```

## Configure the LDP FRR protection timer on the interface of PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)#mpls ldp frr timer protect-time 15
Ruijie(config-if-GigabitEthernet 0/1)#exit
```

## Configure single-hop BFD on the interface of PE 1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)#no bfd echo
Ruijie(config-if-GigabitEthernet 0/1)#bfd interval 50 min_rx 50 multiplier 3
Ruijie(config-if-GigabitEthernet 0/1)#bfd bind peer-ip 20.20.20.20 source-ip 1.1.1.1
process-pst
Ruijie(config-if-GigabitEthernet 0/1)#exit
```

# Configure P1.

## Enable LDP FRR on the interface of P1 so as to generate the backup LSP.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#interface gigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)#mpls ldp frr nexthop 4.4.4.1
Ruijie(config-if-GigabitEthernet 0/2)#exit
```

## Configure the LDP FRR protection timer on the interface of P1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#interface gigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)#mpls ldp frr timer protect-time 15
Ruijie(config-if-GigabitEthernet 0/2)#exit
```

## Configure single-hop BFD on the interface of P1.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#interface gigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)#no bfd echo
Ruijie(config-if-GigabitEthernet 0/2)#bfd interval 50 min_rx 50 multiplier 3
Ruijie(config-if-GigabitEthernet 0/2)#bfd bind peer-ip 1.1.1.1 source-ip 1.1.1.2
process-pst
Ruijie(config-if-GigabitEthernet 0/2)#exit
```

Verification

View MPLS routing information.

Configuring LDP IGP Synchronization

Note

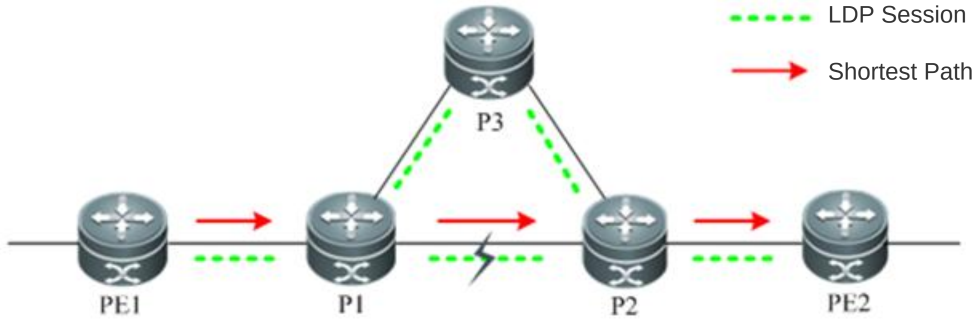
The routers and router icons described in this document represent those in common sense.

Overview

Link Detection Protocol (LDP)-Interior Gateway Protocol (IGP) synchronization is a technology that realizes uniform LDP and IGP convergence by changing the way of route release to avoid Multiple Protocol Label Switching (MPLS) route black holes.

In the MPLS network, LDP establishes Label Switched Paths (LSPs) based on the shortest IP path. As LDP and routing protocols have different convergence conditions and speeds, convergence of LDP LSPs may be inconsistent with that of the shortest IP path.

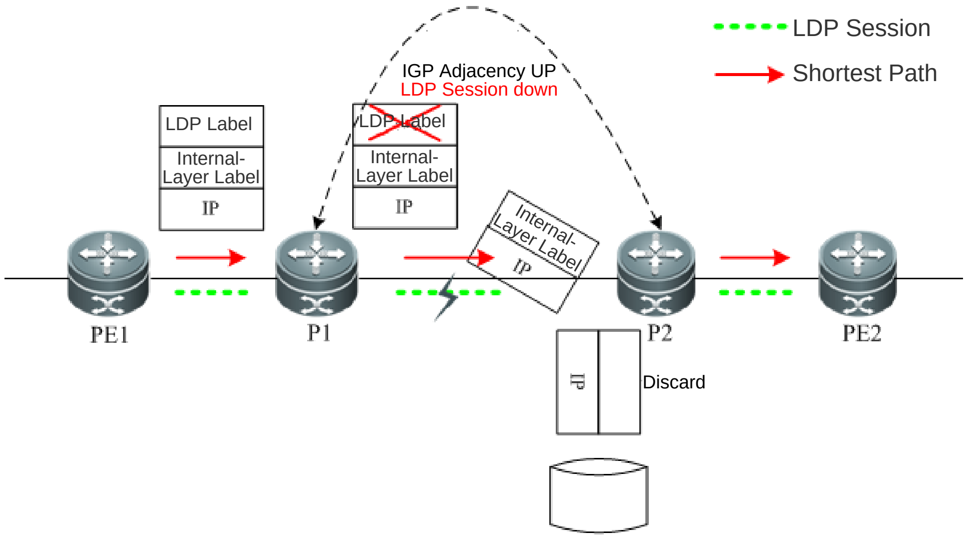
Figure 0-1 MPLS Network Topology



As shown in the figure, the devices are interconnected with each other at the link layer and run routing protocols and LDP. The shortest path from Provider Edge 1 (PE1) to PE2 is PE1-P1-P2-PE2, which covers LDP LSP. Routing protocols will not detect disconnection of the LDP session between P1 and P2 (the P1-P2 link and IGP remain normal) because the network topology is not changed. Although LDP detects the LSP disconnection, LDP cannot trigger route switching to a standby path because it is not a routing protocol. In this case, the shortest path from PE1 to PE2 is still PE1-P1-P2-PE2, but the LSP from PE1 to PE2 is disconnected between P1 and P2.

If MPLS Virtual Private Network (VPN)/6PE traffic is being forwarded through the path, the MPLS traffic will be affected.

Figure 0-2 MPLS VPN/6PE Traffic Being Forwarded through LSP

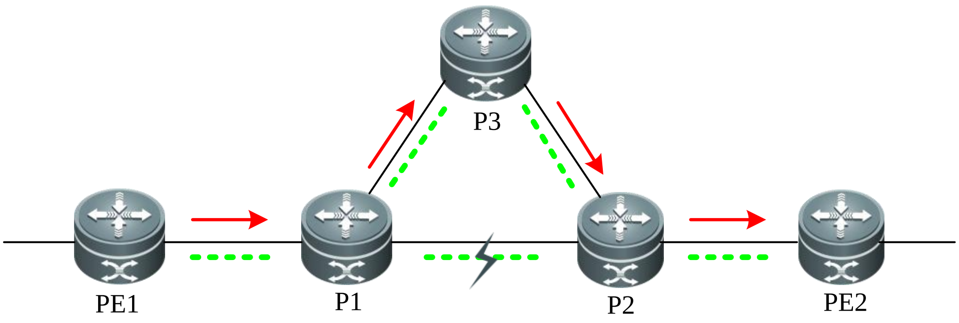


As shown in the figure above, the LSP between PE1 and PE2 is used to forward MPLS VPN/6PE traffic. Label packets are transmitted through the LDP LSP. When the LDP session between P1 and P2 is disconnected, packets have only inbound LDP labels on P1. P1 pops LDP labels upon receipt of the packets, and then forwards the packets with internal-layer labels to P2. However, P2 cannot identify internal-layer labels (because there is no private network route in the IPv4 routing table of the core device P on a public network and internal-layer labels are not assigned by P2), so the packets are discarded between P1 and P2, which results in traffic forwarding black holes.

Therefore, for applications such as MPLS VPN (including L2 VPN and L3 VPN) and 6PE that rely on end-to-end LDP LSPs on an MPLS network, if the convergence of LDP LSPs is inconsistent with that of the shortest IP path, MPLS route black holes will be incurred.

To solve this problem, you can configure LDP IGP synchronization on the core devices.

Figure 0-3 MPLS Network Topology



As shown in the figure, the LSP between PE1 and PE2 is used to forward MPLS VPN/6PE traffic. Label packets are transmitted through the LDP LSP. LDP IGP synchronization is enabled on core devices P1, P2 and P3. When the LDP session between P1 and P2 is disconnected, LDP IGP synchronization triggers IGP and LDP LSP convergence to the standby path P1-P3-P2, and the new path covers IGP and LDP LSP so that MPLS route black holes will not be incurred.

Caution You must to deploy standby paths for active links in the network topology; otherwise, it makes no sense to configure LDP IGP synchronization.

Configuring LDP IGP Synchronization

Scenario

LDP IGP synchronization aims at traffic loss caused by failure of the active LSP link on a network with active and standby LSP links. The following describes major application scenarios:

- When the active link is normal but the LDP session between two nodes on the active link fails, LSP traffic is switched to the standby link, while IGP traffic is still forwarded through the active link, which results in LSP traffic loss.
- When the active link fails, both IGP traffic and LSP traffic are switched to the standby link. However, when the fault is removed, as IGP converges faster than LDP, IGP is switched back to the active link before LDP does, which results in LSP traffic loss.

Prerequisites

Before configuring LDP IGP synchronization, you are advised to do the following:

- Enable MPLS.
- Configure MPLS LDP.

Data

Before configuring LDP IGP synchronization, you are advised to do the following:

- Configure IGP instances for LDP IGP synchronization (interfaces on which LDP IGP synchronization will be enabled).
- Configure the LDP IGP synchronization delay (optional).
- Configure the IGP waiting time for LDP synchronization (optional).

Enabling LDP IGP Synchronization

You can enable LDP IGP synchronization for all the interfaces that run Open Shortest Path First (OSPF) in OSPF routing process configuration mode. The following table describes the steps:

Command	Description
Ruijie # **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router ospf** *process-id* [**vrf** *vrf-name*]	Creates an OSPF process and enters OSPF process configuration mode.
Ruijie(config-router)# **mpls ldp sync**	Enables LDP IGP synchronization.

Run the **no mpls ldp sync** command to disable LDP IGP synchronization.

(Optional) Enabling LDP IGP Synchronization in Interface Configuration Mode

You can enable/disable LDP IGP synchronization in interface configuration mode. By default, LDP IGP synchronization is enabled for all interfaces.

Command	Description
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface type ID**	Enters interface configuration mode.
Ruijie(config-if-type ID)#**mpls ldp igp sync**	Enables LDP IGP synchronization for an interface.

(Optional) Configuring a Timer for LDP IGP Synchronization Delay

You can configure the LDP IGP synchronization delay in interface configuration mode.

Command	Description
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface type ID**	Enters interface configuration mode.
Ruijie(config-if-type ID)#**mpls ldp igp sync delay** *30*	Configures the LDP IGP synchronization delay as 30 seconds.

(Optional) Configuring the IGP Waiting Time for LDP Synchronization

You can configure IGP waiting time for LDP synchronization in interface configuration mode.

Command	Description
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface type ID**	Enters interface configuration mode.
Ruijie(config-if-type ID)#**mpls ldp igp sync holddown***20*	Configures the IGP waiting time for LDP synchronization as 20 seconds.

Displaying Configuration Effect

You can run the following commands to display configurations.

Command	Description
show mpls ldp igp sync [**all | vrf** *vrf-name* **| interface** *interface-name*]	Displays configuration of LDP IGP synchronization.
show ip ospf [*process-id*] **mpls ldp interface** [*interface-name*]	Displays configuration of LDP IGP synchronization for an OSPF-enabled interface.

Configuration Example

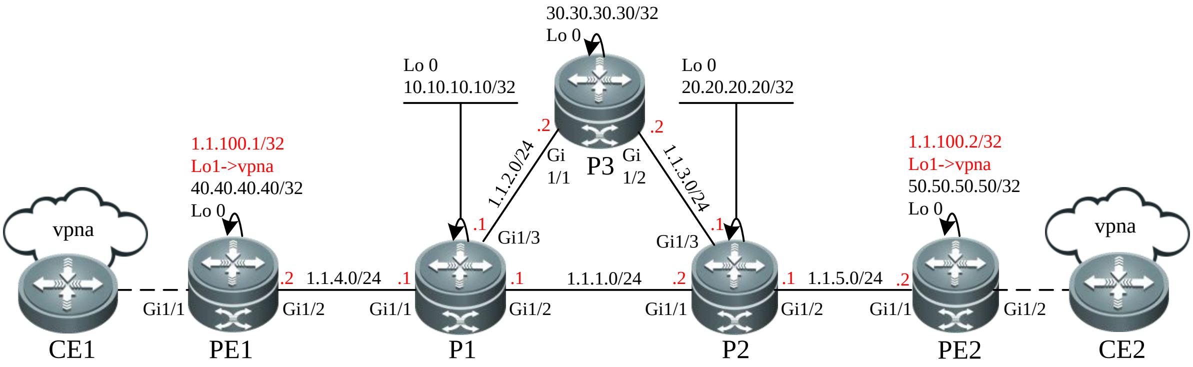
OSPF Network

Networking Requirements

The public network of an Internet Service Provider (ISP) carries VPN traffic. Each device runs OSPF. To improve the network reliability and avoid route black holes caused by inconsistent LDP and OSPF convergence, you can configure LDP IGP synchronization on the core device P.

Network Topology

Figure 0-4 OSPF Network Topology for Configuring LDP IGP Synchronization



Configuration Tips

The following describes Configuration Tips:

- Configure interface IP addresses on each node, configure OSPF and enable LDP.
- Configure VPN route instances and MP-IBGP neighbors and transfer VPN routing information on PEs.
- Enable LDP IGP synchronization on P1, P2 and P3.

Steps

- Configure interface IP addresses on each node, configure OSPF and enable LDP.

# Configure PE1.

## Configure a loopback interface.

```
Ruijie(config)# interface Loopback 0
Ruijie(config-if-Loopback 0)# ip address 40.40.40.40 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

## Enable MPLS and LDP in global configuration mode.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface Loopback 0force
Ruijie(config-mpls-router)# exit
```

## Configure interface IP addresses and enable MPLS and LDP for the interfaces.

```
Ruijie(config)# interface gigabitEthernet 1/2
Ruijie(config-if-GigabitEthernet 1/2)# ip address1.1.4.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/2)# mpls ip
Ruijie(config-if-GigabitEthernet 1/2)# label-switching
Ruijie(config-if-GigabitEthernet 1/2)# exit
```

## Configure IGP (OSPF).

```
Ruijie(config)# router ospf 1
Ruijie(config-router)#network1.1.4.00.0.0.255 area 0
Ruijie(config-router)#network 40.40.40.400.0.0.0 area 0
Ruijie(config-router)# exit
```

# Configure P1.

## Configure a loopback interface.

```
Ruijie(config)# interface Loopback 0
Ruijie(config-if-Loopback 0)# ip address 10.10.10.10 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

## Enable MPLS and LDP in global configuration mode.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface Loopback 0force
Ruijie(config-mpls-router)# exit
```

## Configure interface IP addresses and enable MPLS and LDP for the interfaces.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)# ip address1.1.4.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)# mpls ip
Ruijie(config-if-GigabitEthernet 1/1)# label-switching
Ruijie(config-if-GigabitEthernet 1/1)# exit
Ruijie(config)# interface gigabitEthernet 1/2
Ruijie(config-if-GigabitEthernet 1/2)# ip address1.1.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/2)# mpls ip
Ruijie(config-if-GigabitEthernet 1/2)# label-switching
Ruijie(config-if-GigabitEthernet 1/2)# exit
Ruijie(config)# interface gigabitEthernet 1/3
Ruijie(config-if-GigabitEthernet 1/3)# ip address1.1.2.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/3)# mpls ip
Ruijie(config-if-GigabitEthernet 1/3)# label-switching
Ruijie(config-if-GigabitEthernet 1/3)# exit
```

## Configure IGP (OSPF).

```
Ruijie(config)# router ospf 1
Ruijie(config-router)#network1.1.1.00.0.0.255 area 0
Ruijie(config-router)#network1.1.2.00.0.0.255 area 0
Ruijie(config-router)#network1.1.4.00.0.0.255 area 0
Ruijie(config-router)#network10.10.10.100.0.0.0 area 0
Ruijie(config-router)#exit
```

# Configure P3.

## Configure a loopback interface.

```
Ruijie(config)# interface Loopback 0
Ruijie(config-if-Loopback 0)# ip address 30.30.30.30 255.255.255.255
Ruijie(config-if-Loopback 0)# exit
```

## Enable MPLS and LDP in global configuration mode.

```
Ruijie(config)# mpls ip
Ruijie(config)# mpls router ldp
Ruijie(config-mpls-router)# ldp router-id interface Loopback 0force
Ruijie(config-mpls-router)# exit
```

## Configure interface IP addresses and enable MPLS and LDP for the interfaces.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)# ip address1.1.2.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)# mpls ip
Ruijie(config-if-GigabitEthernet 1/1)# label-switching
Ruijie(config-if-GigabitEthernet 1/1)# exit
Ruijie(config)# interface gigabitEthernet 1/2
Ruijie(config-if-GigabitEthernet 1/2)# ip address1.1.3.2 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/2)# mpls ip
Ruijie(config-if-GigabitEthernet 1/2)# label-switching
Ruijie(config-if-GigabitEthernet 1/2)# exit
```

## Configure IGP (OSPF).

```
Ruijie(config)# router ospf 1
Ruijie(config-router)#network1.1.2.00.0.0.255 area 0
Ruijie(config-router)#network1.1.3.00.0.0.255 area 0
Ruijie(config-router)#network 30.30.30.300.0.0.0 area 0
Ruijie(config-router)#exit
```

# Configuration of P2/PE2 is the same as that of P1/PE1, respectively.

- Configure VPN routing instances and MP-IBGP neighbors and transfer VPN routing information on PEs.

## Configure VPN Routing & Forwarding (VRF): Take PE1 as an example, which is similar to PE2.

```
Ruijie(config)# ip vrf vpna
Ruijie(config-vrf)# rd 65001:20
Ruijie(config-vrf)# route-target both 65001:20
Ruijie(config-vrf)# exit
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)# ip vrf forwarding vpna
Ruijie(config-if-GigabitEthernet 1/1)# ip address 1.1.100.1 255.255.255.0
```

## Configure MP-IBGP neighbors and transfer VPN routing instances: Take PE1 as an example, which is similar to PE2.

```
Ruijie(config)# router bgp 65001
Ruijie(config-router)# neighbor 50.50.50.50 remote-as 65001
Ruijie(config-router)# neighbor 50.50.50.50 update-source Loopback 0
Ruijie(config-router)# address-familyvpnv4
Ruijie(config-router-af)# neighbor 50.50.50.50 activate
Ruijie(config-router-af)# neighbor 50.50.50.50 send-community both
Ruijie(config-router-af)# exit
Ruijie(config-router)# address-family ipv4 vrf vpna

Configuring MPLS ECMP

Note The routers and router icons described in this document represent those in common sense.

Overview

Establishment of Multiple Protocol Label Switching (MPLS) forwarding entries is driven by IP routing. If a Forward Error Correction (FEC) has multiple equal cost next hops, the MPLS signaling protocol can establish multiple equal cost next hops for the FEC, and the FEC traffic can be forwarded through the equal cost paths. When an MPLS network supports Equal-Cost MultiPath (ECMP), Facsimile Transmission Network (FTN) or Identity Lifecycle Manager (ILM) for the same FEC can be mapped to multiple Next Hop Label Forwarding Entries (NHLFEs), and each next hop matches one NHLFE. The FEC packets can be forwarded through the equal cost paths, thereby achieving load balancing.

The following describes the benefits of load balancing:

- Increases the MPLS network bandwidth without updating hardware.
- Strengthens protection of MPLS network links (end-to-end and point-to-point). Balances traffic to multiple links. When one of these links fails, traffic can be forwarded through other links, which improves reliability.
- Balances MPLS traffic toward the same destination on multiple Label Switched Paths (LSPs) and thereby makes the most of network resources.

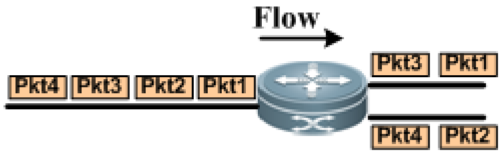
Working Principle

Scheduling Algorithms for MPLS Load Balancing

Scheduling algorithms for MPLS load balancing aim to select a next hop for an FEC packet from multiple equal cost paths. There are many algorithms, among which per packet scheduling and per flow scheduling algorithms are frequently used.

Per Packet Scheduling

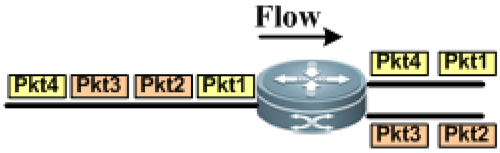
Figure 0-1 Per Packet Scheduling



Per packet scheduling forwards the packets toward the same destination network successively to different equal cost next-hop links to balance the traffic equally. As shown in the following figure, on a Link-State Request (LSR), two equal cost links are destined for the same destination network. There are 4 packets. Packet 1 is transmitted through Link 1, Packet 2 through Link 2, Packet 3 through Link 1, and Packet 4 through Link 2. This is called per packet scheduling.

Per Flow Scheduling

Figure 0-2 Per Flow Scheduling



Under per flow scheduling, the router checks certain fields of packets and uses these fields as key words to map the packets of the same type to the same next-hop link through a hash function. As shown in the figure, there are 4 packets destined for the same destination network. Packet 1 and Packet 4 are of the same type; Packet 2 and Packet 3 are of the same type. Packet 1 and Packet 4 are forwarded to Link 1, and Packet 2 and Packet 3 are forwarded to Link 2 by hashing the fields that mark the packet type. This is called per flow scheduling.

Selection of hash key words:

- MPLS LSP load balancing

  If the MPLS label stack is followed by the IPv4 header, use destination and source IP addresses for hash calculation and select a next hop for packet forwarding. If the MPLS label stack is not followed by the IPv4 header, use the innermost label for hash calculation and select a next hop for packet forwarding; otherwise, hash calculation is not performed and packets are forwarded to the first valid next hop.
- MPLS L3VPN load balancing

  Use destination and source IP addresses for hash calculation and select a next hop to forward packets.
- MPLS Virtual Private Wire Service (VPWS) load balancing

  Use Pseudo Wire (PW) labels for hash calculation and select a next hop to forward packets.
- MPLS Virtual Private LAN Service (VPLS) load balancing

  Use destination and source MAC addresses for hash calculation and select a next hop to forward packets.

Protocols and Standards

N/A.

Defaults

Feature	Default Settings
Load balancing mode	Per flow scheduling is used.
Establish equal cost LSPs for all public network routes	Equal cost LSPs are established only for host routes.

Configuring MPLS ECMP

Establishing Equal Cost LSPs for All Equal Cost Routing FECs

Command	Description

Command	Description
Ruijie#**configure terminal**	Enters global configuration mode.
Ruijie(config)#**mpls router ldp**	Enables MPLS forwarding.
Ruijie(config-mpls-router)# **ldp-ecmp for all-fec**	Establishes equal cost LSPs for all equal cost routing FECs.

Configuring MPLS Load Balancing Mode

Command	Description
Ruijie#**configure terminal**	Enters global configuration mode.
Ruijie(config)# **mpls load-balance** { **flow| packet** }	Configures the MPLS load balancing mode.

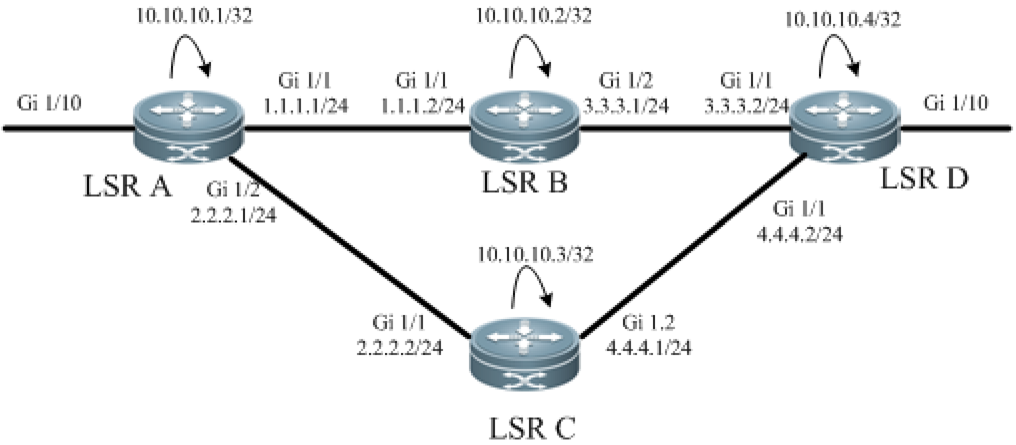
Configuration Example

Networking Requirements

As shown in the following figure, all nodes support MPLS and run Open Shortest Path First (OSPF) as the Interior Gateway Protocol (IGP) on the MPLS backbone network. Two LSPs from LSR A to LSR D are available for load balancing: LSR A→LSR B→LSR D and LSR A→LSR C→LSR D.

Network Topology

Figure 0-3 Network Topology for MPLS Load Balancing



Configuration Tips

The following describes the Configuration Tips of configuration for each node:

Configure the interface IP address and OSPF protocol.

Configure MPLS and MPLS Link Detection Protocol (LDP) in global and interface configuration modes.

Configure the load balancing policy on the start node.

Steps

Configure the interface IP address and OSPF protocol.

# Configure LSR A.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#no switchport
Ruijie(config-if-GigabitEthernet 1/1)#ip address 1.1.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/1)#exit
Ruijie(config)#interface gigabitEthernet 1/2
Ruijie(config-if-GigabitEthernet 1/2)#no switchport
Ruijie(config-if-GigabitEthernet 1/2)#ip address 2.2.2.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 1/2)#exit
Ruijie(config)#interface loopback 0
Ruijie(config-Loopback 0)#ip address 10.10.10.1 255.255.255.255
Ruijie(config-Loopback 0)#exit
Ruijie(config)#router ospf 1
Ruijie(config-router)#network 1.1.1.1 255.255.255.0 area 0
Ruijie(config-router)#network 2.2.2.1 255.255.255.0 area 0
Ruijie(config-router)#network 10.10.10.1 255.255.255.255 area 0
Ruijie(config-router)#exit
```

# Configure other nodes.   The configurations of other nodes are the same as LSR A.

- On each node, enable global MPLS forwarding, interface-based MPLS label packet forwarding as well as interface-based LDP.

# Configure LSR A.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#mpls ip
Ruijie(config)#interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)#label-switching
Ruijie(config-if-GigabitEthernet 1/1)#mpls ip
Ruijie(config-if-GigabitEthernet 1/1)#exit
Ruijie(config)#interface gigabitEthernet 1/2
Ruijie(config-if-GigabitEthernet 1/2)#label-switching
Ruijie(config-if-GigabitEthernet 1/2)#mpls ip
Ruijie(config-if-GigabitEthernet 1/2)#exit
```

# Configure other nodes.   The configurations of other nodes are the same as LSR A.

- Configure LDP to enable MPLS traffic forwarding.

# Configure LSR A.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp router-id interface loopback 0 force
```

# Configure other nodes. The configurations of other nodes are the same as LSR A.

- Configure per packet scheduling and establish equal cost LSPs for all equal cost routes.

# Configure LSR A.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#mpls load-balance packet
Ruijie(config)#mpls router ldp
Ruijie(config-mpls-router)#ldp-ecmp for all-fec
```

Verification

# Display MPLS route information on LSR A.

```
Ruijie#show mpls rib

Link Layer Protocol Configuration

HDLC Configuration

Understanding HDLC

The RGOS supports the Cisco HDLC private protocol. Unlike the ISO HDLC, the Cisco HDLC protocol uses the SDLC frame format and supports synchronous and full-duplex operation, but does not support the traffic control like the ISO HDLC. It is an unreliable connection. After this protocol is encapsulated, the reliable connection is implemented at the upper layer. The HDLC features high efficiency and simple implementation and is a point-to-point (PTP) link protocol.

Note

Reliable connection refers to the message acknowledgement mechanism that is used during data communication. A lost packet will be retransmitted and the connection is interrupted if a packet times out. The PTP protocol means that communication parties are in one-to-one relationship. PPP and SLIP are also PTP protocols, whereas X.25 and Frame Relay are point-to-multipoint protocols.

The working principle of the HDLC is illustrated in the following phases:

- Negotiation and connection establishment: Two parties of the HDLC link send a link detection negotiation message to each other every 10 seconds. The messages are received or sent based on the sequence numbers of messages. Disorder of sequence numbers results in link disconnection. This kind of message that is used to detect whether a PTP link is active is called the keepalive message.
- Message transmission: The IP messages are encapsulated at the HDLC layer. During data transmission, the keepalive message negotiation is still working to detect whether the link is valid.
- Timeout disconnection: When the interface encapsulated with HDLC cannot receive the acknowledgement from the peer to increment the sequence number for 3 times continuous (or 6 times when the packet receiving speed is over 1000 packets/second), the link state changes from UP to Down. At this time, the link is in down state, and data communication fails.

Configuring HDLC

HDLC Configuration Task List

The HDLC configuration is rather simple and involves only the following tasks.

- Configuring the Interface Encapsulation Protocol
- Configuring the Keepalive Time

Configuring the Interface Encapsulation Protocol

The protocol encapsulated on the synchronous interface is HDLC by default.

Use the following command to change the protocol encapsulated on the interface to HDLC.

Command	**Function**

Command	Function
Ruijie(config-if)#**encapsulation hdlc**	Encapsulates the HDLC protocol.

Configuring the Keepalive Time

For the HDLC encapsulated on a synchronous interface, only two parameters are configurable: interval at which the keepalive message is sent and the maximum timeout time of the keepalive message. The interval is 10 seconds by default.

Use the following command to set the interval and maximum timeout time of the keepalive message based on the link traffic.

Command	Function
Ruijie(config-if)#**keepalive** *second*s	Sets the interval at which the keepalive message is sent and the maximum timeout time of the keepalive message. The maximum timeout time is optional. The range of the interval is from 1 to 32767. The range of the maximum timeout time is from 1 to 255.

Monitoring and Maintaining HDLC

Command	Function
Ruijie#**debug hdlc events**	Turns on the HDLC link status event debugging switch.
Ruijie#**debug hdlc packets**	Turns on the HDLC message receiving/transmitting debugging switch.

1) debug hdlc events

If an interface (for example, Serial1/0) is encapsulated with HDLC, the following information is printed during the keepalive message negotiation:

```
%Interface serial 1/0 : receive one HDLC keepalive packet.
%Interface serial 1/0 send one keepalive packet:
   my_seq = 21, my_seen = 20, your_seen = 16
   line protocol is UP, not in loopback state.
%Interface serial 1/0 : receive one HDLC keepalive packet.
%Interface serial 1/0 send one keepalive packet:
   my_seq = 22, my_seen = 21, your_seen = 17
   line protocol is UP, not in loopback state.
```

Where, my_seq is the sequence number of the message sent by the local router, my_seen is the sequence number of the HDLC keepalive message recognized by the peer router, and your_seen means the sequence number of the peer router recognized by the local router. The sequence numbers are incremental. See the following debug information:

```
%Interface serial 1/0 : receive one HDLC keepalive packet.
%Interface serial 1/0 send one keepalive packet:
   my_seq = 21, my_seen = 20, your_seen = 16
   line protocol is UP, not in loopback state.
```

```
%Interface serial 1/0 send one keepalive packet:
   my_seq = 22, my_seen = 20, your_seen = 16
   line protocol is UP, not in loopback state.
%Interface serial 1/0 send one keepalive packet:
   my_seq = 23, my_seen = 20, your_seen = 16
   line protocol is UP, not in loopback state.
```

The local sequence number my_seq increments according to the keepalive time, but the keepalive message of the peer router is not received. The my_seen is always 20. The local party has no way to know the acknowledgement for the increment of your_seen. This means that the message of the peer router cannot reach the local HDLC protocol layer during communication possibly because the peer router is shut down or a fault occurs during line transmission.

2) debug hdlc packets

Use this command to turn on the HDLC receiving/transmitting message debug switch to print the messages received or to be sent by the HDLC, including the message length and received message type. If the message is longer than 64 bytes, only the first 64 bytes are printed, as shown below:

```
Interface serial 1/0 HDLC input:
  packet->len = 22(0x16):
  8F 00 80 35 00 00 00 02 00 00 00 16 00 00 00 1A
  FF FF 00 5C E2 53
  packet->pkt_type = 3(PDD_RARP)
Interface serial 1/0 HDLC output:
  packet->len = 22(0x16):
  8F 00 80 35 00 00 00 02 00 00 00 1B 00 00 00 16
  FF FF 00 5F 8E D9
```

PPP and MP Protocol Configuration

PPP and MP Protocol Introduction

The PPP (Point-to-Point Protocol) is a kind of link layer protocol providing bearer for network data packets over point-to-point links. PPP defines a whole set of protocols, including LCP (Link Control Protocol), NCP (Network Control Protocol) and authentication protocols (PAP and CHAP). PPP is widely used for its ability of authentication, easy to expand and support of synchronization and asynchronization. For the PPP specifications, see RFC 1661.

PPP Working Process and Principle

- The PPP performs LCP negotiation before line setup, including operation mode (SP or MP), authentication method, and maximum transmission unit.
- The PPP enters the Line Establish phase after LCP negotiation. At this time, the LCP state is Opened, indicating that the link has been established.
- If authentication (the remote end authenticates the local end or vice versa) is enabled in the configuration, the PPP enters the Authenticate phase to start CHAP or PAP authentication.
- If authentication fails, it enters the Terminate phase to remove the link, and the LCP status turns to Closed; if the authentication succeeds, it enters the Network consultation phase (NCP), here, the LCP status is still Opened but that of IPCP and IPXCP turns from Closed to Opened.
- The support of NCP negotiation includes IPCP, IPXCP and BRIDGECP negotiation. IPCP negotiation mainly includes the IP addresses of both parties; IPXCP negotiation mainly includes network IDs and node numbers; BRIDGECP negotiation mainly includes the MAC addresses of both parties, MAC address type, spanning tree and Bridge ID. One or more network layer protocols are selected and configured through NCP negotiation. After the successful configuration of each selected network layer protocol, this network layer protocol can send messages through this link.
- This link will keep available for communication, until a definite LCP or NCP frame closes it, or some external events happen.

PPP Authentication Mode

The PPP supports two kinds of authentication modes: PAP and CHAP.

1. The PAP is a two-handshake authentication, and the password is in clear text.The PAP authentication process is as follows:
   1) The party to be authenticated sends the username and password to the authenticating party.
   2) The authenticating party checks whether this user name exists and whether the password is correct according to the user configuration, and then returns a response accordingly.

2. The CHAP refers to challenge handshake authentication protocol, and the password is in cipher text (key). The process of CHAP authentication is as follows:
    1) The authenticating party sends some random reports to the party to be authenticated.
    2) The authenticated party encrypts the random messages using its own password and MD5 algorithm, and sends the generated cipher text back to the authenticating party.
    3) The authenticating party encrypts the original random reports with the stored password of the authenticated party and the MD5 algorithm, compares the two cipher texts, and then returns the relevant response according to the comparison results.

MP Protocol Introduction

The Multi-Link PPP (MP) binds the PPP of multiple physical links to a single logical interface, aiming to increase link bandwidth. Any physical link that supports PPP can enable MP and be bound to the same logical interface Dialer port. The MP allows fragment of the messages on the network layers like IP. The fragments of the message are transmitted via multiple links and arrive at the same destination at the same time, resulting in summarization of the bandwidth of all links.

The operational process of the MP is as follows:

After the negotiation of general LCP parameters is completed, the PPP initiates the MP request again. If the peer link supports MP and responds properly, it is bound to the logical interface together with the other physical links for further NCP (such as IPCP) negotiation. If negotiation succeeds, all MP physical links use the network address of the same logical interface.

PPP Configuration

PPP Configuration Task List

This chapter describes how to configure PPP in the dedicated line mode (including synchronous interface and asynchronous interface). For the PPP configuration for the dialup connection available in the serial interface, additional configurations are needed in addition to the following ones. See Dialup Configuration Guide for details.

- Configure the interface encapsulation protocol
- Configure the PPP CHAP authenticated party
- Configure the PPP CHAP authenticating party
- Configure the PPP PAP authenticated party
- Configure the PPP PAP authenticating party
- Configure the PPP compression mode

Configuring the Encapsulation Protocol on the Interface

To configure the PPP, encapsulate the PPP on the interface. To encapsulate the PPP, run the following commands in the interface configuration mode:

Command	Function
Ruijie(config-if)#**encapsulation ppp**	Encapsulate the PPP on the interface.
Ruijie(config-if)#**no encapsulation ppp**	Remove the PPP encapsulation on the interface.

Configuring the PPP CHAP Authenticated Party

The CHAP authentication generally involves authenticating party and authenticated party. The CHAP negotiation is initiated by the authenticating party, and the authenticated party sends only the username and password for the use of the PPP authentication. By default, the authenticated party sends its own hostname as the PPP username.

To configure the PPP CHAP authenticated party, use the following command at interface configuration mode:

Command	Function
Ruijie(config-if)# **ppp chap hostname** *hostnmae*	Specify the hostname for PPP CHAP authentication.
Ruijie(config-if)# **ppp chap password** {**0|7**} *password*	Specify the password for PPP CHAP. authentication

If the hostname used by the authenticating party is known, the following configuration can be used:

Command	Function
Ruijie(config-if)# **ppp chap hostname** *hostnmae*	Specify the hostname for PPP CHAP authentication.
Ruijie(config)# **username** *username* password {0|7} *password*	Create user database records for the authenticating party hostname, with passwords consistent at both ends.

Note

There are clear text password and cipher text password, "0" for clear text password and 1-7 for cipher text password. The default input method is the clear text password. In this manual, all places involving password setting is suitable for the above rule. In the interconnection with other manufacturers, only the clear text password is accepted. For the configuration of bidirectional authentication, the configuration of authenticating party is also needed.

Configuring the PPP CHAP Authenticating Party

The PPP CHAP authenticating party initiates the authentication proactively. Since the username and password from the peer router shall be validated, the authenticating party shall create and maintain a local user database. To configure the PPP CHAP authenticating party, use the following command at interface configuration mode:

Command	Function
Ruijie(config-if)# **ppp authentication chap [callin]**	Enable the PPP authentication and specify the PPP CHAP authentication method.
Ruijie(config-if)# **no ppp authentication chap**	Disable the PPP CHAP authentication.
Ruijie(config)# **username** *username* **password {0|7}** *password*	Create the user database record.

The authenticating party has the username and related password configured in the user database, where the username is the PPP hostname of the peer router (the authenticated party).

Note

The Callin is an optional command option. With it configured, the CHAP authentication is not initiated unless the peer router (authenticated party) dials to connect the network in dialup mode. For the PPP connection that is set up because the local router dials out, the CHAP authentication is not initiated. Therefore, this command does not affect the dedicated line PPP negotiation.

Configuring the PPP PAP Authenticated Party

The PAP authentication involves authenticating party and authenticated party. For the setting of PAP authenticated party for PPP, run the following commands:

Command	**Function**
Ruijie(config-if)# **ppp pap sent-username** *username* **password {0|7}** *password*	Specify the username and password for PPP PAP authentication.
Ruijie(config-if)# **no ppp pap sent-username**	Remove the PPP PAP authentication settings.

Configuring the PPP PAP Authenticating Party

The commands for setting the PPP PAP authenticating party are as follows:

Command	**Function**
Ruijie(config-if)# **ppp authentication pap [callin]**	Configure the PPP PAP authenticating party
Ruijie(config)# **username** *username* **password {0|7}** *password*	Create the user database record.

Note

The Callin is an optional command option. With it configured, the PAP authentication is not initiated unless the peer router (authenticated party) dials to connect the network via dialup mode. For the PPP connection that is set up because the local router dials out, the PAP authentication is not initiated. Therefore, this command does not affect the dedicated line PPP negotiation.

Configure the PPP Negotiation Parameters

During the PPP negotiation, both LCP and IPCP have timeout periods. Once the period expires, the LCP resends requests. This period can be set by using this command to coordinate the negotiation time in the interconnection with heterogeneous devices.

Command	**Function**
Ruijie(config-if)#**ppp negotiation-timeout** *seconds*	Configure the PPP LCP negotiation time.
Ruijie(config-if)#**no ppp negotiation-timeout**	Restore the PPP negotiation time to the default.

Configuring Sender of PPP LCP Extended Configuration Option

The sender of the PPP LCP configuration option actively adds the extended configuration option to LCP configuration request packets. The IMSI number, the serial number (SN) of the local router, or the MAC address of the local router is sent to the peer end by being carried in the extended configuration option. Run the following command in interface configuration mode to configure the sender of the PPP LCP extended configuration option:

Command	Function
Ruijie(config-if)#**ppp lcp send-option** {**imsi|serial-number|mac-address**}	Sends the LCP extended configuration option carrying the IMSI number, the SN, or the MAC address.

Note

Run the **ppp lcp send-option imsi** command to send the LCP extended configuration option carrying the IMSI number. Run the **ppp lcp send-option serial-number** command to send the LCP extended configuration option carrying the SN. Run the **ppp lcp send-option mac-address** command to send the LCP extended configuration option carrying the MAC address.

Configuring Receiver of PPP LCP Extended Configuration Option

The receiver of the PPP LCP extended configuration option needs to identify the PPP LCP extended configuration option sent from the remote router and send the information in the extended configuration option to the AAA server. Run the following command in interface configuration mode to configure the receiver of the PPP LCP extended configuration option:

Command	Function
Ruijie(config-if)#**ppp lcp accept-option**	Identifies the PPP LCP extended configuration option and sends the information in the extended configuration option to the AAA server.

Note

Run the **ppp lcp accept-option** command to identify the PPP LCP extended configuration option carrying IMSI number. Run the **ppp lcp accept-option** command to identify the PPP LCP extended configuration option carrying the SN. Run the **ppp lcp accpet-option** command to identify the PPP LCP extended configuration option carrying the MAC address.

The preceding command can also send the information in the extended configuration option to the AAA server if the AAA function is enabled.

In addition to the **ppp lcp accept-option** command, run the **force-local-lcp** command on the LNS device to transmit the IMSI, the SN, or the MAC address via the PPP LCP extended configuration option. In addition, the functions must be normal to ensure that the IMSI/MAC/SN extended configuration option is identified.

The LAC device of the operator may not support LCP re-negotiation and the configuration of the **force-local-lcp** command will result in a PPP negotiation failure. As a result, the IMSI/MAC/SN authentication function is unavailable.

Configuring Function of Accepting/Rejecting/Ignoring Received ACFC Negotiation Requests

During PPP link negotiation, run the following command in interface configuration mode to determine whether to accept the Address-and-Control-Field-Compression (ACFC) negotiation request sent from the peer end:

Command	Function
Ruijie(config-if)#**ppp acfc remote** {**apply**|**reject**|**ignore**}	Configures how the local router processes the PPP configuration request packet that carries the ACFC option and that is sent from the remote device.

Note

Run the **ppp acfc remote apply** command to accept ACFC negotiation from the peer end. That is, ACFC is enabled for PPP frames from the peer end, but is enabled or disabled for PPP frames from the local end based on the interface type.

Run the **ppp acfc remote reject** command to reject ACFC negotiation from the peer end.

Run the **ppp acfc remote ignore** command to ignore ACFC negotiation from the peer end . That is, ACFC can be enabled or disabled for PPP frames from the peer end, but is disabled for PPP frames from the local end.

If the **ppp acfc remote** command conflicts with the **ppp acfc local** command, the later configured command shall prevail.

Configuring Function of Initiating/Forbidding ACFC Option

During PPP link negotiation, run the following command in interface configuration mode to determine whether to initiate ACFC negotiation from the local end:

Command	Function
Ruijie(config-if)#**ppp acfc local** {**request**|**forbid**}	Configures how the local router processes the ACFC option in the to-be-sent PPP configuration request.

Note

Run the **ppp acfc local request** command to initiate ACFC negotiation on the local end, that is, the PPP LCP configuration request packet to be sent from the local end carries the ACFC option.

Run the **ppp acfc local forbid** command to forbid ACFC negotiation on the local end, that is, the PPP LCP configuration request packet to be sent from the local end does not carry the ACFC option and the configuration request packet that carries the ACFC option and that is sent from the peer end is rejected.

If the **ppp acfc local** command conflicts with the **ppp acfc remote** command, the later configured command shall prevail.

Configuring Function of Accepting/Rejecting/Ignoring Received PFC Negotiation Requests

During PPP link negotiation, run the following command in interface configuration mode to determine whether to accept the protocol field compression (PFC) negotiation request sent from the peer end:

Command	Function
Ruijie(config-if)#**ppp pfc remote** {**apply**|**reject**|**ignore**}	Configures how the local router processes the PPP configuration request packet that carries the PFC option and that is sent from the remote device.

Note

Run the **ppp pfc remote apply** command to accept PFC negotiation from the peer end. That is, PFC is enabled for PPP frames form the peer end, but is enabled or disabled for PPP frames from the local end based on the interface type.

Run the **ppp pfc remote reject** command to reject PFC negotiation from the peer end.

Run the **ppp pfc remote ignore** command to ignore PFC negotiation from the peer end. That is, PFC can be enabled or disabled for PPP frames from the peer end, but is disabled for PPP frames from the local end.

If the **ppp pfc remote** command conflicts with the **ppp pfc local** command, the last configured command shall prevail.

Configuring Function of Initiating/Forbidding PFC Option

During PPP link negotiation, run the following command in interface configuration mode to determine whether to initiate PFC negotiation from the local end:

Command	Function
Ruijie(config-if)#**ppp pfc local** {**request**|**forbid**}	Configures how the local router processes the PFC option in the to-be-sent PPP configuration request.

Note

Run the **ppp pfc local request** command to initiate PFC negotiation on the local end, that is, the PPP LCP configuration request packet to be sent from the local end carries the PFC option.

Run the **ppp pfc local forbid** command to forbid PFC negotiation on the local end, that is, the PPP LCP configuration request packet to be sent from the local end does not carry the PFC option and the configuration request packet that carries the PFC option and that is sent from the peer end is rejected.

If the **ppp pfc local** command conflicts with the **ppp pfc remote** command, the last configured command shall prevail.

MP configuration

Configuring MP on the Dialer Interface

MP Configuration Task List

The MP can be implemented by configuring the rotary-group on the physical interface layer and binding the dialer logical interface. This chapter describes only the multilink PPP binding the dialer interface and the synchronous serial interface. For the configuration of the dialup multilink of asynchronous serial interface, see DDR Configuration Guide. The list of configuration tasks for the multilink of Dialer interface binding synchronous serial interface is as follows:

- Configuring the synchronous serial interface
- Encapsulating PPP link protocol
- Configuring dialer in-band
- Configuring rotary-group
- The configuration of the rotary-group needs the DDR. So, if the **dialer in-band** has not been configured in advance, it will be automatically configured in configuring **dialer rotary-group**.
- Creating the logical interface dialer
- When you create the logical interface dialer, the physical interface with the rotary group configured must be existent, which maintains the binding by consistency of the rotary group number and the logical interface dialer number. If the logical interface is to be deleted, it is required to delete the rotary group on the physical interface first.
- Configuring the ppp multilink
- Configuring the dialup filtering rule

Configuring the synchronous serial interface

To configure the synchronous serial interface for multilink binding:

Command	Function
Ruijie(config)# **interface serial** *interface-number*	Enter the configuration mode of the specified serial interface.

Encapsulating PPP link protocol

The multilink PPP is a PPP at first. So, it is required to encapsulate the PPP link protocol first no matter whether it is on a physical interface or a logical interface.

Command	Function
Ruijie(config-if)#**encapsulation ppp**	Encapsulate the PPP link protocol.
Ruijie(config-if)#**no encapsulation ppp**	Cancel the encapsulation of the PPP link protocol.

Configuring dialer in-band

To configure the multilink, it is required to configure the DDR on the serial interface configuration layer at first by using the following command, which is the prerequisite for configuring rotary-group:

Command	Function
Ruijie(config-if)#**dialer in-band**	Set the DDR configuration.
Ruijie(config-if)#**no dialer in-band**	Cancel the DDR configuration.

Configuring rotary-group

This command binds the physical interface to the rotary group of logical interface to enable the multilink binding.

Command	Function
Ruijie(config-if)#**dialer rotary-group** *group-number*	Set the number of the rotary group.
Ruijie(config-if)#**no dialer rotary-group** *group-number*	Delete the rotary group.

Note

The configuration of the rotary-group needs the DDR. So, if the **dialer in-band** has not been configured in advance, it will be automatically configured in configuring **dialer rotary-group**.

Creating the logical interface dialer

When the rotary group is set, it is necessary to create the logical interface dialer that individual physical interfaces are bound to. The interface number must be the same as the number of the rotary group. After the logical interface dialer is created, it enters into the dialer logical interface configuration layer. Accordingly, it is required to encapsulate the PPP link protocol, configure the PPP multilink, configure the dialup filtering rule, and so on.

Command	Function
Ruijie(config)#**interface dialer** *group-number*	Create the logical interface dialer.
Ruijie(config)#**no interface dialer** *group-number*	Delete the logical interface dialer.

Note

When you create the logical interface dialer, the physical interface with the rotary group configured must be existent, which maintains the binding by consistency of the rotary group number and the logical interface dialer number. If the logical interface is to be deleted, it is required to delete the rotary group on the physical interface first.

Configuring the ppp multilink

To set the multilink PPP, it is required to configure the **PPP multilink** command on the logical interface to specify the logical interface to use the multilink negotiation mode.

Command	Function
Ruijie(config-if)#**ppp multilink**	Set the multilink negotiation mode.
Ruijie(config-if)#**no ppp multilink**	Cancel the setting of the PPP multilink negotiation mode.

Configuring the dialup filtering rule

On the logical interface, it is required to configure the dialup filtering rule. This rule is powerful enough to use with the ACL. Here is the simplified description for the functions of the **dialer-list**.

Command	Function
Ruijie(config-if)#**dialer-group** *group-number*	Set the dialer group.
Ruijie(config)#**dialer-list** *group-number* **protocol ip permit**	Set the common dialer group list allowing the access to IP packets.

Configuring MP on the Multilink Interface

MP Configuration Task List

The MP can be implemented by configuring the multilink group on the physical interface layer and binding the multilink logical interface. This chapter describes only the multilink PPP of the multilink interface binding the synchronous serial interface. The list of configuration tasks of multilink interface binding synchronous serial interface is as follows:

- Creating the logical interface multilink
- Configuring the synchronous serial interface
- Encapsulating PPP link protocol
- Configuring the ppp multilink
- Configuring the ppp multilink group

Creating the logical interface multilink

To configure the MP binding of the multilink interface, create the logical interface multilink binding individual physical interfaces. After the logical interface multilink is created, it enters into the multilink logical interface configuration layer, where the PPP encapsulation and MP are enabled by default.

Command	Function
Ruijie(config)#**interface multilink** *group-number*	Create the logical interface multilink.
Ruijie(config)#**no interface multilink** *group-number*	Delete the logical interface multilink.

Caution Up to 72 multilink interfaces are supported.

Configuring the synchronous serial interface

To configure the synchronous serial interface for multilink binding, execute the following command:

Command	Function
Ruijie(config)# **interface serial** *interface-number*	Enter the specified serial interface configuration mode.

Encapsulating PPP link protocol

The multilink PPP is a PPP at first. So, it is required to encapsulate the PPP link protocol first on the synchronous serial interface.

Command	Function
Ruijie(config-if)#**encapsulation ppp**	Encapsulate the PPP link protocol.
Ruijie(config-if)#**no encapsulation ppp**	Remove the encapsulation of PPP link protocol.

Configuring the ppp multilink

To set the synchronous interface to use the multilink negotiation mode, execute the **PPP multilink** command on the synchronous serial interface.

Command	Function
Ruijie(config-if)#**ppp multilink**	Set the multilink negotiation mode.
Ruijie(config-if)#**no ppp multilink**	Remove the setting of the PPP multilink negotiation mode.

Configuring the ppp multilink group

To bind the synchronous serial interface to the group of logical interface for multilink binding, execute the following command.

Command	Function
Ruijie(config-if)# **ppp multilink group** *group-number*	Set the number of the multilink group.
Ruijie(config-if)#**no ppp multilink group** *group-number*	Remove the number of the multilink group.

Note The parameter group-number configured here is the same as the multilink interface number in the creation of the multilink. When configuring the ppp multilink group, the multilink interface must exist accordingly. The physical interface uses the multilink group number and the logical interface number of multilink interface to maintain binding. If the logical interface is to be deleted, it is required to delete the multilink group on the physical interface first.

Configuring MP on the Virtual-Template Interface

MP Configuration Task List

The MP can be implemented by configuring the MP on the physical interface layer and binding the virtual template interface. This chapter describes only the multilink PPP of the virtual template interface binding the synchronous serial interface. For details of the virtual template, see VPN Configuration Guide. The list of configuration tasks for the virtual template interface binding synchronous serial interface is as follows:

- Creating the virtual template interface
- Creating the bounded virtual template interface
- For the Virtual-Template multilink binding, in the setup of the binding, a virtual access interface Virtual-Access is created automatically as the binding interface. This command specifies which virtual template copy configuration acts as the settings of the virtual access interface during the creation of the virtual access interface.
- Configuring the synchronous serial interface
- Encapsulating the PPP link protocol
- Configuring the ppp multilink

Creating the virtual template interface

To configure the MP in the Virtual-Template method, it is required to create the Virtual-Template interface. After the Virtual-Template interface is created, it enters into the virtual template interface configuration layer. Accordingly, it is required to encapsulate the PPP link protocol, configure the PPP multilink, configure the dialup filtering rule, and so on.

Command	Function
Ruijie(config)#**interface virtual-template** *number*	Create/configure the specified virtual -template interface
Ruijie(config)#**no interface virtual-template** *number*	Delete the specified virtual -template interface

Creating the bounded virtual template interface

After the virtual template interface is created, the **multilink virtual-template** command is used to specify which virtual template copy binds the interface parameters.

Command	Purpose
Ruijie(config)# **multilink virtual-template** *number*	Specify the virtual template for the MP bundle interface to clone interface parameters
Ruijie(config)# **no multilink virtual-template** *number*	Delete the virtual template for the MP bundle interface to clone interface parameters

Note For the Virtual-Template multilink binding, in the setup of the binding, a virtual access interface Virtual-Access is created automatically as the binding interface. This command specifies which virtual template copy configuration acts as the settings of the virtual access interface during the creation of the virtual access interface.

Configuring the synchronous serial interface

To configure the synchronous serial interface for multilink binding:

Command	Function
Ruijie(config)# **interface serial** *interface-number*	Enter the configuration mode of the specified serial interface

Encapsulating the PPP link protocol

The multilink PPP is a PPP at first. So, it is required to encapsulate the PPP link protocol first no matter whether it is on a synchronous serial interface or a virtual template interface.

Command	Function
Ruijie(config-if)#**encapsulation ppp**	Encapsulate PPP link protocol
Ruijie(config-if)#**no encapsulation ppp**	Cancel the encapsulation of PPP link protocol

Configuring the ppp multilink

To set the virtual template interface and physical interface to use the multilink negotiation mode, execute this command on the virtual template interface and synchronous interface.

Command	Function
Ruijie(config-if)#**ppp multilink**	Set the multilink negotiation mode.
Ruijie(config-if)#**no ppp multilink**	Remove the setting of the PPP multilink negotiation mode.

Note It is not necessary to configure multilink group or rotary-group on the physical interface for virtual template-based binding. It only the **ppp multilink** command is configured on the physical interface but no configuration for which link group or dialup rotary group to belong to, the physical interface will belong to the multilink binding in virtual template mode.

PPP Monitoring and Maintenance

Showing the Protocol Interface Information

Run the following command to show the PPP protocol interface information, which is the first step to debug PPP:

Command	**Function**
Ruijie#**show interface serial** *interface-number*	Show the information of the serial interface.

Take Serial1/0 as an example. The following information in printed after the command is entered:

```
serial 1/0 is UP  , line protocol is UP
Hardware is Infineon DSCC4 PEB20534 H-10 serial
Interface address is: 100.100.100.1/24
 MTU 1500 bytes, BW 2000 Kbit
 Encapsulation protocol is PPP, loopback not set
 Keepalive interval is 10 sec , set
 Carrier delay is 2 sec
 RXload is 1 ,Txload is 1
 LCP Open
 Open: ipcp
 Queueing strategy: WFQ
 5 minutes input rate 30 bits/sec, 0 packets/sec
 5 minutes output rate 30 bits/sec, 0 packets/sec
 49 packets input, 786 bytes, 0 no buffer
 Received 1 broadcasts, 0 runts, 0 giants
 0 input errors, 0 CRC, 0 frame, 0 overrun, 0 abort
 47 packets output, 768 bytes, 0 underruns
 0 output errors, 0 collisions, 1 interface resets
 1 carrier transitions
  V35 DTE cable
 DCD=up  DSR=up  DTR=up  RTS=up  CTS=up
```

First check the link status from the physical layer. The five signals (DCD, DSR, DTR, RTS, CTS) in the last row determine whether the serial is UP or not. This is the prerequisite for PPP Line Protocol UP.

Then, check whether the PPP negotiation is successful by checking whether the LCP status is UP and whether the IPCP status is UP. If yes for both, the line protocol is in the up status, and the link layer shall be available for communication.

Last, refer to the data receiving/transmitting conditions at the bottom layer. Packet Input and Output indicate the number of messages received and transmitted. If there is no interface reset, the message transmission is successful. If there is no number of drops in the Input Queue, it means all messages are received successfully.

PPP Debugging Information

In case of problem with the PPP link layer negotiation, run the following command to debug the PPP:

Command	**Function**
Ruijie# **debug ppp packet**	Print message debug information during PPP

Command	Function
	communication
Ruijie# **debug ppp negotiation**	Print negotiation debug information during PPP communication
Ruijie# **debug ppp authentication**	Print authorization debug information during PPP communication

Packet debugging

In the privileged command layer, enter the **PPP Packet** debug command:

```
Ruijie#debug ppp packet
PPP: serial 1/0 [S] LCP CONFREQ id 3 len 10
  MAGICNUMBER (6) 0x0 0x2b 0x39 0x1b
%LINK CHANGED: Interface serial 1/0, changed state to up
PPP: serial 1/0 [R] LCP CONFREQ id 6 len 10
  MAGICNUMBER (6) 0x29 0xbd 0xea 0xeb
PPP: serial 1/0 [S] LCP CONFACK id 6 len 10
  MAGICNUMBER (6) 0x29 0xbd 0xea 0xeb
PPP: serial 1/0 [R] LCP CONFACK id 3 len 10
  MAGICNUMBER (6) 0x0 0x2b 0x39 0x1b
PPP: serial 1/0 LCP up
PPP: serial 1/0 PPP up.
PPP: serial 1/0 [S] IPCP CONFREQ(2) id 10 len 2
  Address (6) 0x64 0x64 0x64 0x1
PPP: serial 1/0 [R] IPCP CONFREQ(3) id 10 len 2
  Address (6) 0x64 0x64 0x64 0x2
PPP: serial 1/0 [S] IPCP CONFACK(3) id 10 len 2
  Address (6) 0x64 0x64 0x64 0x2
PPP: serial 1/0 [S] LCP PROTREJ id 4 len 10 protocol = 0x82070103
PPP: serial 1/0 [R] IPCP CONFACK(2) id 10 len 2
  Address (6) 0x64 0x64 0x64 0x1
%LINE PROTOCOL CHANGE: Interface serial 1/0, changed state to UP
Ruijie#
PPP: serial 1/0 [S] LCP ECHOREQ id 1 len 12 magic 0x2b391b
```

The above debugging information is for all messages from the start of the PPP negotiation to the Line Protocol Up, without authentication. Pay attention to the bolded debug information: Both routers send the LCP CONFREQ to each other and then respond with the LCP CONFACK. Then it enters into the IPCP negotiation. Also pay attention to the bolded contents. Both routers send IPCP CONFREQ to each other and attach their own IP addresses, and then send the IPCP CONFACK response with the peer IP address attached after the IPCP CONFREQ request is received. Now the PPP negotiation of the interface succeeds.

PPP negotiation debugging information

The negotiation debugging information is used for the debugging trace purpose in negotiating the PPP parameters. For example, in the CHAP authentication of PPP, the **debug ppp negotiation** command can trace the following parameter negotiation information:

```
Ruijie#
PPP: serial 1/0 reset lcp options
```

```
PPP: serial 1/0 sending OPCODE_CONFREQ, type = 5 (LCP_MAGICNUMBER), value = 0x10a5df
%LINK CHANGED: Interface serial 1/0, changed state to up
LCP: received config , type = 5 (MAGICNUMBER) value = 0x29cbca60 acked
PPP: serial 1/0 OPCODE_CONFACK received, type = 5 (LCP_MAGICNUMBER), value = 0x10a5df
PPP: serial 1/0 state = Acksent ppp_recv_confack(0xc021): rcvd id 5
PPP: serial 1/0 reset ipcp options
IPCP: serial 1/0 sending OPCODE_CONFREQ, type = 3 (IPCP_ADDRESS), Address = 100.100.100.1
IPCP: serial 1/0 received ADDR : her address 100.100.100.2 (ACK)
IPCP: ipcp_do_req_cb: returning OPCODE_CONFACK.
IPCP: serial 1/0 OPCODE_CONFACK received, type = 3 (IPCP_ADDRESS), Address = 100.100.100.1
PPP: serial 1/0 state = Acksent ppp_recv_confack(0x8021): rcvd id 3
IPCP: serial 1/0 install route to 100.100.100.2
%LINE PROTOCOL CHANGE: Interface serial 1/0, changed state to UP
```

Pay attention to the bolded contents, which are the options for the LCP and IPCP negotiation parameters.

PPP authentication debugging information

The debug of the authentication information is used to trace the PPP authentication. With PAP as an example, the PAP authenticating party prints the following debugging information:

```
PPP: serial 1/0 PAP authenticating peer DRO36
PPP: serial 1/0 Remote passed PAP authentication sending Auth-Ack to peer.
PPP: serial 1/0 lcp authentication OK#
```

The CHAP authentication party prints the following information when the sent CHAP password is wrong:

```
PPP: serial 1/0 recv CHAP challenge from Router
PPP: serial 1/0 remote router failed CHAP authentication
PPP: serial 1/0 Remote msg is: Authentication failure
```

Typical PPP Configuration Examples

PPP PAP Authentication Example

The example below shows a PAP configuration, username Ruijie, password Router, authenticating party IP address 1.1.1.1/24, authenticated party IP address 1.1.1.2/24, username and password configured same as the authentication method. Router A is the authenticated party and Router B is the authenticating party.

Router A:

```
Ruijie#config terminal
Ruijie(config)#interface Serial1/0
```

# Configure the IP address

```
Ruijie(config-if)#ip address 1.1.1.2 255.255.255.0
```

# Encapsulate PPP protocol

```
Ruijie(config-if)#encapsulation ppp
```

# Configure the username and password for PAP authentication.

```
Ruijie(config-if)#ppp pap sent-username Ruijie password 0 Router
```

Router B:

```
Ruijie#config terminal
Ruijie(config)#username Ruijie password 0 Router
Ruijie(config)#interface Serial1/0
```

# Configure the IP address

```
Ruijie(config-if)#ip address 1.1.1.1 255.255.255.0
```

# Encapsulate PPP protocol

```
Ruijie(config-if)#encapsulation ppp
```

# Specify the PPP authentication mode

```
Ruijie(config-if)#ppp authentication pap
```

PPP CHAP Authentication Example

The example below shows a PPP CHAP authentication configuration, where the Router A is the authenticating party, IP address is 1.1.1.1/24, hostname is RouterA, password is Router, and the user list contains the hostname RouterB; the Router B is the authenticating party, IP address is 1.1.1.2/24, hostname is RouterB and the password sent is Router.

Router A:

```
Ruijie#config terminal
```

# Set the hostname

```
Ruijie(config)#hostname RouterA
```

# Set the username and password list

```
RouterA(config)#username RouterB password 0 Router
RouterA(config)#username RouterC password 0 Router
RouterA(config)#interface serial1/0
```

# Encapsulate protocol

```
RouterA(config-if)#encap ppp
```

# Set IP address

```
RouterA(config-if)#ip address 1.1.1.1 255.255.255.0
```

# Specify the PPP chap authentication mode

```
RouterA(config-if)#ppp authentication chap
```

Router B:

```
Ruijie#config terminal
```

# Set the hostname

```
Ruijie(config)#hostname RouterB
```

# Use the peer hostname as the username, and the password is the same as that configured on the peer router.

```
RouterB(config)#username RouterA password 0 Router
RouterB(config)#interface serial1/0
```

# Encapsulate protocol

```
RouterB(config-if)#encap ppp
```

# Set IP address

```
RouterB(config-if)#ip address 1.1.1.2 255.255.255.0
```

To keep the administration hostname, the hostname configured for the CHAP authentication can be configured by using the **chap hostname *hostname*** command. In the above example, the Router B as the authenticated party uses the default hostname, and the host for the CHAP authentication is RouterB.

Router B:

```
Ruijie#config terminal
Ruijie(config)#
```

# Use the peer hostname as the username, and the password is the same as that configured on the peer router.

```
R(config)#username RouterA password 0 Router
```

```
Ruijie(config)#interface serial1/0
```

# Encapsulate protocol

```
Ruijie(config-if)#encap ppp
```

# Set IP address

```
Ruijie(config-if)#ip address 1.1.1.2 255.255.255.0
```

# Set the local CHAP authentication hostname

```
Ruijie(config-if)#ppp chap hostname RouterB
```

PPP MS-CHAP Authentication

The following example describes the PPP MS-CHAP authentication configuration. Router A is the authentication party, with the IP address being 1.1.1.1/24, host name being RouterA, and password being Router. The user list of Router A includes the host name of Router B. Router B is the authenticated party, with IP address being 1.1.1.2/24, host name being RouterB, and password being Router.

Router A:

```
Ruijie# config terminal
```

#Set a host name.

```
Ruijie(config)# hostname RouterA
```

#Set a username and password list.

```
RouterA(config)#username RouterB password 0 Router
RouterA(config)#username RouterC password 0 Router
RouterA(config)#interface serial 1/0
```

#Set the encapsulation protocol.

```
RouterA(config-if)# encap ppp
```

#Set an IP address.

```
RouterA(config-if)# ip address 1.1.1.1 255.255.255.0
```

#Set the PPP MS-CHAP authentication mode.

```
RouterA(config-if)# ppp authentication ms-chap
```

Router B:

```
Ruijie# config terminal
```

#Set a host name.

```
Ruijie(config)# hostname RouterB
```

#Set the host name of Router A as the username, and set the password to be the same as that of Router A.

```
RouterB(config)# username RouterA password 0 Router
RouterB(config)# interface serial 1/0
```

#Set the encapsulation protocol.

```
RouterB(config-if)# encap ppp
```

#Set an IP address.

```
RouterB(config-if)# ip address 1.1.1.2 255.255.255.0
```

To reserve the host name, run the **ppp chap hostname** *hostname* command to specify the local host name used for MS-CHAP authentication. In the preceding example, the authenticated party Router B uses the default host name RouterB, which is used for MS-CHAP authentication.

Router B:

```
Ruijie# config terminal
Ruijie(config)#
```

#Set the host name of Router A as the username, and set the password to be the same as that of Router A.

```
Ruijie (config)# username RouterA password 0 Router
Ruijie(config)# interface serial 1/0
```

#Set the encapsulation protocol.

```
            Ruijie(config-if)# encap ppp
```

#Set an IP address.

```
            Ruijie(config-if)# ip address 1.1.1.2 255.255.255.0
```

#Set the host name for local MS-CHAP authentication.

```
            Ruijie(config-if)# ppp chap hostname RouterB
```

PPP MS-CHAP-V2 Authentication

The following example describes the PPP MS-CHAP-V2 authentication configuration. Router A is the authentication party, with the IP address being 1.1.1.1/24, host name being RouterA, and password being Router. The user list of Router A includes the host name of Router B. Router B is the authenticated party, with IP address being 1.1.1.2/24, host name being RouterB, and password being Router.

Router A:

```
            Ruijie# config terminal
```

#Set a host name.

```
            Ruijie(config)# hostname RouterA
```

#Set a username and password list.

```
            RouterA(config)#username RouterB password 0 Router
            RouterA(config)#username RouterC password 0 Router
            RouterA(config)#interface serial 1/0
```

#Set the encapsulation protocol.

```
            RouterA(config-if)# encap ppp
```

#Set an IP address.

```
            RouterA(config-if)# ip address 1.1.1.1 255.255.255.0
```

#Set the PPP MS-CHAP-V2 authentication mode.

```
            RouterA(config-if)# ppp authentication ms-chap-v2
```

Router B:

```
            Ruijie# config terminal
```

#Set a host name.

```
            Ruijie(config)# hostname RouterB
```

#Set the host name of Router A as the username, and set the password to be the same as that of Router A.

```
            RouterB(config)# username RouterA password 0 Router
            RouterB(config)# interface serial 1/0
```

#Set the encapsulation protocol.

```
            RouterB(config-if)# encap ppp
```

#Set an IP address.

```
            RouterB(config-if)# ip address 1.1.1.2 255.255.255.0
```

To reserve the host name, run the **ppp chap hostname** *hostname* command to specify the local host name used for MS-CHAP-V2 authentication. In the preceding example, the authenticated party Router B uses the default host name RouterB, which is used for MS-CHAP-V2 authentication.

Router B:

```
            Ruijie# config terminal
            Ruijie(config)#
```

#Set the host name of Router A as the username, and set the password to be the same as that of Router A.

```
            Ruijie (config)# username RouterA password 0 Router
            Ruijie(config)# interface serial 1/0
```

#Set the encapsulation protocol.

```
Ruijie(config-if)# encap ppp
```

#Set an IP address.

```
Ruijie(config-if)# ip address 1.1.1.2 255.255.255.0
```

#Set the host name for local MS-CHAP-V2 authentication.

```
Ruijie(config-if)# ppp chap hostname RouterB
```

MP Configuration Example

The example below shows a multilink configuration, where two synchronous interfaces serial1/0 and serial1/1 are bound to the logical interface dialer 1 to implement the Multilink PPP.

# Create the loopback interface and use its IP address as the IP address of the dialer logical interface

```
interface Loopback0
ip address 192.168.20.2 255.255.255.0
```

# Configure DDR on the physical interfaces serial1/0 and serial1/1, and specify the rotary group number (1 in this example)

```
interface Serial1/0
no ip address
encapsulation ppp
dialer in-band
dialer rotary-group 1
#
interface Serial1/1
no ip address
encapsulation ppp
dialer in-band
dialer rotary-group 1
```

# Create the dialer 1 logical interface and borrow the IP address of loopback0, set the dialer group, and specify the multilink ppp negotiation method.

```
interface Dialer1
ip unnumbered Loopback0
encapsulation ppp
dialer-group 1
ppp multilink
#
dialer-list 1 protocol ip permit
```

The example below uses two synchronous interfaces serial1/0 and serial1/1 are bound to the logical interface multilink 1 to implement the Multilink PPP.

# Create the loopback interface and use its IP address as the IP address of the multilink logical interface

```
interface Loopback0
  ip address 192.168.20.1 255.255.255.0
```

# Configure ppp multilink on the physical interfaces serial1/0 and serial1/1, and specify the multilink group number 1.

```
interface Serial 1/0
  no ip address
  encapsulation ppp
  ppp multilink
  multilink-group 1
interface Serial 1/1
  no ip address
  encapsulation ppp
  ppp multilink
  multilink-group 1
```

# Create the multilink 1 logical interface and borrow the IP address of loopback0.

```
interface multilink 1
  ip unnumbered Loopback0
  encapsulation ppp
  ppp multilink
```

The example below uses two synchronous interfaces serial1/0 and serial1/1 are bound to the virtual template interface to implement the Multilink PPP.

# Create the loopback interface and use its IP address as the IP address of the virtual template interface

```
interface Loopback0
  ip address 192.168.20.1 255.255.255.0
```

# Configure the PPP multilink on physical interfaces serial1/0 and serial1/1

```
interface Serial 1/0
  no ip address
  encapsulation ppp
  ppp multilink
interface Serial 1/1
  no ip address
  encapsulation ppp
  ppp multilink
```

# Create the virtual-template 1 interface and borrow the IP address of loopback0.

```
interface virtual-template 1
  ip unnumbered Loopback0
  encapsulation ppp
  ppp multilink
multilink virtual-template 1
```

# Specify copying parameters from virtual-template 1, to establish the binding from virtual-access interface to synchronous interface.

Configuration of Sender/Receiver of LCP Extended Configuration Option

In the following example, Router A is configured as the sender of the PPP LCP extended configuration option, so as to send the SN of router A to Router B through the LCP extended configuration option; Router B is configured as the receiver of the PPP LCP extended configuration option, identifies the LCP extended configuration option that carries the SN and that is sent from Router A, and then sends the information in the extended configuration option to the AAA server for authentication.

Router A:

```
Ruijie# config terminal
```

#Set a host name.

```
Ruijie(config)# hostname RouterA
```

#Set the encapsulation protocol.

```
RouterA(config-if)# encap ppp
```

#Set an IP address.

```
RouterA(config-if)# ip address 1.1.1.1 255.255.255.0
```

#Set the sender of the PPP LCP extended configuration option.

```
RouterA(config-if)#ppp lcp send-option serial-number
```

Router B:

```
Ruijie# config terminal
```

#Set a host name.

```
Ruijie(config)# hostname RouterB
```

#Set the encapsulation protocol.

```
RouterB(config-if)# encap ppp
```

#Set an IP address.

```
RouterB(config-if)# ip address 1.1.1.2 255.255.255.0
```

#Set the receiver of the PPP LCP extended configuration option.

```
RouterB(config-if)#ppp lcp accept-option
```

ACFC Option Processing

In the following example, the interface Serial 1/3 of Router A is configured to actively send the ACFC option during PPP LCP negotiation, enable ACFC, and reply with an ACK response to the PPP LCP configuration request packet that carries the ACFC option and that is sent from the peer end.

Router A:

```
Ruijie# config terminal
```

#Set a host name.

```
Ruijie(config)# hostname RouterA
```

#Enter the interface configuration mode.

```
Ruijie(config)# interface Serial 1/3
```

#Set the encapsulation protocol.

```
RouterA(config-if)# encap ppp
```

#Set an IP address.

```
RouterA(config-if)# ip address 1.1.1.1 255.255.255.0
```

#Configure the function of actively sending the ACFC option.

```
RouterA(config-if)#ppp acfc local request
```

#Configure the function of accepting the PPP LCP configuration request packet that carries the ACFC option.

```
RouterA(config-if)#ppp acfc remote apply
```

PFC Option Processing

In the following example, the interface Serial 1/3 of Router A is configured to actively send the PFC option during PPP LCP negotiation, enable PFC, and reply with an ACK response to the PPP LCP configuration request packet that carries the PFC option and that is sent from the peer end.

Router A:

```
Ruijie# config terminal
```

#Set a host name.

```
Ruijie(config)# hostname RouterA
```

#Enter the interface configuration mode.

```
Ruijie(config)# interface Serial 1/3
```

#Set the encapsulation protocol.

```
RouterA(config-if)# encap ppp
```

#Set an IP address.

```
RouterA(config-if)# ip address 1.1.1.1 255.255.255.0
```

#Configure the function of actively sending the PFC option.

```
RouterA(config-if)#ppp pfc local request
```

#Configure the function of accepting the PPP LCP configuration request packet that carries the PFC option.

```
RouterA(config-if)#ppp pfc remote apply
```

PPP Troubleshooting

First, use the **show interface serial** *slot-number/interface-number* command to check the interface status. A synchronous interface may have four statuses. Take the serial 1/0 as an example;

Status display	Fault description
serial 1/0 is administratively down, line protocol is down	The interface is shut down by someone.
serial 1/0 is down, line protocol is down	The interface is not activated, or the physical interface has not turned Up
Serial 1/0 is up, line protocol is up	The interface is available for data transmission.
serial 1/0 is up, line protocol is down	The interface has been activated but the link negotiation fails.

Interface Cannot be Up

Firstly: Remove the fault of manual shutdown of the interface.
Secondly: Check the physical layer causes. Run the show interface serial1/0 command to check the interface status. All the physical layer parameters (DCD, DTR, DSR, CTS, RTS) shall be up. If some one is down, verify whether the related V.35 or V.24 cable has problem or not.
Finally: If the cable of the interface is DTE (the connector connected with the line device is a fame-end cable) but the DCD is down, verify whether the line handshake of the Modem connected with the cable is successfully. If so, the DCD or LINE indicator on the Modem shall be always on.

Link Protocol Cannot be Up

The interface is up is the prerequisite for Line Protocol Up. Therefore, first remove the interface down fault in troubleshooting the fault of the link protocol cannot be up. Then, verify the data receiving/transmitting of the link layer: Run the **show interface serial *slot-number/interface-number*** command to note the numbers of Packet Input and Packet Output. If there is no Input message, the peer router may be shut down or the transmission of the peer router has problem.
Run the **Clear Count serial *slot-number/interface-number*** command for a period and note the number of Interface reset. If any, it indicates the local router transmission has problem.
To prevent the loopback problem with the line: Run the **show interface serial *slot-number/interface-number*** command to check whether there is the prompt "Loopback is set". Use the **debug PPP packet** command to check whether the PPP negotiation matches the reply of the peer router Magic Number. If yes, the line may be in the loopback status, causing the link cannot be up. It may also possible that the link is up but the peer cannot be pinged through.
If the data transmission/receiving of the line is normal but the protocol settings of the line do not match, such as HDLC protocol set for the peer router, run the **debug PPP packet** command to view the prompt for protocol type. If so, the line protocol cannot be up.
The fault that the link protocol cannot be up is related with the negotiation parameters. If the line negotiation needs the CHAP or PAP authentication, it is necessary to ensure correct username and password, which can be verified by using the **debug ppp packet** or **debug ppp negotiation** command.

Link is Up but Ping Failed

The status of link up is based on the successful LCP negotiation. If the interface has been configured with an IP address, the Line protocol may also be up but there is no prompt "IPCP Open". As a result, if the IP address of the peer WAN interface cannot be pinged through, remove the fault of the IPCP negotiation failure. If the peer WAN interface can be pinged through but the IP addresses inside the peer LAN cannot be pinged through, troubleshoot from the routing table first. For the related routing configuration, see IP Routing Protocol Configuration Guide.

DLDP Configuration

Overview

Based on the SDH platform, the MSTP supports access, processing, and transmission of multiple services such as TDM, ATM, and Ethernet and provides multi-service nodes with a the unified network management system. The Ethernet access mode is commonly used at user access points. However, link keep-alive protocols are not available on Ethernet, causing exceptions where the link protocol status is normal whereas lines are disonnected when MSTP networks are accessed in Ethernet access mode. In this case, route convergence is slow and faults are more difficult to locate.

The major procedure for device link detection falls into the following stages:

3) Initialization

When DLDP is enabled on the interface, the status of DLDP changes to the initialization state, and then an ARP request is sent to obtain the MAC address of the peer device. If DLDP cannot obtain the MAC address of the peer device, DLDP remains in the initialization stage. In this case, if the DLDP function is disabled, the DLDP status changes to deleted. After the MAC address of the peer device is obtained, the DLDP status changes to link succeeded.

4) Link succeeded status

In this state, a DLDP link detection request can be sent to detect line connectivity. If a DLDP response is received, the corresponding interface is marked as UP. If no response is received, requests are sent until the number of requests exceeds the maximum allowed number of requests. In this case, the link is marked as failed and the DLDP status changes to initialization. If this function is deleted during this process, the DLDP status changes to deleted.

5) Deleted status

In the deleted state, the interface status is not analyzed by the link detection function and remains consistent with the physical channel status.

Configuring Device Link Detection

Task List

Configuring the Ethernet Link Detection Function

This command can be configured on the Ethernet port only. By default, this function is disabled. To activate this function, run the following command:

Command	Function
Ruijie(config-if)#**dldp** *ip [nexthopip]*	Activates the link detection protocol.

Note

1. This function is implemented using ICMP ECHO packets. The ICMP response function needs to be enabled on the peer device.
2. The precondition for enabling this function is that the interface is in the UP state.
3. After this function is enabled, the IP address of the interface cannot be modified when the interface is in the down state .
4. In the case of detection across network segments, the next-hop IP address needs to be configured. For example, If the local interface IP address is 10.1.1.1 and 30.1.1.1 needs to be detected through the 20.1.1.2 gateway, the next-hop IP address 20.1.1.2 needs to be configured.

Configuring the Interval

Setting heartbeat intervals can change the frequency of handshake packet sending for link detection.

Command	Function
Ruijie(config-if)# **dldp** ip **interval** *val*	Sets the interval for device link detection.

Configuring Retry Times

Command	Function
Ruijie(config-if)# **dldp** ip **retry** *val*	Sets the threshold of error times during device link detection.

Configuring Resume Times

Command	Function
Ruijie(config-if)# **dldp** ip **resume** *val*	Sets the resumption threshold of the device link. The threshold indicates the times for receiving continuous DLDP detection packet responses before the link status changes from DOWN to UP. The resumption time is related to the interval for sending link detection packets set by running the **dldp ip interval** command. The line resumption time can be calculated using the following formula: Line resumption time = Resume times x Time configured by using the **dldp ip interval** command.

Note

This function is used to avoid oscillation of device links. For example, if link status changes between connnected and disonnected during the link status detection using the **ping** command, continuous oscillation occurs on the link (Link status changes continuously between UP and DOWN or ARP is continuously switched.). This problem can be avoided by setting a greater resume value. Link status changes from DOWN to UP only when the number of detection packet responses received by the link reached the threshold set by using the **resume** command.

Clearing the Records of the Times When DLDP Status Changes Between UP and DOWN

Command	Function
Ruijie(config-if)# **clear-dldp***[all] [ip [nexthopip]]*	Ruijie routers can record the times when DLDP protocol status changes between UP and DOWN. The **clear-dldp** command can be used to clear the recorded times and start the new recording.

Note

1. The **clear-dldp all** command can be used to clear the recorded times when DLDP status changes between UP and DOWN on an interface within a period of time and to start the new recording from 0.
2. The **clear-dldp ip [nexthopip]** command can be used to clear the recorded times when link status changes between UP and DOWN on a specified interface within a period of time and to start the new recording from 0.

Checking the Times When DLDP Status Changes Between UP and DOWN Within a Period of Time

Command	Function
Ruijie(config-if)# **show dldp** interface *[ ] [FastEthernet/GigabitEthernet number]*	Displays the times when DLDP status changes between UP and DOWN within a period of time.

Note

1. The **show dldp interface** command can be used to check the times when DLDP status changes between UP and DOWN on all interfaces and view the time when the recording starts.
2. The **show dldp interface FastEthernet/GigabitEthernet number** command can be used to check the recorded times when protocol status changes between UP and DOWN on an Ethernet interface and view the time when the recording starts.

BFD Configuration

Understanding BFD

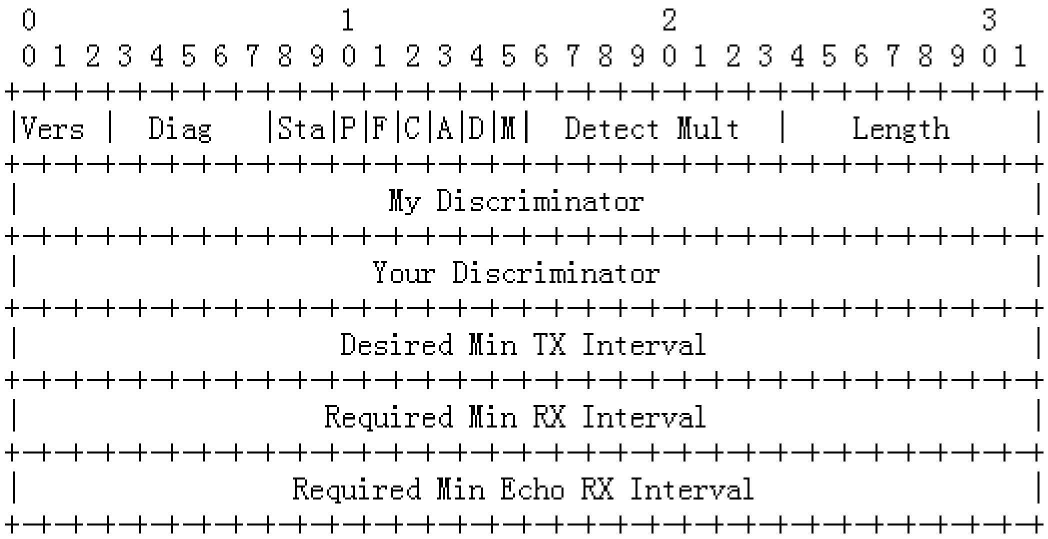
Overview

Bidirectional forwarding detection (BFD) provides low-overhead, short-duration detection of the connectivity in the forwarding path between adjacent routers. The fast detection of failures in the forwarding path speeds up enabling the backup forwarding path and improves the network performance.

BFD Packet Format

The two types of BFD packets are control packets and echo packets. The local end sends echo packets to the peer, which returns the received echo packets back without processing. Therefore, no BFD echo packet format is defined. Only BFD control packet format is defined. There are two versions for the BFD control packet: version 0 and version 1. By default, the BFD session establishment adopts the version 1. However, if one end receives the version 0 control packets from the peer, the default version 1 automatically switches to version 0 to establish the BFD session. You can use the **show bfd neighbors** command to view the version member. The format of the version 1 packet is shown as follows:

Figure 1 Format of BFD control packets (version 1)



```
 0                   1                   2                   3
 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+

+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|                   Required Min RX Interval                    |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|                 Required Min Echo RX Interval                 |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
```

Field	Description
Vers	BFD protocol version. Currently, the value is **1**.
Diag	The following are causes of the latest switchover from the UP state to other states: **0**: indicates no diagnosis. **1**: indicates the control timeout detection. **2**: indicates the echo function failure. **3**: indicates that the neighbor advertising session is down.

Field	Description
	4: indicates that the forwarding plane is reset. **5**: indicates that the channel is invalid. **6**: indicates that the connection channel is invalid. **7**: indicates that administration is down.
Sta	Local status of the BFD. Including: **0**: AdminDown **1**: agent down **2**: agent Init **3**: agent UP
P	When a parameter changes, the sender places this flag in a BFD packet. The receiver must immediately respond the packet.
F	The packet must have the F flag set for responding to the packet with the P flag set.
C	Forward/control separation flag. Once this flag is set, the change of the control plane does not affect the BFD. For example, if the control plane deploys OSPF, the BFD continues with link status detection when OSPF restarts or performs a graceful restart (GR).
A	Authentication flag. If this flag is set, sessions need to be authenticated.
M	Used in point-to-multipoint in the future. Currently, the value must be set to **0**.
Detect Mult	Detection timeout multiples. This flag is used by the detector to compute the timeout duration.
Length	Packet length
My Discriminator	Discriminator used by the BFD session to connect to the local end
Your Discriminator	Discriminator used by the BFD session to connect to the remote end
Desired Min Tx Interval	Minimum BFD packet sending interval supported by the local end
Required Min RX Interval	Minimum BFD packet receiving interval supported by the local end
Required Min Echo RX Interval	Minimum echo packet receiving interval supported by the local end. If the local end does not support the echo function, set the value to 0.
Auth Type	Authentication types (optical), including: Simple Password Keyed MD5 Meticulous Keyed MD5 Keyed SHA1 Meticulous Keyed SHA1
Auth Length	Authentication data length
Authentication Data	Authentication data area

Note

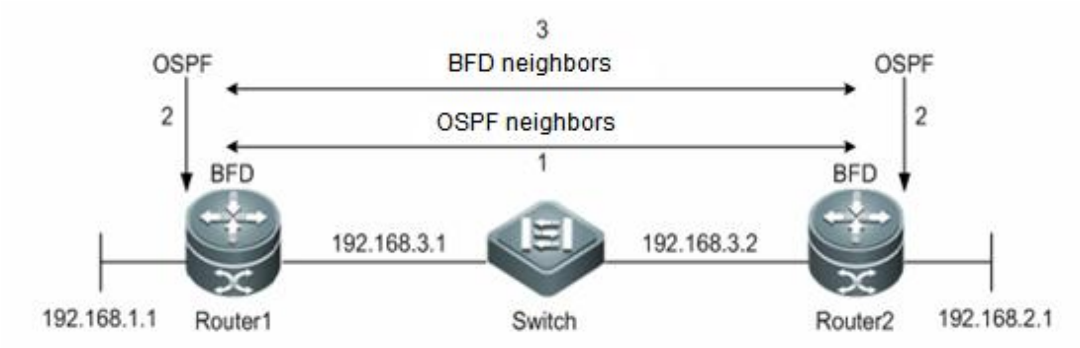
From version 10.3(4b3), the RGOS supports version 1 and version 0 packets. By default, session initiation packets adopt version 1. If one end receives version 0 control packets from the peer, the default version 1 automatically switches to version 0 to establish the session.

BFD Operation Mechanism

The BFD detection mechanism is independent from the applied interface media type, encapsulation format mad, associated upper-layer protocols such as OSPF, BGP, and RIP. The BFD establishes a session between adjacent routers enables the route protocols to re-calculate the route table by rapidly sending the detection fault to the running route protocols and decreases the network convergence time sharply. The BFD cannot discover the neighbors, so it needs the upper-layer protocols to notify the neighbors of which the session is established.

The following figure shows that two routers are connected through a L2 switch. The two routers runs OSPF and BFD.

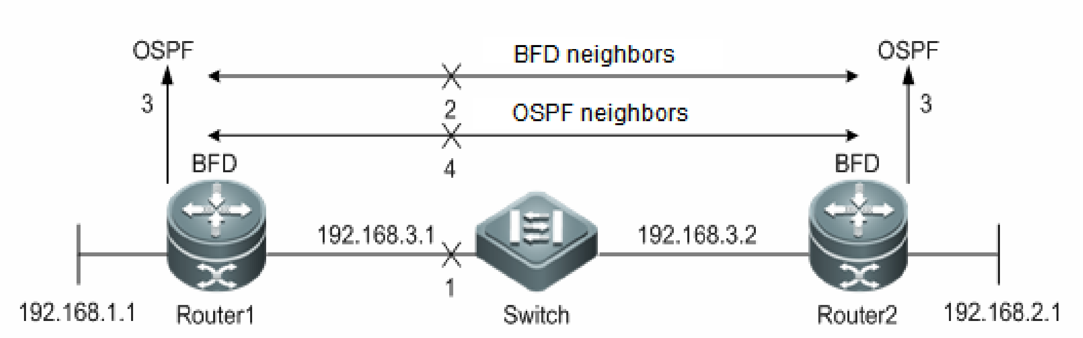
Figure 2 BFD session establishment



The BFD session establishment process is as follows:

6) OSPF discovers neighbors and establishes neighbor relationships.
7) OSPF notifies BFD of establishing the session with the neighbors.
8) BFD establishes the session with the neighbors.

Figure 3 BFD fault detection process



The BFD fault detection process is as follows:

1) Step 1: A link communication failure between Router1 and Router2 occurs.
2) Step 2: BFD session between the Router1 and Router2 detects the fault.
3) Step 3: BFD notifies the fault of the OSPF reachability to the forwarding path of the neighbor.
4) Step 4: OSPF deals with the process of the neighbor Down. If the backup forwarding path exists, and the protocol convergence is performed and the backup forwarding path is enabled.

Related Protocols and Regulations

The related BFD protocols and regulations are:

- draft-ietf-bfd-base-09: Bidirectional Forwarding Detection
- draft-ietf-bfd-generic-05: Generic Application of BFD
- draft-ietf-bfd-mib-06: Bidirectional Forwarding Detection Management Information Base
- draft-ietf-bfd-v4v6-1hop-09: BFD for IPv4 and IPv6 (Single Hop)
- draft-ietf-bfd-multihop-07: BFD for IPv4 and IPv6 (Multihop)
- draft-ietf-bfd-mpls-07: BFD For MPLS LSPs

☑ Currently, no version supports draft-ietf-bfd-mib-06.

BFD Features

This section describes the BFD features.

BFD Session Establishment Mode

The BFD session is established in the following modes:

- Active Mode: Before a session is established, BFD actively sends the BFD control packets regardless of whether any BFD control packet is received from the peer.

BFD Detection Mode

Asynchronous Mode

In the asynchronous mode, the BFD control packets are sent periodically among the systems. If one system receives no BFD control packet from the peer within the BFD interval, the BFD session will be down.

Echo Mode

The local system sends the BFD echo packet periodically. The peer system loops back the echo packet via the forwarding channel. The BFD session will be down if the continuous echo packets are not received within the detection interval. The echo mode can be co-used with the above-mentioned two detection modes. In the echo mode, the packets are forwarded back via the forwarding panel of the peer system rather than the control panel, reducing the delay and speeding up the fault detection in comparison to the control packet sending. In the asynchronous mode, the control packet sending will be decreased with the echo function enabled, for the echo function processes the detection. The echo function must be enabled in the BFD session; otherwise the echo function will be invalid.

☑ Only BFD session version 1 supports the BFD echo function

Caution The **no ip redirects** command must be executed to disable the redirect function of the IP packets and the **no ip deny land** command must be executed to disable the function of anti-attack of the Land-based DDOS before configuring the echo mode.

BFD Session parameters

- BFD session parameters (including Desired Min Tx Interval, Required Min RX Interval, and Detect Mult) must be configured on interfaces at both ends. Otherwise, BFD sessions cannot be created.
- During BFD session creation, interfaces at both ends will negotiate BFD session parameters and accordingly detect the session.
- If BFD session parameters are revised after BFD session creation, interfaces at both ends re-initiate the negotiation. During revision, the BFD session remains in the UP state.

BFD for Dynamic Route Protocols

Configuring BFD for the route protocols improves the convergence performance of the protocol by taking advantages of the faster fault detection of the BFD in comparison to the HELLO mechanism of the protocol. Generally, the fault detection time can be decreased to less than 1s.

Make sure that the BFD for corresponding protocol is enabled on all BFD session neighbors, or the BFD session cannot be established. However, if the dynamic route protocol or other applications have already notify the BFD of establishing the session with the corresponding neighbor, the BFD for this protocol is established.

BFD for Static Route

Configuring BFD for static route prevents the static route from being the forwarding path when the router selects the routing under the circumstances that the configured static route is unreachable. It can rapidly switch to the backup forwarding path if the backup forwarding path exists.

Being different from the dynamic route protocol, the static route protocol has no mechanism of discovering the neighbor. Therefore, when configuring the BFD for static route, the reachability of the next-hop of the static route is dependent on the BFD session state. If the BFD session detects the fault, which means that next-hop of the static route is unreachable; the static route cannot be installed into the RIB. Make sure that the BFD for static route is enabled on all BFD session neighbors, or the BFD session cannot be established. However, if the dynamic route protocol or other applications have already notify the BFD of establishing the session with the corresponding neighbor, the BFD for static route is enabled..

If the BFD session is removed from the peer in the process of the BFD session establishment, the BFD session is down. Under this circumstance, the static route forwarding shall be ensured.

BFD for PBR

Configuring BFD for PBR prevents the PBR from being the forwarding path when the router selects the routing under the circumstances that the configured PBR is unreachable. It can rapidly switch to the backup forwarding path if the backup forwarding path exists.

The method of BFD for PBR is similar to the BFD for static route. If the BFD session detects the fault by following the forwarding path of the specified neighbor, the PBR will be notified of the unreachability to the corresponding next-hop. The PBR reaching the next-hop is ineffective.

Make sure that the BFD for PBR is enabled on all BFD session neighbors, or the BFD session cannot be established. However, if the dynamic route protocol or other applications have already notify the BFD of establishing the session with the corresponding neighbor, the BFD for PBR will be enabled automatically.

If the BFD session is removed from the peer in the process of the BFD session establishment, the BFD session will be down. And under this circumstance, the PBR forwarding shall be ensured.

BFD for VRRP

BFD for VRRP configuration can replace the HELLO mechanism of VRRP itself to realize the fast detection of running state of the master and backup routers and improve the network performance. Generally, the time of failure detection can be shortened to less than 1s.

Make sure that the BFD for VRRP is enabled on the router at both ends, or the BFD session cannot be established. However, if the dynamic route protocol or other applications have already notify the BFD of establishing the session with the corresponding neighbor, the BFD for VRRP will also be configured.

VRRP can also use BFD to follow the specified neighbor. If the BFD session detects the fault of the forwarding path to the neighbor, it will reduce the VRRP priority automatically and trigger the switchover between the master and backup routers. The BFD can be established only when the dynamic route protocol or other applications notify BFD of establishing the session with corresponding neighbor.

BFD Supports to Change the State of Layer3 Interfaces

The BFD supports the function of changing the L3 interface status. In the configuration mode, you can run the **bfd bind peer-ip** command to detect the direct connection address of a specified L3 interface. BFD session status established through this command will generate the corresponding interface BFD status, such as BFD-DOWN/BFD-UP. With this function commonly used in various FRRs, the BFD is used to detect the interface status and perform FRR.

BFD for MPLS-LSP

The BFD for MPLS indicates that the Label Switched Path (LSP) performs fast detection for neighbors through the BFD. The following detection modes are supported:

- Configuring the BFD for static LSP
- Configuring the BFD for LSPs generated by LDP
- Configuring the BFD for LSP reverse links by using IP addresses

BFD for VRF

The BFD supports VPN Routing and Forwarding (VRF) and detects the connectivity of the forwarding path between the Provider Edge (PE) and the Customer Edge (CE).

BFD for Interfaces

Switches: BFD configuration is allowed only on Routed Port and SVI, not on a L3 AP. If the SVI member interface is a L2 AP, BFD session creation fails on the member interface.

Routers: BFD configuration is allowed on synchronous interfaces, asynchronous interfaces, ATM, serial interfaces, frame relay, POS, CPOS, Ethernet interfaces and child interfaces, E1, channelized ATM, and channelized CPOS.

Configuring BFD

Default configurations for the BFD

Function	**Defaults**
BFD session creation mode	Active mode. It cannot be set.
BFD detection mode	Asynchronous mode. The echo function is enabled by default.
BFD session parameter	No default value. It must be set.
BFD authentication method	Disabled. It cannot be set.
BFD for dynamic route protocol	Disabled
BFD for the static route	Disabled
BFD for PBR	Disabled
BFD for VRRP	Disabled
BFD for VRF	Disabled
BFD for MPLS-LSP	Disabled

Configuring BFD Session Parameters

The BFD session parameter has no default value and must be configured. To configure BFD session parameters, run the following command in turn.

Command	**Function**
Ruijie>**enable**	Enters privileged mode.
Ruijie# **configure terminal**	Enters global mode.
Ruijie(config)# **interface** *type number*	Enters interface configuration mode.
Ruijie(config-if)# **bfd interval** *milliseconds* **min_rx** *milliseconds* **multiplier** *interval-multiplier*	Configures BFD session parameters for a specified interface. **interval** *milliseconds*: indicates the minimum sending interval. The unit is millisecond. **min_rx** *milliseconds*: indicates the minimum receiving interval. The unit is millisecond. **multiplier** *interval-multiplier*: indicates the detection timeout multiples.
Ruijie(config-if)# **end**	Exits interface configuration mode and restores privileged mode.

To delete BFD session parameter configurations, run the **no bfd interval** command in interface configuration mode.

The following example shows how to configure BFD session parameters on the Routed Port FastEthernet 0/2.

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# interface fastEthernet 0/2
Ruijie(config-if)# bfd interval 100 min_rx 100 multiplier 3
```

Caution

The difference of the bandwidth transmitted on different interfaces must be considered when configuring the parameters. If the minimum sending and receiving intervals are too low, it may result in the oversized bandwidth of the BFD and affect data transmission.

Switches cannot be configured on the L3 AP interface.

Configuring the BFD Echo Function

The session status is not affected if the echo function is enabled after the BFD session is created. After the echo function is disabled, no echo packet is sent and the forwarding plane ceases to receive echo packets. To configure the BFD echo function, run the following commands in turn.

Command	Function
Ruijie>**enable**	Enters privileged mode.
Ruijie# **configure terminal**	Enters global mode.
Ruijie(config)# **interface** *type number*	Enters interface configuration mode.
Ruijie(config-if)# **bfd echo**	Enables the BFD echo function.
Ruijie(config-if)# **end**	Exits interface mode and returns to privileged mode.

To disable the BFD echo function, run the **no bfd echo** command in interface mode.

The following example shows how to configure the BFD echo function on the Routed Port FastEthernet 0/2:

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# interface fastEthernet 0/2
Ruijie(config-if)# bfd echo
```

To enable the BFD control packet to be sent in a slower frequency after the echo function is enabled in the BFD asynchronous mode, run the following commands in turn.

Command	Function
Ruijie>**enable**	Enters privileged mode.
Ruijie# **configure terminal**	Enters global mode.
Ruijie(config)# **bfd slow-timer** milliseconds	Configures the slow-timer. The default value is 1 second. The value range is from 1000 to 30000 and the

	unit is millisecond.
Ruijie(config)# **end**	Enters global configuration mode.

To restore the default value of the slow-timer, run the **no bfd slow-time** mode in global mode.

The following example shows how to configure the time of the slow-timer to 1400 milliseconds:

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# bfd slow-timer 1400
```

Caution

The local end sends the BFD echo packet to the peer, which returns the received packets with processing on the forwarding panel. In this process, the BFD session detection may fail for the peer has been congested resulting in the loss of the echo packets. Under these circumstances, the corresponding QoS policy is necessary to be configured to make sure that the echo packets take the precedence to be processed or the echo function is disabled.

Configuring the BFD UP-Dampening Time

The BFD up-dampening time configuration solves the problem that the BFD session status frequent switches between DOWN and UP due to the line instability, which results in the frequent forwarding path switchover of the associated application (for example, the static route) and the abnormal operation. This feature allows you to configure the required up-dampening time before advertising the session UP state to a related application. To configure the BFD UP-Dampening function, run the following commands in turn.

Command	**Function**
Ruijie>**enable**	Enters privileged mode.
Ruijie# **configure terminal**	Enters global mode.
Ruijie(config)# **interface** *type number*	Enters interface configuration mode.
Ruijie(config)# **bfd up-dampening** *milliseconds*	Configures the up-dampening time.
Ruijie(config)#**end**	Exits global mode

To restore the default value, run the **no bfd up-dampening** command in interface configuration mode.

The following example shows how to configure the BFD up-dampening time as 60,000ms:

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# interface fastEthernet 0/2
Ruijie(config-if)# bfd up-dampening 60000
```

Caution

In the configuration process, the parameter configurations for two ends of the BFD session must be consistent. This ensures that applications and protocols associated with the BFD take effect simultaneously, and avoid that unidirectional communication occurs on the forwarding path due to different up-dampening time on the two ends.

The dampening function does not take effect in the BFD for OSPFv3.

Configuring the BFD CPP

The BFD protocol is a sensitive protocol. When the device with BFD function enabled suffers from attack (for example, a large amount of Ping packets attack the device), which lead to the BFD session turbulence, the device can be protected by enabling the BFD protection policy. However, if the BFD function and the BFD protection policy are enabled at the same time, the loss of BFD packets on the attacked device occurs when the packets sent from the last-hop device go through this device, influencing the BFD session establishment between the last-hop device and other devices. This function takes effect only for the switches.

To configure the BFD CPP, run the following commands in turn.

Command	Function
Ruijie>**enable**	Enters privileged mode.
Ruijie# **configure terminal**	Enters global mode.
Ruijie(config)# **bfd cpp**	Enables the BFD CPP.
Ruijie(config)# **end**	Exits global configuration mode.

By default, the BFD CPP is enabled. To disable the BFD CPP, run the **no bfd cpp** command in global mode.

The following example shows how to enable the BFD CPP.

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# bfd cpp
```

Configuring the BFD for RIP

RIP sends the route updating information periodically. A route is invalid and RIP cannot rapidly respond to the link failure when no route updating information is received within the specified time.

After enabling the BFD for RIP, the BFD session will be established for the RIP route information source (the source address for RIP route updating packet). Once BFD detects that a neighbor is invalid, RIP route information will directly be in the invalid state and not join in the route forwarding no longer. The convergence time can be decreased from 180s (the default RIP timer) to less than 1s.

Run the **bfd all-interfaces** command to enable BFD for RIP applications on all interfaces. Or run the **ip rip bfd** [**disable**] command in interface configuration mode to enable or disable to allow BFD for RIP applications on specified interfaces.

Command	Function
Ruijie>**enable**	Enters privileged mode.
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router rip**	Enters router configuration mode.
Ruijie(config-router)# **bfd all-interfaces**	Allows the BFD for RIP on all interfaces.
Ruijie(config-router)# **exit**	Exits router configuration mode and returns to global configuration mode. (Optional)
Ruijie(config)# **interface** *type number*	Enters interface configuration mode. (Optional)

Command	**Function**
Ruijie(config-if)#**ip rip bfd** [**disable**]	Allows or prohibits the BFD for RIP on specified interfaces. (Optional)
Ruijie(config-if)#**end**	Exits interface configuration mode. (Optional)
Ruijie#**show bfd neighbors** [**details**]	Displays the BFD session establishment information and whether RIP is for the specified session. (Optional)

To disable to allow the BFD for RIP applications, run the **no bfd all-interfaces** in Router mode.

The following example shows how to enable the BFD for RIP on all interfaces excluding the FastEthernet 0/2:

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# router rip
Ruijie(config-router)# bfd all-interfaces
Ruijie(config-router)# exit
Ruijie(config)# interface FastEthernet 0/2
Ruijie(config-if)# ip rip bfd disable
Ruijie(config-if)#end
```

Caution

The route information sources (source address for RIP route updating packet) of two devices with RIP enabled must be in the same network segment to establish the BFD session between adjacent routers.
BFD session parameters must have been configured. Otherwise, BFD session creation fails.
For the non-unnumbered interface, if the neighbor end and the local end are not connected directly, the BFD for IPv4 PBR fails to be enabled.
BFD session creation fails if an interface specified during BFD session creation is different from the actual BFD packet egress or ingress interface due to IP routing.
BFD session creation fails if an interface specified during BFD session creation is different from the actual BFD packet egress or ingress interface.

Configuring the BFD for OSPF

The OSPF protocol dynamically discovers the neighbors by the Hello packets. With BFD for OSPF configured, the BFD session for the neighbors in FULL relationship will be established and the neighbor state will be detected by the BFD mechanism. Once BFD neighbor is invalid, OSPF processes the network convergence. The convergence time could be from 120s(by default, the sending interval of the OSPF Hello packet in non-broadcast network is 30s, which is a quarter of the invalid time for the adjacency router, namely, 120s) to less than 1s.

Run the **bfd all-interfaces** command to enable BFD for RIP applications on all interfaces. Or run the **ip ospf bfd** [**disable**] command in interface configuration mode to enable or disable to allow the BFD for RIP applications on specified interfaces.

Command	**Function**
Ruijie>**enable**	Enters privileged mode.

Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router ospf** *process-id*	Enters router configuration mode.
Ruijie(config-router)# **bfd all-interfaces**	Allows the BFD for RIP on all interfaces. Prohibits the BFD for RIP on all interfaces by running the **no** command.
Ruijie(config-router)# **exit**	Exits router configuration mode and returns to global configuration mode. (Optional)
Ruijie(config)# **interface** *type number*	Enters interface configuration mode. (Optional)
Ruijie(config-if)#**ip ospf bfd** [**disable**]	Allows or prohibits the BFD for RIP on specified interfaces. (Optional)
Ruijie(config-if)#**end**	Exits interface configuration mode. (Optional)
Ruijie#**show bfd neighbors** [**details**]	Displays the BFD session establishment information and whether OSPF is for the specified session. (Optional)
Ruijie#**show ip ospf**	Displays whether OSPF is for the specified session. (Optional)

To disable to allow the BFD for RIP applications, run the **no bfd all-interfaces** in Router mode.

The following example shows how to enable the BFD for OSPF on all interfaces excluding the FastEthernet 0/2:

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# router ospf 123
Ruijie(config-router)# bfd all-interfaces
Ruijie(config-router)# exit
Ruijie(config)# interface FastEthernet 0/2
Ruijie(config-if)# ip rip bfd disable
Ruijie(config-if)#end
```

☑ 10.3(4b3) or 10.3(5) do not support the BFD for OSPFv3.

⚠ Caution

BFD session parameters must have been configured. Otherwise, BFD session creation fails.

BFD session creation fails if an interface specified during BFD session creation is different from the actual BFD packet egress or ingress interface due to IP routing.

BFD session creation fails if an interface specified during BFD session creation is different from the actual BFD packet egress or ingress interface.

The OSPFv2/OSPFv3 virtual link does not support the BFD monitoring.

Configuring Association Between IS-IS and BFD

The Intermediate System to Intermediate System (IS-IS) protocol dynamically discovers a neighbor via hello packets. When the BFD function is enabled, the device running the IS-IS protocol establishes a BFD session for a neighbor in the UP state, and detects the status of the neighbor via the BFD mechanism. Once the BFD neighbor fails, the device running the IS-IS protocol immediately performs network convergence. The network convergence period can be reduced from 30s to 1s. By default, the transmission interval of point-to-point hello packets is 10s, and the failure period of the neighbor device is 30s (3 times the transmission interval).

Run the **bfd all-interfaces** command to enable association between IS-IS and BFD on all interfaces. Run the **isis bfd [disable]** command in interface configuration mode to enable or disable association between IS-IS and BFD on a specified interface.

Command	Function
Ruijie>**enable**	Enters the privileged EXEC mode.
Ruijie# **configure terminal**	Enters the global configuration mode.
Ruijie(config)# **router isis**	Enters the router configuration mode.
Ruijie(config-router)# **bfd all-interfaces**	Enables association between IS-IS and BFD on all interfaces. Runs the **no** form of this command to disable association between IS-IS and BFD on all interfaces.
Ruijie(config-router)# **exit**	(Optical) Exits the router configuration mode and returns to the global configuration mode.
Ruijie(config)# **interface** *type number*	(Optical) Enters the interface configuration mode.
Ruijie(config-if)#**isis bfd** [**disable**]	(Optical) Enables or disables association between IS-IS and BFD on a specified interface.
Ruijie(config-if)#**end**	(Optical) Exits the interface configuration mode.
Ruijie#**show bfd neighbors** [**details**]	(Optical) Displays BFD session information and checks whether IS-IS is associated with a specified session.
Ruijie# **show isis neighbors detail**	(Optical) Displays information about whether IS-IS is associated with a specified session.

Run the **no bfd all-interfaces** command in router configuration mode to disable association between IS-IS and BFD on all interfaces.

Configuration example:

#Enable association between IS-IS and BFD on interfaces except FastEthernet 0/2.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# router isis
Ruijie(config-router)# bfd all-interfaces
Ruijie(config-router)# exit
Ruijie(config)# interface FastEthernet 0/2
Ruijie(config-if)# isis bfd disable
Ruijie(config-if)#end
```

Caution

BFD session parameters must be configured before enabling association between IS-IS and BFD.

IP routing may cause inconsistency between the interface specified by the BDF session neighbor and the actual BDF packet outbound interface. In this case, BDF sessions cannot be established.

If the interface specified for BFD session establishment is inconsistent with the BFD packet inbound interface, BDF sessions cannot be established.

Configuring the BFD for BGP

Being similar to OSPF, by configuring the BFD for BGP, the BGP protocol rapidly detects the faults, realizes the rapid detection of the neighbor relationship and fastens the protocol convergence. By default, the BGP keepalive interval is 60s and the holdtime is 180s. The minimum value of the keepalive interval and holdtime are 1s and 3s respectively. It is slow to detect the neighbor relationship.

A large amount of the packets will be lost on the interface that receives and sends the packets at the fast speed. With the BFD enabled, the holdtime can decrease to less than 1 second.

Run the **neighbor** *ip-address* **fall-over bfd** command to enable the BFD for BGP.

Command	Function
Ruijie>**enable**	Enters privileged mode.
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **router bgp** *as-tag*	Enters router configuration mode.
Ruijie(config-router)#**neighbor** *ip-address* **fall-over bfd**	Selects BFD keywords to indicate the BFD for BGP to detect the faults of specified neighbors.
Ruijie(config-router)#**end**	Exits router configuration mode. (Optional)
Ruijie#**show bfd neighbors** [**details**]	Displays the BFD session establishment information and whether the BGP is associated to the specified session. (Optional)
Ruijie#**show ip bgp neighbors**	Displays whether the BGP is associated to the specified session. (Optional)

To disable the BFD for BGP applications, run the **no neighbor** *ip-address* **fall-over bfd** in Router mode.

The following example shows how to enable the BFD for BGP, and detect the forwarding path with the neighbor 172.16.0.2:

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# interface FastEthernet 0/1
Ruijie(config-if)# no switchport
Ruijie(config-if)# ip address 172.16.0.1 255.255.255.0
Ruijie(config-if)# bfd interval 50 min_rx 50 multiplier 3
Ruijie(config-if)# exit
Ruijie(config)# router bgp 44000
Ruijie(config-router)# bgp log-neighbors-changes
Ruijie(config-router)# neighbor 172.16.0.2 remote-as 45000
Ruijie(config-router)# neighbor 172.16.0.2 fall-over bfd
Ruijie(config-router)# end
```

☑ 10.3(4b3) and 10.3(5) support the BFD for BGP only when BGP works in IPv4 address families.

Caution

If BGP establishes the session using the loopback address and enables BFD to detect the neighbors, the outbound interface for the BFD packets will be specified according to the result of IP routing. In this situation, before configuring the BFD for BGP, the **bfd interval** command is necessary to be used to configure the BFD session parameter on the possible outbound interface. Otherwise, it may fail to establish the session. The BFD session cannot be established if the specified interface and the actual incoming interface for the BFD packets are inconsistent.

Configuring the BFD for Static Route

To configure the BFD for Static Route, run the following commands in turn.

Command	Function
Ruijie>**enable**	Enters privileged mode.
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **ip route static bfd** [**vrf** *vrf-name*] *interface-type interface-number gateway* [**souce** *ip-address*]	Configures the BFD for the static route. The parameters *interface-type*, *interface-number* and *gateway* indicate the interface and IP address of a neighbor. For multi-hops, **souce** *ip-address* needs to be configured as the session source IP address. BFD session parameters must be configured before the configuration.
Ruijie(config)#{ **ip route** *prefix mask* {*ip-address* | *interface-type interface-number [ip-address*]}	Ensures the parameters *interface-type*, *interface-number* and *gateway* are consistent with that configured in Step 3 before configuring the BFD for the static route.
Ruijie(config)# **end**	Exits global configuration mode.
Ruijie#**show bfd neighbors** [**details**]	Displays the BFD session establishment information and whether the static route is associated to the specified session. (Optional).

To disable the BFD for the static route, run the **no ip route static bfd** [**vrf** *vrf-name*] *interface-type interface-number gateway* command in interface mode.

The following example shows how to enable the BFD for static route, and detect the forwarding path with the neighbor 172.16.0.2:

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
```

```
Ruijie(config)# interface FastEthernet 0/1
Ruijie(config-if)# no switchport (This configuration is unnecessary for routers)
Ruijie(config-if)# ip address 172.16.0.1 255.255.255.0
Ruijie(config-if)# bfd interval 50 min_rx 50 multiplier 3
Ruijie(config-if)# ip route static bfd FastEthernet 0/1 172.16.0.2
Ruijie(config-if)# ip route 10.0.0.0 255.0.0.0 FastEthernet 0/1 172.16.0.2
Ruijie(config-if)# end
```

Configuring the BFD for PBR

To configure the BFD for PBR, run the following commands in turn.

Command	Function
Ruijie>**enable**	Enters privileged mode.
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **route-map** *route-map-name* [**permit** | **deny**] *sequence*	Configures the defined route map to enter route map configuration mode.
Ruijie(config-route-map)#**match ip address** *access-list-number*	Configures the matching access list.
Ruijie(config-route-map)#**set ip next-hop verify-availability** *next-hop-address* { **track** *number* **| bfd** [**vrf** *vrf-name*] *interface-type interface-number gateway* }	Configure the BFD for PBR. The parameters *interface-type*, *interface-number* and *gateway* indicate the interface and IP address of a neighbor. BFD session parameters must be configured before the configuration. The next hop specified by the parameter *next-hop-address* is unreachable if the BFD session detects faults. Run the **no** command to cancel the configuration.
Ruijie(config-route-map)#**exit**	Exits route map configuration mode.
Ruijie(config)# **interface** *type number*	Enters interface configuration mode.
Ruijie(config-if)#**ip policy route-map** *route-map*	Enables the PBR on interfaces.
Ruijie(config-if)#**end**	Exits interface configuration mode.
Ruijie#**show bfd neighbors** [**details**]	Displays the BFD session establishment information and whether the PBR is associated with the specified session. (Optional)
Ruijie#**show route-map**	Displays whether the PBR is associated with the specified session. (Optional)

To disable the BFD for PBR applications, run the **no set ip next-hop verify-availability** [*next-hop-address* [**track** *number*|**bfd** [**vrf** *vrf-name*] *interface-type interface-number gateway*]] command in router-map mode.

The following example shows how to enable the BFD for PBR, and detect the forwarding path with the neighbor 172.16.0.2:

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# route-map Example1 permit 10
Ruijie(config-route-map)# match ip address 1
Ruijie(config-route-map)#set ip next-hop verify-availability 172.16.0.2 bfd FastEthernet 0/1
172.16.0.2
Ruijie(config-route-map)#end
Ruijie(config)#interface FastEthernet 0/1
Ruijie(config-if)#no switchport (This configuration is unnecessary for routers)
Ruijie(config-if)#ip address 172.16.0.1 255.255.255.0
Ruijie(config-if)#bfd interval 50 min_rx 50 multiplier 3
Ruijie(config-if)#ip policy route-map Example1
Ruijie(config-if)#exit
```

☑ The BFD for PBRv6 is not supported in v10.3(4b3) and v10.3(5).

Configuring the BFD for VRRP

To enable the BFD for VRRP groups to detect the master and backup routers, run the following commands in turn.

Command	Function
Ruijie>**enable**	Enters privileged mode.
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type number*	Enters interface mode.
Ruijie(config-if)#**vrrp** *group-number* **ip** [*ip-address*[**secondary**]]	Creates VRRP groups and virtual IP addresses. *ip-address* indicates the IP address of the specified neighbor.
Ruijie(config-if)# **vrrp** *group-number* **bfd** *ip-address*	Configures the BFD for all VRRP groups. *ip-addess* indicates the neighbor IP address.
Ruijie(config-if)# **end**	Exits interface configuration mode.
Ruijie#**show bfd neighbors** [**details**]	Displays the BFD session establishment information and whether the VRRP is associated with the specified session. (Optional).
Ruijie#**show vrrp**	Displays whether the VRRP is associated with the specified session. (Optional)

To disable the BFD for VRRP groups to detect the master and backup routers, run the **no vrrp** *group-number* **bfd** command in interface mode.

The following example shows how to enable the BFD for VRRP, and detect the forwarding path between the master and slave routers:

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface FastEthernet 0/1
Ruijie(config-if)#no switchport (This configuration is unnecessary for routers)
Ruijie(config-if)#ip address 192.168.201.11 255.255.255.0
Ruijie(config-if)#bfd interval 50 min_rx 50 multiplier 3
Ruijie(config-if)#vrrp 1 priority 120
Ruijie(config-if)#vrrp 1 ip 192.168.201.1
Ruijie(config-if)#vrrp 1 bfd 192.168.201.12
Ruijie(config-if)#end
```

To enable the specified VRRP group to track the IP address of the specified neighbor through the BFD, run the following commands in turn.

Command	**Function**
Ruijie>**enable**	Enters privileged mode.
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type number*	Enters interface configuration mode.
Ruijie(config-if)#**vrrp** *group-number* **ip** [*ip-address*[**secondary**]]	Creates VRRP groups and virtual IP addresses on specified interfaces.
Ruijie(config-if)# **vrrp** *group-number* **track bfd** *interface-type interface-number ip-addess* [*priority*]	Configures the specified VRRP group to track the IP address of the specified neighbor through the BFD. Run the **no** command to cancel the configuration.
Ruijie(config-if)# **end**	Exits interface configuration mode.
Ruijie#**show bfd neighbors** [**details**]	Displays the BFD session establishment information and whether the VRRP is associated with the specified session. (Optional).
Ruijie#**show vrrp**	Displays whether the BFD is for VRRP is enabled to track the IP address of the specified neighbor. (Optional).

To disable the specified VRRP group to track the IP address of the specified neighbor through the BFD, run the no **vrrp** *group-number* **track bfd** *interface-type interface-number ip-addess* command in interface mode.

The following example shows how to specify the VRRP to track the specified neighbor 192.168.1.3:.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface FastEthernet 0/1
Ruijie(config-if)#no switchport (This configuration is unnecessary for routers)
Ruijie(config-if)#ip address 192.168.1.1 255.255.255.0
Ruijie(config-if)#bfd interval 50 min_rx 50 multiplier 3
Ruijie(config)#interface FastEthernet 0/2
Ruijie(config-if)#no switchport (This configuration is unnecessary for routers)
Ruijie(config-if)#ip address 192.168.201.17 255.255.255.0
Ruijie(config-if)#vrrp 1 priority 120
Ruijie(config-if)#vrrp 1 ip 192.168.201.1
Ruijie(config-if)#vrrp 1 track bfd FastEthernet 0/1 192.168.1.3 30
Ruijie(config-if)#end
```

Configuring BFD for Changing the State of Layer 3 Interfaces

Generally, it takes a long time for link communication failure or link failure to change the interface state. For various FRRs relying on interface state, high-performance switchover cannot be achieved. Therefore, BFD is generally associated with the layer-3 interface state to realize fast detection of interface state. Execute the following configurations to associate BFD and layer 3 interface states.

Command	**Function**
Ruijie>**enable**	Enters privileged mode.
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface** *type number*	Enters an L3 interface.
Ruijie(config-if)# **bfd bind peer-ip** *ip-address* [**source-ip** *ip-adress*] **process-pst**	Configure the BFD for L3 interfaces. Source-ip specifies the source IP address of a BFD packet for avoiding that the packet is discarded due to uRPF check failure when the uRPF is also used. Process-pst indicates the BFD status of the BFD session generation interface.
Ruijie(config-if)#**end**	Exits interface configuration mode. (Optional).
Ruijie#**show bfd neighbors** [**details**]	Displays the BFD session establishment information and whether the interface is associated with the specified session. (Optional).

To disable the BFD for interfaces, run the **no bfd bind peer-ip** *ip-address* in configuration mode.

The following example shows how to enable the BFD for FastEthernet 0/2.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# interface FastEthernet 0/2
Ruijie(config-if)#no sw (This configuration is unnecessary for routers)
Ruijie(config-if)#ip address 1.1.1.1 255.255.255.0
Ruijie(config-if)#bfd bind peer-ip 1.1.1.2 source-ip 1.1.1.1 process-pst
Ruijie(config-if)#end
```

Configuring the BFD for MPLS

The BFD for MPLS indicates that the BFD performs rapid detection on the LSP on the MPLS network to improve MPLS network reliability.

Configuring the BFD Detection for the Static LSP

Command	**Function**
Ruijie>**enable**	Enters privileged mode.
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **bfd bind static-lsp peer-ip** *ip-address* **source-ip** *ip-address* [**local-discriminator** *discr-value* **remote-discriminator** *discr-value*] [**process-state**]	Configures the BFD for static LSP. You can configure the homing address, next-hop address, and egress interface of the LSP. If no local discriminator is configured, the system automatically elects the local discriminator. If no remote discriminator is configured, the system learns of the remote discriminator in automatic configuration mode.

Configuring the BFD detection for the Dynamic LSP

Command	**Function**
Ruijie>**enable**	Enters privileged mode.
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie#**mpls router ldp**	Enters LDP configuration mode.
Ruijie(config-mpls-router)# **bfd bind ldp-lsp peer-ip** *ip-address* **nexthop** *ip-address* [**interface** *interface-type interface-number*] **source-ip** *ip-address* [**local-discriminator** *discr-value* **remote-discriminator** *discr-value*] [**process-state**]	Configures the BFD for dynamic LSP. You can configure the homing address, next-hop address, and egress interface of the LSP. If no local discriminator is configured, the system automatically elects the local discriminator. If no remote discriminator is configured, the system learns of the remote discriminator in automatic configuration mode.

Configuring the IP Address Mode for Reverse Link Detection in BFD for the LSP

Command	**Function**
Ruijie>**enable**	Enters privileged mode.
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **bfd bind backward-lsp-with-ip peer-ip** *ip-address* [**vrf** *vrf-name*] **interface** *interface-type interface-number* [**source-ip** *ip-address*] {**local-discriminator** *discr-value* **remote-discriminator** *discr-value*}	Configures the IP address mode for reverse link detection in BFD for the LSP. You can configure the source addresses, homing address, and egress interface of the LSP. Both the local and remote discriminators must be manually configured.

For details about enabling the BFD for MPLS-LSP, see the documents *MPLS-CREF* and *MPLS-SCG*.

Displaying BFD Configuration and Status

BFD provides following display commands for checking various configuration and running information. The following table describes functions of commands.

Command	**Function**
show bfd neighbors [**vrf** *vrf-name*] [**ipv4** *ip-addess* [**details**]| **ipv6** *ipv6-addess* [**details**] |**client** {**bgp**|**ospf**|**rip**|**vrrp**|**vrrp-balance** |**ldp-lsp**|**static-lsp**|**backward-lsp-with-ip**|**static-route**| **pbr**|**pst**} **[ipv4** *ip-addess* [**details**] | **ipv6** *ipv6-addess* [**details**]| **details**]]	Displays the BFD session information. For details, see the description about session display fields in Figure 4.
show vrrp	Displays information about enabling the BFD for VRRP.
show route-map	Displays information about enabling the BFD for PBR.
show ip route static bfd	Displays information about enabling the BFD for static route.
show ip bgp neighbors	Displays information about enabling the BFD for BGP.
show ip ospf neighbor	Displays information about enabling the BFD for OSPF.
show ip rip peer	Displays information about enabling the BFD for RIP.

Note The preceding display commands can be configured in any mode except for user mode.

☑ 10.3(4b3), 10.4(1), and later versions support the preceding configurations.

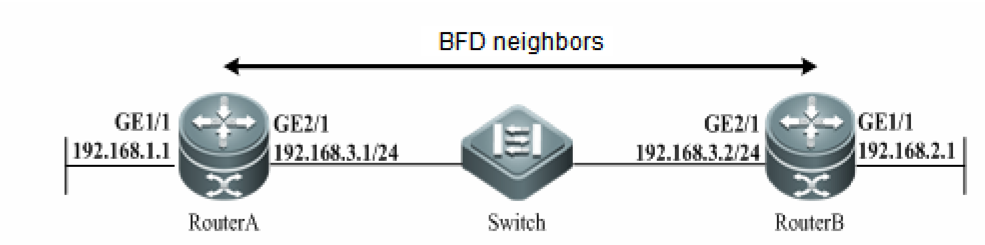
Example of Configuring BFD for RIP

Networking Requirement

Router A and Router B are interconnected through a L2 switch. Both routers run the RIP protocol and enable the BFD for RIP on the interface. After a link failure between Router B and L2 switch occurs, BFD detects the failure and notifies the RIP of the failure, triggering the rapid convergence.

Networking Topology

Figure 4 Topology of configuring BFD for RIP



Configuration Tips

- Router A Configuration

# Configure the Routed Port GE 2/1, the IP address, and the BFD session parameter for Router A.

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# interface GigabitEthernet2/1
Ruijie(config-if)# no switchport (This configuration is unnecessary for routers)
Ruijie(config-if)# ip address 192.168.3.1 255.255.255.0
Ruijie(config-if)# bfd interval 200 min_rx 200 multiplier 5
```

Configure the Routed Port GE1/1.

```
Ruijie(config-if)# exit
Ruijie(config)# interface GigabitEthernet1/1
Ruijie(config-if)# no switchport (This configuration is unnecessary for routers)
Ruijie(config)# ip address 192.168.1.1 255.255.255.0
```

# Enable RIP and configure the BFD for RIP to detect the neighbor 192.168.3.2.

```
Ruijie(config-if)# exit
Ruijie(config)# router rip
Ruijie(config-router)# version 2
Ruijie(config-router)# network 192.168.3.0
Ruijie(config-router)# network 192.168.1.0
Ruijie(config-router)# passive-interface GigabitEthernet 2/1
Ruijie(config-router)# bfd all-interfaces
```

- Router B Configuration

# Configure the Routed Port, the IP address, and the BFD session parameter for Router B.

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# interface GigabitEthernet 2/1
Ruijie(config-if)# no switchport (This configuration is unnecessary for routers)
Ruijie(config-if)# ip address 192.168.3.2 255.255.255.0
Ruijie(config-if)# bfd interval 50 min_rx 50 multiplier 3
```

# Configure the Routed Port GE 1/1.

```
Ruijie(config-if)# exit
Ruijie(config)# interface GigabitEthernet1/1
Ruijie(config-if)# no switchport (This configuration is unnecessary for routers)
Ruijie(config-if)# ip address 192.168.2.1 255.255.255.0
```

# Enable RIP and configure the BFD for RIP to detect the neighbor 192.168.3.1.

```
Ruijie(config-if)# exit
Ruijie(config-router)# router rip
Ruijie(config-router)# version 2
Ruijie(config-router)# network 192.168.3.0
Ruijie(config-router)# network 192.168.2.0
Ruijie(config-router)# passive-interface GigabitEthernet 2/1
Ruijie(config-router)# bfd all-interfaces
Ruijie(config-router)# end
Ruijie#
```

Verification

- View the BFD session of Router A

Field	Description
OurAddr	IP address for the session on the local end
NeighAddr	IP address for the adjacent session
LD/RD	Session ID on the local and remote end
RH/RS	Current status of the session peer end
Holdown(mult)	Time of not receiving the Hello packets on the local end of the session
State	Current session status
Int	Interface number for the session
Session state is UP and using echo function with 50 ms interval	Whether the session is in echo mode and the interval of sending frames. This information is shown only in echo mode.
Local Diag	Diagnosis information of the session
Poll bit	Whether the session configuration is modified.
MinTxInt	Minimum sending interval of the session on the local end
MinRxInt	Minimum receiving interval of the session on the local end
Multiplier	Timeout times detected on the local end
Received MinRxInt	Minimum sending interval of the session on the remote end
Received Multiplier	Timeout times detected on the remote end
Holdown (hits)	Session detection time and the detected timeout times
Hello (hits)	Minimum interval of receiving the Hello packet after the session negotiation
Rx Count	Number of BFD packets received on the local end
Rx Interval (ms) min/max/avg	Minimum/maximum/average interval of receiving the session on the local end
Tx Count	Number of BFD packets sent from the local end

Field	Description
Tx Interval (ms) min/max/avg	Minimum/maximum/average interval of sending the session from the local end
Registered protocols	Type of protocol registered to the session
Uptime	Time of keeping the session UP
Last packet	Last BFD packet received by the local end

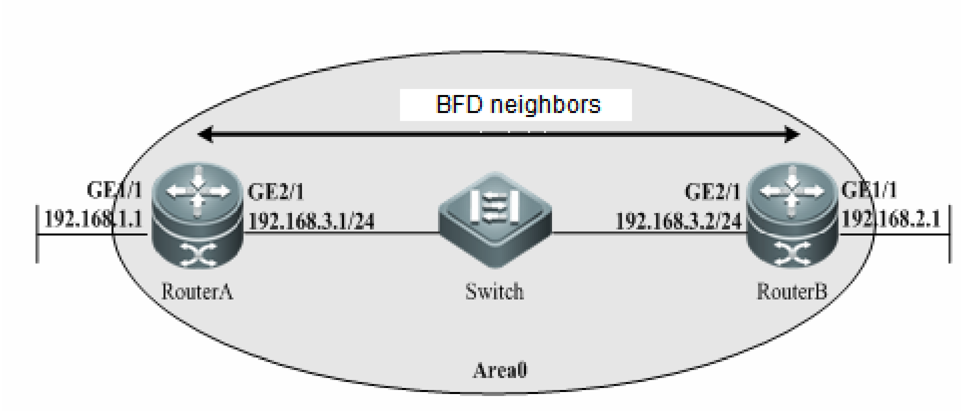
Example of Configuring BFD for OSPF

Networking Requirement

Router A and Router B are interconnected through a L2 switch. Both routers run the OSPF protocol and enable the BFD for OSPF on the interface. After a link failure between Router B and L2 switch occurs, BFD detects the failure and notifies the OSPF of the failure, triggering the rapid convergence.

Networking Topology

Figure 5 Topology of Configuring BFD for OSPF



Configuration Steps

- Router A Configuration

# Configure the Routed Port, the IP address, and the BFD session parameter for Router A.

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# interface GigabitEthernet2/1
Ruijie(config-if)# no switchport (This configuration is unnecessary for routers)
Ruijie(config-if)# ip address 192.168.3.1 255.255.255.0
Ruijie(config-if)# bfd interval 200 min_rx 200 multiplier 5
```

# Configure the Routed Port GE 1/1.

```
Ruijie(config-if)# exit
Ruijie(config)# interface GigabitEthernet1/1
Ruijie(config-if)# no switchport (This configuration is unnecessary for routers)
Ruijie(config)# ip address 192.168.1.1 255.255.255.0
```

# Enable OSPF and configure the BFD for OSPF to detect the neighbor 192.168.3.2.

```
Ruijie(config-if)# exit
Ruijie(config-router)# router ospf 123
Ruijie(config-router)# log-adj-changes detail
Ruijie(config-router)# network 192.168.3.0 0.0.0.255 area 0
Ruijie(config-router)# network 192.168.1.0 0.0.0.255 area 0
Ruijie(config-router)# bfd all-interfaces
Ruijie(config-router)# end
Ruijie#
```

- Router B Configuration

# Configure the Routed Port, the IP address, and the BFD session parameter for Router B.

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# interface GigabitEthernet 2/1
Ruijie(config-if)# no switchport (This configuration is unnecessary for routers)
Ruijie(config-if)# ip address 192.168.3.2 255.255.255.0
Ruijie(config-if)# bfd interval 50 min_rx 50 multiplier 3
```

# Configure the Routed Port GE 1/1.

```
Ruijie(config-if)# exit
Ruijie(config)# interface GigabitEthernet1/1
Ruijie(config-if)# no switchport (This configuration is unnecessary for routers)
Ruijie(config-if)# ip address 192.168.2.1 255.255.255.0
```

# Enable OSPF and configure the BFD for OSPF to detect the neighbor 192.168.3.1.

```
Ruijie(config-if)# exit
Ruijie(config-router)# router ospf 123
Ruijie(config-router)# log-adj-changes detail
Ruijie(config-router)# network 192.168.3.0 0.0.0.255 area 0
Ruijie(config-router)# network 192.168.2.0 0.0.0.255 area 0

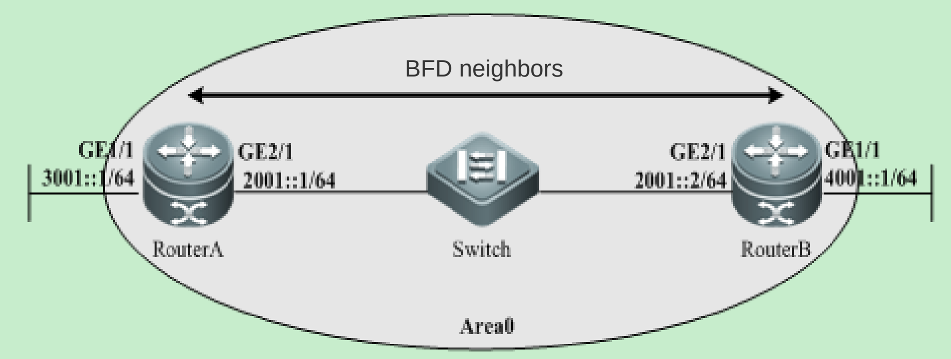
Example of Configuring BFD for OSPFv3

Networking Requirement

Router A and Router B are interconnected through the layer-2 switch. By running the Open Shortest Path First version 3 (OSPFv3) protocol on the switch, routes can be created and association between OSPFv3 and BFD can be enabled on interfaces of both routers. When the link between Router B and the layer-2 switch fails, the BFD function can quickly detect the failure and notify the switch running the OSPFv3 protocol to trigger fast convergence.

Network Topology

Figure 6 Association Between OSPFv3 and BFD



Configuration Tips

- Configure Router A

#Configure an interface (routed port), interface IP address, and BFD session parameters of the interface on Router A.

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# interface GigabitEthernet2/1
Ruijie(config-if)# ipv6 ospf 123 area 0
Ruijie(config-if)# ipv6 address 2001::1/64
Ruijie(config-if)# bfd interval 200 min_rx 200 multiplier 5
```

#Configure the interface GE1/1.

```
Ruijie(config-if)# exit
Ruijie(config)# interface GigabitEthernet1/1
Ruijie(config)# ipv6 ospf 123 area 0
Ruijie(config-if)# ipv6 address 3001::1/64
```

#Enable the OSPFv3 protocol and enable the association between OSPFv3 and BFD to detect neighbors of Router B.

```
Ruijie(config-if)# exit
Ruijie(config-router)# router ospf 123
Ruijie(config-router)# log-adj-changes detail
Ruijie(config-router)# bfd all-interfaces
Ruijie(config-router)# end
Ruijie#
```

- Configure Router B

#Configure an interface (routed port), interface IP address, and BFD session parameters of the interface on Router B.

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# interface GigabitEthernet 2/1
Ruijie(config-if)# ipv6 ospf 123 area 0
Ruijie(config-if)# ipv6 address 2001::1/64
Ruijie(config-if)# bfd interval 50 min_rx 50 multiplier 3
```

#Configure the interface GE1/1.

```
Ruijie(config-if)# exit
Ruijie(config)# interface GigabitEthernet1/1
Ruijie(config)# ipv6 ospf 123 area 0
Ruijie(config-if)# ipv6 address 4001::1/64
```

#Enable the OSPFv3 protocol and enable the association between OSPFv3 and BFD to detect neighbors of Router A.

```
Ruijie(config-if)# exit
Ruijie(config-router)# ipv6 router ospf 123
Ruijie(config-router)# log-adj-changes detail
Ruijie(config-router)# bfd all-interfaces
Ruijie(config-router)# end
Ruijie#
```

Verification

- Display BFD session establishment information on Router A.

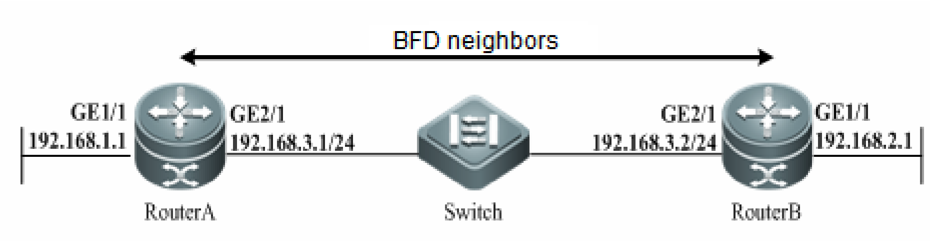
Example of Configuring BFD for Static Route

Networking Requirement

Router A and Router B are interconnected through a L2 switch. Both routers run the static route protocol and enable the BFD for static route on the interface. After a link failure between Router B and L2 switch occurs, BFD detects the failure and notifies the static route of the failure, triggering the static route removal from RIB and preventing the routing error.

Networking Topology

Figure 8 Topology of configuring BFD for Static Route



Configuration Tips

- Router A Configuration

# Configure the Routed Port, the IP address, and the BFD session parameter for Router A.

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# interface GigabitEthernet2/1
Ruijie(config-if)# no switchport (This configuration is unnecessary for routers)
Ruijie(config-if)# ip address 192.168.3.1 255.255.255.0
Ruijie(config-if)# bfd interval 200 min_rx 200 multiplier 5
```

# Configure the Routed Port GE 1/1.

```
Ruijie(config-if)# exit
Ruijie(config)# interface GigabitEthernet1/1
Ruijie(config-if)# no switchport (This configuration is unnecessary for routers)
Ruijie(config)# ip address 192.168.1.1 255.255.255.0
```

# Configure the BFD for static route to detect the neighbor 192.168.3.2.

Example of Configuring BFD for VRRP

Networking Requirement

Router A and Router B are interconnected through a L2 switch. Both routers run the VRRP protocol and enable the BFD for PBR on the interface to detect the master and backup routers. After a link failure between Router A and L2 switch occurs, BFD detects the failure, notifies VRRP of the failure, and triggers the decrease of the priority of the VRRP master router. As a result, the switchover between the master and backup routers, which enables the backup router rapidly.

Router A and Router B access the Internet through Router C and Router D respectively. Configure the static routes to establish the forwarding path between Router A and Router C, Router B and Router D and enable the BFD to detect the neighbor. At the same time, Router A and Router B are configured the BFD for VRRP to detect the forwarding path between the Router A and Router C, Router B and Router D. The detection failure triggers the decrease of the priority for VRRP master router and switchover between the master and backup routers, which enables the backup router rapidly.

Networking Topology

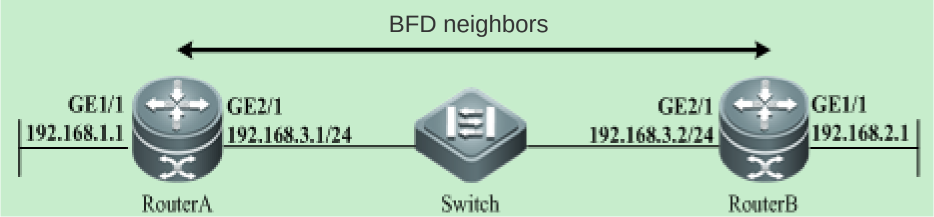
Example of Configuring QoS Policy in ECHO Mode for Guaranteeing Priority

Networking Requirement

Router A and Router B are interconnected through the layer-2 switch. A traffic pumping device of IXIA is used to pump traffic from Router A to Router B. A QoS policy is configured on Router A to guarantee the forwarding priority of echo packets sent from Router B.

Network Topology

Figure 11 QoS Policy Configuration in ECHO Mode



Configuration Tips

- Configuring Router A

#Configure packets of Port 3785 as BFD echo packets in the ACL.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#ip access-list extended 100
Ruijie(config-ext-nacl)#10 permit udp any any eq 3785
Ruijie(config-ext-nacl)#
```

#Configure the port queue template.

```
Ruijie(config)#port-queue 1
```

#Configure the user queue.

```
Ruijie(config)#user-queue uq1 outbound
Ruijie(config-user-queue)# cir 1000000 pir 1000000
Ruijie(config-user-queue)#
Ruijie#
```

#Configure the traffic classifier.

```
Ruijie(config)#traffic classifier tc1 or
Ruijie(config-traffic-classifier)# if-match acl 100
Ruijie(config-traffic-classifier)#
Ruijie#
```

#Configure the traffic behavior.

```
Ruijie(config)#traffic behavior tb1
Ruijie(config-traffic-behavior)# user-queue uq1 outbound
Ruijie(config-traffic-behavior)# service-class cs7 color green
Ruijie(config-traffic-behavior)#
```

#Configure the traffic policy.

```
Ruijie(config)#traffic policy tp1
Ruijie(config-traffic-policy)# classifier tcl behavior tb1 precedence 1
Ruijie(config-traffic-policy)#
```

#Apply the policy to traffic from the interface to application.

```
Ruijie(config)# interface GigabitEthernet2/1
Ruijie(config-if- GigabitEthernet2/1)#traffic-policy tp1 outbound
Ruijie(config-if- GigabitEthernet2/1)#
```

Example of Configuring BFD for the L3 Interface

Because the configuration of BFD for the L3 interface is usually used in FRR application and independent usage is not recommended. For details, see description in *MPLS-SCG.doc*.

Example of Configuring BFD for MPLS

For details, see description in *MPLS-SCG.doc*.

Example of Configuring BFD for VRRP

For details, see description in *VRRP-PLUS-SCG.doc*.

Dialing Configuration

1 Configuring WAN-4G

1.1 Overview

1.1.1 Brief Introduction

The fourth generation (4G) of mobile communication technology is a kind of new mobile communication technology. with a theoretical maximum data transmission rate of 100 Mbps, 4G network can support such high-bandwidth applications as HD video transmission and satellite communication. The following gives a description of some basic concepts involved in 4G function configuration.

1.1.2 Basic Concepts

APN

The Access Point Name (APN) determines the access mode through which the user accesses the 4G network. Currently, Ruijie devices support configuration of 3GNET.

PCO

User name and password.

Track

A Track object can track whether an IP address is reachable and whether an interface is up. The Track function separates the object to be tracked from the module that is interested in the status of this object. When the status of the Track object changes, track function modules can adopt different actions.

1.1.3 Working Principle

The network structure of the 4G mobile system can be divided into three layers: physical network layer, intermediate environment layer and application network layer. The physical network layer provides the access and routing functions, which are completed by the combine format of the wireless network and core network. The intermediate environment layer provides the function such as Qu’s mapping, address translation and completeness management. The interface between the physical network layer and the intermediate environment layer and its application environment is open. It facilitates development and provision of new applications and services, provides seamless and high-rate wireless services, and runs on multiple bands.

The configuration commands described here can implement the 4G interface communication functions of Ruijie devices.

1.1.4 Applications

4G integrates 3G and WLAN and can transmit high-quality video images. Its image transmission quality is equivalent to that of high-definition TV. The 4G system supports a download speed of 100 Mbps, a speed 2,000 times faster than that of current dial-up Internet access, and an upload speed of 20 Mbps, which can satisfy the requirements of almost all the users for wireless services. In addition, 4G network can be deployed in places not covered by DSL and cable TV modems and then expanded to the whole region. Obviously, 4G has incomparable superiority.

1.2 Configuring WAN-4G

To configure WAN-4G, you need to configure the following aspects: dialing function, 4G network access mode selection, protocol status of associated master interface, dial-on-demand, and anti-impact.

1.2.1 Single Card and Single Access Dialing Function

1.2.1.1 Configuration steps

Step	Configuration Task	Description
1	Configuring APN and PCO	Optional
2	Configuring APN and PCO	Optional
3	Configuring a Single 4G Interface to Associate with Track	Mandatory

1.2.1.2 Configuring APN and PCO

➢ Configuration method 1:

Command	Description
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# interface cellular *0/0*	Enters the interface configuration mode.
Ruijie(config-if-Cellular1)# profile create master apn *3gnet*	Configures APN.
Ruijie(config-if-Cellular 0/0)# profile create master username 3gnet password 0 3gnet	Configures the specified user name/password.

1: A public network SIM card can access the network normally without configuring the APN. The APN can also be configured manually by referring to the public network access requirements of the operator's network.

2: The APN needs to be correctly configured for a dedicated line SIM card. If there is an APN configuration error, the SIM card may access a public network.

3: After the APN or PCO configuration is modified, validate the configuration by using any one of the following three methods: Method 1: Execute **reset** on the interface to reset the interface. Method 2: Execute **shutdown** on the interface, and then execute **no shutdown** after waiting for at least two seconds. Method 3: Save the configuration and restart the host. If the configuration under the 4G interface is modified by remotely logging in to the device through the 4G line, only method 1 or 2 can be used. Any of the three methods can be used if the configuration is not modified through the 4G line.

Example: Configure the APN and PCO functions on the interface cellular 0/0.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#interface cellular 0/0
Ruijie(config-if-Cllular 0/0)#profile create master apn 3gnet
Ruijie(config-if-Cllular 0/0)#profile create master username user1 password pass1
Ruijie(config-if-Cllular 0/0)#show run interface cellular 0/0

Building configuration...
```

```
Current configuration: 141 bytes
!
interface cellular 0/0
 profile create master apn 3gnet
profile create master username user1 password pass1
```

Configuration method 2 (recommended):

Command	Description
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# interface cellular *0/0*	Enters the interface configuration mode.
Ruijie(config-if-Cellular 0/0)# plmn sent-username *abc* password 0 *123* [apn *3gnet*]	Configures the user name, password and APN (optional).

1: A public network SIM card can access the network normally without configuring the APN. The APN can also be configured manually by referring to the public network access requirements of the operator's network.

2: The APN needs to be correctly configured for a dedicated line SIM card. If there is an APN configuration error, the SIM card may access a public network.

3: The dialing time is usually within 20s when the mobile network signal is normal. The dialing time is relatively long when the signal is poor. Dialing attempts will continue until the dialing succeeds. The modem will be reset during the period, and then dialing attempts are continuously made.

4: After the router is restarted or the modem is reset, the modem needs to be initialized. In this case, the dialing time is about 90s.

Example: Configure the PCO and APN functions on the interface cellular 0/0.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#interface cellular 0/0
Ruijie(config-if-Cllular 0/0)# plmn sent-username abc password 0 123 apn 3gnet
Ruijie(config-if-Cllular 0/0)#show run interface cellular 0/0

Building configuration...
Current configuration : 141 bytes
!
interface cellular 0/0
 plmn sent-username abc password 0 123 apn 3gnet
```

1.2.1.3 Configuring a Single 4G Interface to Associate with Track

➢ Configuration method 1:

Command	Description
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# ip rns *1*	Enters the IP RNS configuration mode.
Ruijie(config-ip-rns)# icmp-echo *10.1.1.1*	Configures an IP RNS object and uses it to send ICMP packets.
Ruijie(config-ip-rns)# frequency *1000*	The interval for the RNS to send packets, in milliseconds. This interval must be greater than or equal to the timeout duration. The value is 60 seconds by default. The value range is from 10 to 604800000.
Ruijie(config-ip-rns)# timeout *1000*	The time used to judge timeout after the RNS sends packets, in milliseconds. The value is 5 seconds for the ICMP Echo packet and 9 seconds for the DNS packet by default. The value range is from 10 to 604800000 when ICMP Echo detection is used and from 1000 to 604800000 when DNS detection is used.
Ruijie(config)# track *1* rns *1*	Tracks the status of an IP RNS object and enters the Track mode.
Ruijie(config-track)# delay up *30*	(Optional) Specifies a period of time. When the status of a Track object changes, the status will change after this period of time. There is no delay by default.
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# interface cellular *0/0*	Enters the interface configuration mode.
Ruijie(config-if- cellular 1)# profile create master track *1*	Configures the ID of the Track object associated with the 4G interface status.
Ruijie(config-if- cellular 1)# backup-valid-check valid-timer 30 max-check-times 3	Configures the time and count of checking the availability query timer (60 seconds and 3 times by default).

Association of a 4G interface with Track can be configured on a Ruijie 4G router to check the link service status. When the status of the Track object changes to down, 4G link reset can be triggered to initiate a dial-up connection. After successful dialing, if the Track status is not up and remains to be down, the corresponding 4G interface is still unavailable in this situation. In this case, this timer needs to be started to perform check. If it is within the time of set "seconds * max-times", the time is 60s * 3 = 180s (the default configuration is used as an example), the corresponding Track status is still down, and the 4G link is reset again to initiate a dial-up connection, thus ensuring link recovery.

Example: Configure a single 4G card to associate with Track.

```
Ruijie# configure terminal
Enter configuration commands, one per line.   End with CNTL/Z.
Ruijie(config)# ip rns 1
Ruijie(config-ip-rns)# icmp-echo 10.1.1.1
Ruijie(config-ip-rns)# frequency 1000
Ruijie(config-ip-rns)# timeout 1000
Ruijie(config)# track 2 rns 1
Ruijie(config-track)# delay up 30
Ruijie(config-track)# exit
Ruijie(config)# interface cellular 0/0
Ruijie(config-if-cellular 0/0)# profile create master track 1
Ruijie(config-if-cellular 0/0)# backup-valid-check valid-timer 30 max-check-times 3
Ruijie(config-if-cellular 0/0)# show run interface cellular 0/0
Building configuration...
Current configuration : 141 bytes
!
interface cellular 0/0
 backup-valid-check valid-timer 30 max-check-times 3
 profile create master apn 3gnet
 profile create master username 3gnet password 3gnet
 profile create master track 1
```

➢ Configuration method 2 (recommended):

Command	Description
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# ip rns *1*	Enters the IP RNS configuration mode.
Ruijie(config-ip-rns)# icmp-echo *10.1.1.1*	Configures an IP RNS object and uses it to send ICMP packets.
Ruijie(config-ip-rns)# frequency *1000*	The interval for the RNS to send packets, in milliseconds. This interval must be greater than or equal to the timeout duration. The value is 60 seconds by default. The value range is from 10 to 604800000.
Ruijie(config-ip-rns)# timeout *1000*	The time used to judge timeout after the RNS sends packets, in milliseconds. The value is 5 seconds for the ICMP Echo packet and 9 seconds for the DNS packet by default. The value range is from 10 to 604800000 when ICMP Echo detection is used and from 1000 to 604800000 when DNS detection is used.
Ruijie(config)# track *1* rns *1*	Tracks the status of an IP RNS object and enters the Track mode.
Ruijie(config-track)# delay up *30*	(Optional) Specifies a period of time. When the status of a Track object changes, the status will change after this period of time. There is no delay by default.
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# interface cellular *0/0*	Enters the interface configuration mode.
Ruijie(config-if- cellular 0/0)# plmn status track *1*	Configures the ID of the track object associated with the 4G interface status.

Ruijie(config-if- cellular0/0)#backup-valid-check valid-timer 30 max-check-times 3	Configures the time and count of checking the availability query timer (60 seconds and 3 times by default).

Association of a 4G interface with Track can be configured on a Ruijie 4G router to check the link service status. When the status of the Track object changes to down, 4G link reset can be triggered to initiate a dial-up connection. After successful dialing, if the Track status is not up and remains to be down, the corresponding 4G interface is still unavailable in this situation. In this case, this timer needs to be started to perform check. If it is within the time of set "seconds * max-times", the time is 60s * 3 = 180s (the default configuration is used as an example), the corresponding Track status is still down, and the 4G link is reset again to initiate a dial-up connection, thus ensuring link recovery.

Example: Configure a single 4G card to associate with Track.

```
Ruijie# configure terminal
Enter configuration commands, one per line.    End with CNTL/Z.
Ruijie(config)# ip rns 1
Ruijie(config-ip-rns)# icmp-echo 10.1.1.1
Ruijie(config-ip-rns)# frequency 1000
Ruijie(config-ip-rns)# timeout 1000
Ruijie(config)# track 2 rns 1
Ruijie(config-track)# delay up 30
Ruijie(config-track)# exit
Ruijie(config)# interface cellular 0/0
Ruijie(config-if-cellular 0/0)# plmn status track 1
Ruijie(config-if-cellular 0/0)# backup-valid-check valid-timer 30 max-check-times 3
Ruijie(config-if-cellular 0/0)# show run interface cellular 0/0
Building configuration...
Current configuration : 141 bytes
!
interface cellular 0/0
backup-valid-check valid-timer 30 max-check-times 3
plmn status track 1
```

1.2.1.4 Configuring a Single 4G Interface to Associate with BFD

Command	Description
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# interface cellular 0/0	Enters the interface configuration mode.
Ruijie(config-if- cellular 0/0)# plmn status bfd	Configures the 4G interface status to associate with BFD.
Ruijie(config-if- cellular0/0)#backup-valid-check valid-timer 30 max-check-times 3	Configures the time and count of querying the availability query timer (60 seconds and 3 times by default).

Association of a 4G interface with BFD can be configured on a Ruijie 4G router to check the link service status. When the status of the BFD object changes to down, 4G link reset can be triggered to initiate a dial-up connection. After successful dialing, if the BFD status is not up and remains to be down, the corresponding 4G interface is still unavailable in this situation. In this case, this timer needs to be started to perform check. If it is within the time of set "seconds * max-times", the time is 60s * 3 = 180s (the default configuration is used as an example), the corresponding Track status is still down, and the 4G link is reset again to initiate a dial-up connection, thus ensuring link recovery.

Example: Configure a single 4G card to associate with BFD.

```
Ruijie# configure terminal
Enter configuration commands, one per line.    End with CNTL/Z.
Ruijie(config)# interface cellular 0/0
Ruijie(config-if-cellular 0/0)# plmn status bfd
Ruijie(config-if-cellular 0/0)# backup-valid-check valid-timer 30 max-check-times 3
Ruijie(config-if-cellular 0/0)# show run interface cellular 0/0
Building configuration...
Current configuration : 141 bytes
!
interface cellular 0/0
 backup-valid-check valid-timer 30 max-check-times 3
 plmn status bfd
```

1.2.1.5 Configuring a Single 4G Interface and RSSI Status Detection

Command	Description
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# interface cellular 0/0	Enters the interface configuration mode.
Ruijie(config-if- cellular 0/0)# plmn status rssi-detect -100 interval 16 ntimes 4 percent 50	Configures RSSI detection on a 4G interface.

🕮 RSSI status detection can be configured on a Ruijie 4G router to check the link service status for ntimes within the interval. If the current signal intensity is lower than the configured signal intensity value for ntimes * percent, the link is disconnected. Counter check is continued. If the checked signal intensity is greater than the configured signal intensity for ntimes * percent within the interval, the 4G link will be reset again to initiate a dial-up connection, thus ensuring link recovery.

Example: Configure a single 4G card to implement signal intensity detection.

```
Ruijie# configure terminal
Enter configuration commands, one per line.    End with CNTL/Z.
Ruijie(config)# interface cellular 0/0
Ruijie(config-if-cellular 0/0)# plmn status rssi-detect -100 interval 16 ntimes 4 percent 50
Ruijie(config-if-cellular 0/0)# show run interface cellular 0/0
Building configuration...
Current configuration : 141 bytes
!
interface cellular 0/0
 plmn status rssi-detect -100 interval 16 ntimes 4 percent 50
```

1.2.2 Single Card and Multiple Access Dialing Function

This access mode is applicable to the following scenarios: A single card configured with multiple APNs, user names and passwords. Different APNs access the corresponding dedicated line LNS servers. When the LNS server of a dedicated line fails, a normal LNS server can be accessed through another APN.

1.2.2.1 Configuring PCO and APN

Command	Description
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# interface cellular 0/0	Enters the interface configuration mode.
Ruijie(config-if-Cellular 0/0)# profile creat {master | slave} [apn 3gnet] username abc password {0 | 7} 333 {bfd | track 10 }	Configures the APN (optional), user name and password; track and bfd may not be used when slave is configured.

1: A public network SIM card can access the network normally without configuring the APN. The APN can also be configured manually by referring to the public network access requirements of the operator's network.

2: The APN needs to be correctly configured for a dedicated line SIM card. If there is an APN configuration error, the SIM card may access a public network.

3: Any change in the APN, user name and password related to master arising from this command will trigger redialing. Its effect is equal to one time of shutdown and no shutdown. Changes to the related parameters of slave will trigger redialing only when the system operates under a slave user currently.

Example 1: Configure the PCO and APN functions on the interface cellular 0/0.

```
Ruijie#configure terminal
Enter configuration commands, one per line.    End with CNTL/Z.
Ruijie(config)#interface cellular 0/0
Ruijie(config-if-Cllular 0/0)# profile creat master apn 3gnet username abc password 0 333 track 10
Ruijie(config-if-Cllular 0/0)#show run interface cellular 0/0

Building configuration...
Current configuration : 141 bytes
!
interface cellular 0/0
 profile creat master apn 3gnet username abc password 0 333 track 10
```

1.2.2.2 Configuring a Single 4G Interface to Associate with Track

Command	Description
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# ip rns 1	Enters the IP RNS configuration mode.
Ruijie(config-ip-rns)# icmp-echo 10.1.1.1	Configures an IP RNS object and uses it to send ICMP packets.

Ruijie(config-ip-rns)# frequency 1000	The interval for the RNS to send packets, in milliseconds. This interval must be greater than or equal to the timeout duration. The value is 60 seconds by default. The value range is from 10 to 604800000.
Ruijie(config-ip-rns)# timeout 1000	The time used to judge timeout after the RNS sends packets, in milliseconds. The value is 5 seconds for the ICMP Echo packet and 9 seconds for the DNS packet by default. The value range is from 10 to 604800000 when ICMP Echo detection is used and from 1000 to 604800000 when DNS detection is used.
Ruijie(config)# track 1 rns 1	Tracks the status of an IP RNS object and enters the Track mode.
Ruijie(config-track)# delay up 30	(Optional) Specifies a period of time. When the status of a Track object changes, the status will change after this period of time. There is no delay by default.
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# interface cellular 0/0	Enters the interface configuration mode.
Ruijie(config-if- cellular 0/0)# profile creat {master | slave} [apn 3gnet] username abc password {0 | 7} 333 track 10	Configures the ID of the Track object associated with the 4G interface status.
Ruijie(config-if- cellular0/0)#backup-valid-check valid-timer 30 max-check-times 3	Configures the time and count of checking the availability query timer (60 seconds and 3 times by default).

Association of a 4G interface with Track can be configured on a Ruijie 4G router to check the link service status. When the status of the Track object changes to down, 4G link reset can be triggered to initiate a dial-up connection. After successful dialing, if the Track status is not up and remains to be down, the corresponding 4G interface is still unavailable in this situation. In this case, this timer needs to be started to perform check. If it is within the time of set "seconds * max-times", the time is 60s * 3 = 180s (the default configuration is used as an example), the corresponding Track status is still down, and the 4G link is reset again to initiate a dial-up connection, thus ensuring link recovery.

Example: Configure a single 4G card to associate with Track.

```
Ruijie# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)# ip rns 1
Ruijie(config-ip-rns)# icmp-echo 10.1.1.1
Ruijie(config-ip-rns)# frequency 1000
Ruijie(config-ip-rns)# timeout 1000
Ruijie(config)# track 2 rns 1
Ruijie(config-track)# delay up 30
Ruijie(config-track)# exit
Ruijie(config)# interface cellular 0/0
Ruijie(config-if-cellular 0/0)# profile creat master apn 3gnet username abc password 0 333 track 10
Ruijie(config-if-cellular 0/0)# backup-valid-check valid-timer 30 max-check-times 3
Ruijie(config-if-cellular 0/0)# show run interface cellular 0/0
Building configuration...
```

```
Current configuration : 141 bytes
!
interface cellular 0/0
 backup-valid-check valid-timer 30 max-check-times 3
 profile creat master apn 3gnet username abc password 0 333 track 10
```

1.2.2.3 Configuring a Single 4G Interface to Associate with BFD

Command	**Description**
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# interface cellular 0/0	Enters the interface configuration mode.
Ruijie(config-if- cellular 0/0)# profile creat {master | slave} [apn 3gnet] username abc password {0 | 7} 333 bfd	Configures the 4G interface status to associate with BFD.
Ruijie(config-if- cellular0/0)#backup-valid-check valid-timer 30 max-check-times 3	Configures the time and count of querying the availability query timer (60 seconds and 3 times by default).

Association of a 4G interface with BFD can be configured on a Ruijie 4G router to check the link service status. When the status of the BFD object changes to down, 4G link reset can be triggered to initiate a dial-up connection. After successful dialing, if the BFD status is not up and remains to be down, the corresponding 4G interface is still unavailable in this situation. In this case, this timer needs to be started to perform check. If it is within the time of set "seconds * max-times", the time is 60s * 3 = 180s (the default configuration is used as an example), the corresponding Track status is still down, and the 4G link is reset again to initiate a dial-up connection, thus ensuring link recovery.

Example: Configure a single 4G card to associate with BFD.

```
Ruijie# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)# interface cellular 0/0
Ruijie(config-if-cellular 0/0)# plmn status bfd
Ruijie(config-if-cellular 0/0)# backup-valid-check valid-timer 30 max-check-times 3
Ruijie(config-if-cellular 0/0)# show run interface cellular 0/0
Building configuration...
Current configuration : 141 bytes
!
interface cellular 0/0
 backup-valid-check valid-timer 30 max-check-times 3
 profile creat master apn 3gnet username abc password 0 333 bfd
```

1.2.2.4 Configuring Switching of Different Access Points

Command	Description
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# interface cellular 0/0	Enters the interface configuration mode.
Ruijie(config-if-Cellular 0/0)# profile switch access-point	Switches the access point information.

1: Backup is configured. This command can be used to switch between the master account and slave account.

2: If only one access point is configured, the device automatically returns to the original access point if switching fails.

Example 1: Configure different access points on the interface cellular 0/0.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#interface cellular 0/0
Ruijie(config-if-Cllular 0/0)# profile switch access-point
Ruijie(config-if-Cllular 0/0)#show run interface cellular 0/0

Building configuration...

1.2.3 Selecting 4G Network Access Mode

1.2.3.1 Configuration steps

Step	Configuration Task	Description
1	Configuring to Directly Set Current Access Mode (manual handover between 3G/4G)	Mandatory

1.2.3.2 Configuring to Directly Set Current Access Mode

Command	Description
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# interface cellular *0/0*	Enters the interface configuration mode.
Ruijie(config-if-Cellular 1)# plmn mode manual **{ lte | wcdma | ehrpd | gsm | td-scdma | lte-evdo-cdma }**	Configures the current access mode: **lte, wcdma, ehrpd, gsm, td-scdma, lte-evdo-cdma.**
Ruijie(config-if-Cellular 1)# show cellular info network	Displays the current network access mode.

After the access mode configuration is modified, validate the configuration by using any one of the following three methods: Method 1: Execute **reset** on the interface to reset the interface. Method 2: Execute **shutdown** on the interface, and then execute **no shutdown** after waiting for at least two seconds. Method 3: Save the configuration and restart the host. If the configuration under the 4G interface is modified by remotely logging in to the device through the 4G line, only method 1 or 2 can be used. Any of the three methods can be used if the configuration is not modified through the 4G line.

Example: Select the network access mode.

```
Ruijie(config)#interface cellular 0/0
Ruijie(config-if-Cellular 1)# plmn mode manual lte
Ruijie(config-if-Cellular 1)# show cellular info network
 ------Network Information------
System mode = LTE mode(17)
System submode = HSPA+ mode(9)
Service state = Effective service(2)
```

```
Roam state = Not roaming status(0)
Service domain = EPS service(4)
Cell ID = 134326788
LAC = 32796
```

1.2.4 Associating 4G Interface with Interface Protocol Status

1.2.4.1 Configuration steps

Step	Configuration Task	Description
1	Associated Master Interface Protocol Status (BFD or TRACK)	Optional

1.2.4.2 Configuring Association with Master Interface Protocol Status

Command	Description
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# interface cellular *0/0*	Enters the interface configuration mode.
Ruijie(config-if-Cellular 1)# apply detect interface vlan 10 {bfd | track track_id}	Configures the protocol status association between the 4G link and primary link: BFD or TRACK.

Example: Configure association with the BFD protocol.

```
Ruijie(config)#interface cellular 0/0
Ruijie(config-if-Cellular 1)# apply detect interface vlan 10 bfd
Ruijie(config-if-Cellular 1)# show running-config interface cellular 0/0
Building configuration...
Current configuration : 65 bytes
!
interface Cellular 0/0
 apply detect interface vlan 10 bfd
```

1.2.5 Associating 4G Interface with Dial Stimulation (Interesting Traffic) Rule

1.2.5.1 Configuration steps

Step	Configuration Task	Description
1	Dial Stimulation (Interesting Traffic) Rule of 4G Interface Association	Optional

1.2.5.2 Configuring Association with Master Interface Protocol Status

Command	Description
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# interface cellular 0/0	Enters the interface configuration mode.
Ruijie(config-if-Cellular 1)# apply detect dial-list { list_id | list_name [idle-timeout seconds]	Configures the association of the 4G link with the dial stimulation (interesting traffic) rule.

Example: Configure the association with the interesting traffic rule with the ACL ID of 100.

```
Ruijie(config)#interface cellular 0/0
Ruijie(config-if-Cellular 1)# apply detect dial-list 100
Ruijie(config-if-Cellular 1)# show running-config interface cellular 0/0
Building configuration...
Current configuration : 65 bytes
!
interface Cellular 0/0
 apply detect dial-list 100
```

1.2.6 Configuring 4G Backup

1.2.6.1 Configuration steps

Step	Configuration task	Description
1	Configuring 4G Backup Function	Optional

1.2.6.2 Configuring 4G Backup Function

Command	**Description**
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# interface cellular *0/0*	Enters the interface configuration mode.
Ruijie(config-if-Cellular 1)# apply detect interface vlan 10 {bfd | track track_id}	Configures the protocol status association between the 4G link and primary link: BFD or TRACK.
Ruijie(config-if-Cellular 1)#apply dial-on-demand min-delay delay1 max-delay delay2;	Configures dial-on-demand and configures the random delay access range.

1. The association with master interface protocol status must be configured for dial-on-demand.

2. The 4G backup link will be used only when the protocol status of the primary link is down.

Example: Configure backup-on-demand and set the dial delay range to 1-60s.

```
Ruijie(config)#interface cellular 0/0
Ruijie(config-if-Cellular 1)# apply detect interface vlan 10 bfd
Ruijie(config-if-Cellular 1)# apply dial-on-demand min-delay 1 max-delay 60
uijie(config-if-Cellular 1)# show running-config interface cellular 0/0
Building configuration...
Current configuration : 65 bytes
!
interface Cellular 0/0
 apply detect interface vlan 10 bfd
 apply dial-on-demand min-delay 1 max-delay 60
Ruijie#
```

1.2.7 Configuring Interesting Traffic-Triggered Dialing

1.2.7.1 Configuration steps

Step	Configuration Task	Description
1	Configuring Interesting Traffic-Triggered Dialing	Optional

1.2.7.2 Configuring Dial-on-demand

Command	Description
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# interface cellular 0/0	Enters the interface configuration mode.
Ruijie(config-if-Cellular 1)# apply detect dial-list { list_id | list_name [idle-timeout seconds]	Configures the association of the 4G link with the dial stimulation (interesting traffic) rule.
Ruijie(config-if-Cellular 1)#apply dial-on-demand	Configures dial-on-demand and configures the random delay access range.

The association with master interface protocol status must be configured for dial-on-demand.

Example: Configure the interesting traffic-triggered dialing function, and use the ACL rule with the ACL ID 100 as the condition for triggering 4G dialing. In other words, the IP packet with any source address and a destination address of 7.7.7.7 will trigger 4G dialing.

```
Ruijie(config)#interface cellular 0/0
Ruijie(config-if-Cellular 1)# apply detect dial-list 100
Ruijie(config-if-Cellular 1)# apply dial-on-demand
Ruijie(config-if-Cellular 1)# show running-config interface cellular 0/0
Building configuration...
Current configuration : 65 bytes
!
ip access-list extended 100
   10 permit ip any host 7.7.7.7
!
interface Cellular 0/0
 apply detect dial-list 100
apply dial-on-demand
Ruijie#
```

1.2.8 Anti-traffic-impact

1.2.8.1 Configuration Steps

Step	Configuration Task	Description
1.	Configure the ACL for limiting traffic.	Mandatory.
2	Configure the anti-traffic-impact function.	Mandatory.

1.2.8.2 Configuring Anti-traffic-impact Function

Command	Description
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# ip access-list extended 109	Configures the ACL that limits traffic of video servers.
Ruijie(config-ext-nacl)# deny ip any host 192.168.50.246	Limits traffic destined for a specified destination address.
Ruijie(config-ext-nacl)# permit ip any any	Allows other traffic.
Ruijie(config)# interface cellular *0/0*	Enters the interface configuration mode.
Ruijie(config-if-Cellular 1)# apply detect interface vlan 10 {bfd | track track_id}	Configures protocol state association between the 4G link and primary link: BFD or TRACK.
Ruijie(config-if-Cellular 1)# apply traffic-anti-impact interface VLAN 1 list 109	Configures the anti-traffic-impact function.

1. Configure protocol state association of the primary interface to perform dialing on demand.

The anti-traffic-impact function is supported only on 4G mobile routers of the RSR820 series.

Example: Configure dialing on demand and set the dialing delay from 1s to 60s.

```
Ruijie(config)#interface cellular 0/0
Ruijie(config-if-Cellular 1)# apply detect interface vlan 10 bfd
Ruijie(config-if-Cellular 1)# a apply traffic-anti-impact interface VLAN 1 list 109
uijie(config-if-Cellular 1)# show running-config interface cellular 0/0
Building configuration...
Current configuration : 65 bytes
!
interface Cellular 0/0
 apply detect interface vlan 10 bfd
 apply traffic-anti-impact interface VLAN 1 list 109
Ruijie#
```

1.2.9 PIN Code Protection

This function sets a password for a SIM card to prevent unauthorized users from using the SIM card. The PIN code of the SIM card is 1234 by default. Three PIN code protection modes are available, with the differences as follows:

Command	**Use**	**Differences**	**Scenario**
simple	Simple PIN code protection mode: The user needs to use the CLI command to enter the current PIN code of the SIM card. If the PIN code is correct, the simple PIN code protection function is enabled; if the PIN code is wrong, the SIM card cannot be used, and PUK unlocking is needed (for details, refer to operation of the PUK unlocking scenario). Use the NO command to disable the simple PIN code mode.	The numeric string entered by the user is the PIN code corresponding to the SIM card. This PIN code is visible to the PIN code administrator and the security level is low.	The SIM card can be inserted into a router or mobile phone terminal supporting the PIN code input function.
strict-pin	Strict PIN code protection mode: The user needs to use the CLI command to enter the current PIN code of the SIM card and a HASH string. If the PIN code is correct, the strict PIN code protection function is enabled and the HASH string will replace the current PIN code; if the PIN code is wrong, the SIM card cannot be used, and PUK unlocking is needed (for details, refer to operation of the PUK unlocking scenario).	A new PIN code is obtained after the numeric string entered by the user is hashed. The new PIN code is invisible to the PIN code administrator and the security level is high.	The SIM card can only be inserted into Ruijie router for use.
bind-router	Binding the router PIN code protection mode: The user needs to use the CLI command to enter the current PIN code of the SIM card and a HASH string. If the PIN code is correct, the PIN code binding protection function is enabled and the current PIN code is replaced after hashing using the router serial number; if the PIN code is wrong, the SIM card cannot be used, and PUK unlocking is needed (for details, refer to operation of the PUK unlocking scenario).	A new PIN code is obtained after the router serial number is hashed. This PIN code is directly bound with the router and the security level is highest.	The SIM card can only be used on a fixed router of Ruijie.

1.2.9.1 Enabling PIN Code Protection

Command	Description
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# interface cellular 0/0	Enters the interface configuration mode.
Ruijie(config-if-Cellular 1)# plmn pin-protection simple 0 1234	Enables the simple PIN code protection function. The last numeric string in configuration is the PIN code corresponding to the SIM card.
Ruijie(config-if-Cellular 1)# plmn pin-protection bind-router 0 1234	Enables the PIN code protection function of router binding mode. The last numeric string in configuration is the PIN code corresponding to the SIM card.
Ruijie(config-if-Cellular 1)# plmn pin-protection strct-pin 12345678 0 1234	Enables the strictly encrypted PIN code protection function. The last numeric string in configuration is the PIN code corresponding to the SIM card. The first character string is a strictly encrypted hash string.

1. When a 3G card and the corresponding SIM card are inserted for the first time, the initial password of the SIM card is known by the customer. The password is 1234 by default if it was not changed before.

2. The router administrator enables the PIN code protection function through CLI. When this command is enabled, enter the correct initial PIN code of the SIM card. If the PIN code is wrong. The SIM card will be locked. PUK unlocking is needed. Refer to scenario 1 of PUK unlocking.

3. When the router is bound or the strict encryption mode is enabled, the PIN code has been encrypted and is not the original PIN code 1234 any more, and 1234 cannot be used on other devices (such as a mobile phone) to enable the PIN code protection function. Only the **no plmn pin-protection** command can be used on this router to disable the PIN code protection function.

4. In router binding or strict encryption mode, the new PIN code is encrypted for saving and invisible to the administrator.

5. Each time when the SIM card connects to the network in dial-up connection mode, the router will use the new PIN code to unlock the SIM card. If the PIN code is correct, normal dialing can be implemented and the SIM card can be used to access the network normally.

6. The three modes use the same command to cancel the PIN code protection: **no plmn pin-protection**. This command can be executed only when the PIN code protection command is executed.

7. The SIM card is relocated from router A to router B, router B has been configured with the PIN code protection related command, and a new PIN code is available. There are two cases for SIM card replacement:

Case 1: If the PIN code of SIM card is consistent with the PIN code for the CLI command of router B, the related process is the same as the initial use process. The code can be replaced directly for use. The router first uses the initial password to enable PIN code protection. After the function is enabled, a new PIN code is generated according to the binding or strict encryption algorithm. After that, the router will use the new PIN code to unlock the SIM card each time the 3G card connects to the 3G network in dial-up connection mode. If the PIN code is correct, normal dialing can be implemented and the 3G card can be used to access the network normally.

Case 2: If the PIN code of the SIM card inconsistent with the PIN code for the CLI command of router B, directly replacement may lead to locking of the SIM card. In this case, a designated administrator needs to unlock the SIM card by using the PUK code, and then reset the PIN code (for details, refer to the section about PUK unlocking).

Case 2 above can be handled by using the following three methods:

①: Before replacing the SIM card, use another device (such as a mobile phone) to change the PIN code of SIM card to the initial PIN code configured on the router, and then insert the card into the router for use;

②: Before replacing the SIM card, delete router configuration, insert the new card, and then configure the PIN protection function again;

③: The SIM card is locked after replacement. In this case, the corresponding PUN code of SIM card can be used to unlock it. Refer to the description about the PUK unlocking scenario.

Example: Configure PIN code protection (in router binding mode; the configuration for other modes is similar).

```
Ruijie(config)#interface cellular 0/0
Ruijie(config-if-Cellular 1)# plmn pin-protection bind-router 0 1234
uijie(config-if-Cellular 1)# show running-config interface cellular 0/0
Building configuration...
Current configuration : 65 bytes
!
interface Cellular 0/0
 plmn pin-protection bind-router 0 1234
```

1.2.9.2 Changing PIN Code

Use the PIN code changing command to change the PIN code if required.

Command	Description
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# interface cellular 0/0	Enters the interface configuration mode.
Ruijie(config-if-Cellular 1)# plmn pin-protection simple 0 1234	Enables the simple PIN code protection function. The last numeric string in configuration is the PIN code corresponding to the SIM card.
Ruijie(config-if-Cellular 1)# plmn modify 2345	Changes the PIN code.

1. The PIN code changing command can only run in the simple mode.

2. To run this command, judge the modem status. Therefore, the PIN code changing command may fail if the modem status is abnormal. A prompt message is displayed in the system log, and the user can try again later. The PIN code may also be changed through a mobile phone.

3. Command execution may fail if the operator’s network is busy or due to other factors.

4. Use this command with caution. When this command is used, it is necessary to save the existing router configuration.

Example: Configure PIN code protection (in router binding mode; the configuration for other modes is similar).

```
Ruijie(config)#interface cellular 0/0
Ruijie(config-if-Cellular 1)# plmn pin-protection bind-router 0 1234
Ruijie(config-if-Cellular 1)# plmn modify 2345
Proceed with modify pin code and write config?[N0] y
pin code modify success !
Ruijie(config-if-Cellular 1)# show running-config interface cellular 0/0
Building configuration...
Current configuration : 65 bytes
!
interface Cellular 0/0
 plmn pin-protection bind-router 0 2345
```

1.2.9.3 PUK Unlocking

The SIM card will be locked when a wrong PIN code is used to enabled PIN code protection. In this case, PUK unlocking is needed, and a new PIN code needs to be set for the SIM card. When the SIM card is in the PUK locking status, the user will be prompted using the system log printing form, and the user can use the sh cell info command to view the SIM card status.

Command	Description
Ruijie# configure terminal	Enters the global configuration mode.
Ruijie(config)# interface cellular 0/0	Enters the interface configuration mode.
Ruijie(config-if-Cellular 1)# plmn puk-unlock 12345678 1234	PUK unlocking; the first character string is the PUK code and the second character string is the new PIN code.

1. The PUK unlocking is required in the following cases:

Case 1: When the PIN code protection function is enabled, the PIN code behind the command is inconsistent with the corresponding PIN code of SIM card. The SIM card will be locked.

Case 2: After the router binding function of PIN code is enabled, the SIM card is removed and placed in another router with the same configuration for use. The SIM card will be locked.

Case 3: After the strict encryption function of PIN code is enabled, the SIM card is removed and placed in another router with different configuration for PIN code protection. The SIM card will be locked.

Case 4: When the SIM card is replaced, the initial password of the SIM card is inconsistent with the initial PIN code configured for the router. The SIM card will be locked.

2. After PUK unlocking, the PIN code protection is disabled in the SIM card.

3. Use the PUK unlocking command with caution. The SIM card will be damaged when the number of wrong PUK code attempts reaches 10. Before unlocking, you are recommended to first ask the operator about the PUK code corresponding to the SIM card. PUK unlocking can also be implemented through a mobile phone or other terminals.

Example: Configure PIN code protection (in router binding mode; the configuration for other modes is similar).

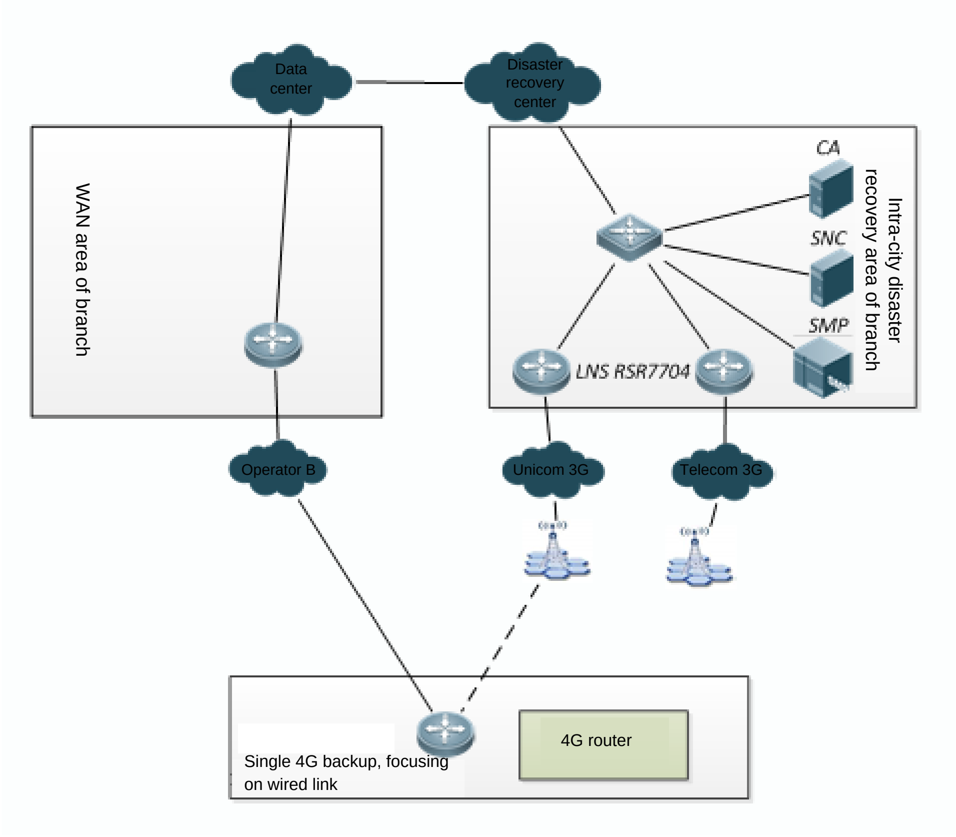
```
Ruijie(config)#interface cellular 0/0
Ruijie(config-if-Cellular 1)# plmn puk-unlock 12345678 1234
```

1.3 Examples of Typical Configuration

1.3.1 Disaster Recovery Scenario of Wired Link and Single 4G Link

1.3.1.1 Network requirements

The scenario involves the wired link and single 4G link disaster recovery. The wired link is used during normal operations. After communication of the wired link is interrupted, the device can automatically detect and then enable the 4G link. The 4G link is disconnected automatically after the wired link is recovered.



Wired and 4G networking topology

1.3.1.2 Configuration steps

Track detection is used in the configuration example. Alternatively, BFD can be used to associate with the wired link. For detailed configuration, refer to the BFD configuration section in the Configuration Manual.

```
(1) Configure the wired link for track detection:
!Here, it is assumed that the IP address of the LNS corresponding to the wired link is 10.10.10.10.
Ruijie(config)#ip rns 1
Ruijie(config-ip-rns-icmp-echo)# icmp-echo 10.10.10.10 out-interface VLAN 1 next-hop 10.10.10.1
Ruijie(config-ip-rns-icmp-echo)# timeout 3000
Ruijie(config-ip-rns-icmp-echo)# frequency 3000
Ruijie(config-ip-rns-icmp-echo)# ntime 3
Ruijie(config)# track 1 rns 1
```

```
(2) Configure 4G dial-on-demand:
Ruijie(config)#interface Cellular 0/0
Ruijie(config-if-Cellular 0/0)# apply detect interface VLAN 1 track 1
Ruijie(config-if-Cellular 0/0)# apply dial-on-demand

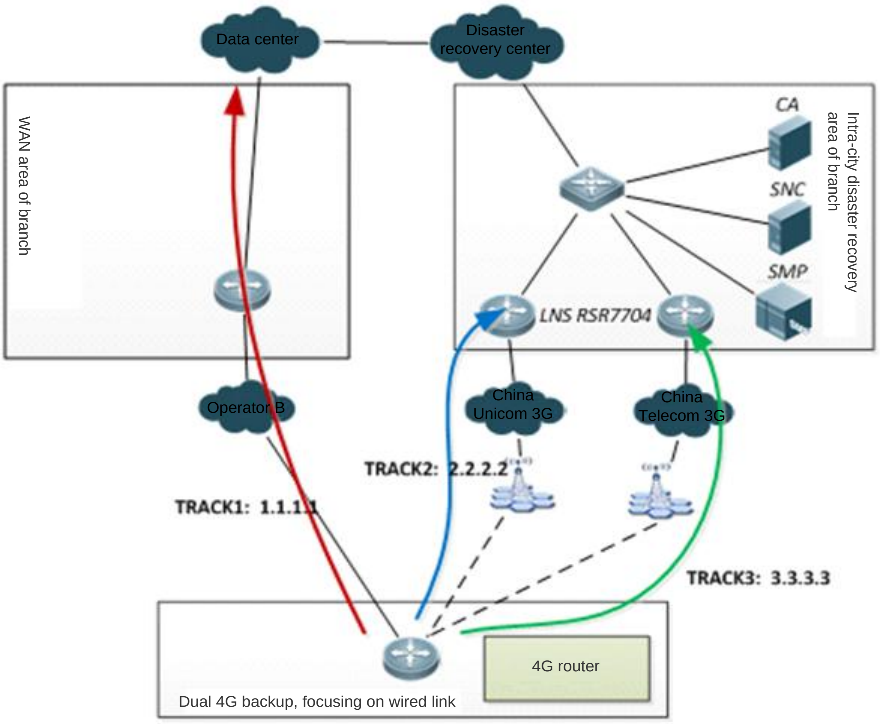
(3) Configure the static route:
Ruijie(config)#ip route 0.0.0.0 0.0.0.0 VLAN 1 track 1
Ruijie(config)#ip route 0.0.0.0 0.0.0.0 Cellular 0/0 100
```

1.3.2 Disaster Recovery Scenario of Wired Link and Dual 4G Links

1.3.2.1 Network requirements

The scenario involves the wired link and dual 4G link disaster recovery. The wired link is used during normal operations. After communication of the wired link is interrupted, the device can automatically detect and then enable backup 4G link 1. After communication of backup 4G link 1 is interrupted, the device can automatically detect and then enable backup 4G link 2. Backup 4G link 2 is disconnected automatically after backup 4G link 1 is recovered. Both backup 4G link 1 and backup 4G link 2 are disconnected after the wired link is recovered.

Note: The RSR820 series mobile routers do not support the use method of this scenario.



Wired link and dual 4G links networking topology

1.3.2.2 Configuration steps

Track detection is used in the configuration example. Alternatively, BFD can be used to associate with the wired link. For detailed configuration, refer to the BFD configuration section in the Configuration Manual.

```
(1) Configure the wired link for track detection:
!Here, it is assumed that the IP address of the LNS corresponding to the wired link is 1.1.1.1.
Ruijie(config)#ip rns 1
Ruijie(config-ip-rns-icmp-echo)# icmp-echo 1.1.1.1 out-interface VLAN 1 next-hop 1.1.1.1
Ruijie(config-ip-rns-icmp-echo)# timeout 3000
Ruijie(config-ip-rns-icmp-echo)# frequency 3000
Ruijie(config-ip-rns-icmp-echo)# ntime 3
Ruijie(config)# track 1 rns 1

!Here, it is assumed that the IP address of the LNS corresponding to backup 4G link 1 is 2.2.2.2.
Ruijie(config)#ip rns 2
Ruijie(config-ip-rns-icmp-echo)# icmp-echo 2.2.2.2 out-interface Cellular 0/0
Ruijie(config-ip-rns-icmp-echo)# timeout 3000
Ruijie(config-ip-rns-icmp-echo)# frequency 3000
Ruijie(config-ip-rns-icmp-echo)# ntime 3
Ruijie(config)# track 2 rns 2

(2) Configure 4G dial-on-demand:
Ruijie(config)#interface Cellular 0/0
Ruijie(config-if-Cellular 0/0)# apply detect interface VLAN 1 track 1
Ruijie(config-if-Cellular 0/0)# apply dial-on-demand

Ruijie(config)#interface Cellular 1/0
Ruijie(config-if-Cellular 1/0)# apply detect interface VLAN 1 track 1
Ruijie(config-if-Cellular 1/0)# apply detect interface Cellular 0/0 track 2
Ruijie(config-if-Cellular 1/0)# apply dial-on-demand min-delay 60 max-delay 120

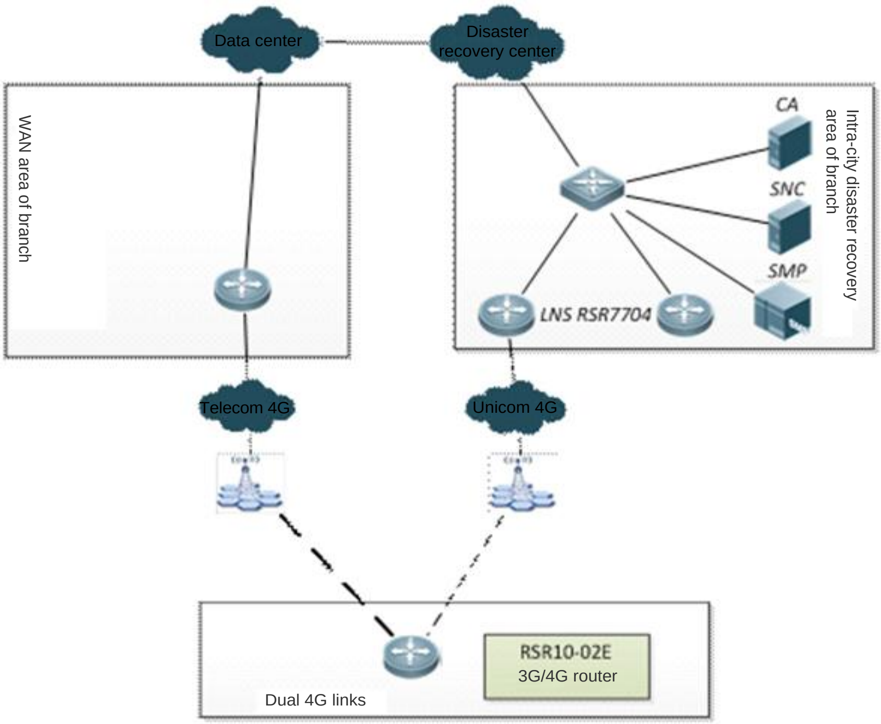
(3) Configure the static route:
ip route 0.0.0.0 0.0.0.0 VLAN 1 track 1
ip route 0.0.0.0 0.0.0.0 Cellular 0/0 100 track 2
ip route 0.0.0.0 0.0.0.0 Cellular 1/0 200 track 3
```

1.3.3 Scenario of Interesting Traffic-Triggered Dialing through Dual 4G Links

1.3.3.1 Network requirements

In this scenario, dialing is triggered by the interesting traffic over the dual 4G links. The active 4G link is used during normal operations, and the active 4G link is in the non-dialing status when there is no interesting traffic. When there is interesting traffic, dialing of the active 4G link is triggered. After communication of the active 4G link is interrupted, the device can automatically detect and then enable the backup 4G link. The backup 4G link needs interesting traffic to trigger dialing. The active 4G link is used preferably when the active 4G link is recovered from the fault.

Note: The RSR820 series mobile routers do not support the use method of this scenario.



Networking topology of interesting traffic-triggered dialing over dual 4G links

1.3.3.2 Configuration steps

```
(1) Configure the active 4G link for track detection:
!Here, it is assumed that the IP address of the LNS corresponding to backup 4G link 1 is 2.2.2.2.
Ruijie(config)#ip rns 2
Ruijie(config-ip-rns-icmp-echo)# icmp-echo 2.2.2.2 out-interface Cellular 0/0
Ruijie(config-ip-rns-icmp-echo)# timeout 3000
Ruijie(config-ip-rns-icmp-echo)# frequency 3000
Ruijie(config-ip-rns-icmp-echo)# ntime 3
Ruijie(config)# track 2 rns 2

(2) Configure the rule of interesting traffic-triggered dialing:
Ruijie(config)#ip access-list extended 100
Ruijie(config-ext-nacl)# 10 permit ip 124.124.124.0 0.0.0.255 any
Ruijie(config-ext-nacl)# 20 permit ip 126.126.126.0 0.0.0.255 any
Ruijie(config-ext-nacl)#!
Ruijie(config-ext-nacl)#!
Ruijie(config-ext-nacl)#ip access-list extended 199
Ruijie(config-ext-nacl)# 10 deny icmp any any
Ruijie(config-ext-nacl)# 20 permit ip any any
Ruijie(config-ext-nacl)#!

(3) Configure the 4G interesting traffic-triggered dialing:
Ruijie(config)#interface Cellular 0/0
Ruijie(config-if-Cellular 0/0)# apply detect dial-list 100
Ruijie(config-if-Cellular 0/0)# apply dial-on-demand

Ruijie(config)#interface Cellular 1/0
Ruijie(config-if-Cellular 0/0)# apply detect dial-list 199
Ruijie(config-if-Cellular 1/0)# apply detect interface Cellular 0/0 track 2
Ruijie(config-if-Cellular 1/0)# apply dial-on-demand min-delay 60 max-delay 120

(3) Configure the static route:
Ruijie(config)#ip route 0.0.0.0 0.0.0.0 Cellular 0/0 track 2
Ruijie(config)#ip route 0.0.0.0 0.0.0.0 Cellular 1/0 100
```

2 Configuring Dialup

2.1 PPPoE Dialup

2.1.1 PPPoE Overview

Ruijie Device supports PPP running on the Ethernet (PPPoE, PPP over Ethernet) interface for DDR. Its characteristics are like the DDR: stimulating dialup if there is data communication and automatically disconnecting the line when it is idle for the specified period.

The PPPoE implementation on Ruijie devices is similar to DDR Profiles, which binds the Ethernet interface to the logical interface and performs the negotiations on the logical interface.

2.1.2 PPPoE Configuration Tasks

From the implementation of PPPoE, the PPPoE configuration tasks include:

- Configuring the Ethernet interface
- Configuring the logical interface
- Configuring the necessary global parameters

2.1.2.1 Configuring the Ethernet interface

The configuration of the Ethernet interface includes:

- Enable the PPPoE on the interface
- Bind the Ethernet interface to the specified dialer pool

Some basic configurations of the Ethernet interface are also required, such as the interface activation (**no shutdown**).

Use the following command to enable PPPoE on the Ethernet interface in interface configuration mode.

Command	Function
Ruijie(config-if)# **pppoe enable**	Enables PPPoE.

Since PPPoE is implemented via DDR Profiles, it is required to bind the Ethernet interface to the specified dialer pool available for the use of the logical interface in DDR Profiles. Use the following commands to bind the Ethernet interface to the specified dialer pool in interface configuration mode.

Command	Function
Ruijie(config-if)# **pppoe-client dial-pool-number** *pool-number* **dial-on-demand**	Binds the Ethernet interface to the specified logical dialer pool (to enable the DDR function. The dialup to the PPPoE server is activated only when there is some message).
Ruijie(config-if)# **pppoe-client dial-pool-number** *pool-number* **no-ddr**	Binds the Ethernet interface to the specified logical dialer pool (to enable automatic dialup to the PPPoE server).

📖 One of **dial-on-demand** and **no-ddr** must be selected. **dial-on-demand** enables the PPPoE DDR function to disconnect the line when the specified idle period expires; **no-ddr** enables the PPPoE auto-dialup function to dial to the PPPoE server automatically.

2.1.2.2 Configuring the logical interface

All PPP negotiations of the PPPoE dialup are based on the logical interface, so it is required to configure the PPPoE dialup related parameters on the logical interfaces.

Use the following commands to configure the logical interface in global configuration mode.

Command	**Function**
Ruijie(config)# **interface dialer** *dialer-number*	Enters the specified logical interface.
Ruijie(config-if)# **ip address negotiate**	Obtains address from negotiation .
Ruijie(config-if)# **dialer pool** *pool-number*	Associates the dialer pool, with the one in the Ethernet interface one-by-one.
Ruijie(config-if)# **dialer idle-timeout** *seconds*	(Optional) Configures the timeout time to disconnect the line when the specified idle time times out.
Ruijie(config-if)# **encapsulation ppp**	Encapsulates PPP because PPPoE is based on PPP.
Ruijie(config-if)# **mtu 1488**	Configures the maximum transmission unit as 1488.
Ruijie(config-if)# **dialer-group** *dialer-group-number*	Sets the dialer group associated with the dialup activation rule.
Ruijie(config-if)# **ppp pap sent-username** *username* **password** *password*	Configures the username and password for authentication.

📖 Except for the command in step 4, all other commands are required. Especially in step 6, the MTU value must be 1488 for normal communication.

If the IP address of the logical interface is modified after a PPPoE connection has been set up, run the **clear pppoe tunnel** command to trigger PPPoE re-negotiation for the modification to take effect in privileged mode.

2.1.2.3 Configuring the necessary global parameters

The necessary PPPoE global parameters include:

- Define the dialup activation rule
- Configure the dialup route

To use PPPoE with other functions, such as NAT, it is required to configure other global parameters. The global parameters must be configured according to the actual conditions.

Use the following command to define the dialup activation rule in global configuration mode.

Command	**Function**
Ruijie(config)# **dialer-list** *dialer-group- number* **protocol** *protocol-name* {**permit** | **deny** | **list** *access-list-number* }	Defines the dialup activation rule.

Since the IP address of the interface is generally obtained from the negotiation and there is no directly-connected route of the logical interface, it is required to configure a dialup route to the destination for the logical interface with the PPPoE dialup, so that the data can be forwarded via the PPPoE interface.

Use the following command to configure the dialup route in global configuration mode.

Command	Function
Ruijie(config)# **ip route 0.0.0.0 0.0.0.0 dialer** *dialer-number* [**permanent**]	Sets the default route. The **permanent** option enables the route always valid, even when the logical interface is in the line invalid period (enable-timeout) (here, the logical interface is in the down status).

📖 It is also possible that the dialup route is not configured as the default route, and the specified route is configured as required. In whatever conditions, a dialup route must be configured to make dialup possible.

2.1.3 Monitoring PPPoE

Use the following commands to monitor the PPPoE in privileged EXEC mode.

Command	Function
Ruijie# **show pppoe** {**tunnel** | **session**}	Shows the PPPoE configuration.
Ruijie# **show interfaces dialer** *dialer-number*	Shows the logical interface configuration.
Ruijie# **debug pppoe** {**datas**|**errors**|**events**|**packets** }	Turns on the PPPoE debug switch.

2.2 Callback

2.2.1 Callback Overview

2.2.1.1 Introduction

The callback needs the client/server relation between the two parties of the dialup. One remote callback client dials to connect the callback server, and the callback server performs authentication for the dial-in user. If the authentication passes, the callback server uses the related information of the remote host for callback.

📖 If the callback fails due to busy line, no reply, or other reasons, no redialing is done. If the callback server has no available interface for callback, no retry will be done.

Callback client: remote device or host that requests the callback

Callback server: the device that accepts the callback request, and if the authentication passes, disconnects the current connection and locally initiates the dialing to the remote client.

2.2.1.2 Purposes

The callback is generally used in the following three scenarios:

- Save cost: The call charge may be different for different areas. For example, the dialing from village to city may be more expensive than the reverse direction, so it is possible to save cost by calling back from the city to village.

- Unified call charge: An organization may have quite a lot of branches. It is possible to call back from the center to the branches so that the calls are all paid by the center to facilitate the financial management and statistics.
- Security considerations: The callback numbers set for the callback server are the reliable and valid numbers that have been configured. This helps ensure the location of the callback client is valid, forbidding the invalid dialing from the range out of control.

2.2.1.3 Callback configuration tasks

Before configuring the callback, make sure the global DDR configuration preparations are completed. The callback configuration tasks involve:

- Configure the callback client
- Configure the callback server

Configuring the callback client

Use the following commands to configure the callback client for the device in global configuration mode.

Command	**Function**
Ruijie(config)# **interface** *type number*	Specifies the interface and enters the interface configuration mode.
Ruijie(config-if)# **dialer in-band**	Enables DDR.
Ruijie(config-if)# **encapsulation ppp**	Encapsulates PPP.
Ruijie(config-if)# **ppp authentication** {**chap** | **pap**}	Configures the PPP authentication.
Ruijie(config-if)# **dialer map** *protocol next-hop-address* **name** *hostname dial-string*	Maps the callback server hostname, address and telephone number.
Ruijie(config-if)# **ppp callback request**	Configures the current interface as the callback client.
Ruijie(config-if)# **dialer hold-queue** *[packets* [**timeout** *seconds*]]	(Optional) Configures the hold queue on the interface.
Ruijie(config-if)# **dialer-group** *group*	Associates the dialup activation rule.
Ruijie(config-if)# **async mode dedicated**	Enables automatic negotiation of the dialup mode.

Configuring the callback server

Use the following commands to configure the callback server for the device in global configuration mode.

Command	**Function**
Ruijie(config)# **interface** *type number*	Specifies the interface and enters the interface configuration mode.
Ruijie(config-if)# **dialer in-band**	Enables DDR.
Ruijie(config-if)# **encapsulation ppp**	Encapsulates PPP.
Ruijie(config-if)# **ppp authentication** {**chap** | **pap**}	Configures the PPP authentication.
Ruijie(config-if)# **dialer map** *protocol next-hop-address* **name** *hostname* **class** *classname dial-string*	Maps the callback client hostname, address and telephone number.
Ruijie(config-if)# **dialer hold-queue** *[packets]* [**timeout**	(Optional) Defines the hold queue on the interface.

Command	Function
seconds]]	
Ruijie(config-if)# **dialer enable-timeout** *seconds*	(Optional) Configures the line invalid waiting time (i.e. waiting time before the callback).
Ruijie(config-if)# **ppp callback accept**	Accepts the callback request.
Ruijie(config-if)# **dialer-group** *group*	Associates the dialup activation rule.
Ruijie(config-if)# **async mode dedicated**	Enables automatic negotiation of the dialup mode.
Router(config-pmap)# **exit**	Returns to the global configuration mode.
Ruijie(config)# **map-class dialer** *classname*	Defines the dialup mapping class and enters the mapping class configuration mode.
Ruijie(config-map-class)# **dialer callback-server** [**username**] [**dial-string**]	Configures the dialup mapping class as the callback server.

🕮 On the callback server, **dialer enable-timeout** controls the callback start time. If not configured, the default time is used, namely 15 seconds.

2.2.2 Monitoring Callback

Use the following command to monitor the callback in privileged EXEC mode.

Command	Function
Ruijie # **debug dialer packet**	Turns on the DDR debug switch.

2.3 Dialer Watch

2.3.1 Dialer Watch Overview

2.3.1.1 Introduction

The principle of the Dialer Watch is that the local route in the device is detected, and the backup dialup interface is triggered to dial if the specified route monitored does not exist in the routing table. If the specified route monitored appears in the routing table, the backup dialup interface will be triggered to disconnect the dialup line.

2.3.1.2 Purposes

For the general dialup backup, when the master line is disconnected, the backup link just turns from the standby status to the spoof up status but this does not indeed trigger the dialup. The dialup is triggered only when there is some traffic stimulation.

The purpose of the Dialer Watch is that it triggers the dialup as long as the monitored route disappears, freeing away the dependence of the traffic stimulation.

2.3.2 Dialer Watch Configuration Tasks

Before configuring the dialer watch, make sure the global DDR configuration preparations are completed. The dialer watch configuration tasks involve:

- Configure the backup interface for the DDR dialup
- Configure the monitored route for the dialup
- Configure how long to trigger dialup after the monitored route disappears
- Configure how long to disconnect the dialup after the monitored route appears

2.3.2.1 Configuring dialer watch

Use the following commands to configure the dialer watch in global configuration mode.

Command	**Function**
Ruijie(config)# **interface** *type number*	Specifies the interface and enters the interface configuration mode.
Ruijie(config-if)# **dialer watch-group** *group-number*	Enables dialer watch on the backup line.
Ruijie(config)# **dialer watch-list** group-number **ip** *ip-address address-mask*	Defines all the routes to be monitored. The dialer watch function can monitor multiple routes.
Ruijie(config)# **dialer watch-list** group-number **delay** {**connect** *connect-time* }	Configures how long to trigger dialup on the backup interface after the monitored route disappears. If not configured, the dialup is triggered immediately by default.
Ruijie(config)# **dialer watch-list** group-number **delay** {**disconnect** *disconnect-time* }	Configures how long to disconnect the dialup on the backup interface after the monitored route appears. By default, it is disconnected immediately.

Reliability Configuration

1. Configuring RLDP
2. Configuring MSTP
3. Configuring LLDP
4. Configuring VRRP
5. Configuring Hot Swapping
6. Configuring Multilink Gateway Load Balancing
7. Configuring Rns & track

Configuring RLDP

Overview

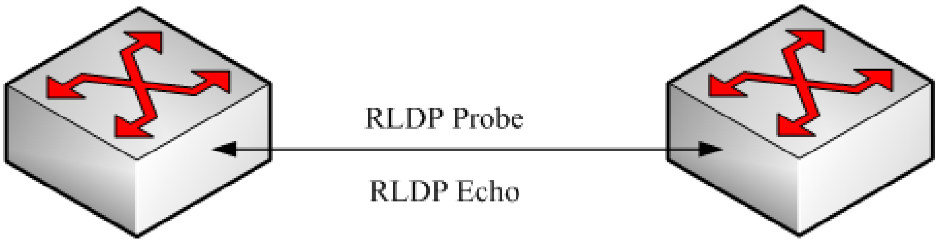
The Rapid Link Detection Protocol (RLDP) is one of Ruijie's proprietary link protocol designed to detect Ethernet link fault quickly.

General Ethernet link detection mechanism only makes use of the status of the physical connections and detects the connectivity of the link via the auto-negotiation of the physical layer. This detection mechanism has restrictions and sometimes cannot provide reliable link detection information for the user. For example, if the optical fiber receiving line pair on the optical interface is misconnected, due to the existence of the optical converter, the related port of the device is "linkup" physically but actually the corresponding layer-2 link cannot work for communications. Here is another example. There is an intermediate network between two Ethernet devices. Due to the existence of the network transmission relay devices, the same problem may occur if those relay devices are faulty.

The RLDP enables easy detection of Ethernet device link fault, including the one-way link fault, two-way link fault and loop link fault.

The RLDP implements the detection by exchanging the RLDP messages at the two ends of the link, as shown in Figure-1:

Figure-1:



The RLDP defines two protocol messages: Probe message and Echo message. The RLDP sends the Probe message of this port to the port with RLDP configured and in linkup status on regular basis, and waits for the Echo message from the neighbor port and waits for the Probe message sent by the neighbor ports. If a link is correct both physically and logically, a port shall be able to receive the Echo message of the neighbor port as well as the Probe message of the neighbor port. Otherwise, the link is considered abnormal.

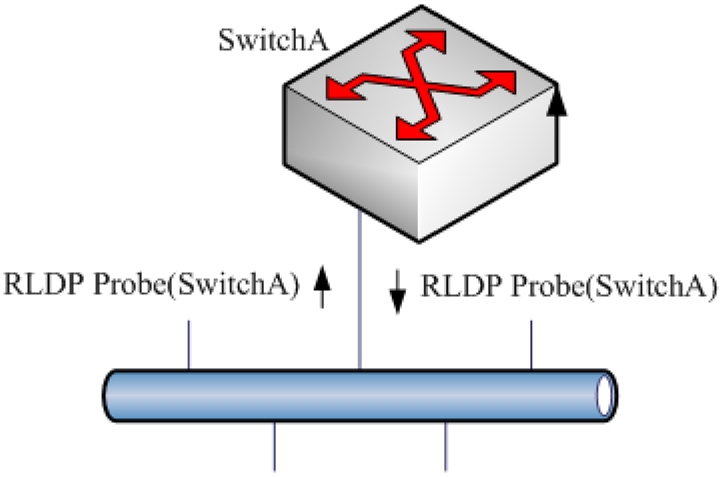
Note

To make use of the one-way detection and two-way detection functions of the RLDP, it is necessary to ensure the RLDP is enabled on the ports at both ends of the link. And, it is not allowed for a port with RLDP enabled to connect multiple neighbor ports. Otherwise, the RLDP cannot detect the health conditions of every neighbor link.

Typical Application

Loop detection:

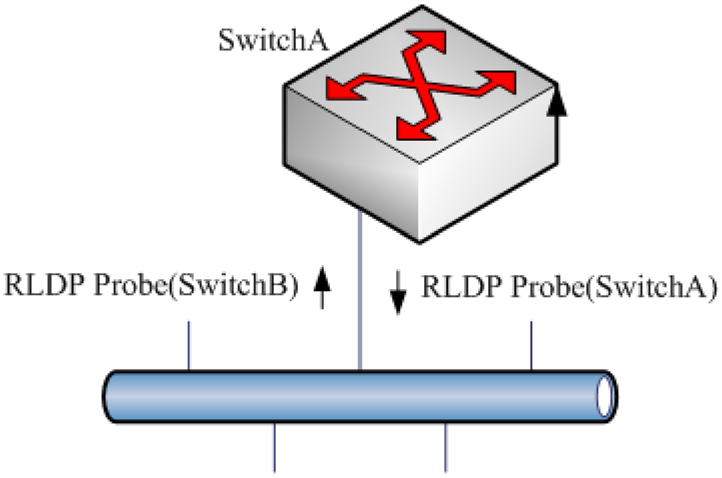
Figure-2: Loop detection



The so-called loop fault means that a loop appears on the links connected with the port. A shown above, on a port the RLDP receives the RLDP message sent from its machine, so the port is considered as loop fault. So, the RLDP deals with the fault according to the user configurations, including alarming, setting port violation, turning off the SVI with that port, turning off the port learning forwarding, and more.

One-way link detection:

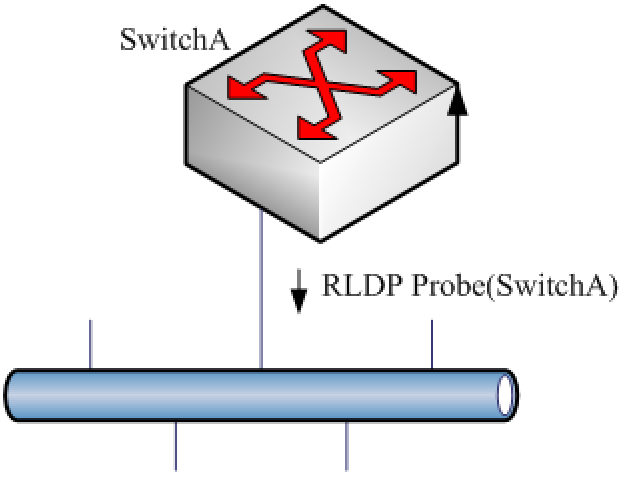
Figure-3: One-way link detection



The so-called one-way link detection means the link connected with the port can receive message only or send messages only (due to misconnection of the optical receiving line pair, for example). As shown above, the RLDP only receives the detection message from the neighbor port on a port, so it is considered one-way link fault. So, the RLDP deals with the fault accordingly according to the user configurations. In addition, if the port cannot receive any RLDP detection message, it is also considered one-way link fault.

Two-way link detection:

Figure-4:Two-way link detection



This means that fault occurs at the frame transmission/receiving at both ends of the link. As shown above, the port of the device sends the RLDP probe message but has never received the Echo message or the Probe message from the neighbors. So, it is considered two-way link fault. From the nature of the fault, the two-way fault actually includes the one-way fault.

Note

If the party at one of the two link ends has not enabled the RLDP, the diagnosis also shows two-way or one-way link fault. So, in configuring two-way link detection or one-way link detection, the administrator shall make sure that the RLDP is enabled at both ends to avoid the incorrect diagnosis information.

Default Configuration

Global RLDP status	Disabled
Port RLDP status	Disabled
Detection interval	3 seconds
Maximum detection times	2

Caution

The RLDP can be configured only on the basis of the switching interface (including AP) and the routing interface.

Caution All RLDP frames are untagged.

Caution In the RLDP fault processing type, the block function and the STP are mutually exclusive. In other words, if the fault processing type configured on the port is "block", it is recommended to disable STP; otherwise, since the STP cannot recognize one-way link, possibly the STP allows port forwarding but the RLDP is configured with port blocking.

Configuring RLDP

Enabling RLDP Globally

The RLDP works on the port only when the global RLDP is enabled.

In global configuration mode, follow these steps to enable RLDP:

Command	Function
Ruijie(config)# **rldp enable**	Enables global RLDP function.
Ruijie(config)# **end**	Returns to privileged EXEC mode.

Use the **no** form of this command to disable global RLDP.

Configuring RLDP on the Port

The RLDP operation is port-based, so the user needs to explicitly configure which ports shall run RLDP. In configuring the port RLDP, it is required to specify the diagnosis type and the troubleshooting method for the port at the same time. The diagnosis types include unidirection-detect, bidirection-detect and loop-detect. The troubleshooting methods include warning, block, shutdown-port, and shutdown-svi.

In global configuration mode, follow these steps to configure the RLDP on the port:

Command	Function
Ruijie(config)# **interface** *interface-id*	Enters interface configuration mode.
Ruijie(config-if)# **rldp port** {**unidirection-detect** | **bidirection-detect** | **loop-detect** } {**warning** | **shutdown-svi** | **shutdown-port** | **block**}	Enables RLDP on the port and configures the diagnosis type and troubleshooting method at the same time.
Ruijie(config-if)# **end**	Returns to privileged EXEC mode.

The **no** form of this command disables RLDP on the port and the configured detection types one by one.

In the example below, the RLDP is configured on GigabitEthernet 0/5, and multiple diagnosis types and troubleshooting methods are specified:

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitEthernet 0/5
Ruijie(config-if)# rldp port unidirection-detect
shutdown-svi
Ruijie(config-if)# rldp port bidirection-detect warning
Ruijie(config-if)# rldp port loop-detect block
Ruijie(config-if)# end
Ruijie# show rldp interface gigabitEthernet 0/5
port state     : normal
local bridge    : 00d0.f822.33ac
neighbor bridge : 0000.0000.0000
neighbor port   :
unidirection detect information:
action : shutdown svi
state  :  normal
bidirection detect information :
action : warnning
state  :  normal
loop detect  information    :
action : block
state  :  normal
```

Several precautions in configuring port detection:

- The routing interface does not support the shutdown-svi error handling method, so this method is not executed in case of the occurring of detection error.
- In configuring loop detection, the neighbor devices downward connected with the port cannot enable the RLDP detection; otherwise, the port cannot have correct detection.
- If the block method is configured on the aggregated port and the link detection error happens, do not change the member port relations of the aggregate port before the port reset detection; otherwise, the forwarding status of the member interface may have unexpected effects of forwarding status.
- If the RLDP detects link error, alarm information will be given. The user can send the alarm information to the log server by configuring the log function. At least 3 levels of log shall be ensured.
- You are recommended to specify the diagnosis type of the loop detection to shutdown-port for the reason that for some devices, even if the device detects the loop and specifies the block port, a large amount of packets will be sent to the CPU for the hardware chip limitation.
- If you configure RLDP on AP port, you are recommended to specify the diagnosis type of loop detection to shutdown-port.

Configuring RLDP Detection Interval

The port with the RLDP function enabled will send the RLDP Probe messages on a regular basis.

In global configuration mode, follow these steps to configure the RERP detection interval:

Command	**Function**
Ruijie(config)# **rldp detect-interval** interval	Configures the detection interval within the range 2-15s, 3s by default.
Ruijie(config)# **end**	Returns to privileged EXEC mode.

The **no** form of the command restores the value to its default.

Configuring the Maximum RLDP Detection Times

If the port with RLDP enabled cannot receive messages from neighbors in the maximum detection period (maximum detection times X detection interval), that port will be diagnosed as faulty. See the Overview for details of the fault types.

In global configuration mode, follow these steps to configure the RERP maximum detection times:

Command	**Function**
Ruijie(config)# **rldp detect-max** Num	Configures the maximum detection times, num range 2-10, 2 by default.
Ruijie(config)# **end**	Returns to privileged EXEC mode.

The **no** form of this command restores the value to its default.

Note

The maximum detection times only take effect in the unidirectional link detection and bidirectional link detection, and will not take effect if only loop detection is enabled on a port.

Restoring the RLDP Status of the Port

The port with shutdown-port troubleshooting method configured cannot resume the RLDP detection actively after a fault occurs. If the user confirms the fault removed, run the recovery command to restart the RLDP on the shutdown port. This command sometimes may make the other ports with detection errors resume.

In privileged EXEC mode, follow these steps to resume the RLDP detection of the port:

Command	**Function**
Ruijie# **rldp reset**	Makes any port with RLDP detection failure resume the detection.

Note

The **errdisable recover** command can be used in the global configuration mode to restart, instantly or at fixed time, the RLDP detection of the port that is set violation by RLDP. It is worth mentioning that when there are some relay devices between rldp ports, if you use **errdisable recover interval** to restore the fault timely, you need to set the value of rldp detection time greater than that of **errdisable recover interval**, that is, the value of detect-interval* detect-max total time is greater than that of **errdisable recover interval** to prevent error judgment.

Enabling RLDP Neighbor Negotiation

RLDP neighbor negotiation is disabled by default.

In global configuration mode, follow these steps to configure RLDP neighbor negotiation:

Command	Function
Ruijie(config)# **rldp neighbor-negotiation**	Enables RLDP neighbor negotiation.
Ruijie(config)# **no rldp neighbor-negotiation** Ruijie(config)# **default rldp neighbor-negotiation**	Disables RLDP neighbor negotiation.

Note

With neighbor negotiation enabled, RLDP unidirectional-/bidirectional-link detection starts only after the neighbor negotiation is successful. (Receiving the Prob message from the neighbor indicates the neighbor negotiation is successful.)

Displaying RLDP Configuration

Displaying the RLDP Status of All Ports

In privileged EXEC mode, run the following commands to display the RLDP global configuration and the port detection information with RLDP detection configured:

Command	Function
Ruijie# **show rldp**	Displays the RLDP global configuration and the port detection information with RLDP detection configured

In the example below, the **show rldp** command is used to display the detection information of all RLDP ports:

```
Ruijie# show rldp
rldp state          : enable
rldp hello interval     : 2
rldp max hello      : 3
rldp local bridge   : 00d0.f8a6.0134
```

```
------------------------------------------------
interface GigabitEthernet 0/1
port state:normal
neighbor bridge     : 00d0.f800.41b0
neighbor port   : GigabitEthernet 0/2
unidirection detect information:
action  : shutdown svi
state   : normal

interface GigabitEthernet 0/24
port state:error
neighbor bridge     : 0000.0000.0000
neighbor port   :
bidirection detect information :
action  : warnning
state   : error
```

As shown above, port GigabitEthernet 0/1 is configured with unidirection detection. No error is detected now, and the port status is normal. Port GigabitEthernet 0/24 is configured with bidirection detection, and bidirection fault is detected.

Displaying the RLDP Status of the Specified Port

In privileged EXEC mode, run the following command to display the RLDP detection information of the specified port:

Command	Function
Ruijie# **show rldp interface** *interface-id*	Displays the RLDP detection information of interface-id.

In the example below, the **show rldp interface GigabitEthernet** *0/1* command is used to display the RLDP detection information of port fas0/1:

```
Ruijie# show rldp int GigabitEthernet 0/1
port state     :error
local bridge   : 00d0.f8a6.0134
neighbor bridge : 00d0.f822.57b0
neighbor port   : GigabitEthernet 0/1
unidirection detect information:
action: shutdown svi
state :  normal
bidirection detect information :
action : warnning
state :  normal
loop detect  information    :
action: shutdown svi
state :  error
```

As shown above, the port GigabitEthernet 0/1 is configured with three detection types: unidirection detection, bidirection detection and loop detection. The troubleshooting methods are shutdown-svi and warning. Error is found in loop detection so the current port status is error. Accordingly, the SVI of the port is shutdown.

Configuring MSTP

STP and RSTP Overview

Ruijie series supports both the STP protocol and the RSTP protocol, as well as complying with the IEEE 802.1D and IEEE 802.1w standards.

The STP protocol can prevent broadcast storm caused by link loops and provide link redundancy and backup.

For the layer 2 Ethernet, there is only one active channel between two LANs to avoid broadcast storm. However, it is necessary to set up redundant links to improve the reliability of a LAN. Furthermore, some channels should be in the backup status in order to take up its work when a link fails. It is obviously hard to control this process by manual. The STP protocol can complete this work automatically. It enables a device in a LAN to:

- Discover and activate an optimal tree-type topology of the LAN.
- Detect and fix failures and automatically update the network topology to offer the possible optimal tree-type structure at any time.

The LAN topology is automatically calculated by a set of bridge parameters set by the administrator. The proper configuration of these parameters is helpful to offer an optimal solution.

The RSTP protocol is completely compatible with the 802.1D STP protocol downward. As with traditional protocol, the RSTP protocol can prevent loop and offer link redundency. The most critical feature of the RSTP protocol is quickness. If the bridges in a LAN support the RSTP protocol and are configured appropriately by administrators, it will take no more than 1 second to re-span the topology tree once the network topology changes (it takes about 50 seconds for traditional STP protocol to re-span the topology tree).

Caution

For the switch buffer control, see the chapter *Buffer Control* in *Configuring QOS*.

Bridge Protocol Data Units (BPDU):

A stable tree-type topology depends on the following elements :

- The unique bridge ID of each bridge consists of the bridge priority and the MAC address.
- The root path cost refers to the cost from a bridge to the root bridge.
- Each port ID consists of the port priority and port number.

By exchanging the Bridge Protocol Data Units (BPDU) frame destined to the multicast address 01-80-C2-00-00-00 (in hex), bridges gets the information necessary for building the optimal tree-type topology.

A BPDU is comprised of the following elements:

- Root Bridge ID (root bridge ID that a bridge considers)
- Root Path cost (Root Path cost of a bridge).
- Bridge ID (ID of a bridge).

- Message age (the live time of the message)
- Port ID (port ID sending the message).
- Forward-Delay Time, Hello Time and Max-Age: time parameters.
- Other flag bits, such as network topology change and port status.

Once a port of a bridge receives a BPDU message whose priority is higher than its priority (or smaller bridge ID and smaller root path cost), the bridge will store this message on the port while updating and propagating them to all other ports. If the BPDU with lower priority is received, the bridge will discard this message.

This mechanism propagates a BPDU message of higher priority in the whole network. As a result:

- A bridge is elected to be the root bridge in the network.
- Each bridge other than the root bridge has a root port that offers a shortest path to the root bridge.
- Each bridge will calculate the shortest path to the root bridge.
- Each LAN has a designated bridge that lies in the shortest path between this LAN and the root bridge. The port for connecting the designated bridge and the LAN is referred to as the designated port.
- The root port and the designated port are in the forwarding status.
- Other ports beyond the spanning tree are in the discarding status.

Bridge ID

As specified in IEEE 802.1W standard, each bridge has an unique bridge ID based on which the root bridge is elected in spanning tree algorithm. The bridge ID consists of eight bytes, in which the last six bytes are the MAC address of the bridge, and the first two bytes are shown in the table below. Of which, the first four bits denote the priority, while the last twelve bits denote the system ID for extending the protocol in the future. This value is 0 in the RSTP, so the priority of the bridge should be configured as the multiple of 4096.

	Priority value				**System ID**											
Bit	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
Value	32768	16384	8192	4096	2048	1024	512	256	128	64	32	16	8	4	2	1

Spanning-Tree Timers

The following describes three timers impacting the performance of spanning tree.

- Hello timer: Interval to send the BUDU message.
- Forward-Delay timer: Interval to change the port status, that is, the time interval at which the port switches from the listening status to the learning status and vice versa when the RSTP protocol runs in the compatible STP protocol mode.
- Max-Age timer: The longest time for the BPDU message. The system will discard the message when the timer times out.

Port Roles and Status

A port plays a role to present its function in the network topology.

- Root port: The port that provides the shortest path to the root bridge.
- Designated port: The port through which each LAN is connected to the root bridge.

- Alternate port: The alternate port of the root port that will take up its work when the root port fails.
- Backup port: The backup port of the designated port. If two ports of a bridge are connected to a LAN, the port with higher priority is the designated port and the other one is the backup port.
- Disable port: The port that is not in the active status, namely, the ports whose operation status is down.

Figure 1, Figure 2 and Figure 3 below show the roles of various ports:

R = Root port D = Designated port A = Alternate port B = Backup port

Unless otherwise stated, the priorities of these ports are in the descending order from left to right.

Figure-1

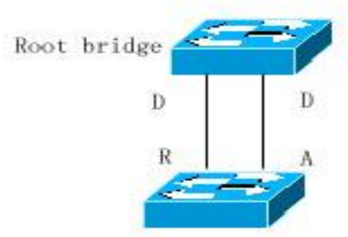


Figure-2

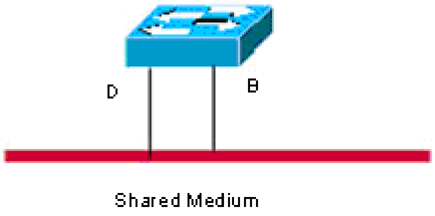

Figure-3

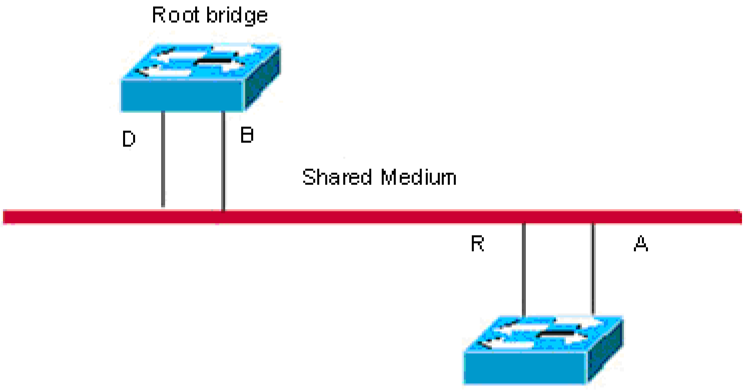


There are three port states for every port to indicate whether the data packet is forwarded and control the topology of the whole spanning tree.

- Discarding: Neither forward the received frame nor learn about the source Mac address.
- Learning: Do not forward the received frame, but learn about the source Mac address, so it is a transitional status.

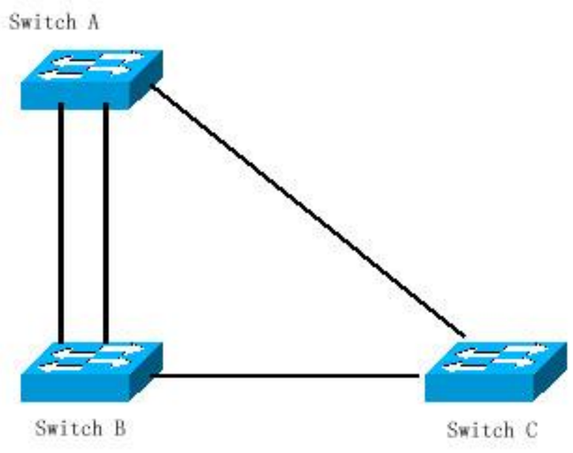
- Forwarding: Both forward the received frame and learn about the source Mac address.

For the stable network topology, only the root port and designated port can be the forwarding status, while other ports are only in the discarding status.

Generating a Network Topology Tree (Typical Application Solution)

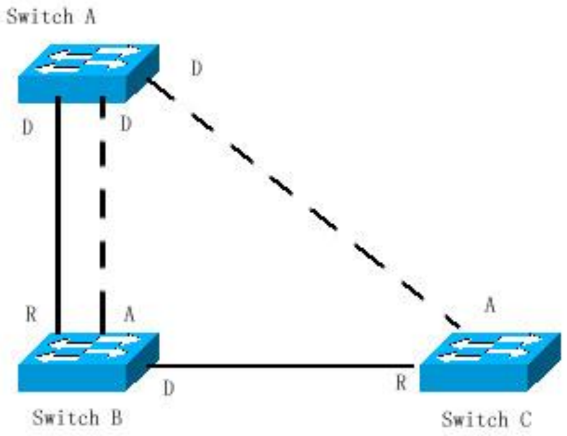
We now describe how the STP and RSTP protocols span a tree-type structure by the mixed network topology. As shown in Figure 4, the bridge IDs of Switches A, B and C are assumed in the ascending order. Namely, Switch A presents the highest priority. There is the 1000M link between switch A and switch B, and the 10M link between switch A and switch C, while it is the 100M link between switch B and switch C. Switch A acts as the backbone switch of this network and implements the link redundancy for both Switch B and Switch C. Obviously, broadcast storm would occur if all these links are active.

Figure-4



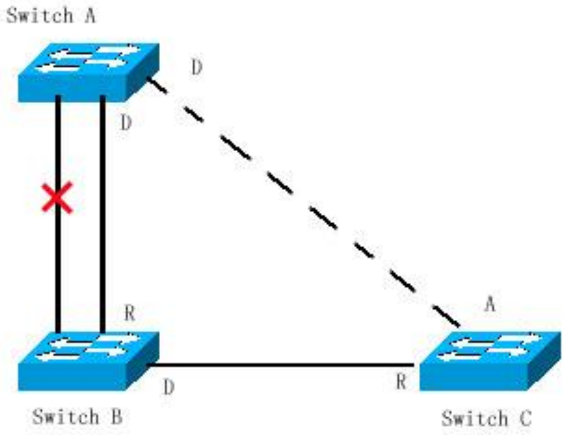
If all of these three switches enable the Spanning Tree protocol, they will select switch A as the root bridge by exchanging BPDU message. Once Switch B detects that two ports are connected to Switch A, it will select the port with the highest priority as the root port, while another one is selected as the alternate port. Meanwhile, Switch C detects that it can reach Switch A through Switch B or directly. However, Switch C discovers that the cost of the path from Switch B to Switch A is lower than that directly (For the costs corresponding to various paths, refer to table ***), so Switch C selects the port connected with Switch B as the root port, while the one that connected with Switch A as the alternate port. Various ports enter the corresponding status after their roles are determined. As a result, the network topology is generated as shown in Figure 5.

Figure-5



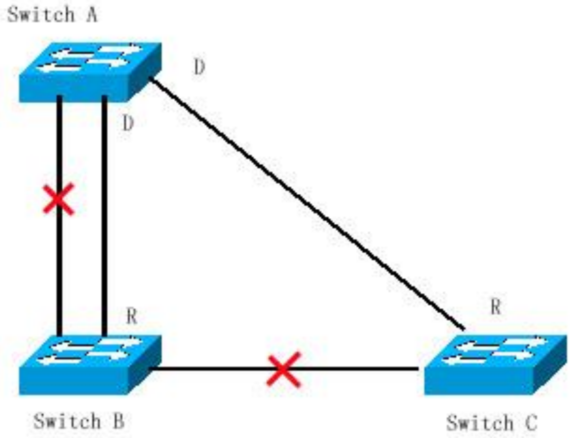
If the active path between Switch A and Switch B fails, the backup path will work. Consequently, the network topology is generated as shown in Figure 6.

Figure-6



If the path between Switch B and Switch C fails, Switch C will automatically switch the alternate port to the root port. Consequently, the network topology is generated as shown in Figure 7.

Figure-7



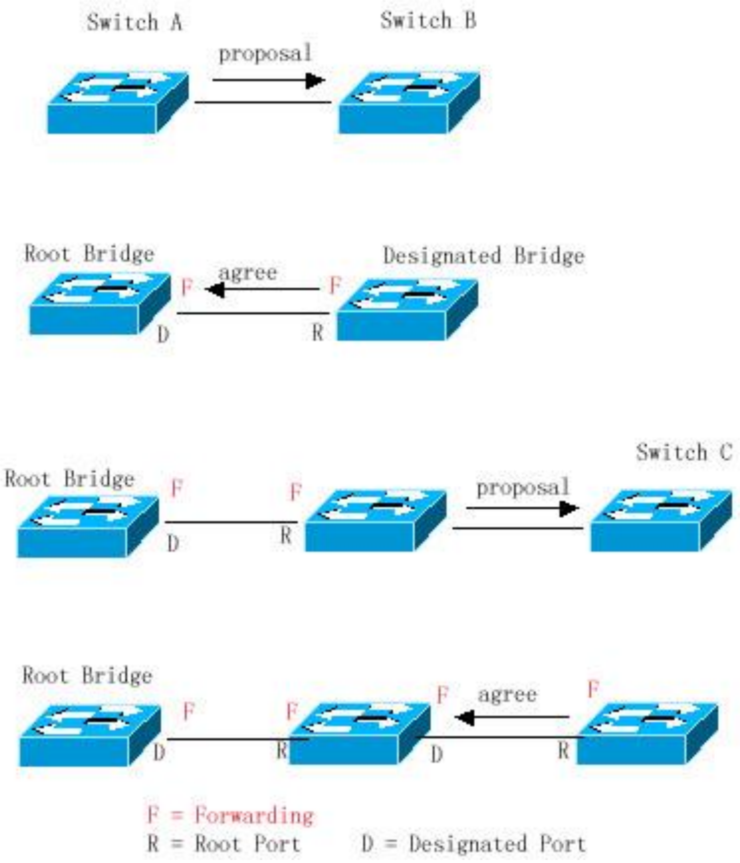
Rapid Convergence of RSTP

The following introduces the special function of RSTP: enabling rapid forwarding on a port.

The STP protocol will forward packets after 30s since the port roles are selected, which is twice as the Forward-Delay Time (you can set the Forward-Delay Time, which is 15s by default). Furthermore, the root port and designated port of each bridge will carry out the forwarding again after 30s, so it will take about 50s to stabilize the tree-type structure of the whole network topology.

The forwarding procedure of the RSTP protocol is different from that of the STP protocol. As shown in Figure 8, Switch A sends the specific proposal message of the RSTP protocol. Switch B detects that the priority of Switch A is higher than itself, takes the Switch A as the root bridge and the port that receives the message as the root port and forwards the proposal message. Then it sends the Agree message to Switch A through the root port. Upon the receipt of the proposal message, Switch A will forward the message through its designated port. After that, Switch sends the proposal message through the designated port to extend the spanning tree in turn. In theory, the RSTP protocol can immediately restore the tree-type network structure to implement rapid convergence when the network topology changes.

Figure-8



Caution

Point-to-point Connection” between ports is required for the above “handshaking” process. In order to make full use of you device, do not use non-point-to-point connection between devices.

Other than Figure 9, other schematics in this chapter are the point-to-point connection. The following lists the example figure of the non point-to-point connection.

Example of Non Point-to-point Connection:

Figure-9

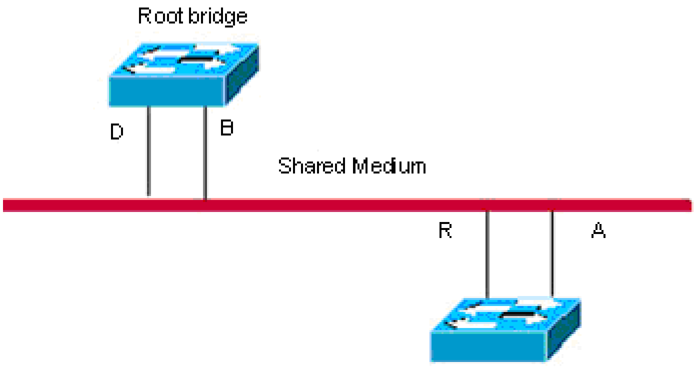


Figure-10

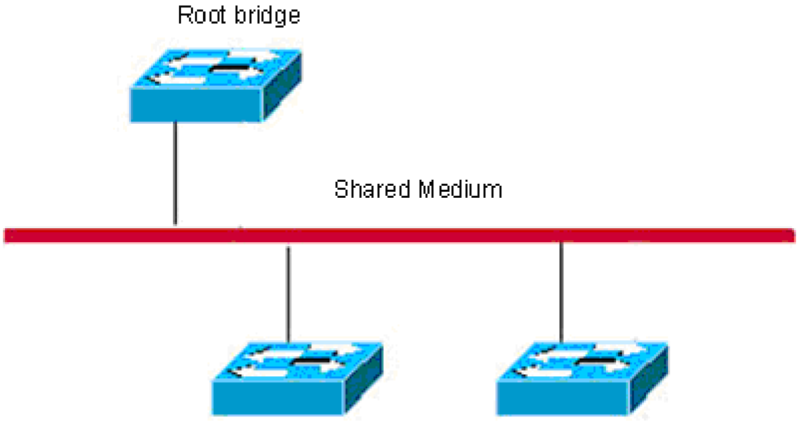
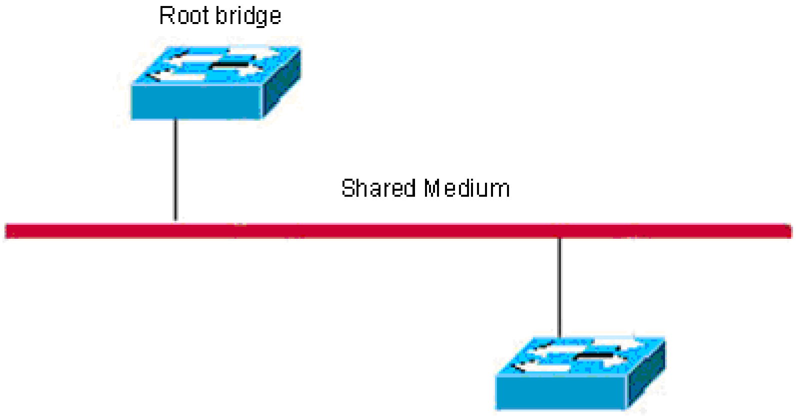


In addition, the following figure is a point-to-point connection and should be differentiated by users carefully.

Figure-11



Compatibility of RSTP and STP

The RSTP protocol is completely compatible with the STP protocol. It will judge whether the connected bridge supports the STP protocol or the RSTP protocol by the version number of the received BPDU message automatically. Only the forwarding process of the STP protocol is executed in the case of that the bridge supports the STP protocol. This cannot maximize the performance of the RSTP protocol.

Furthermore, using the RSTP protocol and the STP protocol will cause a problem. As shown in Figure 17-12, Switch A supports the RSTP protocol, while Switch B supports the STP protocol. Both switches are connected with each other. Switch A will send the STP BPDU message to Switch B for compatibility. However, if Switch A is connected with the RSTP-enabled Switch C, Switch A still sends the STP BPDU message, and thus causing that Switch C considers Switch A a STP-enabled bridge. As a result, two RSTP-supported switches run the STP protocol, reducing their efficiency greatly.

For this reason, the RSTP protocol provides the protocol-migration function to send the RSTP BPDU message forcibly in case that the peer bridge must support RSTP. In this way, Switch C will detect the bridge connected with it supports the RSTP protocol, so both two devices can run the RSTP protocol as shown in Figure 13.

Figure-12 Protocol Migration

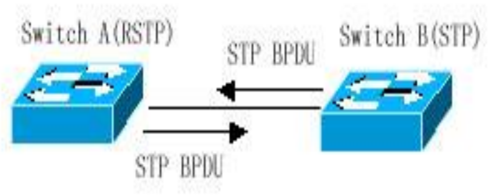


Figure-13

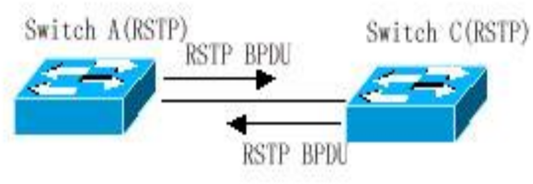


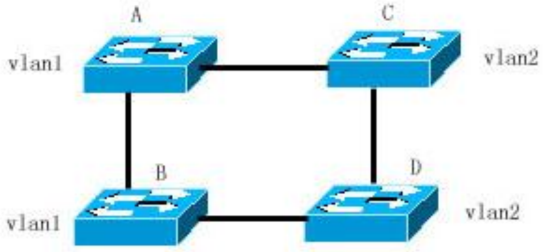
MSTP Overview

Ruijie series supports the MSTP protocol, a new spanning-tree protocol derived from the traditional STP and RSTP protocols that includes the rapid forwarding mechanism of the RSTP protocol itself.

Since traditional spanning tree protocols are not related to a VLAN, the following problems may occur in a specific network topology.

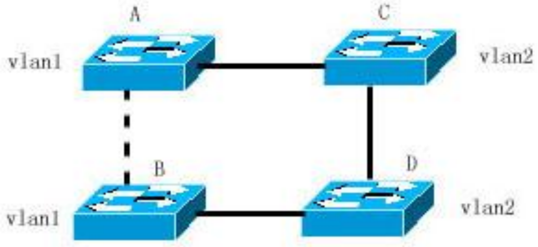
As shown in Figure 14, Switches A and B are located in Vlan1, and switches C and D in Vlan2. They form a loop.

Figure-14



If the cost of the path from Switch A through Switch C, Switch D to Switch B is smaller than that of the direct path from Switch A to Switch B, the latter path will be torn down, as shown in Figure 15. Packets in Vlan1 can not be forwarded because Switches C and D do not contain Vlan1. In this way, Vlan1 of Switch A cannot communicate with Vlan1 of Switch B.

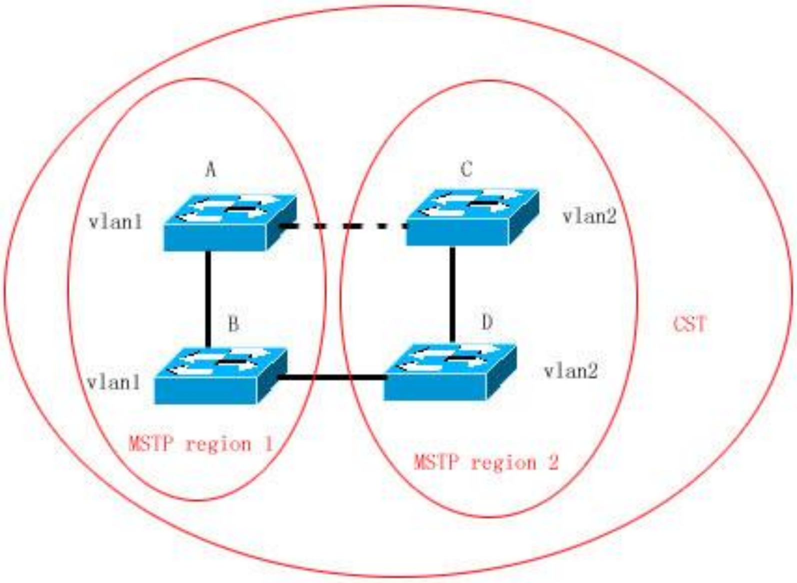
Figure-15



The MSTP protocol is developed to address this problem. It partitions one or more vlans of the switch into an instance, so the switches with the same instance configuration form a region (MST region) to run a separated spanning tree (this internal spanning-tree is referred to as the IST). The MST region is equivalent to a large device, which executes the spanning tree algorithm with other MST regions to obtain a whole spanning tree, referred to as the common spanning tree (CST).

With this algorithm, the above mentioned network can form the topology shown in Figure 16. Switches A and B are within the MSTP region 1 without a loop, so no path is discarded. This is also the case in the MSTP region 2. Region 1 and region 2 serve as two large devices respectively. There is a loop between them, so one path is discarded according to related configuration.

Figure-16



In this way, no loop occurs and the communication between the devices in a VLAN works as well.

How to Partition MSTP regions

According to above description, MSTP regions should be partitioned rationally and the switches in a MSTP region should be configured similarly for the MSTP protocol to work properly.

The MST configuration information contains:

- MST region name (name): A string of up to 32 bytes identifying the MSTP region.
- MST revision number: A revision number of 16 bits identifying the MSTP region.
- MST instance-vlan table: Each device can create up to 64 instances with IDs ranging from 1 to 64). Instance 0 always exists, so the system totally supports 65 instances. You can allocate 1 to 4094 VLANs for different instances (0 to 64) as needed, and the unallocated VLANs belong to instance 0 by default. In this way, each MSTI (MST instance) is a VLAN group and executes the spanning tree algorithm within the MSTI according to the MSTI information of the BPDU without the effect of the CIST and other MSTIs.

You can use the **spanning-tree mst configuration** command in the global configuration mode to enter the MST configuration mode and configure above information.

The MSTP BPDU carries above information. If a device has received the same MST configuration information of the BPDU as that of itself, it considers that the device connecting to this port belong to the same MST region as itself.

You are recommended to configure the instance-vlan table while the STP protocol is disable, and then enable the MSTP protocol to ensure the stability and convergence of the network topology.

Spanning Tree within a MSTP region (IST)

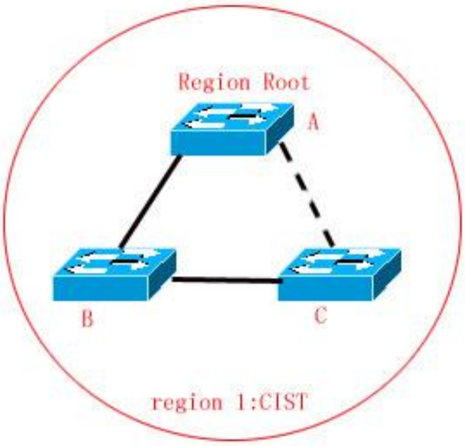
After MSTP regions are partitioned, a root bridge is elected for every instance within a region and the port role is determined for every port on a switch. A port is forwarded or discarded within an instance depneds on its role.

In this way, the IST (Internal Spanning Tree) is formed by exchanging the MSTP BPDU message, and various instances have their own spanning trees (MSTI). The spanning tree corresponding to the instance 0 is referred to as the CIST (Common Instance Spanning Tree) in conjunection with CST. That is to say, each instance provides each VLAN group with a single network topology without loop.

As shown in the following figure, Switches A, B and C form a loop within the region 1.

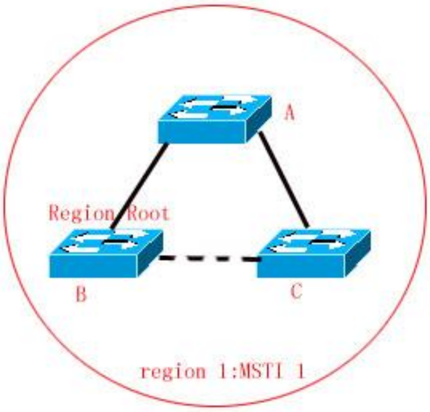
Switch A with the highest priority is selected as the region root in the CIST (instance 0). Then, the path between Switches A and C is discarded according to other parameters. Hence, for the VLAN group of instance 0, only the path from switch A to B and switch B to switch C are available, which break the loop of the VLAN group.

Figure-17



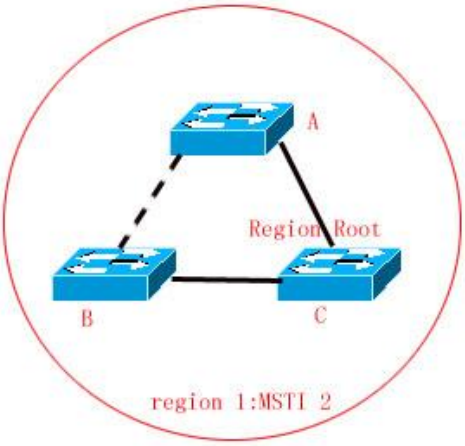
As shown in Figure 18, switch C with the highest priority is selected as the region root in the MSTI 1 (instance 1). Then, the path between switch A and B is discarded according to other parameters. Hence, for the VLAN group of instance 1, only the path from switch A to switch B and switch A to switch C are available, which break the loop of the VLAN group.

Figure-18



As shown in Figure 19, switch B with the highest priority is selected as the region root in the MSTI 2 (instance 2). Then, the path between switch B and switch C is discarded according to other parameters. Hence, for the VLAN group of instance 2, only the path from switch A to switch B and switch B to switch C are available, which break the loop of the VLAN group.

Figure-19

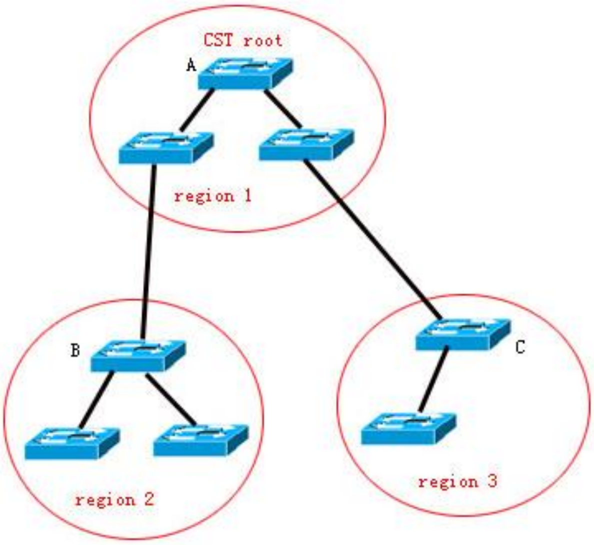


It should note that the MSTP protocol is not concerned on which VLAN a port belongs to, so users should configure corresponding path costs and priorities for ports according to actual VLAN configuration to prevent the MSTP protocol from breaking the loop unnecessarily.

Spanning Tree between MSTP regions (CST)

For CST, each MSTP region is equivalent to a large-sized device, and different MSTP regions also form a large-sized network topology tree, referred to as CST (common spanning tree). As shown in Figure 20, for CST, switch A with the smallest bridge ID is selected as the root of the entire CST (CST Root) and the CIST Regional Root in this region. In Region 2, since the root path cost from switch B to the CST root is the lowest one, switch B is selected as the CIST Regional Root in this region. Similarly, switch C is selected as the CIST Regional Root in Region 3.

Figure-20



The CIST Regional Root is not necessarily the device with the smallest bridge ID in that region. It is the device in the region that has the lowest root path cost to the CST root.

At the same time, the root port of the CIST regional root takes a new port role for the MSTI, namely the **Master port,** as the outlet of all instances, which is forwarded to all instances. In order to make the topology more stable, it is recommended to configure the outlet of the regions to the CST root on one device of this region as much as possible!

Hop Count

The IST and MSTI will not take the message age and Max age to calculate whether the BPDU message is timeout. Instead, they use the mechanism similar to the TTL of IP packets, namely hop count.

You can set it by using the **spanning-tree max-hops** command in the global configuration mode. The hop count is reduced by 1 when the BPDU message psses through a device in a region starting from the region root bridge until it is 0, which means the BPDU message is timeout. A device will discard the BPDU message whose hop count is 0.

In order to be compatible with the STP protocol and the RSTP protocol out a region, the MSTP protocol still remains the Message age and Max age mechanisms.

Compatibility of MSTP with RSTP and STP

For the STP protocol, the MSTP protocol will send the STP BPDU to be compatible with it like the RSTP protocol. For detailed information, refer to the Compatibility of RSTP and STP section.

For the RSTP protocol, it will process the CIST part of the MSTP BPDU, so it is not necessary for the MSTP to send the RSTP BPDU to be compatible with it.

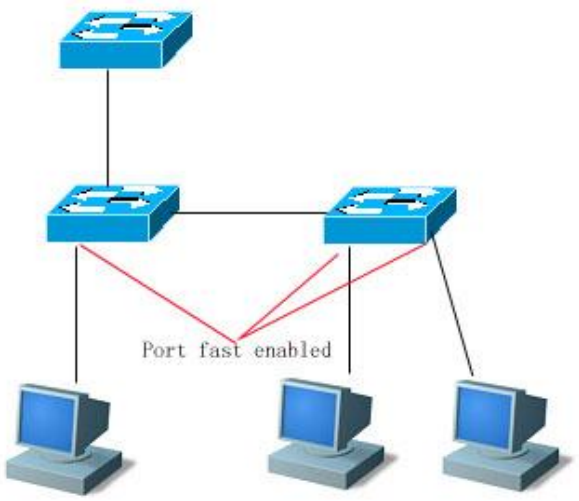
Each device that runs the STP or RSTP protocol is an independent region, and does not form the same region with any other device.

Overview of Optional Features of MSTP

Understanding Port Fast

If a port of a device is connected with the network terminal directly, this port can be set as the Port Fast to forward packets directly. The port does not need to wait 30 seconds before forwarding packets, which is the case when the port is not set to Port Fast. The following figure indicates which ports of a device can be set to Port Fast.

Figure-21



If the BPDU message is received from the Port Fast enabled port, its Port Fast operational state is disabled. At this time, this port will execute the forwarding by normal STP algorithm.

Understanding AutoEdge

If the specified port doesn't receive the BPDU message sent by the downstream port within a certain period of time (3 seconds), the port will be considered that it connects a network device and set as an edge port to enter the Forwarding status directly. An edge port will be automatically identified as a non-edge port after receiving the BPDU message.

You can disable the automatic identification function of the edge port by the **spanning-tree autoedge disabled** command.

This function is enabled by default.

Caution

When the AutoEdge function conflicts with the manually-configured Port Fast function, the latter shall prevail.

AutoEdge function can be used for rapid negotiation forwarding between the designated port and the downstream port, so the STP protocol doesn't support AutoEdge. If the designated port is in the forwarding status, Autoedge does not take effect on the port. It will take effect during repaid renegotiation such as pluging/unpluging network cables.

If a port enables the BPUD Filter, it forwards the BPDU message directly, but not be identified as the edge port automatically.

AutoEdge function is only applicable for the designated port.

AutoEdge complies with the standard definition of IEEE 802.1D (version 2004), in which the parameter range of Bridge Hello Time has been modified as 1.0-2.0. Therefore, you shall confirm that the Hello Time value is within the range when using AutoEdge function, or the risk of temporary loop will occur. It is recommended to disable AutoEdge function if it is neccesary to exceed the range of Hello Time.

Understanding BPDU Guard

The BPDU guard can be enabled globally or on individual interface. There are some slightly difference between these two ways.

You can use the **spanning-tree portfast bpduguard default** command to open the global BPDU guard enabled status in the global configuration mode. In this status, if the BPDU message is received through a Port Fast-enabled port or a AutoEdge port, this port will enter the error-disabled status, indicating the configuration error. At the same time, the port will be closed to show that some illegal users may add a network device to the network, which change the network topology.

You can also use the **spanning-tree bpduguard enable** command to enable BPDU guard on individual interface in the interface configuration mode (it is not related to whether it is AutoEdge port or not). Under this situation, it will enter the error-disabled status if this interface receives the BPDU message.

Understanding BPDU Filter

The BPDU filter can be enabled globally or on individual interface. There are some slightly difference between these two ways.

You can use the **spanning-tree portfast bpdufilter default** command to enable the BPDU filter globally in the global configuration mode. In this status, the BPDU messages can not be received or sent through a Port Fast-enabled port or a AutoEdge port, leading to no BPDU messages received by the host directly connecting the port. The BPDU filter will be disabled when the Port Fast is disabled for the AutoEdge port receives the BPDU message.

You can also use the **spanning-tree bpdufilter enable** command to enable the BPDU filter on individual interface in the interface configuration mode (it is not related to whether it is AutoEdge port or not). In this situation, this interface will not receive or transmit the BPDU message, but execute the forwarding directly.

Understanding Tc-protection

TC-BPDU messages are BPDU messages carrying with TC flag. When the L2 switch receives these messages, the network topology will change and the MAC address table will be deleted. And for L3 switch, the route table will be deleted and the port state in the ARP entry will change. To prevent the switch from processing abovementioned operations when pseudo TC-BPDU messages attack maliciously, too-heavy burden and network turbulance, the TC-protection function comes into being.

Tc-protection can only be enabled or disabled globally. It is enabled by default.

Once Tc-protection is enabled, the switch will delete the message within a certain period of time (usually 4 seconds) after receiving the TC-BPDU message while monitoring the TC-BPDU message. If it receives the TC-BPDU message during this period, it will perform the delete operation again after this period expires. This eliminates the need of frequently deleting MAC address entries and ARP entries.

Understanding TC Guard

The Tc-Protection function can reduce the removal of MAC address entries and ARP entries when a lot number of TC messages are generated in a network. However, you need to do more delete oeprations in case of TC message attack. Furthermore, the TC message is propagated and will have an effect on the whole network. The TC Guard function allows you to disable the propagation of the TC message globally or on ports. When TC Guard function is configured globally or on a port, the port will shield the TC messages received or produced to prevent from propagating them to other ports. In this way, this funciton can manage TC message attack in the network and maintain the network stability. Moreover, this function can prevent from interrupting core routes due to the oscillation of the devices on the access layer.

Caution

Network communication will be broken off if you use tc-guard function incorrectly.

You are recommended to enable this function when you ensure that there is illegal tc message attack in the network.

If you enable global tc-guard, then all the ports will not spread tc message. It is applicable for those devices that are accessed on the desk to enable this function.

If you enable interface tc-guard, then the topology change and tc message received on this port will not be spreaded to other ports. It is applicable for up-link ports especially aggregated ports to enable this function.

Understanding TC Filtering

With the TC Guard function enabled, the port will not propagate TC message to other ports participating in the spanning tree calculation on the local device. The TC message here includes the TC message received on the port, and the TC mesasge produced by the port itself. The latter one refers to the TC message generated when the forwarding state of the port changes (For example, port state change from block to forwarding), which indicates the topology may be changed.

As TC message propagation is prevented by TC Guard, the device will not clear the MAC addresses of the coppresponding ports when the topology changes, resulting in data forwarding failure.

TC filtering is introduced to solve the above problems. TC filtering will process the TC message in the condition of normal topology change instead of the TC message received on the port, so that address clearing and core route interruption caused by frequent UP/DOWN on the port without Portfast configured can be solved, and the core routing entries can be updated in time when the topology changes.

Caution

By default, the TC filtering function is disabled.

Understanding BPDU Source MAC Check

The gobal of the BPDU source MAC check funciton is to prevent malicious attack on the switch by sending the BPDU message manually and thus cause the MSTP protocol work abnormally. When the peer switch connected to a port in the point-to-point mode is determined, enabling the BPDU source MAC check function can receive only the BPDU message from the remote switch and discard all other BPDU messages to protect against malicious attacks. You can configure the corresponding MAC addresses for the BPDU source MAC check fucntion on a specific port in the interface mode. Only one MAC address is configured for one port. BPDU source MAC check can be disabled by using the **no bpdu src-mac-check** command. In this case, any BPDU message is received on the port.

Understanding Invalid Length Filtering for BPDU

When the Ethernet length field of the BPDU message exceeds 1500 bits, this BPDU message is discarded in order to avoid receiving invalid BPDU messages.

Understanding ROOT Guard

In network design, root bridge and backup root bridge are always divided in the same region. Due to error configuration of accendant and malicious attack in the network, it is possible that root bridge receives configuration message of higher priority and loses the current root bridge position, leading to error turbulance of network topology, which Root Guard function can prevent from occuring.

When enabling Root Guard, it enforces the port role of all the instances as specified port. Once the port receives configuration message of higher priority, Root Guard will set the interface as root-inconsistent (blocked). If there is no configuration message of higher priority during the time long enough, the port will be restored to be the original normal status.

You shall disable ROOT Guard function if this function results in the blocked status for interfaces and it needs manual configuration to restore to the normal status. You can use the command **spanning-tree guard none** in the interface configuration mode to disable Root Guard function. This function is enabled by default.

Caution

Incorrectly using ROOT Guard leads to network link breakdown.
If you enable ROOT Guard on non-designated port, the non-designated port will be enforced as designated port and show BKN status (blocking status).
If MST0 enters BKN status because it receives configuration message of higher priority on a port, ROOT Guard will enforce the port in all the other instances to enter BKN status.
ROOT Guard or LOOP Guard takes effect at the same time. That is , they cannot both take effect at the same time .
The AutoEdge function is disabled when enabling the ROOT Guard-enabled port.

Understanding LOOP Guard

Due to breakdown of one-way link, root port or backup port becomes designated port, being ready to forward because they can not receive BPDU, causing the loop in the network, which Loop Guard function can prevent.

For the ports configured loop guard, if they can not receive BPDU, the port roles will be migrated. However, the port state is always set as discarding till the port receive BPDU again and recalculate spanning tree.

Caution

You can enable LOOP Guard based on global or interface.
ROOT Guard or LOOP Guard takes effect at the same time. That is , they can not both take effect at the same time .
The AutoEdge function on all interfaces is ineffective when enabling LOOP Guard function globally.
The AutoEdge function on the interface is ineffective when enabling LOOP Guard function in the interface configuration mode.

Configuring MSTP

Default Spanning Tree Configuration

The following table lists the default configuration of the Spanning Tree protocol.

Item	Default value
Enable State	Disable
STP MODE	MSTP
STP Priority	32768
STP port Priority	128
STP port cost	Automatically determine according to port rate.
Hello Time	2 seconds
Forward-delay Time	15 seconds
Max-age Time	20 seconds
Default calculation method of the Path Cost	Long
Tx-Hold-Count	3
Link-type	Automatically determine by the duplex status of the port.
Maximum hop count	20
Corresponding relationship between vlan and instance	All VLANs belong to instance 0 Only instance 0 exists

You can restore the STP parameters to its default configuration (except for disabling STP) by using the **spanning-tree reset** command.

Enabling and Disabling the Spanning Tree Protocol

The spanning tree protocol is disabled on the device by default.

To enable the spanning tree protocol, execute the following command in the privileged EXEC mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **spanning-tree**	Enable the spanning tree protocol.
Ruijie(config)# **end**	Return to the privileged EXEC mode.
Ruijie# **show spanning-tree**	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

To disable the spanning tree protocol, use the **no spanning-tree** command in the global configuration mode.

Configuring the Spanning Tree Mode

According to the 802.1-related protocols, it is not necessary for administrators to set much for three versions of the spanning tree protocols such as the STP, RSTP and MSTP. These versions are compatible with one another naturally. However, given that some manufacturers will not develop the spanning tree protocol by standards, it may cause some compatibility problem. Hence, we provide a command to facilitate administrators to switch to the lower version of the spanning tree protocol for compatibility when they detect that this device is not compatible with that of other manufacturers.

Note: When you switch to the RSTP or STP version from the MSTP version, all information about MSTP Region will be cleared.

The default mode of the device is MSTP.

To enable the spanning tree protocol, execute the following command in the privileged EXEC mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **spanning-tree mode** [**stp** | **rstp** | **mstp**]	Set the spanning tree version.
Ruijie(config)# **end**	Return to the privileged EXEC mode.
Ruijie# **show spanning-tree**	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

To restore the spanning tree mode to the default value, use the **no spanning-tree mode** command in the global configuration mode.

Configuring Switch Priority

Switch priority allows you to select the root and draw the topology of a network. It is recommended that administrators set the core device with higher priority (or smaller value) to facilitate the stablization of the whole network. You can assign different switch priorities for various instances so that various instances can run separate spanning tree protocol.Only the priority of CIST (Instance 0) is related to the devices between different regions.

As mentioned in Bridge ID, there are 16 values for the priority, and all of them are multiples of 4096, which are 0, 4096, 8192, 12288, 16384, 20480, 24576, 28672, 32768, 36864, 40960, 45056, 49152, 53248, 57344, and 61440. The default value is 32768.

To configure switch priority, execute the following command in the global configuration mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **spanning-tree** [**mst** *instance-id*] **priority** *priority*	Configure different switch priorities for different instances. This command configures the switch priority for instance 0 without the instance-id parameter. *instance-id*: ID of the instance in the range from 0 to 64. *priority*: switch priority in the range from 0 to 61440 and is increased by the integral multiple of 4096, 32768 by default.
Ruijie(config)# **end**	Return to the privileged EXEC mode.
Ruijie# **show running-config**	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

To restore the switch priority to the default value, use the **no spanning-tree mst** *instance-id* **priority** command in the global configuration mode.

Configuring Port Priority

When two ports are connected to the shared media, the device will set the one of the higher priority (or smaller value) to be the forwarding status and the one of the lower priority (or larger value) to be the discarding status.If the two ports are of the same priority, the device will set the one with the smaller port number to the forwarding status. You can assign different port priorities to various instances on one port, by which various instances can run the separated spanning tree protocols.

Same as device priority, it has 16 values, all a multiple of 16. They are 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 176, 192, 208, 224, and 240 respectively. The default value is 128.

To configure a port priority, execute the following commands in the privileged EXEC mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **interface** *interface-id*	Enter the interface configuration mode. A legal interface contains a physical port and an aggregate Link.
Ruijie(config-if)# **spanning-tree** [**mst** *instance-id*] **port-priority** *priority*	Configure different priorities for different instances. The command without the *instance-id* parameter will configure a port priority for instance 0. *instance-id*: Interface ID in the range from 0 to 64. *priority*: Port priority of an instance in the range from 0 to 240. Furthermore, it is increased by the integral multiple of 16, 128 by default.
Ruijie(config-if)# **end**	Return to the privileged EXEC mode.
Ruijie# **show spanning-tree** [**mst** *instance-id*] **interface** *interface-id*	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

To restore the port priority to the default value, execute the **no spanning-tree mst** *instance-id* **port-priority** command in the interface configuration mode.

Configuring Path Cost of a Port

The switch determines a root port upon the total of the path costs along the path from a port to the boot bridge. The port the total of paths costs from the port to the root brdige is the smallest is elected the root port. Its default value is calculated by the media speed of the port automatically. The higher the media speed, the smaller the cost is. It is not necessary for administrators to change it for the path cost calculated in this way is most scientific. You can assign different cost paths for various instances on one port, by which various instances can run the separated spanning tree protocols.

To configure the path cost of a port, execute the following commands in the privileged EXEC mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.

Ruijie(config)# **interface** *interface-id*	Enter the interface configuration mode. A legal interface contains a physical port and an aggregate Link.
Ruijie(config-if)# **spanning-tree** [**mst** *instance-id*] **cost** *cost*	Configure different priorities for different instances. The command without the *instance-id* parameter will configure a port priority for instance 0. *instance-id*: Interface ID in the range of 0 to 64. *cost*: Path cost of the port in the range of 1 to 200,000,000. The default value is calculated by the media rate of the port automatically.
Ruijie(config-if)# **end**	Return to the privileged EXEC mode.
Ruijie# **show spanning-tree** [**mst** *instance-id*] **interface** *interface-id*	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

To restore the path cost of a port to the default value, execute the **no spanning-tree mst** *cost* command in the interface configuration mode.

Configuring the Default Calculation Method of Path Cost (path cost method)

If the path cost of a port is the default value, the device will calculate the path cost of this port by port rate. However, IEEE 802.1d-1998 and IEEE 802.1t specify different path cost values for a port rate respectively. The value range of the 802.1d-1998 is short (1 to 65535), while the value range of the 802.1t is long (1 to 200,000,000).

There are two modes for the Cost value of AP: 1) our private mode fixes it to: the Cost value of the physical port * 95%; 2) the standard value is 20,000,000,000/ the actual link bandwidth of AP (The actual link bandwidth is: the bandwidth of member port * the number of UP member ports). Administrators should unify the path cost standard of the whole network. The default mode is long (IEEE 802.1t Mode).

The following table lists the path costs set for different port rates in two standards.

Port Rate	Interface	IEEE 802.1d (short)	IEEE 802.1t (long)	IEEE 802.1t (long standard)
10M	Common Port	100	2000000	2000000
	Aggregate Link	95	1900000	2000000 ÷ linkupcnt
100M	Common Port	19	200000	200000
	Aggregate Link	18	190000	200000 ÷ linkupcnt
1000M	Common Port	4	20000	20000
	Aggregate Link	3	19000	20000 ÷ linkupcnt
10000M	Common Port	2	2000	2000
	Aggregate Link	1	1900	2000 ÷ linkupcnt

Caution

1. The default path cost mode is long. After changing the path cost to the standard mode, the cost of AP will vary with the number of UP member ports. The change of port cost value may result in network topology change.
2. For the static AP, the linkupcnt in the table is the number of UP member ports; for the LACP AP, the linkupcnt refers to the number of member ports participating in AP data forwarding. If there is no linkup on the member port, the linkupcnt is 1. For detailed configurations about AP and LACP, refer to *AP-SCG* and *LACP-SCG*.

To configure the default calculation method of path cost, execute the following commands in the privileged EXEC mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **spanning-tree pathcost method** { { **long** [**standard**] } | **short** }	Configure the default calculation method of the port path cost as long, standard long or short, with long by default.
Ruijie(config)# **end**	Return to the privileged EXEC mode.
Ruijie# **show running-config**	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

To restore the setting to the default value, execute the **no spanning-tree pathcost** method command in the global configuration mode.

Configuring Hello Time

Configure the interval of sending the BPDU message. The default value is 2s.

To configure the Hello Time, execute the following commands in the privileged EXEC mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **spanning-tree hello-time** *seconds*	Configure the hello time ranging from 1 to 10s, 2s by default.
Ruijie(config)# **end**	Return to the privileged EXEC mode.
Ruijie# **show running-config**	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

To restore the hello time to the default value, execute the **no spanning-tree hello-time** command in the global configuration mode.

Configuring Forward-Delay Time

Configure the interval for changing port status. The default value is 15s.

To configure the forward-delay time, execute the following commands in the global configuration mode:

Command	Function

Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **spanning-tree forward-time** *seconds*	Configure the forward delay time ranging from 4 to 30 seconds, 15 seconds by default.
Ruijie(config)# **end**	Return to the privileged EXEC mode.
Ruijie# **show running-config**	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

To restore the forward-delay time to the default value, execute the **no spanning-tree forward-time** command in the global configuration mode.

Configuring Max-Age Time

Configure the maximum period of time before the BPDU message is aged out. The default value is 20s.

In the privilege mode, perform these steps to configure the Max-Age Time:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **spanning-tree max-age** *seconds*	Configure the max age time ranging from 6 to 40 seconds, 20 seconds by default.
Ruijie(config)# **end**	Return to the privileged EXEC mode.
Ruijie# **show running-config**	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

To restore the max age time to the default value, execute the **no spanning-tree max-age** command in the global configuration mode.

Caution

Hello Time, Forward-Delay Time and Max-Age Time have their own value ranges. Meanwhile, the following condition must be addressed: 2*(Hello Time + 1.0 seconds) <= Max-Age Time <= 2*(Forward-Delay – 1.0 second). Otherwise, it may cause the topology instability.

Configuring Tx-Hold-Count

Configure the maximum number of the BPDU message sent per second, 3 by default.

To configure the Tx-Hold-Count, execute the following commands in the global configuration mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **spanning-tree tx-hold-count** *numbers*	Configure the maximum number of the BPDU message sent per second in the range of 1 to10, 3 by default.
Ruijie(config)# **end**	Return to the privileged EXEC mode.
Ruijie# **show running-config**	Verify the configuration.

Ruijie# **copy running-config startup-config**	Save the configuration.

To restore the default setting, execute the **no spanning-tree tx-hold-count** command in the global configuration mode.

Configuring Link-type

Configure the link-type of a port. This is crucial for rapid RSTP convergence. For details, refer to Rapid RSTP Convergence. Without configuration, the device will set the link type of a port according to its duplex status automatically, with point-to-point for the full duplex port and shared for the half duplex port.

To configure the link type of a port, execute the following commands in the interface configuration mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **interface** *interface-id*	Enter the interface configuration mode.
Ruijie(config-if)# **spanning-tree link-type point-to-point**/**shared**	Configure the link type of the interface, with point-to-point for the full duplex port and shared for the half duplex port. Point-to-point indicates the rapid forwarding is enabled on the port.
Ruijie(config-if)# **end**	Return to the privileged EXEC mode.
Ruijie# **show running-config**	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

To restore the link type of a port to the default value, execute the **no spanning-tree link-type** command in the interface configuration mode.

Configuring Protocol Migration Processing

This command is to check the version globally or on individual port. For related information, refer to Compatibility of RSTP and STP.

Command	Function
Ruijie# **clear spanning-tree detected-protocols**	Forcibly check the version on all ports.
Ruijie# **clear spanning-tree detected-protocols interface** *interface-id*	Check the version forcibly on the port.

Configuring an MSTP Region

To deploy several devices in the same MSTP Region, you have to configure these devices with the same name, the same revision number, and the same Instance-VLAN table.

You can assign a VLAN to instances 0 to 64 respectively as required. The remaining VLANs will be automatically assigned to instance 0. One vlan can only be of an instance.

It is recommended to configure the Instance-VLAN table when the MSTP protocol is disabled. After configuration, you should enable the MSTP protocol again to ensure the stability and convergence of the network topology.

To configure an MSTP region, execute the following commands in the global configuration mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **spanning-tree mst configuration**	Enter the MST configuration mode.
Ruijie(config-mst)# **instance** *instance-id* **vlan** *vlan-range*	Add a VLAN group to a MST instance. *instance-id*: Instance ID ranging from 0 to 64. *vlan-range:* VLAN range in the range 1 to 4094. For instance: The **instance 1 vlan 2-200** command is to add VLAN 2-200 to instance 1. The **instance 1 vlan 2,20,200** command is to add VLAN 2, VLAN 20 and VLAN 200 to instance 1. You can use the **no** option of this command to delete a VLAN from an instance, and the deleted VLAN will be added to instance 0 automatically.
Ruijie(config-mst)# **name** *name*	Specify the MST configuration name, a string of up to 32 bytes.
Ruijie(config-mst)# **revision** *version*	Specify the MST revision number in the range 0 to 65535. The default value is 0.
Ruijie(config-mst)# **show spanning-tree mst configuration**	Verify the configuration.
Ruijie(config-mst)# **end**	Return to the privileged EXEC mode.
Ruijie# **copy running-config startup-config**	Save the configuration.

To restore the MST region configuration to the default value, execute the **no spanning-tree mst configuration** command in the global configuration mode. You can use the **no instance** *instance-id* command to delete an instance. Similarly, the **no name** and **no revision** commands can be used to restore the MST name and MST revision number settings to the default value, respectively.

The following is the example of configuration:

```
Ruijie(config)# spanning-tree mst configuration
Ruijie(config-mst)# instance 1 vlan 10-20
Ruijie(config-mst)# name region1
Ruijie(config-mst)# revision 1
Ruijie(config-mst)# show spanning-tree mst configuration
Multi spanning tree protocol : Enable Name [region1]
Revision 1
Instance Vlans Mapped
-------- ---------------------
0 1-9,21-4094
```

```
1 10-20
-------------------------------
Ruijie(config-mst)# exit
Ruijie(config)#
```

Caution

Before configuring vlan and instance mapping relationship, please ensure that all configured VLANs have been created. Otherwise, the association of vlan and instance on part of the products may be failed.

Configuring Maximum-Hop Count

Maximum-Hop Count means how many devices the BPDU message will pass through in a MSTP region before being discarded. This parameter takes effect for all instances.

To configure the Maximum-Hop Count, execute the following commands in the global configuraiton mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **spanning-tree max-hops** *hop-count*	Configure the Maximum-Hop Count ranging from 1 to 40, 20 by default.
Ruijie(config)# **end**	Return to the privileged EXEC mode.
Ruijie# **show running-config**	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

To restore the Maxium-Hop Count to the default value, execute the **no spanning-tree max-hops** command in the global configuration mode.

Configuring Intereface Compatibility Mode

In interface compatibility mode, when a port sends BPDU, it will carry different MSTI information according to the current port attribute to realize interconnection with other vendors.

To configure the interface compatibility mode, execute the following commands in the interface configuration mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)#**interface** *interface-id*	Enter the Interface configuration mode.
Ruijie(config-if)# **spanning-tree compatible enable**	Enable interface compatibility mode.
Ruijie(config-if)# **end**	Return to the privileged EXEC mode.
Ruijie# **show running-config**	Check configuration items.
Ruijie# **copy running-config startup-config**	Save the configuration.

To remove the settings, you can execute command **no spanning-tree compatible enable.**

Configuring Optional MSTP Features

Default Setting of Optional Spanning Tree Features

All the optional features are disabled by default, except for AutoEdge function.

Enabling Port Fast

Enabling Port Fast lets a port directly forward the BPDU message. When Port Fast is disabled due to the receipt of the BPDU message, the port will participate in the STP algorithm and forward the BPDU message normally.

To enable Port Fast, execute the following commands in the global configuraiton mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **interface** *interface-id*	Enter the interface configuration mode. A legal interface contains a physical port and an Aggregate Link.
Ruijie(config-if)# **spanning-tree Portfast**	Enable Port Fast on the interface.
Ruijie(config-if)# **end**	Return to the privileged EXEC mode.
Ruijie# **show spanning-tree interface** *interface-id* **portfast**	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

To disable Port Fast, execute the **spanning-tree portfast disable** command in the interface configuration mode.

You can use the **spanning-tree portfast default** command in the global configuration mode to enable Port Fast on all ports.

Enabling BPDU Guard

After BPDU Guard is enabled, a port will in the error-disabled status after receiving the BPDU packet.

To configure the BPDU guard, execute the following commands in the global configuration mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **spanning-tree portfast Bpduguard default**	Enable the BPDU Guard globally.
Ruijie(config)# **interface** *interface-id*	Enter the interface configuration mode. A legal interface contains a physical port and an aggregate link.
Ruijie(config-if)# **spanning-tree portfast**	Enable Port Fast on the interface before the bpduguard configuration takes effect globally.
Ruijie(config-if)# **end**	Return to the privileged EXEC mode.
Ruijie# **show running-config**	Verify the configuration.

Ruijie# **copy running-config startup-config**	Save the configuration.

To disable BPDU Guard, execute the **no spanning-tree portfast bpduguard default** command in the global configuration command.

To enable or disable BPDU Guard on an interface, execute the **spanning-tree bpduguard enable** command or the **spanning-tree bpduguard disable** command on the interface respectively.

Enabling BPDU Filter

A port neither transmit nor receive the BPDU message after the BPDU filter is enabled.

To configure the BPDU Filter, execute the following commands in the global configuration mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **spanning-tree portfast bpdufilter default**	Enable BPDU filter globally.
Ruijie(config)# **interface** *Interface-id*	Enter the interface configuration mode. A legal interface contains a physical port and an aggregate link.
Ruijie(config-if)# **spanning-tree Portfast**	Enable portfast on this interface before the bpduguard configuration takes effect globally.
Ruijie(config-if)# **end**	Return to the privileged EXEC mode.
Ruijie# **show running-config**	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

To restore the default setting, execute the **no spanning-tree portfast bpdufilter default** command in the global configuration mode.

To enable or disable BPDU Filter on an interface, execute the **spanning-tree bpdufilter enable** command or the **spanning-tree bpdufilter disable** command in the interface configuration mode.

Enabling Tc_Protection

To configure Tc_Protection, execute the following commands in the global configuration mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **spanning-tree tc-protection**	Enable Tc-Protection
Ruijie(config)# **end**	Return to the privileged EXEC mode.
Ruijie# **show running-config**	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

To disable Tc_Protection, execute the **no spanning-tree tc-protection** command in the global configuration mode.

Enabling TC Guard

To enable TC Guard globally, execute the following commands in the global configuration mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **spanning-tree tc-protection tc-guard**	Enable TC Guard globally.
Ruijie(config)# **end**	Return to the privileged EXEC mode.
Ruijie# **show running-config**	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

To configure TC Guard on an interface, execute the following commands in the interface configuration mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **interface** *Interface-id*	Enter the interface configuration mode. A legal interface includes a physical port and an aggregate link.
Ruijie(config-if)# **spanning-tree tc-guard**	Enable TC Guard on this interface.
Ruijie(config-if)# **end**	Return to the privileged EXEC mode.
Ruijie# **show running-config**	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

Enabling TC Filtering

To enable TC filtering, execute the following commands:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **interface** *interface-id*	Enter interface configuration mode. The valid interface includes physical port and Aggregate Link.
Ruijie(config)# **spanning-tree ignore tc**	Enable TC filtering for this interface.
Ruijie(config)# **end**	Return to the privileged EXEC mode.
Ruijie# **show running-config**	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

To disable TC filtering, use the **no spanning-tree ignore tc** command in interface configuration mode.

Enabling BPDU Source MAC check

After the BPDU source MAC check is enabled, the switch accepts only the BPDU message from the specified MAC address.

To configure the BPDU source MAC check, execute the following commands in the interface configuration mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **interface** *interface-id*	Enter the interface configuration mode. A legal interface includes a physical port and an aggregate link.
Ruijie(config-if)#**bpdu src-mac-check** H.H.H	Enable the BPDU source MAC address check function on the interface.
Ruijie(config-if)# **end**	Return to the privileged EXEC mode.
Ruijie# **show running-config**	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

To disable BPDU source MAC check, execute the **no bpdu src-mac-check** command in the interface mode.

Enabing Root Guard

To configure interface ROOT Guard, execute the following commands in the privileged mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **interface** *interface-id*	Enter the interface configuration mode. Valid interface includes physical port and Aggregate Link.
Ruijie(config-if)# **spanning-tree guard root**	Enable interface ROOT Guard.
Ruijie(config-if)# **end**	Return to the privileged EXEC mode.
Ruijie# **show running-config**	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

Enabling Loop Guard

To configure global LOOP Guard, execute the following commands in the privileged EXEC mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **spanning-tree loopguard default**	Enable global LOOP Guard.
Ruijie(config)# **end**	Return to the privileged EXEC mode.
Ruijie# **show running-config**	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

To configure interface LOOP Guard, execute the following commands in the privileged EXEC mode:

Command	Function
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **interface** *interface-id*	Enter the interface configuration mode. Valid interface includes physical port and Aggregate Link.
Ruijie(config-if)# **spanning-tree guard loop**	Enable interface Loop Guard.

Ruijie(config-if)# **end**	Return to the privileged EXEC mode.
Ruijie# **show running-config**	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

Disabling Interface Guard

To disable interface ROOT or LOOP Guard, execute the following commands in the privileged EXEC mode:

Command	**Function**
Ruijie# **configure terminal**	Enter the global configuration mode.
Ruijie(config)# **interface** *interface-id*	Enter the interface configuration mode. Valid interface includes physical port and Aggregate Link.
Ruijie(config-if)# **spanning-tree guard none**	Disable interface Loop Guard.
Ruijie(config-if)# **end**	Return to the privileged EXEC mode.
Ruijie# **show running-config**	Verify the configuration.
Ruijie# **copy running-config startup-config**	Save the configuration.

Showing MSTP Configuration and Status

You can use the following show commands to view the configuration of MSTP:

Command	**Meaning**
Ruijie# **show spanning-tree**	Display the information on the parameters and topology of MSTP.
Ruijie# **show spanning-tree summary**	Display the information on various instances and port forwarding status of MSTP.
Ruijie# **show spanning-tree inconsistentports**	Display the block port due to root guard or loop guard.
Ruijie# **show spanning-tree mst configuration**	Display the configuration information of the MST region.
Ruijie# **show spanning-tree mst** *instance-id*	Display the MSTP information of an instance.
Ruijie# **show spanning-tree mst** *instance-id* **interface** *interface-id*	Display the MSTP information of the specified instance of the interface.
show spanning-tree mst *instance-id* **topochange record**	Display the STP topology change record.
Ruijie# **show spanning-tree interface** *interface-id*	Display the MSTP information of all the instances of the interface.
Ruijie# **show spanning-tree forward-time**	Display forward-time.
Ruijie# **show spanning-tree Hello Time**	Display Hello time.
Ruijie# **show spanning-tree max-hops**	Display max-hops.

Ruijie# **show spanning-tree tx-hold-count**	Display tx-hold-count.
Ruijie# **show spanning-tree pathcost Method**	Display pathcost method.

Configuring LLDP

LLDP Overview

Drafted by IEEE 802.1AB, LLDP (Link Layer Discovery Protocol) can detect network topology change and identify what the change is. With LLDP, a device sends local device information as TLV (Type, Length and Value) triplets in LLDP Data Units (LLDPDUs) to the neighbor devices, and at the same time, stores the device information received in LLDPDUs sent from the LLDP neighbors in a standard management information base (MIB) to be accessed by the network management system.

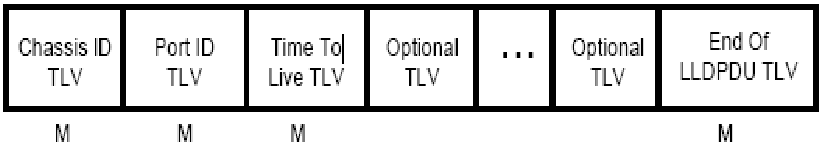
Through LLDP, the network management system can learn about the state of topological connections, such as which ports of the device are connected to other devices, the rate of ports on both sides of link, and whether the duplex mode is matched. The network administrator can quickly locate and eliminate faults according to such information.

Basic Concepts

LLDPDU

LLDPDU refers to the data units encapsulated in LLDP packets, and comprises multiple TLV sequences, including three fixed TLVs, a number of optional TLVs and an End of TLV. The detailed format of LLDPDU is shown in Fig 1:

Fig 1-1 LLDPDU format



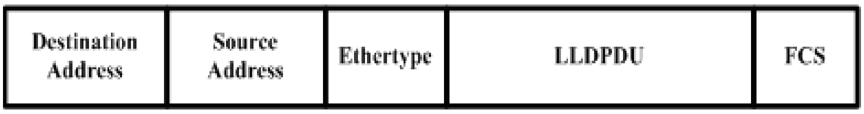
- * M refers to fixed TLV.
- In LLDPDU, Chassis ID TLV, Port ID TLV, Time To Live TLV and End Of LLDPDU TLV are fixed TLVs, while other TLVs are optional.

LLDPDU Encapsulation Format

LLDP packet supports two encapsulation formats: Ethernet II and SNAP (Subnetwork Access Protocols).

Ethernet II encapsulated LLDPDU format is shown in Fig 2:

Figure 1-2 Ethernet II encapsulated LLDPDU format



Specifically:

- Destination Address: destination MAC address. It is fixed to 01-80-C2-00-00-0E, a multicast address.

- Source Address: source MAC address, layer-2 MAC address of device.

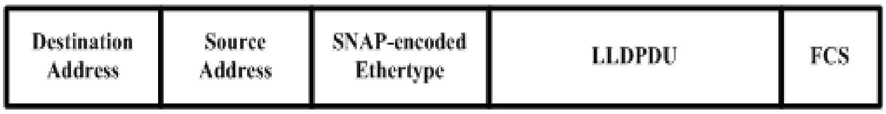
- Ethertype: the Ethernet type, 0x88CC.

- LLDPDU: LLDP Data Unit.

- FCS: frame check sequence.

SNAP-encapsulated LLDPDU format is shown in Fig 3:

Figure 1-3 SNAP-encapsulated LLDPDU format



Destination Address	Source Address	SNAP-encoded Ethertype	LLDPDU	FCS

Specifically:

- Destination Address: destination MAC address. It is fixed to 01-80-C2-00-00-0E, a multicast address.

- Source Address: source MAC address, layer-2 MAC address of device.

- SNAP-encoded Ethertype: SNAP-encapsulated Ethernet type, AA-AA-03-00-00-00-88-CC.

- LLDPDU: LLDP Data Unit.

- FCS: frame check sequence.

TLV

TLVs encapsulated in LLDPDU can fall into two broad categories:

- Basic management TLVs

- Organizationally specific TLVs

Basic management TLVs are a group of basic TLVs for network management. The organizationally specific TLVs are TLVs defined by standards organizations and other organizations, such as IEEE 802.1, IEEE 802.3 and etc.

1) Basic management TLVs

Basic management TLVs include two types of TLVs: fixed TLVs and optional TLVs. Fixed TLVs must be included in LLDPDU, while optional TLVs can be included or excluded according to need.

Basic management TLVs are shown in Table 1:

Type	Description	Use in LLDPDU
End Of LLDPDU TLV	End mark of LLDPDU, occupying 2 bytes	Fixed
Chassis ID TLV	Used to identify the device, and is generally represented with MAC address	Fixed
Port ID TLV	ID of the LLDPDU sending port	Fixed
Time To Live TLV	Life of local information on the neighbor device. When TLV with 0 TTL is received, the corresponding neighbor information must be deleted.	Fixed
Port Description TLV	Port description of LLDPDU sending port	Optional
System Name TLV	Name of the sending device	Optional
System Description TLV	Description of the sending device, including hardware/software version, operating system and etc.	Optional
System Capabilities TLV	Identifies the primary functions of the sending device, such as bridging, routing and relaying.	Optional
Management Address TLV	Management address, including interface number and OID (object Identifier).	Optional

Table 1 Basic management TLV

☑ Basic management TLVs are supported by the LLDP protocol used by Ruijie switch products.

2) Organizationally specific TLVs

Different organizations (such as IEEE 802.1, IEEE 802.3, IETF or device suppliers) may define specific TLVs to advertise specific information about the device, and OUI (Organizationally Unique Identifier) is used to identify different organizations.

Organizationally specific TLVs are optional TLVs advertised in LLDPDU according to user's actual needs. Currently, commonly found organizationally specific TLVs include:

1) IEEE 802.1 organizationally specific TLVs

IEEE 802.1 organizationally specific TLVs are shown in Table 2:

Type	Description
Port VLAN ID TLV	VLAN identifier of the sending port
Port And Protocol VLAN ID TLV	Protocol VLAN identifier of the sending port
VLAN Name TLV	Name of VLAN with which the device is configured
Protocol Identity TLV	Protocols supported by the port

Table 2 IEEE 802.1 organizationally specific TLVs

☑ LLDP protocol used by Ruijie switch products doesn't support the sending of Protocol Identity TLV, but allows the reception of such TLV.

2) IEEE 802.3 organizationally specific TLVs

IEEE 802.3 organizationally specific TLVs are shown in Table 3:

Type	Description
MAC/PHY Configuration/Status TLV	The bit-rate and duplex capabilities of the sending port and support for auto negotiation.
Power Via MDI TLV	Power supply capability of the port
Link Aggregation TLV	Indicate the link aggregation capability of the port and the aggregation status.
Maximum Frame Size TLV	The maximum frame size supported by the port.

Table 3 IEEE 802.3 organizationally specific TLVs

☑ IEEE 802.3 organizationally specific TLVs are supported by the LLDP protocol used by Ruijie switch products.

3) LLDP-MED TLVs

LLDP-MED is the extension of IEEE 802.1AB LLDP protocol, so that the user can conveniently deploy VoIP (Voice Over IP) network and fault detection. It provides multiple applications such as network policy configuration, device detection, PoE management and directory management, providing a cost-effective and easy-to-use solution for deploying voice devices in Ethernet.

LLDP-MED TLVs are shown in Table 4:

Type	**Description**
LLDP-MED Capabilities TLV	Whether the device supports LLDP-MED, the type of LLDP-MED TLV encapsulated in LLDPDU, and the type of current device (network connection device or endpoint)
Network Policy TLV	Advertise VLAN configuration of the specific port, supported applications (voice and video, for example), and the Layer 2 priorities.
Location Identification TLV	Location identifier information for an endpoint, used to accurately locate the endpoint in applications such as network topology collection.
Extended Power-via-MDI TLV	Provide more advanced power supply management.
Inventory – Hardware Revision TLV	Hardware version of MED device
Inventory – Firmware Revision TLV	Firmware version of MED device
Inventory – Software Revision TLV	Software version of MED device
Inventory – Serial Number TLV	Serial number of MED device
Inventory – Manufacturer Name TLV	Vendor name of MED device
Inventory – Model Name TLV	Model name of MED device
Inventory – Asset ID TLV	Asset ID of MED device, used for directory management and asset tracking.

Table 4 LLDP-MED TLVs

☑ LLDP-MED TLVs are supported by the LLDP protocol used by Ruijie switch products.

Working Principles

Operating Modes of LLDP

LLDP provides three operating modes:

- TxRx: sending and receiving LLDPDUs.
- Rx Only: only sending LLDPDUs.
- Tx Only: only receiving LLDPDUs.

When the LLDP operating mode of a port changes, the port will initialize the protocol state machine. To prevent LLDP from being initialized too frequently during times of frequent operating mode change, you can configure a re-initialization delay.

Mechanism for Transmitting LLDPDUs

An LLDP-enabled port operating in TxRx mode or Tx Only mode will send LLDPDUs both periodically and when the local device information changes. To avoid frequent LLDPDU sending during times of frequent local device information change, an interval is introduced between two successive LLDPDUs. This interval can be configured manually.

LLDP provides two types of packets:

- Standard LLDPDUs: including the management and configuration information about local device.
- Shutdown LLDPDU: When LLDP sending mode is disabled or when the port is administratively shut down, shutdown LLDPDU will be sent. Shutdown LLDPDU generally comprises Chassis ID TLV, Port ID TLV, Time To Live TLV and End Of LLDP TLV, with the TTL in Time To Live TLV being 0. When the device receives shutdown LLDPDUs, it will consider the neighbor on longer available and delete neighbor information.

When LLDP operating mode changes from shutdown or Rx to TxRx or Tx, or when a new neighbor is detected (namely new LLDPDUs are received and no such neighbor information is stored locally), to allow the neighbor device to quickly study the information about this device, the fast sending mechanism will be initiated. The fast sending mechanism adjusts the LLDPDU sending interval to 1 second and continuously transmits a certain number of LLDPDUs.

Mechanism for Receiving LLDPDUs

A LLDP-enabled port operating in TxRx mode or Rx Only mode will be able to receive LLDPDUs, and will check the validity of received LLDPDUs to verify they are new neighbor information or updates of existing neighbor information. The neighbor information will be stored on the local device. Meanwhile, an aging timer will be set according to the value in TTL TLV carried in the LLDPDU. If the TTL value is zero, the information is aged out immediately.

Protocol Specifications

The protocols and standards related to LLDP include:

- IEEE 802.1AB 2005: Station and Media Access Control Connectivity Discovery

- ANSI/TIA-1057: Link Layer Discovery Protocol for Media Endpoint Devices

Configuring LLDP Basic Functions

Function	**Default setting**
Globally enable LLDP	Enabled
Enable LLDP on the port	Enabled
Operating mode of LLDP	TxRx
Port re-initialization delay	2 seconds
LLDPDU transmit interval	30 seconds
LLDPDU transmit delay	2 seconds
Neighbor information aging timer	120 seconds
LLDPDU encapsulation format	Ethernet II
Enable LLDP Trap	Disabled
LLDP error detection	Enabled

Enabling LLDP

By default, LLDP is enabled globally and on each port. To make LLDP take effect on certain ports, you must enable LLDP both globally and on these ports.

Execute the following steps to disable LLDP globally and on each port.

Command	**Function**
Ruijie(config)#**no lldp enable**	Disable LLDP globally.

Ruijie(config)# **interface** *interface-name*	Enter interface configuration mode. LLDP runs on the actual physical interface (for AP port, it runs on AP's member port). LLDP is not supported on stacking port or VSL port.
Ruijie(config-if)#**no lldp enable**	Disable LLDP on the interface.
Ruijie(config-if)#**show lldp status**	Display LLDP state.

To enable LLDP globally or on the port, execute "lldp enable" command.

Caution

Disabling the LLDP globally will disable LLDP on the device. Meanwhile, the device will send Shutdown LLDPDUs to neighbor devices in order to delete the corresponding LLDP information.

Note

The port can learn up to 5 neighbors.

If a neighbor device does not support the LLDP, but its downlink device does, the information of non-directly connected devices may be learnt on the port as the neighbor device may forward the LLDP packets.

Configuration example:

# Globally disable LLDP and display LLDP state.

```
Ruijie(config)#no lldp enable

Ruijie(config)#show lldp status

Global status of LLDP: Disable
```

Configuring LLDP Operating Mode

By default, LLDP is enabled on the interface and operates in TxRx mode. The user can change the operating mode to Tx mode or Rx mode as needed. Execute the following steps to configure LLDP operating mode.

Command	**Function**
Ruijie(config)# **interface** *interface-name*	Enter interface configuration mode. LLDP runs on the actual physical interface (for AP port, it runs on AP's member port). LLDP is not supported on stacking port or VSL port.

Ruijie(config-if)#**lldp mode** { **tx** | **rx** | **txrx** }	Configure LLDP operating mode. The configurable operating modes include Tx, Rx and TxRx.
Ruijie(config-if)#**show lldp status interface** *interface-name*	Display LLDP state on the interface.

Configuration example:

# Configure LLDP operating mode as Tx on the interface and display LLDP state on the interface

```
Ruijie(config)#interface gigabitethernet 0/1
Ruijie(config-if)#lldp mode tx
Ruijie(config-if)#show lldp status interface gigabitethernet 0/1
Port [GigabitEthernet 0/1]
Port status of LLDP           : Enable
Port state                   : UP
Port encapsulation            : Ethernet II
Operational mode              : TxOnly
Notification enable           : NO
Error detect enable           : YES
Number of neighbors           : 0
Number of MED neighbors        : 0
```

Configuring the Advertisable TLVs

By default, all TLVs other than Location Identification TLV can be advertised on the interface. Execute the following steps to configure advertisable TLVs on the interface.

Command	**Function**

Ruijie(config)# **interface** *interface-name*	Enter interface configuration mode. LLDP runs on the actual physical interface (for AP port, it runs on AP's member port). LLDP is not supported on stacking port or VSL port.
Ruijie(config-if)# **lldp tlv-enable** { **basic-tlv** { **all** | **port-description** | **system-capability** | **system-description** | **system-name** } | **dot1-tlv** { **all** | **port-vlan-id** | **protocol-vlan-id** [*vlan-id*] | **vlan-name** [*vlan-id*] } | **dot3-tlv** { **all** | **link-aggregation** | **mac-physic** | **max-frame-size** | **power** } | **med-tlv** { **all** | **capability** | **inventory** | **location** { **civic-location** | **elin** } **identifier** *id* | **network-policy profile** [*profile-num*] | **power-over-ethernet** } }	Configure the TLV types that the interface allows the port to advertise. By default, all TLVs other than Location Identification TLV can be advertised on the interface.
Ruijie(config-if)# **show lldp tlv-config interface** *interface-name*	Display the attributes of advertisable TLVs.

Note

When configuring basic management TLVs, IEEE 802.1 organizationally specific TLVs and IEEE 802.3 organizationally specific TLVs, if "all" parameter is specified, all corresponding optional TLVs will be advertised.

When configuring LLDP-MED TLVs, if "all" parameter is specified, all LLDP-MED TLVs other than Location Identification TLV will be advertised.

Configure to allow the advertisement of LLDP-MED MAC/PHY TLVs before that of LLDP-MED Capability TLVs.

Configure to cancel the advertisement of LLDP-MED Capability TLVs before that of LLDP-MED MAC/PHY TLVs.

When configuring LLDP-MED TLVs, the LLDP-MED Capability TLV shall be configured as advertisable in order to further configure other LLDP-MED TLVs as advertisable.

In order not to advertise LLDP-MED Capability TLV, other LLDP-MED TLVs shall be configured as non-advertisable, so that LLDP-MED TLVs are not advertised.

For the meaning of respective key words of "lldp tlv-enable", please refer to the descriptions given in "LLDP-CREF".

When associating the device with an IP phone, you can configure the network policy TLV delivery policy to the IP phone if it supports LLDP-MED. Then, the IP phone modifies the voice flow tag and QoS. At this time, the voice VLAN function is not required, but it is required to configure the port connecting to the IP phone as the QoS trusted port. If the IP phone does not support LLDP-MED, the voice VLAN configuration is required and the phone MAC address must be manually configured to the voice VLAN OUI list.

Configuration example:

# Configure to disable the advertisement of Port And Protocol VLAN ID TLV specified by IEEE 802.1.

```
Ruijie(config)#interface gigabitethernet 0/1

Ruijie(config-if)#no lldp tlv-enable dot1-tlv protocol-vlan-id

Ruijie(config-if)#show lldp tlv-config interface gigabitethernet 0/1

LLDP tlv-config of port [GigabitEthernet 0/1]

            NAME               STATUS DEFAULT

------------------------------ ------ -------

Basic optional TLV:

Port Description TLV            YES   YES

System Name TLV                 YES   YES

System Description TLV          YES   YES

System Capabilities TLV         YES   YES

Management Address TLV          YES   YES

IEEE 802.1 extend TLV:

Port VLAN ID TLV                YES   YES

Port And Protocol VLAN ID TLV   NO    YES

VLAN Name TLV                   YES   YES

IEEE 802.3 extend TLV:

MAC-Physic TLV                  YES   YES
```

```
Power via MDI TLV               YES    YES

Extended Power via MDI TLV       YES    YES

Inventory TLV                    YES    YES
```

Configuring the Management address Advertised in LLDPDU

The management address of a device is used by the network management system to identify and manage the device.

Execute the following steps to configure the management address to be advertised in LLDPDU:

Command	Function
Ruijie(config)# **interface** *interface-name*	Enter interface configuration mode. LLDP runs on the actual physical interface (for AP port, it runs on AP's member port). LLDP is not supported on stacking port or VSL port.
Ruijie(config-if)#**lldp management-address-tlv** [*ip-address*]	Configure the management address advertised in the LLDP packet.
Ruijie(config-if)#**show lldp local-information interface** *interface-name*	Display LLDP local information about a specific interface.

Note

By default, the management address is advertised in LLDPDU, and is the IPv4 address of the lowest-ID VLAN carried on the port. If IPv4 address is not configured for this VLAN, the next lowest-ID VLAN carried on the port will be tried until the IPv4 address is obtained.

If the IPv4 address is still not found, the IPv6 address of the lowest-ID VLAN carried on the port will be tried.

If the IPv6 address is still not found, the MAC address of the device will be advertised as the management address.

Configuration example:

# Configure the management address advertised in LLDPDU as 192.168.1.1 and display the corresponding configuration.

```
Ruijie(config)#interface gigabitethernet 0/1
Ruijie(config-if)#lldp management-address-tlv 192.168.1.1
Ruijie(config-if)#show  lldp local-information interface GigabitEthernet 0/1

```

Configuring the Number of Fast Sent LLDPDUs

When a new neighbor is detected or when LLDP operating mode changes from shutdown or Rx to TxRx or Tx, to allow the neighbor device to quickly study the information about this device, the fast sending mechanism will be initiated. The fast sending mechanism shortens the LLDPDU sending interval to 1 second and continuously transmits a certain number of LLDPDUs before restoring to the normal transmit interval.

Command	**Function**
Ruijie(config)#**lldp fast-count** *count*	Configure the number of fast sent LLDPDUs in the range from 1 to 10. The default is 3.
Ruijie(config-if)#**show lldp status**	Display LLDP state.

Configuration example:

# Configure the number of fast sent LLDPDUs to 5.

```
Ruijie(config)#lldp fast-count 5
Ruijie(config)#show lldp status
Global status of LLDP               : Enable
Neighbor information last changed time :
Transmit interval                   : 30s
Hold multiplier                     : 4
Reinit delay                       : 2s
Transmit delay                     : 2s
Notification interval               : 5s
Fast start counts                   : 5
```

Configuring TTL Multiplier and LLDPDU Transmit interval

The value of Time To Live TLV in LLDPDU = TTL multiplier × LLDPDU transmit interval + 1. Therefore, the TTL of local device information on the neighbor device can be controlled by adjusting TTL multiplier.

The LLDPDU transmit interval can be adjusted. Execute the following steps to configure TTL multiplier and LLDPDU transmit interval.

Command	**Function**

Ruijie(config)#**lldp hold-multiplier** *value*	Configure TTL multiplier in the range from 2 to 10. The default is 4.
Ruijie(config)#**lldp timer tx-interval** *seconds*	Configure LLDPDU transmit interval in the range from 5 to 32768 in the unit of seconds. The default is 30.
Ruijie(config-if)#**show lldp status**	Display LLDP state.

Configuration example:

# Configure TTL multiplier to 3 and LLDPDU transmit interval to 20 seconds. By this time, the TTL of local device information on the neighbor device is 61 seconds.

```
Ruijie(config)#lldp hold-multiplier 3

Ruijie(config)#lldp timer tx-interval 20

Ruijie(config)#show lldp status

Global status of LLDP               : Enable

Neighbor information last changed time :

Transmit interval                   : 20s

Hold multiplier                    : 3

Reinit delay                       : 2s

Transmit delay                     : 2s

Notification interval               : 5s

Fast start counts                   : 3
```

Configuring LLDPDU Transmit Delay

An LLDP-enabled port will send LLDPDUs when the local device information changes. To avoid frequent LLDPDU sending during times of frequent local device information change, we can configure LLDPDU transmit delay to control the frequent transmission of LLDPDUs. The default transmit delay is 2 seconds. Execute the following steps to configure the LLDPDU transmit delay.

Command	**Function**

Ruijie(config)#**lldp timer tx-delay** *seconds*	Configure LLDPDU transmit delay
Ruijie(config)#**show lldp status**	Display LLDP state.

Configuration example:

# Configure LLDPDU transmit delay to 3 seconds and display LLDP state.

```
Ruijie(config)#lldp timer tx-delay 3

Ruijie(config)#show lldp status

Global status of LLDP               : Enable

Neighbor information last changed time :

Transmit interval                   : 30s

Hold multiplier                    : 4

Reinit delay                       : 2s

Transmit delay                     : 3s

Notification interval               : 5s

Fast start counts                   : 3
```

Configuring Port Re-initialization Delay

When the LLDP operating mode of a port changes, the port will initialize the protocol state machine. To prevent LLDP from being initialized too frequently during times of frequent operating mode change, you can configure port re-initialization delay. Execute the following steps to configure port re-initialization delay:

Command	**Function**
Ruijie(config)#**lldp timer reinit-delay** *seconds*	Configure port re-initialization delay.
Ruijie(config)#**show lldp status**	Display LLDP state.

Configuration example:

# Configure the port re-initialization delay to 3 seconds and display LLDP state.

```
Ruijie(config)#lldp timer reinit-delay 3

Ruijie(config)#show lldp status

Global status of LLDP               : Enable

Neighbor information last changed time :

Transmit interval                   : 30s

Hold multiplier                    : 4

Reinit delay                       : 3s

Transmit delay                     : 2s

Notification interval               : 5s

Fast start counts                   : 3
```

Configuring LLDP Trap

By configuring LLDP Trap, the LLDP information of local device (such as information about the detection of new neighbor or the fault on the communication link) can be sent to the network management server. The administrator can monitor the network operation status according to such information.

To prevent excessive LLDP traps from being sent, you can set an interval for sending LLDP Traps. If LLDP information change is detected during this interval, traps will be sent to the network management server.

By default, LLDP Trap is disabled.

Execute the following steps to configure LLDP Trap:

Command	Function
Ruijie(config)#**lldp timer notification-interval** *seconds*	Configure the interval for sending LLDP Traps in the range from 5 to 3600 in the unit of seconds. The default is 5.
Ruijie(config)# **interface** *interface-name*	Enter interface configuration mode. LLDP runs on the actual physical interface (for AP port, it runs on AP's member port). LLDP is not supported on stacking port or VSL port.
Ruijie(config-if)#**lldp notification remote-change enable**	Enable LLDP Trap. LLDP Trap is disabled by default.

Ruijie(config-if)#**show lldp status**	Display LLDP state.

Configuration example:

# Enable LLDP Trap and configure the interval for sending LLDP Traps to 10 seconds.

```
Ruijie(config)#lldp timer notification-interval 10
Ruijie(config)#interface gigabitethernet 0/1
Ruijie(config-if)#lldp notification remote-change enable
Ruijie(config-if)#show lldp status
Global status of LLDP               : Enable
Neighbor information last changed time :
Transmit interval                   : 30s
Hold multiplier                    : 4
Reinit delay                       : 2s
Transmit delay                     : 2s
Notification interval               : 10s
Fast start counts                   : 3
------------------------------------------------------------
Port [GigabitEthernet 0/1]
------------------------------------------------------------
Port status of LLDP           : Enable
Port state                   : UP
Port encapsulation            : Ethernet II
Operational mode              : RxAndTx
Notification enable           : YES
```

```
Error detect enable           : YES
Number of neighbors           : 0
Number of MED neighbors        : 0
```

Configuring LLDP Error Detection

Configure LLDP error detection, including the detection of VLAN configurations on both sides of the link, port state detection, port aggregation configuration detection, MTU configuration detection and loop detection. If any error is detected by LLDP, LOG information will be printed to notify the administrator.

Execute the following steps to configure LLDP error detection:

Command	**Function**
Ruijie(config)# **interface** *interface-name*	Enter interface configuration mode. LLDP runs on the actual physical interface (for AP port, it runs on AP's member port). LLDP is not supported on stacking port or VSL port.
Ruijie(config-if)#**lldp error-detect**	Configure LLDP error detection. LLDP error detection is enabled by default.
Ruijie(config-if)#**show lldp status interface** *interface-name*	Display LLDP state on the interface.

Configuration example:

# Configure LLDP error detection.

```
Ruijie(config)#interface gigabitethernet 0/1
Ruijie(config-if)#lldp error-detect
Ruijie(config-if)#show lldp status interface gigabitethernet 0/1
Port [GigabitEthernet 0/1]
Port status of LLDP           : Enable
Port state                   : UP
Port encapsulation            : Ethernet II
Operational mode              : RxAndTx
```

```
Notification enable           : NO

Error detect enable           : YES

Number of neighbors           : 0

Number of MED neighbors        : 0
```

Configuring LLDPDU Encapsulation Format

By default, LLDPDUs are encapsulated in Ethernet II frames. The configurable encapsulation formats include Ethernet II and SNAP.

When configured to Ethernet II format, the device can only send and receive Ethernet II-encapsulated LLDP packets.

When configured to SNAP format, the device can only send and receive SNAP-encapsulated LLDP packets.

Execute the following steps to configure LLDPDU encapsulation format:

Command	**Function**
Ruijie(config)# **interface** *interface-name*	Enter interface configuration mode. LLDP runs on the actual physical interface (for AP port, it runs on AP's member port). LLDP is not supported on stacking port or VSL port.
Ruijie(config-if)#**lldp encapsulation snap**	Configure LLDPDU encapsulation format to SNAP.
Ruijie(config-if)#**show lldp status interface** *interface-name*	Display LLDP state on the interface.

Caution

To guarantee normal communication between local device and neighbor device, the same LLDPDU encapsulation format must be used.

Configuration example:

# Configure LLDPDU encapsulation format to SNAP and display the corresponding configuration.

```
Ruijie(config)#interface gigabitethernet 0/1

Ruijie(config-if)#lldp encapsulation snap

Ruijie(config-if)#show lldp status interface gigabitethernet 0/1
```

```
Port [GigabitEthernet 0/1]
Port status of LLDP           : Enable
Port state                   : UP
Port encapsulation            : Snap
Operational mode              : RxAndTx
Notification enable           : NO
Error detect enable           : YES
Number of neighbors           : 0
Number of MED neighbors        : 0
```

Displaying and Clearing Configurations

Command	Function
Ruijie(config)# **lldp network-policy profile** *profile-num*	Enter the LLDP network-policy configuration mode.
Ruijie(config-lldp-network-policy)# { **voice** | **voice-signaling** } **vlan** { { *vlan-id* [**cos** ***cvalue*** | **dscp** *dvalue*] } | { **dot1p** [**cos** ***cvalue*** | **dscp** *dvalue*] } | **none** | **untagged** } **no** { **voice** | **voice-signaling** } **vlan**	Configure the LLDP network-policy.

Configuration example:

# Configure the LLDP packet advertised from interface 1 as follows:
Network Policy TLV: **1**
voice VLAN ID: **3**
cos: **4**
dscp: **6**

```
Ruijie#config
Ruijie(config)#lldp network-policy profile 1
Ruijie(config-lldp-network-policy)# voice vlan 3 cos 4
Ruijie(config-lldp-network-policy)# voice vlan 3 dscp 6

Ruijie(config-lldp-network-policy)#exit

Ruijie(config)# interface gigabitethernet 0/1

Ruijie(config-if-GigabitEthernet 0/1)# lldp tlv-enable med-tlv network-policy profile 1
```

Configuring the Civic Address Information of a Device

Run the commands listed in the following table to configure the address information of a device.

Command	**Function**
Ruijie(config)# **lldp location civic-location identifier** *id*	Enters the LLDP Civic Address configuration mode
Ruijie(config-lldp-civic**)# device-type** *device-type*	Configure the device type. The default device type is a switch.
Ruijie(config-lldp-civic)# **civic-location** { **country** | **state** | **county** | **city** | **division** | **neighborhood** | **street-group** | **leading-street-dir** | **trailing-street-suffix | street-suffix** | **number** | **street-number-suffix** | **landmark** | **additional-location-information** | **name** | **postal-code** | **building** | **unit** | **floor** | **room** | **type-of-place |** **postal-community-name** | **post-office-box** | **additional-code** } *ca-word*	Configure the LLDP civic address information.

Configuration example:

# Configure the address of device interface 1 as follows:
Device type: switch
Country: CH
City: Fuzhou
Postal-code: 350000

```
Ruijie#config

Ruijie(config)#lldp location civic-location identifier 1

Ruijie(config-lldp-civic)# country CH

Ruijie(config-lldp-civic)# city Fuzhou
Ruijie(config-lldp-civic)# postal-code 350000

Ruijie(config-lldp-civic)# exit

Ruijie(config)# interface gigabitethernet 0/1

Ruijie(config-if-GigabitEthernet 0/1)# lldp tlv-enable location civic-location identifier 1
```

Configuring the Emergency Call Number

Run the commands listed in the following table to configure the emergency call number of a device.

Command	Function
Ruijie(config)# **lldp location elin identifier** *id* **elin-location** *tel-number*	Configure the emergency call number.

Configuration example:

# Configure the emergency call number of device interface 1 as 085285555556.

```
Ruijie#config

Ruijie(config)#lldp location elin identifier 1 elin-location 085283671111

Ruijie(config)# interface gigabitethernet 0/1

Ruijie(config-if-GigabitEthernet 0/1)# lldp tlv-enable location elin identifier 1
```

Viewing and Clearing Configurations

Command	Function
show lldp local-information [**global** | **interface** *interface-name*]	Show the device information to be sent to a neighbor.
show lldp location { **civic-location** | **elin** } { **identifier** ***id*** | **interface** *interface-name* | **static** }	Show the civic address information or emergency call number of a local device.
show lldp neighbors [**interface** *interface-name*] [**detail**]	Show the device information about an adjacent neighbor.

show lldp network-policy profile [*profile-num*]	Show the LLDP network-policy configuration.
show lldp statistics [**global** | **interface** *interface-name*]	Show the LLDP statistics.
show lldp status [**interface** *interface-name*]	Show the LLDP status.
show lldp tlv-config [**interface** *interface-name*]	Show the optional TLVs that can be advertised.
clear lldp statistics [**interface** *interface-name*]	Clear LLDP statistics.
clear lldp table [**interface** *interface-name*]	Clear the information about LLDP neighbors.

Configuration example:

# Show the device information about an adjacent neighbor connecting a specified port.

```
Ruijie# show lldp neighbors detail

Lldp neighbor-information of port [GigabitEthernet 0/1]

  Neighbor index                 : 1

  Device type                   : LLDP Device

  Update time                   : 12minutes 40seconds

Typical LLDP Configuration Examples

Use LLDP to View Topological Connections

Networking Requirements

Devices required

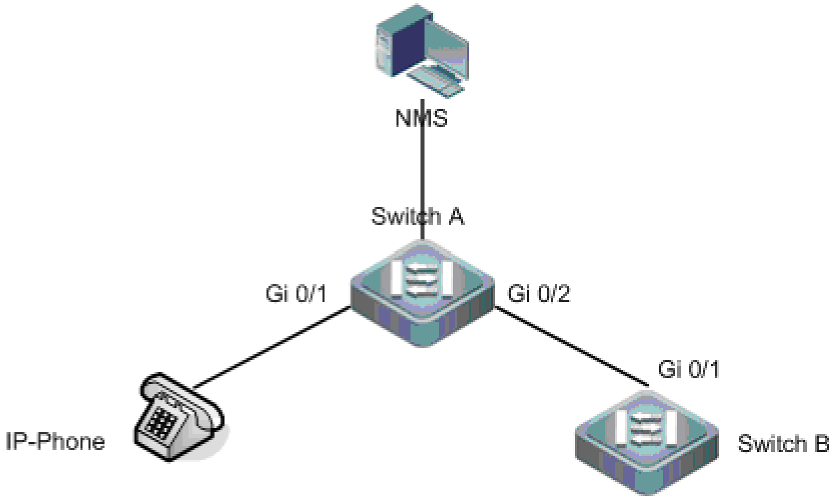
Two Ethernet switches (Switch A and Switch B), one MED device (taking IP Phone as the example) and one NMS (Network management System).

Configuration required

LLDP is enabled by default. No further configuration is needed.

Network Tpology

Fig 4 Basic topological diagram of LLDP



Configuration Tips

- LLDP operating mode on the port is TxRx.

- LLDPDU transmit times will use default values, namely LLDPDU transmit interval is 30 seconds and LLDPDU transmit delay is 2 seconds.

Configuration Steps

By default, LLDP is enabled, and no further configuration is needed.

Verification

- Display the information about the neighbor device connecting with Switch A.

# Display the information about the neighbor device on Switch A.

```
Ruijie# show lldp neighbors gigabitethernet 0/2

Capability codes:

Use LLDP Error Detection Feature to Perform Error Detection

Networking Requirements

- Devices required

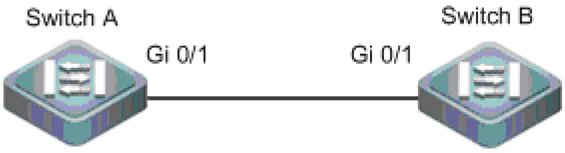
two Ethernet switches (Switch A and Switch B)

- Configuration required

LLDP is enabled by default. No further configuration is needed.

Network Topology

Fig 5 Basic topological diagram of LLDP



Configuration Tips

- LLDP operating mode on the port is TxRx.
- LLDPDU transmit times will use default values, namely LLDPDU transmit interval is 30 seconds and LLDPDU transmit delay is 2 seconds.
- LLDP error detection is enabled by default. No further configuration is needed.

Configuration Steps

1. Configure the bit-rate of port Gi 0/1 of Switch A to 100M.

```
Ruijie#config

Ruijie(config)#interface gigabitethernet 0/1

Ruijie(config-if)#speed 100

%Warning: the speed/duplex of port GigabitEthernet 0/1 may not match with it's neighbor.
```

The above messages show that bit-rate and duplex capabilities of port 1 may not match with that of port on neighbor device.

Verification

While the administrator is carrying out VLAN configuration, port bit-rate and duplex configuration, aggregation port configuration and port MTU configuration, if the information doesn't match with the configurations of neighbor device the corresponding error messages will be prompted.

Configuring VRRP

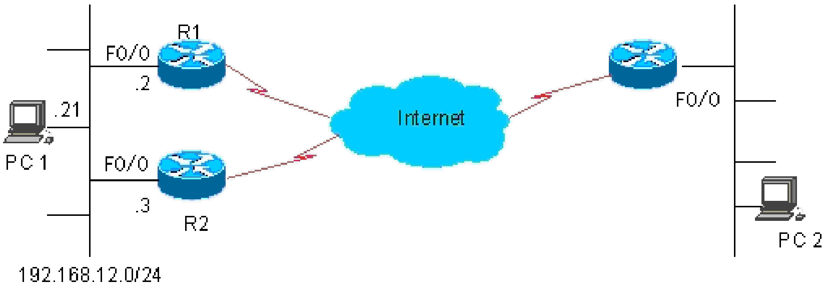
Overview

The Virtual Router Redundancy Protocol (VRRP) is designed to work in master/backup mode, so that traffic can switch over to a backup router without affecting internal or external data communication when the master router fails. In this process, parameters of the internal network do not need to be modified. Multiple routers in a VRRP group map to one virtual router. VRRP ensures that only one router transmits packets at a time, whereas hosts send data packets to the virtual router. The router that forwards data packets is elected as the master router. If the master router cannot work due to certain reasons at a time, a backup router is used to perform tasks of the original master router. Using VRRP allows all hosts in a local area network (LAN) looking like using only one router, and guarantees route connectivity even if the first-hop router fails.

RFC 2338, RFC 3768, and RFC 5798 define the format and operating mechanism of VRRP packets. A VRRP packet is a multicast packet with a specified destination address. It is sent by the master router to indicate that the master router is running properly or used to elect the master router. VRRP allows another router to automatically take over the router that fails to support the routing and forwarding function in an IP LAN, therefore implementing the hot backup and error tolerance of IP routes. VRRP also guarantees the communication continuity and reliability of hosts inside the LAN. One VRRP group consists of multiple routers in redundancy mode. At any moment, however, only one router serves as the master router to perform routing and forwarding functions. All other routers in the VRRP group are backup routers. The switchover between routers in the VRRP group is completely transparent to hosts in the LAN. RFC defines the following router switchover rules:

- VRRP elects the master router using a simple election method. First, it compares the VRRP priority of interfaces on various routers in the VRRP group and elects the router with the highest interface priority as the master router. The status of the elected router changes to Master. If the routers have the same priority, VRRP compares the primary IP address of network interfaces of the routers. The router with the biggest primary IP address becomes the master router to provide actual routing and forwarding services.
- After the master router is elected, other routers serve as backup routers whose status changes to Backup. These backup routers monitor the status of the master router by receiving VRRP packets that are periodically sent by the master router. When working normally, the master router sends a VRRP multicast packet that is known as an advertisement packet at a certain interval to inform the backup routers that the master router itself is running properly. If a backup router in the VRRP group does not receive any advertisement packet from the master router within the specified time, it sets its own status to Master. If multiple routers in the VRRP group exist in Master state, an election process as described previously is implemented again so that a router with the highest priority is selected as the new master router to implement the backup function of the VRRP.

Figure 1 Operating principles of VRRP



Once the master router is selected out of the VRRP group, the packets of all hosts in the LAN are routed and forwarded by the master router. Figure 1 shows the specific communication process. Routers R1 and R2 are connected to the LAN segment 192.168.12.0/24 through the Ethernet interface F0/0. VRRP is enabled on the Ethernet interface F0/0 of routers R1 and R2. The virtual router IP address of the VRRP group is set as the default gateway on all hosts in the LAN. Hosts in the LAN can detect only the virtual router of the VRRP group, whereas the master router that practically performs routing and forwarding functions is transparent to all of them. For example, the host PC 1 in the LAN sends a data packet to PC 2 by using the virtual router of the VRRP group as the default gateway so as to communicate with PC 2 in the same LAN. Upon receipt of the data packet, the master router of the VRRP group forwards the data packet to PC 2. In this communication process, PC 1 can detect only the virtual router but does not know whether R1 or R2 is the master router that plays the role of the virtual router. The master router of the VRRP group is selected between R1 and R2. Once the master router fails, the other router takes over traffic and becomes the new master router.

RFC 5798 redefines the format of a VRRP packet. The RGOS IPv6 VRRP complies with RFC 5798. In later descriptions, RGOS IPv6 VRRP is called VRRPv3 for short whereas the original VRRP implementation is simply called VRRPv2. In IPv4 VRRP, VRRPv2 and VRRPv3 are strictly distinguished from each other. The two VRRP standards define different fields in a VRRP packet. For this reason, RGOS IPv4 VRRP supports VRRPv3 and provide compatibility with VRRPv2. In contrast, IPv6 does not distinguish VRRPv2 from VRRPv3, because IPv6 VRRP is defined only in VRRPv3.

Currently, VRRP is defined in the following three protocols:

- RFC 2338
- RFC 3768
- RFC 5798

RFC 3768 is an update of RFC 2338 and defines mechanisms such as IPv4 VRRP. RFC 5798 is an improvement and extension of RFC 3768, and defines IPv4 VRRP and IPv6 VRRP.

Caution To provide compatibility with widely deployed devices that do not support VRRPv3, IPv6 VRRP, however, invariably uses VRRPv3.

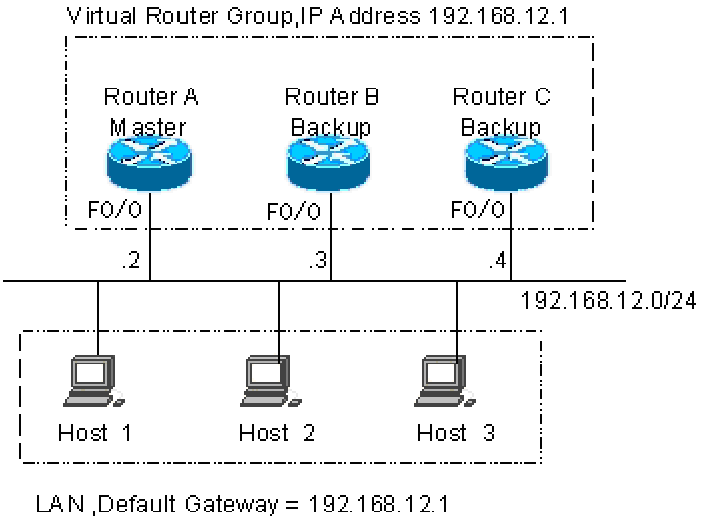
VRRP Application

VRRP supports two application modes: basic applications and advanced applications. In basic applications, only one VRRP group is used to implement simple route redundancy. In advanced applications, multiple VRRP groups are used to implement route redundancy and load balancing.

Route Redundancy

Figure 2 shows an example of basic VRRP applications.

Figure 2 Example of basic VRRP applications

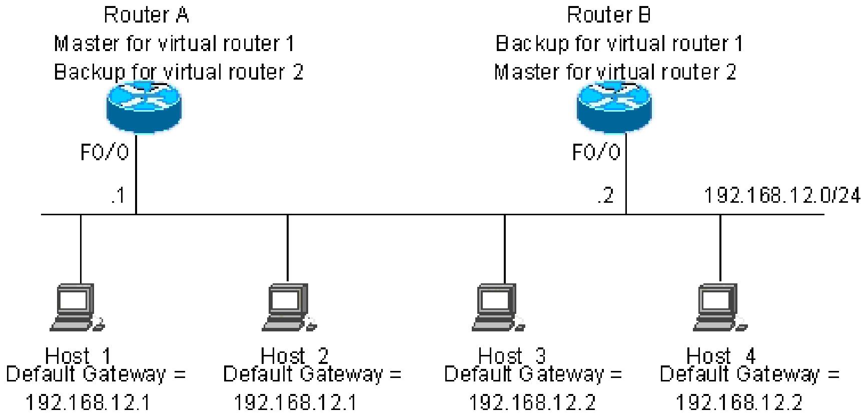


As shown in Figure 2, routers A, B, and C are connected to a LAN through Ethernet interfaces on which VRRP is enabled. Routers A, B, and C belong to the same VRRP group. The virtual IP address of the VRRP group is 192.168.12.1. Router A is elected as the master router of the VRRP group, whereas routers B and C are backup routers. The virtual router IP address 192.168.12.1 is set as the default gateway on hosts 1, 2, and 3 in the LAN. Data packets from hosts in the LAN to other networks are routed and forwarded by the master router A. If router A fails, a new master router is elected between routers B and C to route and forwards packets as a virtual router, therefore implementing simple route redundancy.

Load Balancing

Figure 3 shows an example of advanced VRRP applications.

Figure 3 Example of advanced VRRP applications



As shown in Figure 3, two virtual routers are set. For virtual router 1, the IP address 192.168.12.1 of the Ethernet interface F0/0 on router A is set as the IP address of the virtual router, so router A is the master router and router B is a backup router. For virtual router 2, the IP address 192.168.12.2 of the Ethernet interface F0/0 on router B is set as the IP address of the virtual router, so router B is the master router and router A is a backup router. The IP address 192.168.12.1 of virtual router 1 is set as the default gateway on hosts 1 and 2, and the IP address 192.168.12.2 of virtual router 2 is set as the default gateway on hosts 3 and 4 in the LAN. In this VRRP application example, routers A and B back up each other to implement route redundancy and share traffic from the LAN to implement load balancing.

Configuring VRRP

VRRP Configuration Task List

VRRP is applicable to multicast or broadcast LANs, such as Ethernets. VRRP configurations are mostly Ethernet interface configurations and involve the following configuration tasks:

- Enabling the VRRP function (Mandatory)
- Setting the authentication string of the VRRP group (Optional)
- Setting the advertisement interval of the VRRP group (Optional)
- Setting the preemption mode of the router in the VRRP group (Optional)
- Setting the Accept_Mode of the IPv6 VRRP virtual router
- Setting the priority of the router in the VRRP group (Optional)
- Setting the tracked interface of the VRRP group (Optional)
- Setting the tracked IP address of the VRRP group (Optional)
- Setting the periodic learning function of VRRP advertisement packets (Optional)
- Setting the description string of the VRRP group on the router (Optional)
- Setting the start delay of the VRRP group (Optional)
- Setting the IPv4 VRRP version (Optional)

You can determine which tasks to be configured based on your actual requirement.

Enabling the VRRP Function

You can add a VRRP group to a specific LAN segment by setting a group number and a virtual IPv4/IPv6 address for the VRRP group so as to enable the VRRP function on the corresponding Ethernet interface.

Command	Function
Ruijie(config-if)# **vrrp** *group* **ip** *ipaddress* [**secondary**]	Enables IPv4 VRRP.
Ruijie(config-if)# **no vrrp** *group* **ip** *ipaddress* [**secondary**]	Disables IPv4 VRRP.
Or:	
Ruijie(config-if)# **vrrp** *group* **ipv6** *ipv6-address*	Enables IPv6 VRRP.
Ruijie(config-if)# **no vrrp** *group* **ipv6** *ipv6-address*	Disables IPv6 VRRP.

The group number specified by the *group* parameter ranges from 1 to 255. If the virtual IP address is not specified, the router does not participate in the VRRP group. If the *secondary* parameter is not specified, the specified IP address becomes the primary IP address of the virtual router. The system does not identify whether an IPv6 address is a primary or secondary address. The first virtual IP address configured for an IPv6 VRRP group, however, must be a link-local address.

Caution

If the virtual IP address (primary or secondary) or virtual IPv6 address (link-local or non-link-local) of the VRRP group is consistent with the IP address (primary or secondary) or IPv6 address (link-local or non-link-local) of an Ethernet interface, the VRRP group is considered as owning the real IP address of the

Ethernet interface. In this case, the priority of the VRRP group is 255. If the Ethernet interface is available, the VRRP group is automatically in Master state.

☑ The NMX-2GEH line card supports listening to a maximum of 15 MAC addresses. The number of configurable VRRP groups depends on the number of MAC addresses supported by the current line card. If the number of configured VRRP groups is larger than the maximum number allowed by the line card, an error message is displayed. Note that the line card may also need to support MAC address listening according to other protocols, such as Open Shortest Path First (OSPF) and Routing Information Protocol (RIP).

Setting the Authentication String of the VRRP Group

VRRP supports two authentication modes: plain text authentication and no-authentication. When setting the authentication string of a VRRP group, you can also set the authentication mode of the VRRP group to plain text authentication or no-authentication. All members of the VRRP group must be set to the same authentication mode so as to normally communicate with one another. In plain text authentication mode, all routers in the VRRP group must have the same authentication password. The plain text authentication password does not guarantee security but is used only to prevent or prompt VRRP configuration errors.

Command	**Function**
Ruijie(config-if)# **vrrp group authentication** *string*	Sets the authentication string of the IPv4 VRRP group.
Ruijie(config-if)# **no vrrp group authentication**	Sets the authentication mode of the IPv4 VRRP group to no-authentication.

By default, the authentication mode of a VRRP group is no-authentication. If the plain text authentication mode is specified, the plain text authentication password consists of up to eight bytes.

⚠ Caution The authentication mode is already abandoned in RFC 5798 and no longer adopted in new specifications. Therefore, the user-specified authentication mode is applicable to VRRPv2 packets only.

Setting the Advertisement Interval of the VRRP Group

Command	**Function**
Ruijie(config-if)# **vrrp group timers advertise** { *advertise-interval* | **csec** *centisecond-interval* }	Sets the VRRP advertisement interval of the IPv4 VRRP master router.
Ruijie(config-if)# **no vrrp group timers advertise**	Restores the default VRRP advertisement interval of the IPv4 VRRP master router.
Or:	
Ruijie(config-if)# **vrrp ipv6 group timers advertise**{ *advertise-interval* | **csec** *centisecond-interval* }	Sets the VRRP advertisement interval of the IPv6 VRRP master router.
Ruijie(config-if)# **no vrrp ipv6 group timers advertise**	Restores the default VRRP advertisement interval of the IPv6 VRRP master router.

If the current router is the master router of the VRRP group, it sends VRRP advertisement packets at the set interval to advertise its own VRRP status, priority, and other information. By default, the master router sends VRRP advertisement packets at an interval of one second. The time for a VRRP backup router to switch over to the master router is defined in

RFC 2338, RFC 3768, and RFC 5798. It is three times the advertisement interval plus a Skew_Time. The Skew_Time is calculated with the following formula: Skew_Time = (((256 – Priority of the VRRP group) x VRRP advertisement interval) / 256). VRRPv3 supports a VRRP advertisement interval of the master router ranging from 50 to 99 milliseconds to accelerate VRRP convergence time without correlation with BFD. If the network traffic is heavy, an interval in milliseconds is not recommended, as the backup router may fail to receive the VRRP advertisement packets from the master router within the interval due to heavy traffic, causing status change.

Caution

If periodic VRRP learning is not enabled on routers, the same VRRP advertisement interval must be set on all routers in a VRRP group; otherwise, backup routers discard received VRRP advertisement packets.

Setting the Preemption Mode of the Router in the VRRP Group

A router in a VRRP group that works in preemption mode preempts other routers in the VRRP group to become the master router once detecting that its own priority is higher than the priority of the existing master router. If the VRRP group works in non-preemption mode, the router does not preempt other routers in the VRRP group to become the master router even when detecting that its own priority is higher than the priority of the existing master router. Setting the preemption mode is insignificant for a VRRP group whose virtual router address is an Ethernet interface IP address, because the router configured with the Ethernet interface IP address has the highest priority and automatically becomes the master router of the VRRP group.

Command	**Function**
Ruijie(config-if)# **vrrp** *group* **preempt** [**delay** *seconds]*	Sets the IPv4 VRRP group to the preemption mode.
Ruijie(config-if)# **no vrrp** *group* **preempt** [**delay]**	Sets the IPv4 VRRP group to the non-preemption mode or restores the default delay.
or	
Ruijie(config-if)# **vrrp ipv6** *group* **preempt** [**delay** *seconds]*	Sets the IPv6 VRRP group to the preemption mode.
Ruijie(config-if)# **no vrrp ipv6** *group* **preempt** [**delay]**	Sets the IPv6 VRRP group to the non-preemption mode or restores the default delay.

The optional parameter *delay seconds* defines a delay before a backup VRRP router advertises itself as the master router of the VRRP group. It is 0 seconds by default. Once the VRRP function is enabled, the VRRP group works in preemption mode by default.

Setting the Accept_Mode of the IPv6 VRRP Virtual Router

The Accept_Mode can be set for the IPv6 VRRP virtual router that serves as the master router to determine whether to receive and process packets destined to the IP address of the IPv6 VRRP virtual router itself. If the Accept_Mode is enabled, the IPv6 VRRP virtual router receives and processes packets destined to the IP address of the virtual router itself. If the Accept_Mode is not enabled, the IPv6 VRRP virtual router discards packets destined to the IP address of the virtual router itself but does not discard NA and NS packets. By default, the Accept_Mode is disabled. In addition, the IPv6 VRRP virtual router in Owner state receives and processes packets destined to the IP address of the virtual router itself, no matter whether the Accept_Mode is enabled or disabled.

Command	**Function**

Ruijie(config-if)# **vrrp ipv6** *group* **accept_mode**	Enables the Accept_Mode for an IPv6 VRRP group.
Ruijie(config-if)# **no vrrp ipv6** *group* **accept_mode**	Disables the Accept_Mode for an IPv6 VRRP group.

Setting the Priority of the Router in the VRRP Group

According to VRRP, the role of a router in a VRRP group is determined by the priority of the router in the VRRP group. A router in a VRRP group becomes the active or master router of the VRRP group if it works in preemption mode, has the highest priority, and has obtained a virtual IP address. The other routers that have a priority lower than the priority of the master router in the VRRP group becomes backup or listening routers. Once the VRRP function is enabled on a router, the priority of the router in a VRRP group is 100 by default.

Command	Function
Ruijie(config-if)# **vrrp** *group* **priority** *level*	Sets the priority of a router in an IPv4 VRRP group.
Ruijie(config-if)# **no vrrp** *group* **priority**	Restores the default priority of a router in an IPv4 VRRP group.
Or:	
Ruijie(config-if)# **vrrp ipv6** *group* **priority** *level*	Sets the priority of a router in an IPv6 VRRP group.
Ruijie(config-if)# **no vrrp ipv6** *group* **priority**	Restores the default priority of a router in an IPv6 VRRP group.

The priority defined by the *level* parameter ranges from 1 to 254. If the virtual IP address of a VRRP group is consistent with the real IP address of an Ethernet interface on the local router, the priority of the local router in the VRRP group is 255. In this case, the VRRP group configured on the router is automatically in Master state as long as the Ethernet interface is available, no matter whether the VRRP group works in preemption mode or not.

Setting the Tracked Interface of the VRRP Group

After a tracked interface is set for the VRRP group, the system dynamically adjusts the priority of the local router according to the status of the tracked interface. When the tracked interface becomes unavailable, the local router decreases its VRRP group priority based on settings. At this time, another router in the VRRP group may become the active or master router of the VRRP group if its status is more stable and its priority is higher.

Command	Function
Ruijie(config-if)# **vrrp** *group* **track** *interface-type number* [*interface-priority*]	Sets the tracked interface of an IPv4 VRRP group.
Ruijie(config-if)# **no vrrp** *group* **track** *interface-type number*	Cancels the tracked interface set for an IPv4 VRRP group.
Or:	
Ruijie(config-if)# **vrrp ipv6** *group* **track** *interface-type number* [*interface-priority*]	Sets the tracked interface of an IPv6 VRRP group.
Ruijie(config-if)# **no vrrp ipv6** *group* **track** *interface-type number*	Cancels the tracked interface set for an IPv6 VRRP group.

By default, no tracked interface is set for a VRRP group. The value of the *interface-priority* parameter ranges from 1 to 255. It is 10 by default if not specified.

Note The tracked interface can only be a reachable logical Layer 3 (L3) interface, such as a routed port, SVI, loopback interface, or tunnel interface.

Setting the Tracked IPv4/IPv6 Address of the VRRP Group

After a tracked IP address is set for the VRRP group, the system dynamically adjusts the priority of the local router depending on whether the tracked IP address is reachable. When the tracked IP address is unreachable and cannot be pinged, the local router decreases its VRRP group priority based on settings. At this time, another router in the VRRP group may become the active or master router of the VRRP group if its priority is higher. In the following commands, the optional parameter *interval* defines an interval at which the system detects whether the destination address is reachable, the optional parameter *timeout* defines a timeout interval that is used to determine that the destination is unreachable, and the optional parameter *retry* defines the number of retries when the destination is unreachable.

Command	Function
Ruijie(config-if)# **vrrp** *group* **track** *ip-address* [**interval** *interval-value]* [**timeout** *timeout-value]* [**retry** *retry-value]* [*priority]*	Sets the tracked IP address of an IPv4 VRRP group.
Ruijie(config-if)# **no vrrp** *group* **track** *ip-address*	Cancels the tracked IP address set for an IPv4 VRRP group.
Or:	
Ruijie(config-if)# **vrrp ipv6** *group* **track** { *ipv6-global-address* | { *ipv6-linklocal-address interface-type number* } } [**interval** *interval-value]* [**timeout** *timeout-value]* [**retry** *retry-value]* [*priority]*	Sets the tracked IP address of an IPv6 VRRP group.
Ruijie(config-if)# **no vrrp ipv6** *group* **track** { *ipv6-global-address* | { *ipv6-linklocal-address interface-type number* } }	Cancels the tracked IP address set for an IPv6 VRRP group.

By default, no tracked IP address is set for a VRRP group. The value of the *interval-value* parameter ranges from 1 to 3600 seconds. It is 3 seconds by default if not specified. The value of the *timeout-value* parameter ranges from 1 to 60 seconds. It is 1 second by default if not specified.

The value of the *timeout-value* parameter must be smaller than or equal to that of the *interval-value* parameter. The value of the *retry-value* parameter ranges from 1 to 60. It is 1 by default if not specified. The value of the p*riority* parameter ranges from 1 to 255. It is 10 seconds by default if not specified. A VRRP IPv6 link-local IP address is preferred as the tracked IP address of an IPv6 VRRP group. If you set the tracked IP address to a link-local IP address, you must also set the specified interface.

Setting the Periodic Learning of VRRP Advertisement Packets

If the periodic learning function is enabled on the local router that is a VRRP backup router, the local router learns a VRRP advertisement interval from VRRP advertisement packets sent by the master router and calculates a VRRP master invalidity interval using the learned VRRP advertisement interval instead of the VRRP advertisement interval set on the local router itself. This command enables a backup router to synchronize the VRRP advertisement interval locally set on itself to the VRRP advertisement interval of the master router.

Command	Function
Ruijie(config-if)# **vrrp** *group* **timers learn**	Enables the periodic learning of IPv4 VRRP advertisement packets.
Ruijie(config-if)# **no vrrp** *group* **timers learn**	Disables the periodic learning of IPv4 VRRP advertisement packets.
Or:	
Ruijie(config-if)# **vrrp ipv6** *group* **timers learn**	Enables the periodic learning of IPv6 VRRP advertisement packets.
Ruijie(config-if)# **no vrrp ipv6** *group* **timers learn**	Disables the periodic learning of IPv6 VRRP advertisement packets.

By default, the periodic learning function is disabled for a VRRP group.

Note

If the advertisement interval that a VRRP backup router learns from a received VRRP advertisement packet is inconsistent with the VRRP advertisement interval locally set on the VRRP backup router and the periodic learning function is disabled on the VRRP backup router, the VRRP backup router discards the VRRP advertisement packet. Otherwise, the VRRP backup router receives the VRRP advertisement packet and calculates a VRRP master invalidity interval using the advertisement interval carried in the VRRP advertisement packet.

Setting the Description String of the VRRP Group on the Router

You can set a description string for a VRRP group to distinguish it from other VRRP groups.

Command	Function
Ruijie(config-if)# **vrrp** *group* **description** *text*	Sets the description string of an IPv4 VRRP group.
Ruijie(config-if)# **no vrrp** *group* **description**	Cancels the description string set for an IPv4 VRRP group.
Or:	
Ruijie(config-if)# **vrrp ipv6** *group* **description** *text*	Sets the description string of an IPv6 VRRP group.
Ruijie(config-if)# **no vrrp ipv6** *group* **description**	Cancels the description string set for an IPv6 VRRP group.

By default, no description string is set for a VRRP group. The description string of a VRRP group consists of at most 80 bytes.

Note

If the description string of a VRRP group contains blanks, the quotation mark (") must be used to identify the description string.

Setting the Start Delay of the VRRP Group

You can set the start delay of a VRRP group on a certain interface. The system supports two types of delay: system start delay and interface activity delay, which can be configured separately or together.

In non-preemption mode, a router with a higher VRRP group priority does not preempt the master router in the same VRRP group when it is started. In some cases, however, a router newly started preempts other routers to become the VRRP master router, even if it is set to the non-preemption mode. This is because the VRRP group on the interface does not receive the VRRP advertisement packet from the master router in the same VRRP group in time when the router is started or the interface becomes active.

To resolve the preceding problem, you can run a command to configure a start delay for the VRRP group. Then the VRRP group on the interface waits for a certain time before being started when the router is started or the interface becomes active, so that the non-preemption configuration takes effect.

If a VRRP advertisement packet is received on the interface after the start delay is set, the start delay is canceled and VRRP is immediately started on the interface.

Command	Function
Ruijie(config-if)# **vrrp delay** { **minimum** *min-seconds* | **reload** *reload-seconds* }	Sets the start delay of the VRRP group on the interface.
Ruijie(config-if)# **no vrrp delay**	Cancels the start delay set for the VRRP group on the interface.

By default, no start delay is configured for the VRRP group on an interface. Both the system start delay and the interface activity delay as mentioned previously range from 0 to 60 seconds. After this command is configured on an interface, the configurations apply to both IPv4 VRRP and IPv6 VRRP groups on the interface.

Setting the IPv4 VRRP Version

You can set the version of IPv4 VRRP to VRRPv2 or VRRPv3. By default, VRRPv2 is applied.

Command	Function
Ruijie(config-if)# **vrrp** *group* **version** { **2 | 3** }	Sets the IPv4 VRRP version.
Ruijie(config-if)# **no vrrp** *group* **version**	Uses the VRRPv2 by default.

Monitoring and Maintenance of VRRP

The **show vrrp**, **show ipv6 vrrp**, and **debug vrrp** commands are available for monitoring and maintaining VRRP. You can run the **show vrrp** command to check the IPv4 VRRP status of the local router, the **show ipv6 vrrp** command to check the IPv6 VRRP status of the local router, and the **debug vrrp** command to check VRRP information, such as status changes to a VRRP group, VRRP advertisement transmitting/receiving, and VRRP events.

show vrrp

Run the following **show vrrp** commands to check the IPv4 VRRP status of the local router:

Command	Function
Ruijie# **show** [**ipv6] vrrp** [**brief** | *group]*	Displays the IPv4 or IPv6 VRRP status of the local router.

Ruijie# **show** [**ipv6**] **vrrp interface** *type number* [**brief**]	Displays the IPv4 or IPv6 VRRP status of a specific network interface.

Command examples:

3) show [ipv6] vrrp

```
Ruijie# show vrrp
FastEthernet 0/0 - Group 1
State is Backup
Virtual IP address is 192.168.201.1 configured
Virtual MAC address is 0000.5e00.0101
Advertisement interval is 3 sec
Preemption is enabled
min delay is 0 sec
Priority is 100
Master Router is 192.168.201.213 , priority is 120
Master Advertisement interval is 3 sec
Master Down interval is 10.82 sec
FastEthernet 0/0 - Group 2
State is Master
Virtual IP address is 192.168.201.2 configured
Virtual MAC address is 0000.5e00.0102
Advertisement interval is 3 sec
Preemption is enabled
min delay is 0 sec
Priority is 120
Master Router is 192.168.201.217 (local), priority is 120
Master Advertisement interval is 3 sec
Master Down interval is 10.59 sec
Ruijie#show ipv6 vrrp
GigabitEthernet 0/13 - Group 1
  State is Master
  Virtual IPv6 address is as follows:
    FE80::2
    1::2
  Virtual MAC address is 0000.5e00.0201
  Advertisement interval is 1 sec
  Preemption is enabled
    min delay is 0 sec
  Priority is 100
  Master Router is FE80::1 (local), priority is 100
  Master Advertisement interval is 1 sec
  Master Down interval is 3.60 sec
```

The command outputs include the following information:

- Names of Ethernet interfaces where IPv4/IPv6 VRRP groups are configured

- ID, status, priority, preemption mode, VRRP advertisement interval, virtual IP address, and virtual MAC address of each VRRP group configured on the interfaces
- IP address, priority, advertisement interval, and invalidity interval of the master router in each VRRP group
- Tracked interface and priority change metric of each VRRP group

4) show [ipv6] vrrp brief

```
Ruijie# show vrrp brief
Interface       Grp  Pri  Time  Own  Pre  State   Master addr     Group addr
FastEthernet 0/0  1   100  3.60  -    P   Backup  192.168.201.213  192.168.201.1
FastEthernet 0/0  2   120  3.53  -    P   Master  192.168.201.217  192.168.201.2
Ruijie#show ipv6 vrrp brief
Interface           Grp  Pri  timer  Own  Pre  State   Master addr   Group addr
GigabitEthernet 0/13  1   100  3.60   -    P    Master  FE80::1      FE80::2
```

- The command outputs include the following information:
- Names of Ethernet interfaces where IPv4/IPv6 VRRP groups are configured
- ID, status, priority, preemption mode, and virtual IP address of each VRRP group configured on the interfaces
- IP address of the mater router in each VRRP group

5) show [ipv6] vrrp interface

```
Ruijie# show vrrp interface FastEthernet 0/0
FastEthernet 0/0 - Group 1
State is Backup
Virtual IP address is 192.168.201.1 configured
Virtual MAC address is 0000.5e00.0101
Advertisement interval is 3 sec
Preemption is enabled
VRRP standard version is V3
min delay is 0 sec
Priority is 100
Master Router is 192.168.201.213 , priority is 120
Master Advertisement interval is 3 sec
Master Down interval is 10.82 sec
FastEthernet 0/0 - Group 2
State is Master
Virtual IP address is 192.168.201.2 configured
Virtual MAC address is 0000.5e00.0102
Advertisement interval is 3 sec
Preemption is enabled
min delay is 0 sec
Priority is 120
Master Router is 192.168.201.217 (local), priority is 120
Master Advertisement interval is 3 sec
Master Down interval is 10.59 sec
Ruijie#
Ruijie#show ipv6 vrrp inter gig 0/13
GigabitEthernet 0/13 - Group 1
  State is Master
```

```
 Virtual IPv6 address is as follows:
   FE80::2
   1::2
 Virtual MAC address is 0000.5e00.0201
 Advertisement interval is 1 sec
 Preemption is enabled
   min delay is 0 sec
 Priority is 100
 Master Router is FE80::1 (local), priority is 100
 Master Advertisement interval is 1 sec
 Master Down interval is 3.60 sec
```

The command outputs include the following information:

- Names of Ethernet interfaces where IPv4/IPv6 VRRP groups are configured
- ID, status, priority, preemption mode, VRRP advertisement interval, virtual IP address, and virtual MAC address of each VRRP group configured on the interfaces
- IP address, priority, advertisement interval, and invalidity interval of the master router in each VRRP group
- Tracked interface and priority change metric of each VRRP group

Debug vrrp

You can run the following **debug [ipv6] vrrp** commands to enable or disable VRRP debugging on the local router:

Command	Function
Ruijie# **debug [ipv6] vrrp errors**	Enables VRRP error debugging.
Ruijie# **no debug** [**ipv6**] **vrrp errors**	Disables VRRP error debugging.
Ruijie# **debug [ipv6] vrrp events**	Enables VRRP event debugging.
Ruijie# **no debug** [**ipv6**] **vrrp events**	Disables VRRP event debugging.
Ruijie# **debug [ipv6] vrrp packets**	Enables VRRP packet debugging.
Ruijie# **no debug** [**ipv6**] **vrrp packets**	Disables VRRP packet debugging.
Ruijie# **debug [ipv6] vrrp state**	Enables VRRP status debugging..
Ruijie# **no debug** [**ipv6**] **vrrp state**	Disables VRRP status debugging.
Ruijie# **debug [ipv6] vrrp**	Enables VRRP debugging.
Ruijie# **no debug** [**ipv6**] **vrrp**	Disables VRRP debugging.

Command examples:

1) **debug [ipv6] vrrp**

```
Ruijie# debug vrrp
Ruijie#
%VRRP-6-STATECHANGE: FastEthernet 0/0 IPv4 VRRP Grp 1 state Master -> Backup
VRRP: IPv4 VRRP Grp 1 Advertisement from 192.168.201.213 has invalid virtual address 192.168.1.1
VRRP: IPv4 VRRP Grp 1 on interface Gi0/13 is sending IPv4 VRRP V2 advertisement checksum a352.
Ruijie# debug ipv6 vrrp
Ruijie#
VRRP: IPv6 VRRP Grp 1 Event - Advert higher or equal priority
%VRRP-6-STATECHANGE: FastEthernet 0/0 IPv6 VRRP  Grp 1 state Backup -> Master
```

```
Ruijie#
VRRP: IPv6 VRRP Grp 1 on interface Gi0/13 is sending IPv6 VRRP v3 advertisement checksum 6de3.
```

The **debug [ipv6] vrrp** command is equivalent to a combination of commands **debug [ipv6] vrrp errors**, **debug [ipv6] vrrp events**, **debug [ipv6] vrrp packets**, and **debug [ipv6] vrrp state**.

2) debug [ipv6] vrrp errors

```
Ruijie# debug vrrp errors
Ruijie#
VRRP: IPv4 VRRP Grp 1 Advertisement from 192.168.1.1 has wrong checksum.
VRRP: IPv4 VRRP Grp 1 Advertisement from 192.168.1.1 has wrong checksum.
VRRP: IPv4 VRRP Grp 1 Advertisement from 192.168.1.1 has wrong checksum.
```

The preceding information indicates that the local router has received VRRP advertisement packets that contain checksum errors for IPv4 VRRP group 1 from 192.168.1.1.

```
Ruijie# debug ipv6 vrrp errors
Ruijie#
VRRP: IPv6 VRRP Grp 1 Advertisement from FE80::2D0:F8FF:FE22:DE00 has different IP address.
VRRP: IPv6 VRRP Grp 1 Advertisement from FE80::2D0:F8FF:FE22:DE00 has different IP address.
VRRP: IPv6 VRRP Grp 1 Advertisement from FE80::2D0:F8FF:FE22:DE00 has different IP address.
```

The preceding information indicates that the local router has received VRRP advertisement packets that carry different IPv6 group addresses for the same IPv6 VRRP group.

3) debug [ipv6] vrrp events

```
Ruijie# debug vrrp events
Ruijie#
VRRP: IPv4 VRRP Grp 1 Event - Advert higher or equal priority
VRRP: IPv4 VRRP Grp 1 Event - Advert higher or equal priority
Ruijie# debug ipv6 vrrp events
VRRP: IPv6 VRRP Grp 1 Event - Advert higher or equal priority
Ruijie#
```

The preceding information indicates that the local router has received VRRP advertisement packets with a priority higher than or equal to the local priority for local IPv4 VRRP and IPv6 VRRP groups.

4) debug [ipv6] vrrp packets

```
Ruijie# debug vrrp packets
Ruijie#
VRRP: IPv4 VRRP Grp 1 on interface Gi0/13 is sending IPv4 VRRP V2 advertisement checksum a352.
VRRP: IPv4 VRRP Grp 1 on interface Gi0/13 is sending IPv4 VRRP V2 advertisement checksum a352.
Ruijie# debug ipv6 vrrp packets
VRRP: IPv6 VRRP Grp 1 on interface Gi0/13 is sending IPv6 VRRP v3 advertisement checksum 6de3.
VRRP: IPv6 VRRP Grp 1 on interface Gi0/13 is sending IPv6 VRRP v3 advertisement checksum 6de3.
```

The preceding information indicates that local IPv4 VRRP group 1 and local IPv6 VRRP group 1 are sending VRRP advertisement packets.

```
Ruijie# debug vrrp packets
```

```
Ruijie#
VRRP: IPv4 VRRP Grp 1 on interface Gi0/13 received ipv4 v2 advertisement priority 100, source
192.168.1.1.
Ruijie# debug ipv6 vrrp packets

VRRP: IPv6 VRRP Grp 1 on interface Gi0/13 received ipv6 v3 advertisement priority 100, source
FE80::1.
```

The preceding information indicates that the local router has received a VRRP advertisement packet with the priority of 100 for IPv4 VRRP group 1 from 192.168.1.1 and also a VRRP advertisement for IPv6 VRRP group 1 from fe80::1.

5) debug [ipv6] vrrp state

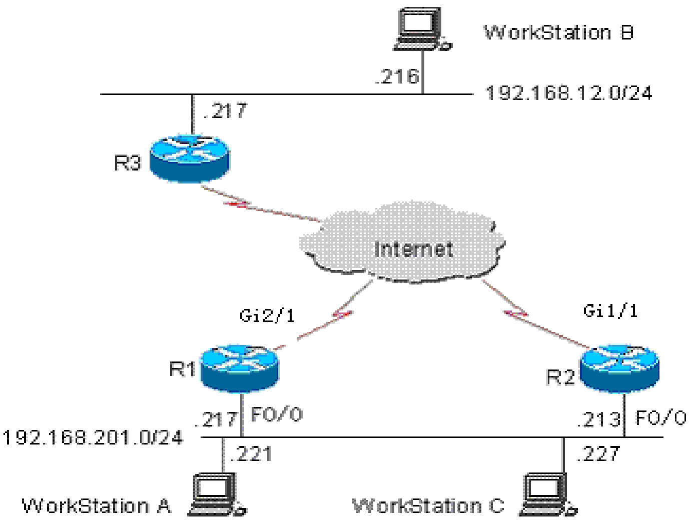
```
Ruijie# debug vrrp state
Ruijie#
VRRP: IPv4 VRRP Grp 1 add primary virtual IP, startup
Ruijie# debug ipv6 vrrp state
VRRP: IPv6 VRRP Grp 1 add primary virtual IP, startup.
```

The preceding information indicates that both the IPv4 VRRP group and the IPv6 VRRP group on the interface FastEthernet 0/0 are configured with a primary IP address and started.

Example of Configuring an IPv4 VRRP Group

As shown in Figure 4, a VRRP group is configured on routers R1 and R2 to provide the VRRP service for the internal network segment 192.168.201.0/24, whereas only the common routing function instead of any VRRP group is enabled on R3. This example shows VRRP-related configurations on routers R1 and R2 only.

Figure 4 VRRP network topology



In the following example, the configuration of router R3 is invariable. The following shows configurations on R3:

```
!
!
hostname "R3"
!
```

```
!
!
interface FastEthernet 0/0
/* The no switchport command needs to be run on a switch only*/
no switchport
ip address 192.168.12.217 255.255.255.0
!
interface GigabitEthernet 1/1
/* The no switchport command needs to be run on a switch only*/
no switchport
ip address 60.154.101.5 255.255.255.0
!
interface GigabitEthernet 2/1
/* The no switchport command needs to be run on a switch only*/
no switchport
ip address 202.101.90.61 255.255.255.0
!
router ospf
network 202.101.90.0 0.0.0.255 area 10
network 192.168.12.0 0.0.0.255 area 10
network 60.154.101.0 0.0.0.255 area 10
!
!
!
end
```

Example of Configuring a VRRP Group

Devices are connected, as shown in Figure 1-4. In this example, a workstation group (192.168.201.0/24) uses a VRRP group formed by routers R1 and R2. Its gateway is set to the virtual router IP address 192.168.201.1 of the VRRP group, so that the workstation group can access a remote workstation group whose network address is 192.168.12.0/24 through the virtual router 192.168.201.1. Here, R1 is set as the master router of the VRRP group. In normal cases, R1 provides the gateway (192.168.201.1) function. If R1 is unreachable because it is shut down or faulty, R2 takes the place of R1 to provide the gateway function. Below are related configurations on R1 and R2.

Configurations on R1:

```
!
!
hostname "R1"
!
!
interface FastEthernet 0/0
ip address 192.168.201.217 255.255.255.0
vrrp 1 priority 120
vrrp 1 version 3
vrrp 1 timers advertise 3
vrrp 1 ip 192.168.201.1
!
interface GigabitEthernet 2/1
ip address 202.101.90.63 255.255.255.0
!
router ospf
network 202.101.90.0 0.0.0.255 area 10
network 192.168.201.0 0.0.0.255 area 10
!
```

Configurations on R2:

```
!
hostname "R2"
!
interface FastEthernet 0/0
ip address 192.168.201.213 255.255.255.0
vrrp 1 ip 192.168.201.1
 vrrp 1 version 3
vrrp 1 timers advertise 3
!
interface GigabitEthernet 1/1
/* The no switchport command needs to be run on a switch only*/
no switchport
ip address 60.154.101.3 255.255.255.0
!
!
router ospf
network 60.154.101.0 0.0.0.255 area 10
network 192.168.201.0 0.0.0.255 area 10
!
!
end
```

As can be seen, R1 and R2 belong to IPv4 VRRP group 1. Both routers use VRRPv3, point to the same virtual router IP address 192.168.201.1, and work in VRRP preemption mode. Since the priority of R1 in the IPv4 VRRP group is 120 but that of R2 is the default value 100, R1 works as the master router of the IPv4 VRRP group in normal cases.

Example of Configuring the Tracked Interface of an IPv4 VRRP Group

Devices are connected, as shown in Figure 4. In this example, a workstation group (192.168.201.0/24) uses a VRRP group formed by routers R1 and R2. Its gateway is set to the virtual router IP address 192.168.201.1 of the VRRP group, so that the workstation group can access a remote workstation group whose network address is 192.168.12.0/24 through the virtual router 192.168.201.1. Here, R1 is set as the master router of the VRRP group. Different from the example as described previously for configuring a single VRRP group, a VRRP tracked interface (GigabitEthernet 2/1) is set on R1. In normal cases, R1 provides the virtual gateway (192.168.201.1) function. If R1 is unreachable because it is shut down or faulty, R2 takes the place of R1 to provide the virtual gateway function. In particular, when the interface GigabitEthernet

2/1 on R1 to connect to a wide area network (WAN) is unavailable, R1 decreases its VRRP group priority based on settings, so that R2 has a chance to become the master router and provide the virtual gateway function. If the interface GigabitEthernet 2/1 on R1 is recovered later, R1 restores its own VRRP group priority and then become the master router to provide the virtual gateway function. Below are related configurations on R1 and R2.

Configurations on R1:

```
!
!
hostname "R1"
!
!
interface FastEthernet 0/0
ip address 192.168.201.217 255.255.255.0
vrrp 1 priority 120
vrrp 1 timers advertise 3
vrrp 1 ip 192.168.201.1
vrrp 1 track GigabitEthernet 2/1 30
!

interface GigabitEthernet 2/1
ip address 202.101.90.63 255.255.255.0
!
router ospf
network 202.101.90.0 0.0.0.255 area 10
network 192.168.201.0 0.0.0.255 area 10
!
!
end
```

Configurations on R2:

```
!
!
hostname "R2"
!
interface FastEthernet 0/0
ip address 192.168.201.213 255.255.255.0
vrrp 1 ip 192.168.201.1
vrrp 1 timers advertise 3
!
interface GigabitEthernet 1/1
ip address 60.154.101.3 255.255.255.0
!
router ospf
network 60.154.101.0 0.0.0.255 area 10
network 192.168.201.0 0.0.0.255 area 10
```

```
!
!
end
```

As can be seen, R1 and R2 belong to VRRP group 1. Both routers use the same VRRP group authentication mode (no-authentication), point to the same virtual router IP address 192.168.201.1, and work in VRRP preemption mode. The VRRP advertisement interval is set to three seconds on both R1 and R2. Since the priority of R1 in the VRRP group is 120 but that of R2 is the default 100, R1 works as the master router of the VRRP group in normal cases. If R1 detects that its interface GigabitEthernet 2/1 to the WAN is unavailable, it decreases its VRRP group priority by 30 to 90, so that R2 becomes the master router. If R1 detects later that its interface GigabitEthernet 2/1 to the WAN is available again, it increases its own VRRP group priority by 30 to 120, so that R1 again becomes the master router.

Configuring Multiple IPv4 VRRP Groups

Multiple VRRP groups can be configured on one Ethernet interface to implement load balancing and backup one another to provide more reliable and stable network services.

Devices are connected, as shown in Figure 4. In this example, a workstation group (192.168.201.0/24) uses two VRRP groups formed by routers R1 and R2. The gateway of some workstations such as workstation A is set to the virtual IP address 192.168.201.1 of VRRP group 1, and that of the rest workstations such as workstation C is set to the virtual IP address 192.168.201.2 of VRRP group 2. R1 serves as the master router of VRRP group 2 and the backup router of VRRP group 1, whereas R2 serves as the master router of VRRP group 1 and the backup router of VRRP group 2. Below are related configurations on R1 and R2.

Configurations on R1:

```
!
!
hostname "R1"
!
interface FastEthernet 0/0
ip address 192.168.201.217 255.255.255.0
vrrp 1 timers advertise 3
vrrp 1 ip 192.168.201.1
vrrp 2 priority 120
vrrp 2 timers advertise 3
vrrp 2 ip 192.168.201.2
vrrp 2 track GigabitEthernet 2/1 30
!
interface GigabitEthernet 2/1
ip address 202.101.90.63 255.255.255.0
!
router ospf
network 202.101.90.0 0.0.0.255 area 10
network 192.168.201.0 0.0.0.255 area 10
!
!
end
```

Configurations on R2:

```
!
!
hostname "R2"
!
interface FastEthernet 0/0
ip address 192.168.201.213 255.255.255.0
vrrp 1 ip 192.168.201.1
vrrp 1 timers advertise 3
vrrp 1 priority 120
vrrp 2 ip 192.168.201.2
vrrp 2 timers advertise 3
!
interface GigabitEthernet 1/1

end
```

As can be seen, R1 and R2 back up each other. They serve as the master router in VRRP group 1 or 2 to provide different virtual gateways.

Example of Configuring an IPv6 VRRP Group

Configuring a VRRP Group

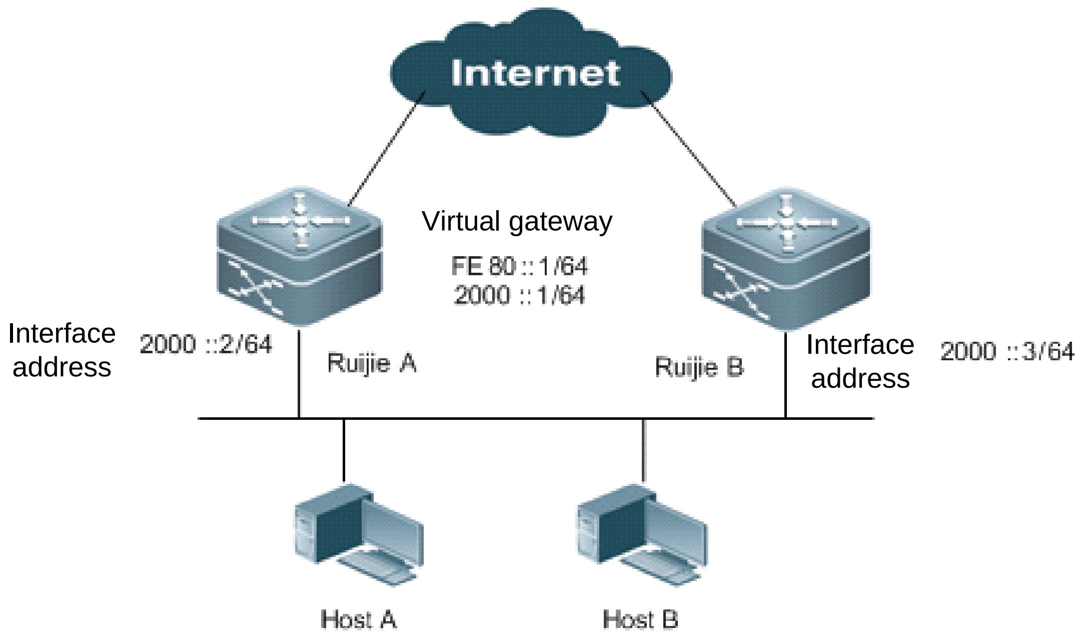
Networking Requirements

This configuration instance is applicable to both switches and routers.

- Hosts A and B access the Internet through a gateway. The default gateway is 2000::1/64 on both hosts.
- Ruijie A and Ruijie B are two routers that form IPv6 VRRP group 1. The virtual addresses are 2000::1/64 and FE80::1.
- When Ruijie A works properly, the packets of Host A to the Internet are forwarded by Ruijie A. When Ruijie A fails, the packets of Host A to the Internet are forwarded by Ruijie B.

Networking Topology

Figure 5 Network topology of the example for configuring an IPv6 VRRP group



Configuration Steps

Configurations on Ruijie A:

# Configure an IPv6 address on an interface to enable the IPv6 service on the interface.

```
interface FastEthernet 0/1
```

/* The **no switchport** command needs to be run on a switch only*/

```
no switchport
ipv6 address 2000::2/64
!
```

# Create IPv6 VRRP group 1 and configure virtual IPv6 addresses FE80::1 and 2000::1.

```
interface FastEthernet 0/0
vrrp 1 ipv6 FE80::1
vrrp 1 ipv6 2000::1
```

# Change the priority of IPv6 VRRP group 1 to 120.

```
vrrp ipv6 1 priority 120
```

# Change the advertisement interval of IPv6 VRRP group 1 to 3s.

```
vrrp ipv6 1 timers advertise 3
```

# Set the Accept_Mode of the IPv6 VRRP group.

```
vrrp ipv6 1 accept_mode
!
```

Configurations on Ruijie B:

# Create IPv6 VRRP group 1 and configure virtual IPv6 addresses FE80::1 and 2000::1.

```
interface FastEthernet 0/1
```

/* The **no switchport** command needs to be run on a switch only*/

```
no switchport
ipv6 address 2000::3/64
!
```

# Create IPv6 VRRP group 1 and configure virtual IPv6 addresses FE80::1 and 2000::1.

```
interface FastEthernet 0/0
vrrp 1 ipv6 FE80::1
vrrp 1 ipv6 2000::1
```

# Change the priority of IPv6 VRRP group 1 to 120.

```
vrrp ipv6 1 priority 100
```

# Change the advertisement interval of IPv6 VRRP group 1 to 3s.

```
vrrp ipv6 1 timers advertise 3
```

# Set the Accept_Mode of the IPv6 VRRP group.

```
vrrp ipv6 1 accept_mode
```

As can be seen, Ruijie A and Ruijie B belong to IPv6 VRRP group 1, point to the same virtual router IPv6 address (2000::1), and work in VRRP preemption mode. Since the priority of Ruijie A in the IPv6 VRRP group is 120 and that of Ruijie B is the default 100, Ruijie A works as the master router of the IPv6 VRRP group in normal cases.

Verification

Run the **show ipv6 vrrp 1** command to check VRRP configuration information after the configuration is complete.

# Show configurations on Ruijie A

```
Ruijie#show ipv6 vrrp 1
FastEthernet 0/1 - Group 1
  State is Master
  Virtual IPv6 address is as follows:
FE80::1
2000::1
  Virtual MAC address is 0000.5e00.0201
  Advertisement interval is 3 sec
  Accept_Mode is enabled
  Preemption is enabled
    min delay is 0 sec
  Priority is 120
  Master Router is FE80::1234 (local), priority is 120
  Master Advertisement interval is 3 sec
  Master Down interval is 10.59 sec
```

# Show configurations on Ruijie B

```
Ruijie#show ipv6 vrrp 1
FastEthernet 0/1 - Group 1
  State is Backup
  Virtual IPv6 address is as follow:
FE80::1
2000::1
  Virtual MAC address is 0000.5e00.0201
  Advertisement interval is 3 sec
  Accept_Mode is enabled
  Preemption is enabled
    min delay is 0 sec
  Priority is 100
  Master Router is FE80::1234, priority is 120
  Master Advertisement interval is 3 sec
  Master Down interval is 10.82 sec
```

Example of Configuring the Tracked Interface of an IPv6 VRRP Group

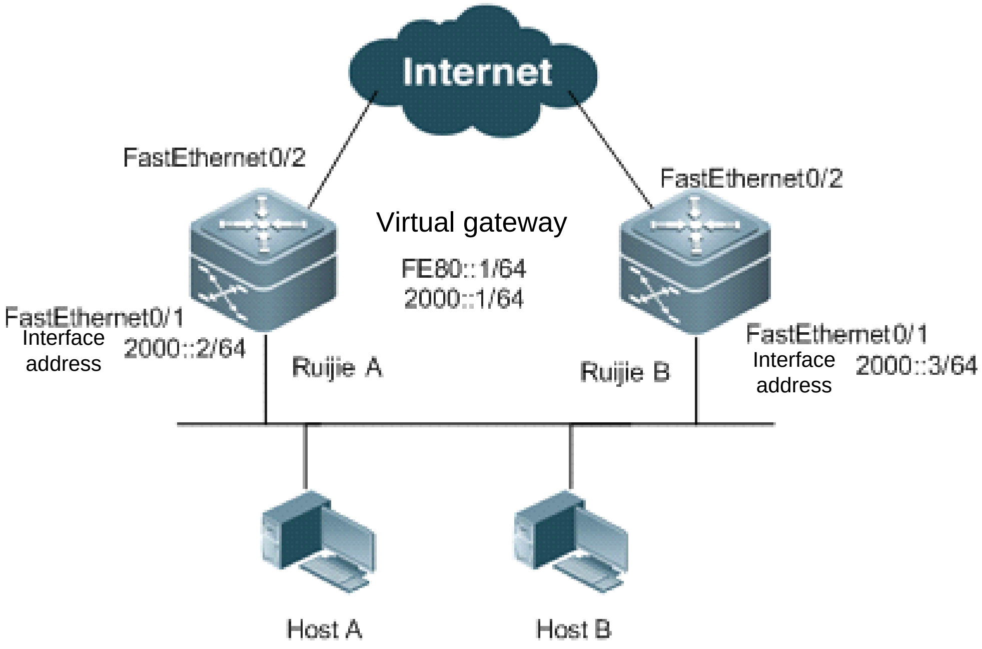
Networking Requirements

This configuration instance is applicable to both switches and routers.

- Host A and Host B access the Internet through a gateway. The default gateway is 2000::1/64 on both hosts.
- Ruijie A and Ruijie B are two routers that form IPv6 VRRP group 1. The virtual addresses are 2000::1/64 and FE80::1.
- Ruijie A tracks the interface FastEthernet 0/2 to the Internet. When the interface FastEthernet 0/2 is unavailable, Ruijie A decreases its VRRP group priority so that Ruijie B serves as the master router to provide the gateway function.

Networking Topology

Figure 6 Network topology of the example for configuring the tracked interface of an IPv6 VRRP group



Configuration Steps

Configurations on Ruijie A:

# Configure an IPv6 address on an interface to enable the IPv6 service on the interface.

```
interface FastEthernet 0/0
```

/* The **no switchport** command needs to be run on a switch only*/

```
no switchport
ipv6 address 2000::2/64
!
```

# Create IPv6 VRRP group 1 and configure virtual IPv6 addresses FE80::1 and 2000::1.

```
interface FastEthernet 0/0
vrrp 1 ipv6 FE80::1
vrrp 1 ipv6 2000::1
!
```

# Change the priority of IPv6 VRRP group 1 to 120.

```
vrrp ipv6 1 priority 120
!
```

# Change the advertisement interval of IPv6 VRRP group 1 to 3s.

```
vrrp ipv6 1 timers advertise 3
!
```

# Configure the tracked interface FastEthernet 0/2 for IPv6 VRRP group 1.

```
vrrp ipv6 1 track FastEthernet 0/2 50
```

# Set the Accept_Mode of the IPv6 VRRP group.

```
vrrp ipv6 1 accept_mode
```

Configurations on Ruijie B:

# Create IPv6 VRRP group 1 and configure virtual IPv6 addresses FE80::1 and 2000::1.

```
interface FastEthernet 0/0
```

/* The **no switchport** command needs to be run on a switch only*/

```
no switchport
ipv6 address 2000::3/64
!
```

# Create IPv6 VRRP group 1 and configure virtual IPv6 addresses FE80::1 and 2000::1.

```
interface FastEthernet 0/0
vrrp 1 ipv6 FE80::1
vrrp 1 ipv6 2000::1
```

# Change the priority of IPv6 VRRP group 1 to 100.

```
vrrp ipv6 1 priority 100
!
```

# Change the advertisement interval of IPv6 VRRP group 1 to 3s.

```
vrrp ipv6 1 timers advertise 3
```

# Set the Accept_Mode of the IPv6 VRRP group.

```
vrrp ipv6 1 accept_mode
```

As can be seen, Ruijie A and Ruijie B belong to IPv6 VRRP group 1, point to the same virtual router IPv6 address (2000::1), and work in IPv6 VRRP preemption mode. Since the priority of Ruijie A in the IPv6 VRRP group is 120 and that of Ruijie B is the default 100, Ruijie A works as the master router of the IPv6 VRRP group in normal cases. If Ruijie A detects that its interface FastEthernet 0/2 is unavailable, it decreases its VRRP group priority by 50 to 70, so that Ruijie B becomes the master router. If Ruijie A detects later that its interface FastEthernet 0/2 is available again, it increases its VRRP group priority by 50 to 120, so that Ruijie A again becomes the master router.

Verification

Run the **show ipv6 vrrp 1** command to check VRRP configuration information after the configuration is complete.

# Show configurations on Ruijie A

```
Ruijie#show ipv6 vrrp 1
FastEthernet 0/1 - Group 1
  State is Master
  Virtual IPv6 address is as follows:
```

```
FE80::1
2000::1
  Virtual MAC address is 0000.5e00.0201
  Advertisement interval is 3 sec
  Accept_Mode is enabled
  Preemption is enabled
    min delay is 0 sec
  Priority is 120
  Master Router is FE80::1234 (local), priority is 120
  Master Advertisement interval is 3 sec
  Master Down interval is 10.59 sec
Tracking state of 1 interface, 1 up:
    up FastEthernet 0/2 priority decrement=50
```

# Show configurations on Ruijie B

```
Ruijie#show ipv6 vrrp 1
FastEthernet 0/1 - Group 1
  State is Backup
  Virtual IPv6 address is as follow:
FE80::1
2000::1
  Virtual MAC address is 0000.5e00.0201
  Advertisement interval is 3 sec
  Accept_Mode is enabled
  Preemption is enabled
    min delay is 0 sec
  Priority is 100
  Master Router is FE80::1234, priority is 120
  Master Advertisement interval is 3 sec
  Master Down interval is 10.82 sec
```

Example of Configuring Multiple IPv6 VRRP Groups

Multiple VRRP groups can be configured on one Ethernet interface to implement load balancing and backup one another to provide more reliable and stable network services.

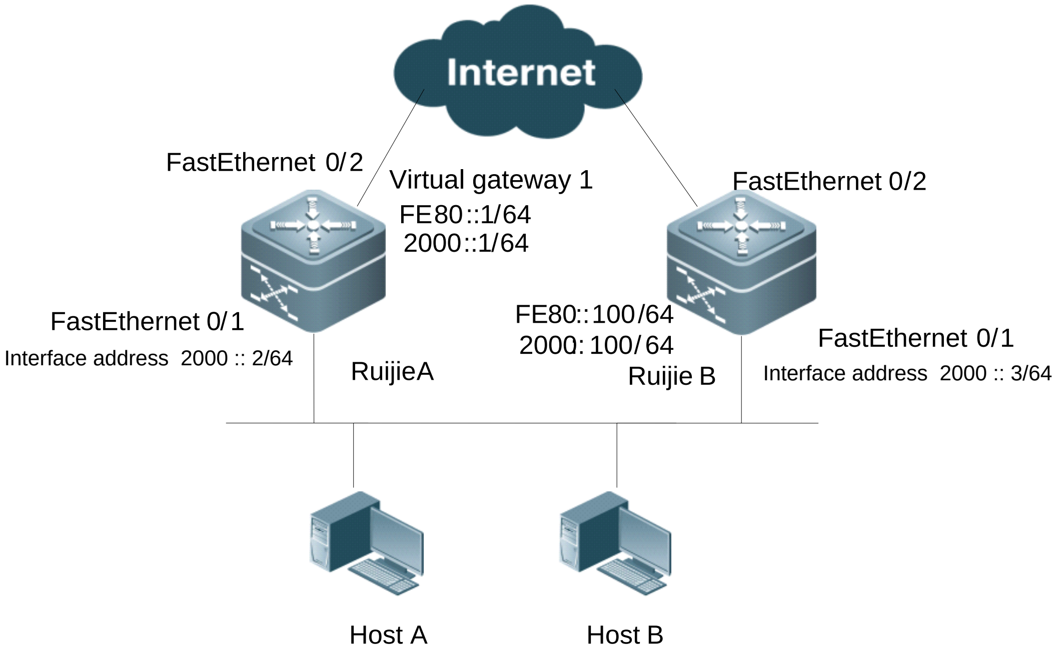
Networking Requirements

This configuration instance is applicable to both switches and routers.

- Host A and Host B access the Internet through gateways. The default gateway for Host A is 2000::1/64, and that for Host B is 2000::100/64.
- Ruijie A and Ruijie B are two routers that form IPv6 VRRP group 1. The virtual addresses are 2000::1/64 and FE80::1.
- Ruijie A and Ruijie B also form IPv6 VRRP group 2. The virtual addresses are 2000::100/64 and FE80::100.
- Ruijie A and Ruijie B serve as gateways to forward traffic and back up each other.

Networking Topology

Figure 7 Network topology of the example for configuring multiple IPv6 VRRP groups



Configuration Steps

Configurations on Ruijie A:

# Configure an IPv6 address on an interface to enable the IPv6 service on the interface.

```
interface FastEthernet 0/0
```

/* The **no switchport** command needs to be run on a switch only*/

```
no switchport
ipv6 address 2000::2/64
!
```

# Create IPv6 VRRP group 1 and configure virtual IPv6 addresses FE80::1 and 2000::1.

```
interface FastEthernet 0/0
vrrp 1 ipv6 FE80::1
vrrp 1 ipv6 2000::1
!
```

# Change the priority of IPv6 VRRP group 1 to 120.

```
vrrp ipv6 1 priority 120
!
```

# Change the advertisement interval of IPv6 VRRP group 1 to 3s.

```
vrrp ipv6 1 timers advertise 3
```

# Set the Accept_Mode of IPv6 VRRP group 1.

```
vrrp ipv6 1 accept_mode
!
```

# Create IPv6 VRRP group 2 and configure virtual IPv6 addresses FE80::100 and 2000::100.

```
vrrp 2 ipv6 FE80::100
vrrp 2 ipv6 2000::100
!
```

# Change the priority of IPv6 VRRP group 2 to 100.

```
vrrp ipv6 2 priority 100
```

# Change the advertisement interval of IPv6 VRRP group 2 to 3s.

```
vrrp ipv6 2 timers advertise 3
```

# Set the Accept_Mode of IPv6 VRRP group 2.

```
vrrp ipv6 2 accept_mode
```

Configurations on Ruijie B:

```
interface FastEthernet 0/0
```

/* The **no switchport** command needs to be run on a switch only*/

```
no switchport
ipv6 address 2000::3/64
!
```

# Create IPv6 VRRP group 1 and configure virtual IPv6 addresses FE80::1 and 2000::1.

```
interface FastEthernet 0/0
vrrp 1 ipv6 FE80::1
vrrp 1 ipv6 2000::1
```

# Change the priority of IPv6 VRRP group 1 to 100.

```
vrrp ipv6 1 priority 100
!
```

# Change the advertisement interval of IPv6 VRRP group 1 to 3s.

```
vrrp ipv6 1 timers advertise 3
```

# Set the Accept_Mode of IPv6 VRRP group 1.

```
vrrp ipv6 1 accept_mode
!
!
```

# Create IPv6 VRRP group 2 and configure virtual IPv6 addresses FE80::100 and 2000::100.

```
vrrp 2 ipv6 FE80::100
vrrp 2 ipv6 2000::100
!
```

# Change the priority of IPv6 VRRP group 2 to 120.

```
vrrp ipv6 2 priority 120
```

# Change the advertisement interval of IPv6 VRRP group 2 to 3s.

```
vrrp ipv6 2 timers advertise 3
!
```

# Set the Accept_Mode of IPv6 VRRP group 2.

```
vrrp ipv6 2 accept_mode
!
```

As can be seen, Ruijie A and Ruijie B belong to IPv6 VRRP group 1, point to the same virtual router IPv6 address (2000::1), and work in IPv6 VRRP preemption mode. Since the priority of Ruijie A in IPv6 VRRP group 1 is 120 and that of Ruijie B is the default 100, Ruijie A works as the master router of IPv6 VRRP group 1 in normal cases. In IPv6 VRRP group 2, however, the priority of Ruijie A is 100 and that of Ruijie B is 120 and IPv6 VRRP group 2 works in preemption mode. Therefore, Ruijie B works as the master router of IPv6 VRRP group 2 in normal cases. For hosts in the same LAN, Host A uses IPv6 VRRP group 1 as the default gateway whereas Host B uses IPv6 VRRP group 2 as the default gateway. Route redundancy is implemented between Ruijie A and Ruijie B, which share LAN traffic and implement load balancing. In this example, default gateways must be manually set on IPv6 hosts to implement load balancing based on IPv6 VRRP groups.

Verification

Run the **show ipv6 vrrp** command to check VRRP configuration information after the configuration is complete.

# Show configurations on Ruijie A

```
Ruijie#show ipv6 vrrp
FastEthernet 0/1 - Group 1
  State is Master
  Virtual IPv6 address is as follows:
FE80::1
2000::1
  Virtual MAC address is 0000.5e00.0201
  Advertisement interval is 3 sec
  Accept_Mode is enabled
  Preemption is enabled
    min delay is 0 sec
  Priority is 120
  Master Router is FE80::1234 (local), priority is 120
  Master Advertisement interval is 3 sec
  Master Down interval is 10.59 sec
FastEthernet 0/1 - Group 2
  State is Backup
  Virtual IPv6 address is as follows:
FE80::100
2000::100
  Virtual MAC address is 0000.5e00.0202
  Advertisement interval is 3 sec
  Accept_Mode is enabled
  Preemption is enabled
    min delay is 0 sec
  Priority is 100
  Master Router is FE80::5678, priority is 120
  Master Advertisement interval is 3 sec
  Master Down interval is 10.82 sec
```

# Show configurations on Ruijie B

```
Ruijie#show ipv6 vrrp 1

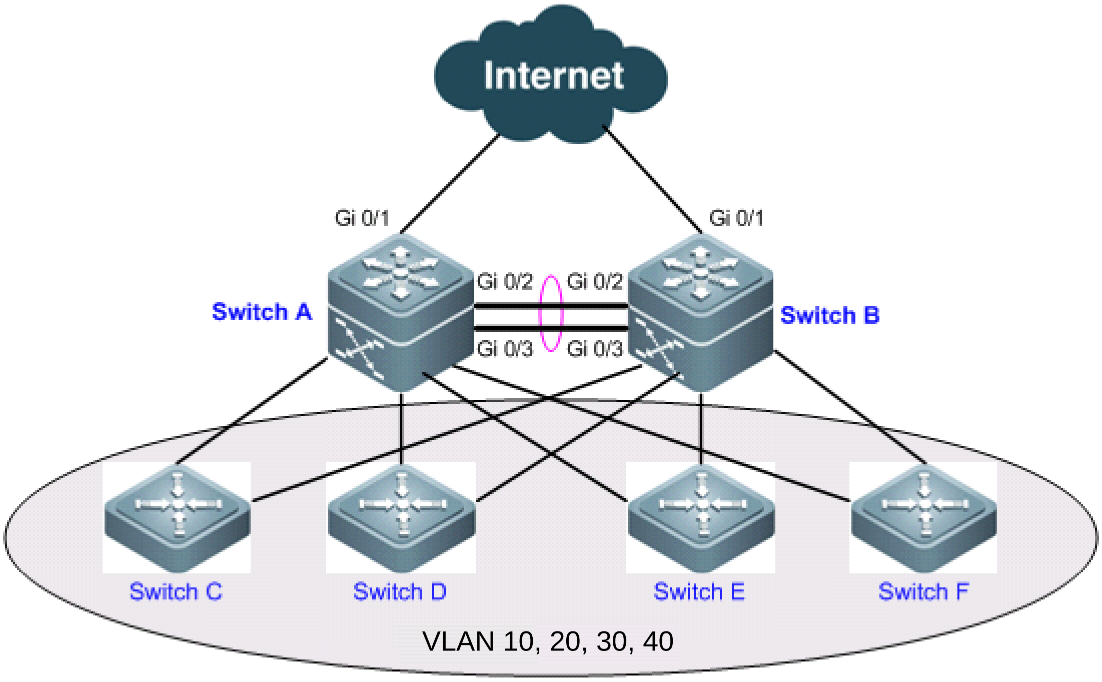
  State is Backup
  Virtual IPv6 address is as follow:
FE80::1
2000::1
  Virtual MAC address is 0000.5e00.0201
  Advertisement interval is 3 sec
  Accept_Mode is enabled
  Preemption is enabled
    min delay is 0 sec
  Priority is 100
  Master Router is FE80::1234, priority is 120
  Master Advertisement interval is 3 sec
  Master Down interval is 10.82 sec

FastEthernet 0/1 - Group 2
  State is Master
  Virtual IPv6 address is as follows:
FE80::100
2000::100
  Virtual MAC address is 0000.5e00.0202
  Advertisement interval is 3 sec
  Accept_Mode is enabled
  Preemption is enabled
    min delay is 0 sec
  Priority is 120
  Master Router is FE80::5678(local), priority is 120
  Master Advertisement interval is 3 sec
  Master Down interval is 10.59 sec
```

Configuring VRRP+MSTP

Networking Topology

Figure 8 Network topology of the VRRP dual-core solution



Networking Requirements

Figure 8 shows a typical network topology of the dual-core solution. This configuration instance is applicable to switches or switching cards of routers only. Users access Switches C, D, E, and F, which belong to VLAN 10, 20, 30, and 40 respectively. Switches A and B serve as gateways to enable users to communicate with external networks. The specific application requirements are described as follows:

- The Multiple Spanning Tree Protocol (MSTP) runs on devices to back up physical links and avoid loops. Different VLAN packets are forwarded along respective instances to implement layer 2 traffic load balancing.
- VRRP runs on devices to back up gateway routes and share LAN traffic.
- All links from access switches to the master router are monitored. When a link to the master router fails, the backup router immediately takes over the master router to forward data.

Configuration Tips

- Enable the MSTP function on devices (Switches A, B, C, D, E, and F in this example), configure mappings between VLANs and instances (VLANs 10 and 20 map to instance 1, VLANs 30 and 40 map to instance 2, and the rest VLANs map to instance 0 in this example), and set gateways (Switches A and B in this example) as the root bridges of respective instances.
- Add the switch virtual instances (SVIs) of various VLANs to respective VRRP groups, and set the master and backup routers of respective VRRP groups as gateways. The following table shows the specific configurations.

Gateway	VLAN ID	SVI	VRRP Group	Virtual IP Address	Status
Switch A	10	192.168.10.2	VRRP 10	192.168.10.1	Master
Switch B		192.168.10.3			Backup
Switch A	20	192.168.20.2	VRRP 20	192.168.20.1	Master
Switch B		192.168.20.3			Backup
Switch A	30	192.168.30.2	VRRP 30	192.168.30.1	Backup

Gateway	VLAN ID	SVI	VRRP Group	Virtual IP Address	Status
Switch B		192.168.30.3			Master
Switch A	40	192.168.40.2	VRRP 40	192.168.40.1	Backup
Switch B		192.168.40.3			Master

- Set the uplink ports on the master routers of VRRP groups as the tracked interfaces of the master routers. In this example, the tracked interfaces are two ports Gi 0/1 on Switches A and B.

Caution

When setting the tracked interface of a VRRP group, ensure that the value of the *Priority decrement* parameter is larger than the difference between the priority of the master router and the priority of the backup router. The system automatically decreases or increases the priority value of a router according to the status of the tracked interface on the router.

Configuration Steps

In this example, only VRRP+MSTP configurations on Switches A and B are listed. This example does not provide details about how to define VLANs on Switches C, D, E, and F or how to configure MSTP on devices. For details about MSTP configuration, see *MSTP Configuration*.

- Step 1: Create VLANs on devices.

！ Create VLANs 10, 20, 30, and 40 on Switch A:

```
SwitchA#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
SwitchA(config)#vlan range 10,20,30,40
SwitchA(config-vlan-range)#exit
```

！ Configure the same as above on Switch B.

- Step 2: Configure the Multiple Spanning Tree (MST) domain.

！ Configure mappings from VLANs 10 and 20 to instance 1, from VLANs 20 and 30 to instance 2, and from the rest VLANs to instance 0 on Switch A.

```
SwitchA(config)#spanning-tree mst configuration
SwitchA(config-mst)#instance 1 vlan 10,20
%Warning: you must create vlans before configuring instance-vlan relationship
SwitchA(config-mst)#instance 2 vlan 30,40
%Warning: you must create vlans before configuring instance-vlan relationship
SwitchA(config-mst)#exit
```

! Configure the same as above on Switch B.

Step 3: Set Switch A as the root bridges of MST instances 0 and 1, and set Switch B as the root bridge of MST instance 2.

! Set the priority of MST instances 0 and 1 to 4096 and that of MST instance 2 to 8192 on Switch A.

```
SwitchA(config)#spanning-tree mst 0 priority 4096
SwitchA(config)#spanning-tree mst 1 priority 4096
SwitchA(config)#spanning-tree mst 2 priority 8192
```

! Set the priority of MST instances 0 and 1 to 8192 and that of MST instance 2 to 4096 on Switch B.

```
SwitchB(config)#spanning-tree mst 2 priority 4096
SwitchB(config)#spanning-tree mst 0 priority 8192
SwitchB(config)#spanning-tree mst 1 priority 8192
```

- Step 4: Enable MSTP.

! Enable MSTP on Switch A.

```
SwitchA(config)#spanning-tree
Enable spanning-tree.
```

! Configure the same as above on Switch B.

- Step 5: Configure the SVIs of VLANs, add the SVIs to VRRP groups, and set the virtual IP addresses of VRRP groups. For details, see the preceding table.

! Configurations on Switch A:

```
SwitchA(config)#interface vlan 10
SwitchA(config-if-VLAN 10)#ip address 192.168.10.2 255.255.255.0
SwitchA(config-if-VLAN 10)#vrrp 10 ip 192.168.10.1
SwitchA(config-if-VLAN 10)#exit
SwitchA(config)#interface vlan 20
SwitchA(config-if-VLAN 20)#ip address 192.168.20.2 255.255.255.0
SwitchA(config-if-VLAN 20)#vrrp 20 ip 192.168.20.1
SwitchA(config-if-VLAN 20)#exit
SwitchA(config)#interface vlan 30
SwitchA(config-if-VLAN 30)#ip address 192.168.30.2 255.255.255.0
SwitchA(config-if-VLAN 30)#vrrp 30 ip 192.168.30.1
SwitchA(config-if-VLAN 30)#exit
SwitchA(config)#interface vlan 40
SwitchA(config-if-VLAN 40)#ip address 192.168.40.2 255.255.255.0
SwitchA(config-if-VLAN 40)#vrrp 40 ip 192.168.40.1
SwitchA(config-if-VLAN 40)#exit
```

! Configurations on Switch B:

```
SwitchB(config)#interface vlan 10
SwitchB(config-if-VLAN 10)#ip address 192.168.10.3 255.255.255.0
SwitchB(config-if-VLAN 10)#vrrp 10 ip 192.168.10.1
SwitchB(config-if-VLAN 10)#exit
SwitchB(config)#interface vlan 20
SwitchB(config-if-VLAN 20)#ip address 192.168.20.3 255.255.255.0
SwitchB(config-if-VLAN 20)#vrrp 20 ip 192.168.20.1
SwitchB(config-if-VLAN 20)#exit
SwitchB(config)#interface vlan 30
SwitchB(config-if-VLAN 30)#ip address 192.168.30.3 255.255.255.0
SwitchB(config-if-VLAN 30)#vrrp 30 ip 192.168.30.1
SwitchB(config-if-VLAN 30)#exit
SwitchB(config)#interface vlan 40
SwitchB(config-if-VLAN 40)#ip address 192.168.40.3 255.255.255.0
SwitchB(config-if-VLAN 40)#vrrp 40 ip 192.168.40.1
SwitchB(config-if-VLAN 40)#exit
```

- Step 6: Configure the master and backup routers of VRRP groups.

! Raise the priority of VRRP groups 10 and 20 on Switch A to 120, so that Switch A works as the master router of VRRP groups 10 and 20.

```
SwitchA(config)#interface vlan 10
SwitchA(config-if-VLAN 10)#vrrp 10 priority 120
SwitchA(config-if-VLAN 10)#exit
SwitchA(config)#interface vlan 20
SwitchA(config-if-VLAN 20)#vrrp 20 priority 120
SwitchA(config-if-VLAN 20)#exit
```

! Similarly, raise the priority of VRRP groups 30 and 40 on Switch B to 120.

```
SwitchB(config)#interface vlan 30
SwitchB(config-if-VLAN 30)#vrrp 30 priority 120
SwitchB(config-if-VLAN 30)#exit
SwitchB(config)#interface vlan 40
SwitchB(config-if-VLAN 40)#vrrp 40 priority 120
SwitchB(config-if-VLAN 40)#exit
```

- Step 7: Set the uplink ports on the master routers of VRRP groups as the tracked interfaces of VRRP groups. Ensure that the configured tracked interfaces are L3 interfaces.

! Set the port Gi 0/1 on Switch A as a route port and its IP address to 10.10.1.1/24.

```
SwitchA(config)#interface gigabitEthernet 0/1
SwitchA(config-if-GigabitEthernet 0/1)#no switchport
SwitchA(config-if-GigabitEthernet 0/1)#ip address 10.10.1.1 255.255.255.0
SwitchA(config-if-GigabitEthernet 0/1)#exit
```

! Set the port Gi 0/1 on Switch A as the tracked interface of VRRP groups 10 and 20, and *Priority decrement* to 30.

```
SwitchA(config)#interface vlan 10
SwitchA(config-if-VLAN 10)#vrrp 10 track gigabitEthernet 0/1 30
SwitchA(config-if-VLAN 10)#exit
SwitchA(config)#interface vlan 20
SwitchA(config-if-VLAN 20)#vrrp 20 track gigabitEthernet 0/1 30
SwitchA(config-if-VLAN 20)#exit
```

! Set the port Gi 0/1 on Switch B as a route port and its IP address to 10.10.2.1/24.

```
SwitchB(config)#interface gigabitEthernet 0/1
SwitchB(config-if-GigabitEthernet 0/1)#no switchport
SwitchB(config-if-GigabitEthernet 0/1)#ip address 10.10.2.1 255.255.255.0
SwitchB(config-if-GigabitEthernet 0/1)#exit
```

! Set the port Gi 0/1 on Switch B as the tracked interface of VRRP groups 30 and 40, and *interface-priority* to 30.

```
SwitchB(config)#interface vlan 30
SwitchB(config-if-VLAN 30)#vrrp 30 track gigabitEthernet 0/1 30
SwitchB(config-if-VLAN 30)#exit
SwitchB(config)#interface vlan 40
SwitchB(config-if-VLAN 40)#vrrp 40 track gigabitEthernet 0/1 30
SwitchB(config-if-VLAN 40)#exit
```

- Step 8: Set the interconnection ports between the two core devices (Switches A and B) as aggregation ports.

! Configurations on Switch A:

# Set ports Gi 0/2 and Gi 0/3 as aggregation ports, which serve as trunk ports.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#interface range gigabitEthernet 0/2-3
Ruijie(config-if-range)#port-group 1
Ruijie(config)#interface aggregateport 1
Ruijie(config-if-AggregatePort 1)#switchport mode trunk
```

! Configure the same as above on Switch B.

Verification

- Step 1: Check configuration information on devices.

! Check configuration information on Switch A.

```
SwitchA#show running-config

 vrrp 40 track GigabitEthernet 0/1 30
```

- Step 2: Check the VRRP status of each device.

! Check the VRRP status of Switch A.

```
SwitchA#show vrrp brief
Interface  Grp  Pri  timer  Own  Pre  State   Master addr   Group addr
VLAN 10    10   120  3      -    P    Master  192.168.10.2  192.168.10.1
VLAN 20    20   120  3      -    P    Master  192.168.20.2  192.168.20.1
VLAN 30    30   100  3      -    P    Backup  192.168.30.3  192.168.30.1
VLAN 40    40   100  3      -    P    Backup  192.168.40.3  192.168.40.1
```

! Check the VRRP status of Switch B.

```
SwitchB#show vrrp brief
Interface  Grp  Pri  timer  Own  Pre  State   Master addr   Group addr
VLAN 10    10   100  3      -    P    Backup  192.168.10.2  192.168.10.1
VLAN 20    20   100  3      -    P    Backup  192.168.20.2  192.168.20.1
VLAN 30    30   120  3      -    P    Master  192.168.30.3  192.168.30.1
VLAN 40    40   120  3      -    P    Master  192.168.40.3  192.168.40.1
```

As can be seen from above, Switch A serves as the master router of VRRP groups 10 and 20 and has a priority of 120 when links are normal, whereas Switch B serves as the backup routers of VRRP groups 10 and 20.

- Step 3: Disconnect the uplink of Switch A, and then check the VRRP status of Switches A and B.

! Check the VRRP status of Switch A.

```
SwitchA#show vrrp brief
Interface  Grp  Pri  timer  Own  Pre  State   Master addr   Group addr
VLAN 10    10   90   3      -    P    Backup  192.168.10.3  192.168.10.1
VLAN 20    20   90   3      -    P    Backup  192.168.20.3  192.168.20.1
VLAN 30    30   100  3      -    P    Backup  192.168.30.3  192.168.30.1
VLAN 40    40   100  3      -    P    Backup  192.168.40.3  192.168.40.1
```

! Check the VRRP status of Switch B.

```
SwitchB#show vrrp brief
Interface  Grp  Pri  timer  Own  Pre  State   Master addr   Group addr
VLAN 10    10   100  3      -    P    Master  192.168.10.3  192.168.10.1
VLAN 20    20   100  3      -    P    Master  192.168.20.3  192.168.20.1
VLAN 30    30   120  3      -    P    Master  192.168.30.3  192.168.30.1
VLAN 40    40   120  3      -    P    Master  192.168.40.3  192.168.40.1
```

As can be seen from above, when the uplink of Switch A fails, the system automatically decreases the priority of VRRP groups 10 and 20 to 90 and changes the VRRP status of Switch A to Backup, so that Switch B becomes the master router of VRRP groups 10 and 20.

Fault Diagnosis and Clearance

You can analyze and clear VRRP faults by checking configuration and debugging information. Below are some common faults and analysis methods:

Symptom

The virtual IPv4/IPv6 address of a VRRP group cannot be pinged.

Analysis

- Ensure that at least one router is active in the VRRP group.
- If the virtual IPv4/IPv6 address cannot be pinged from a device on another network, possibly the fault is caused because a short time is needed for VRRP status switching. Run the **show [ipv6] vrrp** command to check VRRP information and verify the root cause.
- If the virtual IPv4/IPv6 address cannot be pinged from a local network device in the same network segment as the virtual router, check whether the ARP table or neighbor discovery (ND) table on the local network device contains an ARP entry for the virtual IPv4/IPv6 address. If there is no ARP entry for the virtual IPv4/IPv6 address, check network lines.
- If the virtual IPv4/IPv6 address cannot be pinged from a local network device in a network segment that is different from the network segment where the virtual router resides, check whether a route to the virtual IPv4/IPv6 address has been configured on the local network device.

Symptom

Multiple master routers exist in a VRRP group.

Analysis

- Ethernet interfaces on the routers of the VRRP group are set to different VRRP group authentication modes.
- For VRRPv2, Ethernet interfaces on the routers of the VRRP group are set to the same plain text authentication mode but the configured authentication strings are inconsistent.
- The cables of the Ethernet interfaces on the routers of the VRRP group are disconnected, but the routers fail to detect the disconnection.
- The VRRP advertisement intervals configured on routers of the VRRP group are inconsistent, and the periodic learning of VRRP advertisement packets is disabled on the routers.
- Different virtual IPv4/IPv6 addresses are set for routers of the VRRP group.

Configuring Hot Swapping

Understanding Hot Swap

Overview

Hot swap refers to the ability of allowing removing a faulty line card and inserting the standby line card in a high-reliable system without restarting and shutting down the system.

Ruijie designs hot-swap products by complying with the rule of separating software settings from hardware application and separating the existence of line cards from the startup of line cards.

Ruijie employs the install/no install concept so that users can run the **install** command to pre-install and pre-configure a certain type of line card in a slot even if no line card is inserted in the slot. Management software can reserve all configurations of the line card. Whether to configure hardware depends on actual situations.

After users save settings, all pre-configuration information is stored. After routers are reset, this pre-configuration information is still effective.

During normal running of routers, removing and then inserting a line card will not lead to the loss of related hardware settings.

If the actual type of the newly inserted line card is different from the pre-configured type, the inserted line card is not enabled and users need to uninstall the original configuration to enable the line card.

The concept of “Two Hosts” is introduced in RSR30-X series routers. Every RSR30-X series router includes an LPU expansion box like an LPU-4HNM expansion box. One such LPU expansion box is under the management of two PSP30-X hosts with one host as a MASTER and another as SLAVE. MASTER serves as the major manager and SLAVE as the standby manager. When MASTER is faulty, SLAVE manages LPU. In this way, two hosts guarantee the reliability of LPU.

⚠ Caution

Comply with the following rules during hot swap to avoid causing abnormalities of software and hardware or even damaging line cards:

Operation Limits	Description
Remove Line Cards	1. Run the **remove** or **no install** commands, and remove line cards after the commands are executed. Print log similar to the one below to confirm that the **remove** or **no install** commands are fully executed. *May 17 10:24:03: %HOTPLUG-5-DISABLE_LINE_CARD_BEGIN: Begin to disable the line card in slot 1/0. *May 17 10:24:07: %HOTPLUG-5-DISABLE_LINE_CARD_OK: Disable line card in slot 1/0 OK.

	2. Remove one line card only at a time;
	3. Smoothly and securely remove line cards;
	4. During system startup, the line card must not be inserted;
	5. Print log similar to the one below to confirm that line cards are removed.
	`*May 17 10:28:38: %HOTPLUG-5-PULL_LINE_CARD_BEGIN: Begin process PULL event in slot 1/0.`
	`*May 17 10:28:38: %HOTPLUG-5-PULL_LINE_CARD_OK: PULL event in slot 1/0 process OK.`

Insert Line Cards	1. Line cards can only be inserted into slots after the completion of execution of the hot swap commands or previous removal of line cards. 2. Insert one line card only at a time; 3. Smoothly and securely insert line cards; 4. During system startup, the line card must not be inserted; 5. Line cards are only allowed to be inserted again after they are completely removed (slots and line cards are fully disconnected).

Configuring Hot Swap

Hot Swap Configuration Task List

Hot swap can be configured by following the task list below:

Installing and Uninstalling a Line Card Module

The pre-configuration function of Ruijie products allows users to run the **install** command to virtualize a line card module of the specified type (the line card module is not actually inserted in the slot), and then configure the line card module. After the line card module is inserted in the slot, all configuration automatically takes effect.

Command	Function
Ruijie(config)# **install** *slot-num moduletype*	Installs a line card module.
Ruijie(config)# **no install** *slot-num*	Uninstalls a line card module.

Inserting and Removing a Line Card Module

Follow the rules in the "Overview" section to insert and remove a line card.

You do not need to configure a command to insert a line card.

Before removing a line card, run the **remove** command.

Command	Function
Ruijie(config)# **remove** *slot-num*	Removes a line card.

Ruijie(config)# **no remove** *slot-num*	Restores line card configuration.

Note

When you run the **no remove** command, or directly insert the NMX-8E1/CE1 or NMX-4E1/CE1 line card, the communication over the interface that is not added to the fast forwarding group is interrupted for about 30 seconds. Therefore, it is not recommended that you carry out such operation during peak hours of communication.

During system startup, the line card must not be inserted or removed.

A line card can be inserted and removed only after the system is started completely (namely, the console prompts “%SYS-5-WARMSTART:System warmstart.” or “%SYS-5-WARMSTART:System coldstart.”).

Resetting a Line Card Module Hot Swap

Hot swap resetting includes a series of operations: run the **remove** command, remove a line card, run the **no install** command, run the **install** command, and insert the line card. After the hot swap resetting is complete, line card hardware is reset and configuration information on the software is initialized again.

Command	**Function**
Ruijie(config)# **reset** *slot-num*	Resets a line card module hot swappable.

Monitoring and Maintaining Hot Swap

The **show version slots** command is used to display the information of the line card modules in each slot, including line card types configured by users, actual line card types, and hot swap status of line cards.

Command	**Function**

Ruijie# **show version slots, or** Ruijie(config)#**show version slots**	Display information about line-card modules in all slots, including the type of the line cards configured by users, the type of the inserted line cards, the hos swap status of the line cards, and information about MASTER and SLAVE. 3 status of the management board: none- No management board is inserted in the slot; slave- The management board in the slot is SLAVE. MASTER- The management board in the slot is MASTER. 8 status of line cards: ● None: Neither a line card nor a pre-configured line card is in the slot. ● Installed: No line card is in the slot, but a line card is configured. ● running-config: MASTER is downloading configuration for the line card. ● running: The line card is running properly. ● run-remove: The user has run the **remove** command but has not removed the line card. ● conflict: The inserted line card is not the type pre-configured by the user. ● unins-remove: The user has run the **no install** command but has not removed the line card. ● standby: this status only works for the LPU expansion box and the device is SLAVE.

MASTER/SLAVE Switchover of LPU Expansion Boxes

Under the mode of “Two Hosts”, when MASTER is faulty, MASTER/SLAVE switchover will happen automatically. However, manual switchover is demanded in some cases, such as demonstration of the function. So, the **switchover** command is offered to serve this aim.

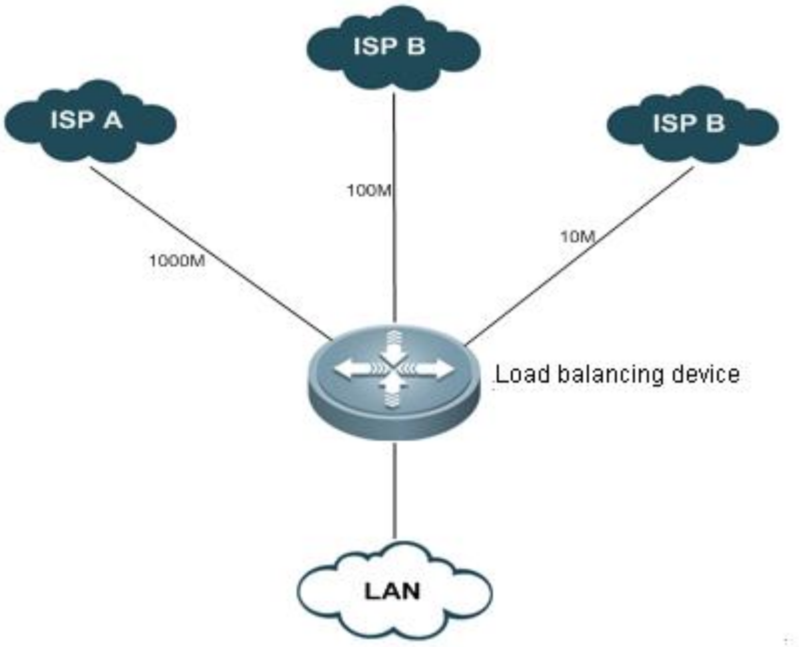
Command	Function

Ruijie(config)#**switchover** *slot-num*	Realizes manual switchover between MASTER and SLAVE.

Configuring Multilink Gateway Load Balancing

Introduction to Multilink Gateway Load Balancing

Fig 1 Typical application diagram of multilink gateway load balancing



Overview

The network gateway is generally connected with two or more ISP links. For example, the gateway of an educational institution will be connected with an education communication link and a Telecom/CNC link; the gateway of a governmental agency may be connected with a Telecom link and a CNC link. Multiple ISP links handles traffic as per certain policy or act as the backup link.

Multilink load balancing allows reasonable flow distribution among multiple links as per certain policy, well improving the utilization efficiency of link resources.

Basic Concept

Link Bandwidth

Link bandwidth is the indicator for measuring available resources, and is different from the transmission rate of physical interface. It is the maximum transmission rate provided by ISP, and generally refers to the inbound bandwidth.

Link Latency

When there are multiple gateways, packets can reach the same destination address through different gateways. The link latency used in load balancing refers to the different response times when packets reach the same destination address through different gateways. It is used to compare the access speed of different gateways, focusing mainly on the difference between links in terms of latency.

Link Load

Link load refers to the current resource utilization rate of the link. It can be calculated by dividing the packet reception rate of physical interface by link bandwidth.

Load Balancing Policy

The policy to share traffic between different links. You can choose load balancing according to bandwidth, access speed, link utilization rate, comprehensive link bandwidth, latency, or load.

Working Principle

In accordance with the load balancing policy selected, the system will calculate the weight of respective links according to link bandwidth, latency and load, and regenerate WCMP routes as per the weight of each link. The subsequent traffic will select the gateway according to the routes generated, thus controlling the traffic handled by each link.

Protocol Specification

NA

Default Configurations

The following table describes the default configurations of multilink gateway load balancing.

Function	Default setting
Configure multilink gateway load balancing	Disabled

Configuring Multilink Gateway Load Balancing

The following section describes how to configure multilink load balancing:

- (Required) Enable/disable multilink load balancing
- (Optional) Configure link bandwidth
- (Optional) Configure link load threshold
- (Optional) Configure load balancing policy
- (Optional) Configure weight base
- Display configurations

Enabling/Disabling Multilink Load Balancing

By default, multilink load balancing function is disabled on the device. Enter privilege mode and execute the following steps to enable multilink load balancing:

Command	Function
Ruijie# **configure terminal**	Enter global configuration mode.
Ruijie(config)# **mllb enable**	Enable multilink load balancing
Ruijie(config)# **no mllb enable**	Disable multilink load balancing

Configuration example:

# Enable global multilink load balancing

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# mllb
```

# Disable global multilink load balancing

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# no mllb
```

Configuring Link Bandwidth

To configure the bandwidth of interface, execute the following commands in interface configuration mode:

Command	Function
Ruijie# **configure terminal**	Enter global configuration mode.
Ruijie(config)# **interface** *interface-name*	Enter interface configuration mode.
Ruijie(config-if)# **bandwidth** *kilobits*	Configure link bandwidth.
Ruijie(config-if)# **no bandwidth**	Restore link bandwidth to default value.

Configuration example:

# Configure link bandwidth to 1M:

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# interface fastEthernet 0/1
Ruijie(config-if)# bandwidth 1000
```

# Remove link bandwidth configurations:

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# interface fastEthernet 0/1
Ruijie(config-if)# no bandwidth
```

Configuring Link Load Threshold

If the link load exceeds the threshold configured, the system will then no longer use this link as the gateway link for load balancing. This threshold shall apply to all gateway links. The load threshold will be expressed in percentage (1-100).

To configure link load threshold, execute the following steps:

Command	Function
Ruijie# **configure terminal**	Enter global configuration mode.
Ruijie(config)# **mllb threshold** *percent*	Configure link load threshold to "percent" (integer between 1-100).
Ruijie(config)# **no mllb threshold**	Restore the link load threshold to the default value of 100.

Configuration example:

# Configure link load threshold to 95:

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# mllb threshold 95
```

# Restore link load threshold to the default value:

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# no mllb threshold
```

Configuring Load Balancing Policy

Load balancing policy provides four different load balancing options for the user. In case of bandwidth based load balancing, the gateway traffic will be shared according to gateway bandwidth; in case of latency based load balancing, the link with shorter latency will handle more traffic and the link with longer latency will handle less traffic; in case of load based load balancing, the traffic will be shared according to the load situation of each gateway link, so that loads are balanced on links; in case of intelligent load balancing, the traffic will be routed by giving comprehensive consideration to bandwidth, latency and load. The user can further configure the weight base of these three factors (see "Configure weight base"), so as to adjust the specific influence of the corresponding factor on flow distribution.

To configure load balancing policy, execute the following steps:

Command	Function
Ruijie# **configure terminal**	Enter global configuration mode.
Ruijie(config)# **mllb policy** { **bandwidth** | **latency** | **load** | **intelligent** }	Specify load balancing policy as bandwidth/latency/load/intelligent policy, with bandwidth being the default policy.
Ruijie(config)# **no mllb policy**	Restore load balancing policy to default setting

Configuration example:

# Configure load balancing policy to bandwidth:

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# mllb policy bandwidth
```

Configuring Weight Base

This refers to the corresponding weight base for calculating the link weight as per bandwidth, latency and load when intelligent is selected as the load balancing policy. By adjusting the weight base of bandwidth, latency and load, we can change the specific influence of these three factors on the link weight.

Configure the weight base of bandwidth, latency and load according to the following steps.

Command	Function
Ruijie# **configure terminal**	Enter global configuration mode.
Ruijie(config)# **mllb policy intelligent** [**bandwidth** *base1*] [**latency** *base2*] [**load** *base3*] }	Configure the weight bases of bandwidth, latency and load to base1, base2 and base3 respectively (1-100, with 1 being the default value).
Ruijie(config)# **no mllb policy intelligent**	Restore all weight bases to default value.

Configuration example:

# Configure load balancing policy to bandwidth, and configure the weight bases of bandwidth, latency and load to 20, 50 and 100 respectively:

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# mllb policy intelligent bandwidth 50 latency 20 load 100
```

Note

Weight base will only take effect when load balancing policy is configured to intelligent.

Displaying Configurations

In privilege mode, execute "show mllbconfig" command to display configurations related to multilink load balancing.

Command	Function
Ruijie (config)# **show mllb config**	Display system configurations, including load balancing configurations.

Configuration example:

# In privilege mode, execute "**show running-config**" command to display load balancing configurations:

```
Ruijie# show mllb config
muti-link load balance configure:
muti-link load balance state: enabled
```

```
muti-link load balance threshold: 95
muti-link load balance policy: intelligent
    bandwidth weight base = 100
    latency weight base = 100
    load weight base = 100
```

Typical Multilink Load Balancing Configuration Example

Networking Requirements

One 1000M telecom link is connected to interface gigabitEthernet 0/1 of the device, while two CNC links (with bandwidth being 100M and 10M respectively) are connected to interface gigabitEthernet 0/2 and interface gigabitEthernet 0/3 of the device.

Network Topology

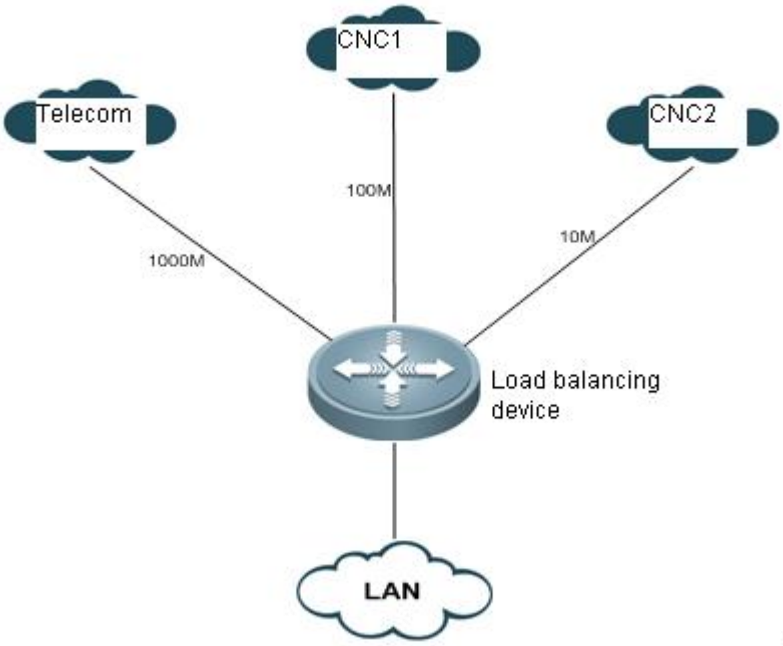


Fig 2 Networking topology of multilink load balancing

Configuration Steps

1) Enable multilink load balancing

# Enable global multilink load balancing

```
Ruijie# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# mllb enable
```

2) Configure link bandwidth

```
Ruijie# configure terminal
```

```
Enter configuration commands, one per line.  End with CNTL/Z.
```

# Configure the bandwidth of telecom link

```
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# bandwidth 1000000
Ruijie# exit
```

# Configure the bandwidth of CNC link 1

```
Ruijie(config)# interface gigabitEthernet 0/2
Ruijie(config-if)# bandwidth 100000
Ruijie# exit
```

# Configure the bandwidth of CNC link 2

```
Ruijie(config)# interface gigabitEthernet 0/3
Ruijie(config-if)# bandwidth 10000
Ruijie# exit
```

3) Configure load balancing policy to bandwidth load balancing

```
# Configure load balancing policy to bandwidth
Ruijie(config)#mllb policy bandwidth
```

4) Configure link load threshold

# Configure link load threshold to 95

```
Ruijie(config)# mllb threshold 95
```

Configuring RNS & Track

Introduction to RNS

RNS (Ruijie Network Service) monitors the integrity of end-to-end connection by detecting whether the reply message is sent by the peer device. The icmp echo packets and dns request packets can be sent.

List of RNS Configuration Tasks

To configure rns, please follow these tasks:

- Configuring rns to detect icme echo
- Configuring rns to detect dns

Configuring RNS to Detect Icme Echo

General steps:

Configure a RNS object to send ICMP echo packets

1 **enable**
2 **configure terminal**
3 **ip rns** *operation-number*
4 **icmp-echo** destination-hostname [**source-ipaddr** *ip-address*] [**out-interface** *type number* [**next-hop** *nhop-ip*]]
5 **frequency** *milliseconds*
6 **timeout** *milliseconds*
7 **ntime** *number*
8 **exit**

Command	**Function**
Ruijie> **enable**	Enter privilege mode
Ruijie# **configure terminal**	Enter global configuration mode
Ruijie(config)# **ip rns** *operation-number*	Enter IP RNS configuration mode
Ruijie(config-ip-rns)# **icmp-echo destination-hostname** [*source-ipaddr* ip-address] [**out-interface** *type number* [**next-hop** *nhop-ip*]]	Configure an IP RNS object to send ICMP packets, and Enter icmp echo configuration mode If the optional parameter of “out-interface” is applied, note the following points: If out-interface is an Ethernet port, then next-hop has to be configured; if not, then next-hop is optional.
Ruijie(config-ip-rns-icmp-echo)**# frequency** *milliseconds*	(Optional) Set an interval of sending packets. The value of the interval should exceed or equal the timeout.

Ruijie(config-ip-rns-icmp-echo)# **timeout** *milliseconds*	(Optional) Set timeout of sending packets
Ruijie(config-ip-rns-icmp-echo)# **ntime** *number*	(Optional) Set detection times of packets

Configuration example:

```
Ruijie> enable
Ruijie# configure terminal
Ruijie(config)# ip rns 1
Ruijie(config-ip-rns)# icmp-echo 10.1.1.1
Ruijie(config-ip-rns-icmp-echo)# ntime 3
```

Display the configurations of RNS object:

```
Ruijie# show ip rns configuration
Ip rns id:1
Type of operation to perform: icmp-echo
Target address/Source address:10.1.1.1/0.0.0.0
Out interface/next hop: /0.0.0.0
Operation timeout (milliseconds):5000
Vrf Name:
Operation frequency (milliseconds):60000
Operation ntime: 3
```

Display statistics of RNS object:

```
Ruijie# show ip rns statistics
IP rns index   1
Number of successes:0
Number of failures:174
Round-trip min/avg/max = 0/0/0 ms
```

Configuring RNS to Detect DNS

General steps:

Configure a RNS object to send ICMP echo packets

1 **enable**
2 **configure terminal**
3 **ip rns** *operation-number*
4 **dns** *work* **name-server** *a.b.c.d*
5 **frequency** *milliseconds*
6 **timeout** *milliseconds*
7 **ntime** *number*
8 **exit**

Command	**Function**

Ruijie> **enable**	Enter privilege mode
Ruijie# **configure terminal**	Enter global configuration mode
Ruijie(config)# **ip rns** *operation-number*	Enter IP RNS configuration mode
Ruijie(config-ip-rns)# **dns** *work* **name-server** *a.b.c.d*	Configure an IP RNS object to send DNS packets and enter DNS configuration mode.
Ruijie(config-ip-rns-dns)# **frequency** *milliseconds*	(Optional) Set an interval of sending packets. The value of the interval should exceed or equal the timeout.
Ruijie(config-ip-rns-dns)# **timeout** *milliseconds*	(Optional) Set timeout of sending packets
Ruijie(config-ip-rns-dns)# **ntime** *number*	(Optional) Set detection times of packets

Configuration example:

```
Ruijie> enable
Ruijie# configure terminal
Ruijie(config)# ip rns 1
Ruijie(config-ip-rns) # dns www.ruijie.com name-server 1.1.1.1
Ruijie(config-ip-rns-icmp-echo) # frequency 50000
```

Display the configurations of RNS object:

```
Ruijie# show ip rns configuration
Ip rns id:1
Type of operation to perform: dns
Domain name: www.ruijie.com
Name server:1.1.1.1
Operation timeout (milliseconds):9000
Operation frequency (milliseconds):50000
Operation ntime: 1
```

Display statistics of RNS object:

```
Ruijie# show ip rns statistics
IP rns index   1
Number of successes:0
Number of failures:8
Round-trip min/avg/max = 0/0/0 ms
```

Introduction to Track

A track object can track whether an IP address is reachable and whether an interface is UP. The track feature separates a tracked object from the modules which are interested in this object, such as PBR and VRRP. When the states of track object changes, they can take different actions.

List of Track Configuration Tasks

To configure track, please follow these tasks:

- Tracking the link state of an interface
- Tracking the state of a RNS object

Tracking the Link State of an Interface

Execute this task to track the link state of an interface. A layer-2 interface is considered UP as long as the interface is powered up; a layer-3 interface is considered UP as long as the layer-2 interface of this interface-3 interface is UP; a logic interface like loopback interface is considered UP as long as it is not shut down.

General steps:

1. **enable**
2. **configure terminal**
3. **track** *object-number* **interface** *type number* **line-protocol**
4. **delay** {**up** *seconds* [**down** *seconds*] | [**up** *seconds*] **down** *seconds*}
5. **end**
6. **show track** *object-number*

Detailed steps:

Command	**Function**
Ruijie> **enable**	Enter privilege mode
Ruijie# **configure terminal**	Enter global configuration mode
Ruijie(config)# **track** *object-number* **interface** *type number* **line-protocol**	Track the state of an interface and enter track mode
Ruijie(config-track)# **delay** {**up** *seconds* [**down** *seconds*] | [**up** *seconds*] **down** *seconds*}	(Optional) Specify a delay time after which the state of track object will change when interface state changes. There is no delay by default.
Ruijie(config-track)# **show track** *object-number*	(Optional) Display the information about track object. You can use this command to verify whether the configurations are correct.

Configuration example:

```
Ruijie> enable
Ruijie# configure terminal
Ruijie(config)# track 3 interface FastEthernet 1/0 line-protocol
Ruijie(config-track)# delay up 30
Ruijie(config-track)# show track 3
```

Configure a track object to track the state of an interface. The following example shows relevant information:

```
Ruijie# show track 3
Track 3
```

```
interface FastEthernet 1/0
The state is Up
1 change,current state last:11 secs
Delay up 10 secs,down 10 secs
```

Tracking the State of a RNS Object

We uses a track object to track the state of RNS object; If the RNS object receives the reply packets, then the state of track object is UP; otherwise, the state of track object is DOWN.

Caution When track object is used to track a nonexistent RNS object, the state of this track object is UP.

General steps:

First configure an IP RNS object

1. **enable**
2. **configure terminal**
3. **ip rns** *operation-number*
4. **icmp-echo destination-hostname** [*source-ipaddr ip-address*]
5. **frequency** *seconds*
6. **exit**

Then configure a track object:

1. **enable**
2. **configure terminal**
3. **track** *object-number* **rns** *entry-number*
4. **delay up** *seconds* **down** *seconds*
5. **end**
6. **show track object-number**

Configure a route-map and apply the aforementioned track object:

1. **route-map map-tag [permit | deny]** [*sequence-number*]
2. **set ip next-hop verify-availability** [*next-hop-address sequence* **track** *object*]

Apply policy-based routing to an interface:

1. **interface** *type number*
2. **ip address** *ip-address* **mask** *[secondary]*
3. **ip policy route-map map-tag**
4. **exit**

Detailed steps:

Command	Function
Ruijie(config)# **track** *object-number* **rns** *entry-number*	Track the state of an IP RNS object and enter track mode.

Ruijie(config-track)# **delay** {**up** *seconds* [**down** *seconds*] | [**up** *seconds*] **down** *seconds*}	(Optional) Specify a delay time after which the state of track object will change when its state changes. There is no delay by default.
Ruijie(config-track)# **exit**	Return to global configuration mode.
Ruijie(config)# **interface** *type number*	Enter interface configuration mode.
Ruijie(config-if)# **ip address** *ip-address* **mask** [*secondary*]	Configure an IP address for the interface.
Ruijie(config-if)# **ip policy route-map map-tag**	Apply policy-based routing to this interface.
Ruijie(config-if)# **exit**	Return to global configuration mode.
Ruijie(config)# **route-map map-tag** [**permit | deny**] [*sequence-number*]	Configure a route-map.
Ruijie(config-route-map)# **set ip next-hop verify-availability** [*next-hop-address sequence* **track** *object*]	The route map configured is used to track the state of a track object

Configuration example:

```
Ruijie(config)# track 123 rns 1
Ruijie(config-track)# delay up 30
Ruijie(config-track)# exit
Ruijie(config)# interface ethernet 0
Ruijie(config-if)# ip address 10.1.1.11 255.0.0.0
Ruijie(config-if)# ip policy route-map alpha
Ruijie(config-if)# exit
Ruijie(config)# route-map alpha
Ruijie(config-route-map)# set ip next-hop verify-availability 10.1.1.1 10 track 123
```

Display the state of a track object:

```
Track 2
Ruijie Network Service 1
The state is Down
1 change,current state last:7 secs
Delay up 30 secs,down 0 secs
```

Application of Track Feature

We can achieve the following function by tracking the UP/DOWN state of track object:

■ Associating the next hop of PBR with a track object

Associating the Next Hop of PBR with a Track Object

In policy-based routing, we can associate the next hop of PBR with a track object. When the state of track object becomes DOWN, this next hop will be disabled, namely PBR will not use this next hop as the next hop for packets.

General steps:

First configure an IP RNS object (please refer RNS configurations given above).

Then configure a track object (please refer to track configurations given above).

Configure a route-map and apply the track object configured above:

1. **route-map map-tag [permit | deny]** [*sequence-number*]
2. **set ip next-hop verify-availability track** *object*

Apply policy-based routing to an interface:

1. **interface** *type number*
2. **ip address** ip-address **mask** [secondary]
3. **ip policy route-map map-tag**
4. **exit**

Detailed steps:

Command	**Function**
Ruijie(config)# **interface** *type number*	Enter interface configuration mode.
Ruijie(config-if)# **ip address** *ip-address mask* [*secondary*]	Configure an IP address for the interface.
Ruijie(config-if)# **ip policy route-map** *map-tag*	Apply policy-based routing to this interface.
Ruijie(config-if)# **exit**	Return to global configuration mode.
Ruijie(config)# **route-map** *map-tag* [**permit** | **deny**]	Configure a route-map.
Ruijie(config-route-map)# **set ip next-hop verify-availability track** *object*	The route map configured is used to track the state of a track object.

Configuration example:

```
Ruijie(config)# interface ethernet 0
Ruijie(config-if)# ip address 10.1.1.11 255.0.0.0
Ruijie(config-if)# ip policy route-map alpha
Ruijie(config-if)# exit
Ruijie(config)# route-map alpha
Ruijie(config-route-map)# set ip next-hop verify-availability 10.1.1.1  track 123
```

The policy-based routing to be achieved: When packets are received by fa 0/0 and the IP address of 10.1.1.1 is reachable, the next hop of packets is configured as 10.1.1.1 (IP address of the interface on router 2). If 10.1.1.1 is unreachable, the next hop of packets is configured as 10.2.2.2 (IP address of the interface on router 3). If 10.2.2.2 is also unreachable, PBR fails. Packets will be forwarded as per ordinary route according to the query result of core routing table.

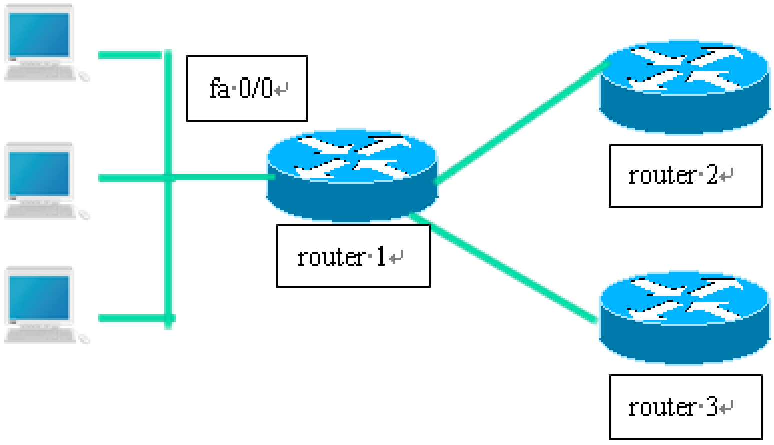

Figure 1

Configurations of Router 1:

# Define two IP RNS objects to track whether the remote IP address is reachable.

```
ip rns 1
icmp-echo 10.1.1.1
ip rns 2
icmp-echo 10.2.2.2
```

# Define track object

```
track 123 rns 1
track 124 rns 2
```

# Apply PBR to the interface

```
interface FastEthernet 0/0
ip address 10.4.4.4 255.255.255.0
ip policy route-map alpha
```

# 10.1.1.1 is the following interface

```
interface fa 0/1
ip address 10.1.1.254 255.255.255.0
```

# 10.2.2.2 is the following interface

```
interface fa 0/2
ip address 10.2.2.254 255.255.255.0
```

# Configure a route-map; the availability of next hop depends on the reachability of track object.

```
route-map alpha
set ip next-hop verify-availability 10.1.1.1  track 123
set ip next-hop verify-availability 10.2.2.2  track 124
```

IPv6 Configuration

Configuring IPv6

Understanding IPv6

Overview

As the Internet is growing rapidly and the IPv4 address space is exhausting, the limitation of the IPv4 is more obvious. The research and practice of the next generation Internet Protocol (IPng) become popular. Furthermore, the IPng working group of the IETF has determined the protocol specification of IPng referred to as IPv6. See RFC 2460 for details.

Key Features

- More address space

The length of an address is extended to 128 bits from 32 bits of IPv4. Namely, there are 2^128-1 addresses for IPv6. IPv6 adopts hierarchical address mode and supports multiple-level IP address assignment, for example, from the Internet backbone network to the internal subnet of enterprises.

- Simplified format of packet header

The design principle of the new IPv6 packet header is to minimize the overhead. For this reason, some non-critical fields and optional fields are removed from the packet header and placed into the extended packet header. The length of an IPv6 address is 4 times the length of an IPv4 address; the size of the IPv6 packet header is only 2 times the size of the IPv4 packet header. The improved IPv6 packet header is more efficient for forwarding, for example, there is no checksum in the IPv6 packet header and it is not necessary for an IPv6 device to process the fragments during forwarding (the fragments are completed by the originator).

- High-efficient hierarchical addressing and routing structure

IPv6 adopts the aggregation mechanism and defines a flexible hierarchical addressing and routing structure, and several networks at the same level are represented with a unified network prefix at a higher-layer device. So it obviously reduces the routing entries that the device must maintain and greatly minimizes the routing and storage overhead.

- Simple management: plug and play

The management and maintenance of network nodes are simplified by the implementation of a series of auto-discovery and auto-configuration functions. For example, the neighbor discovery, MTU discovery, router advertisement (RA), router solicitation (RS) and auto-configuration technologies provide the related service for plug and play. It should be mentioned that IPv6 supports such address configuration methods as stateful configuration and stateless configuration. In IPv4, the Dynamical Host Configuration Protocol (DHCP) implements the automatic configuration of a host IP address and related configuration, while IPv6 inherits this auto-configuration service of IPv4 and refers to it as the stateful auto-configuration. Furthermore, IPv6 also adopts an auto-configuration service, referred to as stateless auto-configuration. During the stateless auto-configuration, the host obtains the link-local address, the address prefix of the local device and some other related configuration information automatically.

- Security

IPSec is an optional extended protocol of IPv4, but it is only a component of IPv6 used to provide security. At present, IPv6 implements the authentication header (AH) and encapsulated security payload (ESP) mechanisms. The former authenticates the integrity of data and the source of an IP packet to ensure that the packet does come from the node marked by the source address, while the latter provides the data encryption function to implement end-to-end encryption.

- More excellent QoS support

A new field in the IPv6 packet header defines how to identify and process a data flow. The Flow Label field in an IPv6 packet header is used to identify the data flow ID, by which IPv6 allows users to put forward the requirement for the QoS of communication. The device can identify all packets of a specified data flow by this field and provide special processing for these packets as required.

- New protocol for interactions between neighbor nodes

The Neighbor Discovery Protocol of IPv6 uses a series of IPv6 control information messages (ICMPv6) to manage the interactions between neighbor nodes (the nodes on the same link). The Neighbor Discovery Protocol and high-efficient multicast and unicast neighbor discovery messages replace the previous broadcast-based Address Resolution Protocol (ARP) and the ICMPv4 router discovery messages.

- Extensibility

IPv6 provides powerful extensibility and the new features can be added to the extended packet header after the IPv6 packet header. Unlike the IPv4 packet header, the IPv6 packet header can only support the options of up to 40 bytes, while the size of the IPv6 extended packet header is only limited by the maximum number of bytes of the whole IPv6 packet.

IPv6 supports the following features:

- IPv6 protocol
- IPv6 address format
- Type of IPv6 address
- ICMPv6
- IPv6 neighbor discovery
- Path MTU discovery
- ICMPv6 redirection
- Duplicate address detection
- IPv6 stateless auto-configuration
- IPv6 address configuration
- IPv6 route forwarding (supporting static route configuration)
- Configuration of various IPv6 parameters
- Diagnosis tool ping IPv6

IPv6 Address Format

The basic format of an IPv6 address is X : X : X : X : X : X : X : X, where X is a 4-digit hexadecimal integer (16 bits). Each digit contains 4 bits, each integer contains 4 hexadecimal digits, and each address contains 8 integers, so the address includes a total of 128 bits. Some legal IPv6 addresses are as follows:

2001:ABCD:1234:5678:AAAA:BBBB:1200:2100

800 : 0 : 0 :0 : 0 : 0 : 0 : 1

1080 : 0 : 0 : 0 : 8 : 800 : 200C : 417A

These integers are hexadecimal integers, where A to F denote 10 to 15 respectively. Each integer in the address must be denoted and the starting 0 need not be denoted. Some IPv6 addresses may contain a series of 0s (such as the second and third examples). In this case, colons (: :) are allowed to denote this series of 0s. Namely, the address 800:0:0:0:0:0:0:1 can be denoted as: 800 :: 1.

These two colons denote that this address can be extended to a complete 128-bit address. In this way, the 16-bit group can be replaced with two colons only when they are all 0s and the two colons can only be present once.

In the hybrid environment of IPv4 and IPv6, there is a hybrid denotation method. The lowest 32 bits in an IPv6 address can be used to denote an IPv4 address. The address can be expressed in a hybrid mode, that is, X: X : X : X : X : X : d . d . d . d, where, X denotes a 16-bit integer, while d denotes an 8-bit decimal integer. For instance, the address 0 : 0 : 0 : 0 : 0 : 0 : 192 .168 . 20 : 1 is a legal IPv6 address. After the abbreviated expression method is used, this address can be denoted as follows: : : 192.168. 20. 1. One typical example is an IPv4-compatible IPv6 address, which is expressed as "::A.B.C.D", with the first 96 bits being all 0s, such as "::1.1.1.1", but this expression method is revoked. Another typical example is an IPv4-mapped IPv6 address, which is expressed as "::FFFF:A.B.C.D" and used to express an IPv4 address as an IPv6 address, that is, map the IPv4 address"1.1.1.1" to the IPv6 address"::FFFF:1.1.1.1".

Because the IPv6 address is divided into two parts, the subnet prefix and the interface identifier, it can be denoted as an address including an additional numeric value by the method like the CIDR address. This numeric value indicates how many bits represent the network part (the network prefix). Namely the IPv6 node address indicates the length of the prefix, and the length is differentiated from the IPv6 address by a slash. For instance: 12AB::CD30:0:0:0:0/60. The length of the prefix used for routing in this address is 60 bits.

Type of IPv6 Address

RFC 4291 defines three types of IPv6 addresses:

- Unicast: Identifier of a single interface. The packet to be sent to a unicast address will be transmitted to the interface identified by this address.
- Anycast: Identifiers of a set of interfaces. The packet to be sent to an anycast address will be transmitted to one of the interfaces identified by this address (the nearest one is selected according to the routing protocol).
- Multicast: Identifiers of a set of interfaces (In general, these interfaces belong to different nodes). The packet to be sent to a multicast address will be transmitted to all the interfaces that join this multicast address.

Caution The broadcast address is not defined in IPv6.

The following describes these types of addresses one by one.

Unicast Addresses

The unicast addresses are divided into unspecified address, loopback address, link-local address, site-local address and global unicast address. Now the site-local address has been revoked. The unicast addresses excepting the unspecified address, loopback address and link-local address are all global unicast addresses.

1) Unspecified address

The unspecified address is 0:0:0:0:0:0:0:0, generally abbreviated as :: and used for the following purposes.

- If there is no unicast address when a host is started, use the unspecified address as the source address, send an RS, and obtain the prefix information from the gateway to automatically generate the unicast address.
- When configuring an IPv6 address for the host, check whether the IPv6 address conflicts with the address of any other host in the same network segment or not. If so, use the unspecified address as the source address to send a neighbor solicitation (NS) message, same as free ARP.

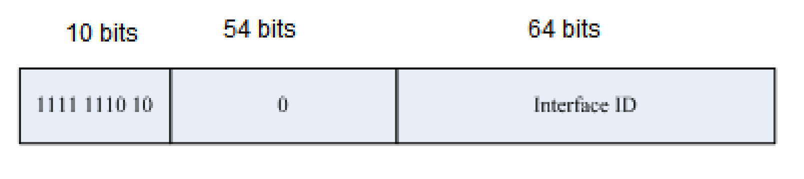
2) Loopback address

The loopback address is 0:0:0:0:0:0:0:1, abbreviated as ::1, which is equal to the IPv4 address 127.0.0.1 and used when the node sends the packets to itself.

3) Link–local address

The format of link-local address:

Figure 1

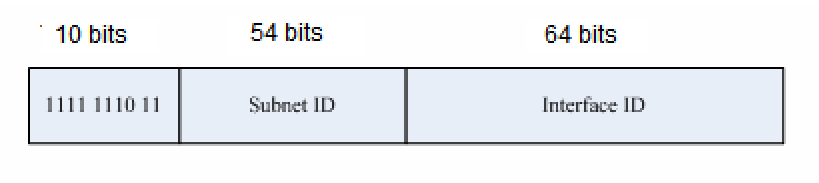


The link-local address is used to number the host on the single network link. The address identified by the first 10 bits of the prefix is the link-local address. The device will never forward the packet of the source address or the destination address with the link-local address. The intermediate 54 bits are all 0s. The last 64 bits indicate the interface identifier, and this part allows the single network to connect up to 2^{64}-1 hosts.

4) Site-local address

The format of site-local address:

Figure 2

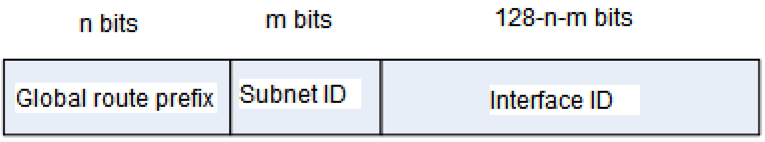


The site-local address can be used to transmit data within the site, and the device will not forward the packet of the source address or the destination address with the site-local address to the Internet. Namely, such packet can only be forwarded within the site, but cannot be forwarded out of the site. The site may be deemed as the LAN of a company, and the site-local address is similar to a private IPv4 address, for example, 192.168.0.0/16. RFC 3879 has revoked the site-local address. In new implementations, this prefix is no longer supported and is uniformly deemed as a global unicast address. In existing implementations and deployments, this prefix may be still used.

5) Global unicast address

The format of global unicast address:

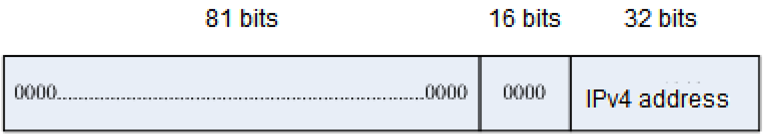
Figure 3



One class of the global unicast address is the IPv6 address embedded with an IPv4 address, which is used to interconnect the IPv4 nodes and the IPv6 nodes and divided into IPv4-compatible IPv6 address and IPv4-mapped IPv6 address.

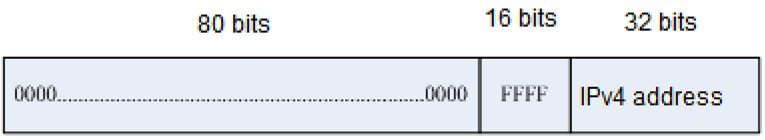
The format of IPv4-compatible IPv6 address:

Figure 4



The format of IPv4-mapped IPv6 address:

Figure 5



The IPv4-compatible IPv6 address is mainly used for automatic tunneling, which supports both IPv4 and IPv6. The IPv4-compatible IPv6 address is used to transmit an IPv6 packet via an IPv4 device in the tunneling way. Now the IPv4-compatible IPv6 address has been revoked. The IPv4-mapped IPv6 address is used by IPv6 nodes to access the nodes that only support IPv4. For example, when one IPv6 application of the IPv4/IPv6 host requests the resolution of a host name (the host only supports IPv4), the name server will internally generate an IPv4-mapped IPv6 address dynamically and return it to the IPv6 application.

Multicast Addresses

The format of the IPv6 multicast address is as follows:

```
|    8     |  4 |  4 |                      112 bits                       |

+----------+----+----+-------------------------------------------------------------+

|11111111|flgs|scop|                         group ID                       |

+----------+----+----+-------------------------------------------------------------+
```

The first byte of the address format is all 1s, which denote a multicast address.

- Flag field:

It consists of 4 bits. At present, only the fourth bit is specified. The bit is used to indicate whether the address is a known multicast address specified by the Internet Assigned Numbers Authority (IANA) or a temporary multicast address used on a specific occasion. If this flag bit is 0, it indicates this address is a known multicast address. If this bit is 1, it indicates that this address is a temporary one. Other 3 flag bits are reserved for future use.

- Range field:

The Range field is composed of 4 bits and used to denote the range of multicast, namely, whether the multicast group contains the local node, the local link and the local site or nodes in any positions in the IPv6 global address space.

- Group ID field:

This field is 112 bits long and used to identify a multicast group. Depending on whether a multicast address is temporary or known and the range of the address, a multicast identifier can denote different groups.

The multicast address of IPv6 is this type of address using FF00::/8 as the prefix. One multicast address of IPv6 usually identifies the interfaces of a serial of different nodes. When one packet is sent to one multicast address, this packet will be distributed to the interfaces of each node with this multicast address. One node (host or device) should join the following multicast addresses:

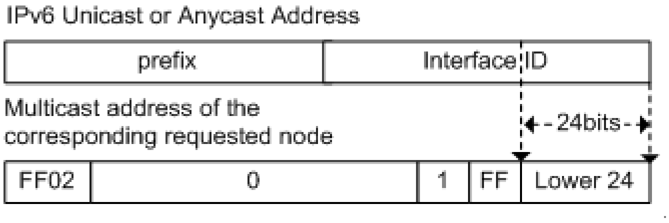
- The multicast address of all nodes on the local link, that is, FF02::1
- The multicast address of the solicited node, with the prefix of FF02:0:0:0:0:1:FF00:0000/104

For the device, it is necessary to join the multicast address FF02::2 of all devices on the local link.

If the multicast address of the solicited node corresponds to the IPv6 unicast and anycast address, it is necessary for the IPv6 node to join the corresponding multicast address of the solicited node for each configured unicast address and anycast address. The prefix of the multicast address of the solicited node is FF02:0:0:0:0:1:FF00:0000/104, another 24 bits are comprised of the unicast address or the lower 24 bits of the anycast address, for example, the multicast address of the solicited node corresponding to the unicast address FE80::2AA:FF:FE21:1234 is FF02::1:FF21:1234.

The multicast address of the solicited node is usually used in an NS message. The format of the solicited node is as follows:

Figure 6



IPv6 Unicast or Anycast Address
prefix
Interface ID
Multicast address of the corresponding requested node
24bits
FF02
0
1
FF
Lower 24

Anycast Addresses

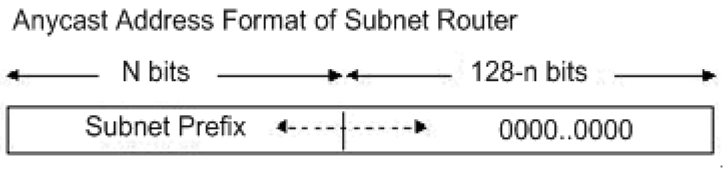
The anycast address is similar to the multicast address as more than one node shares an anycast address. The difference is that only one node expects to receive the data packet of the anycast address, while all nodes of the multicast group members expect to receive all packets sent to this address. The anycast address is assigned to the normal IPv6 unicast address space, so the anycast address cannot be differentiated from the unicast address from the style. For this reason, each member of an anycast group represented by an anycast address must be configured explicitly to identify the anycast address.

Caution The anycast address can only be assigned to the device, but cannot be assigned to the host. Furthermore, the anycast address cannot be used as the source address of the packet.

RFC 2373 predefines an anycast address, referred to as the anycast address of a subnet router. The following figure shows the anycast address format of the subnet router, which consists of the subnet prefix followed by a series of 0s (as the interface identifier).

The subnet prefix identifies a specified link (subnet) and the packet to be sent to the anycast address of the subnet router will be distributed to a device of this subnet. The anycast address of the subnet router is usually used for a node which needs to communicate with one device of a remote subnet.

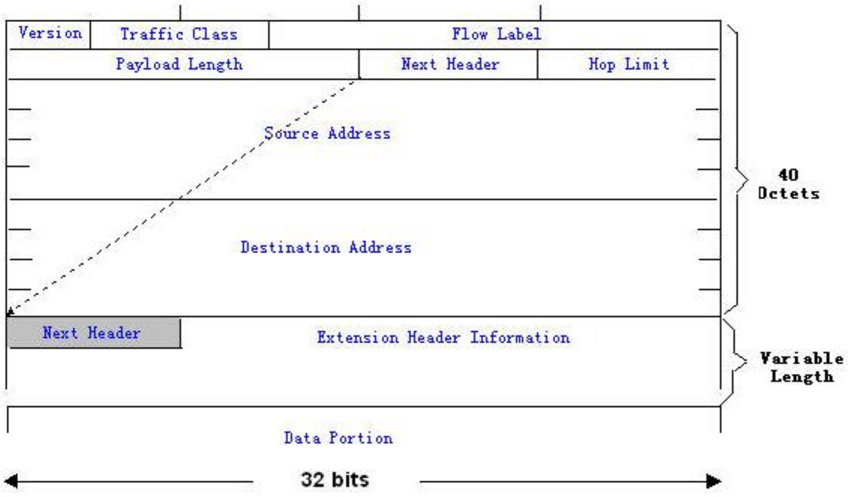
Figure 7



IPv6 Packet Header Structure

The format of the IPv6 packet header is shown in the following figure.

Figure 8



In IPv4, the packet header is measured in units of 4 bytes; in IPv6, the packet header is measured in units of 8 bytes, and the total size of the packet header is 40 bytes. In the IPv6 packet header, the following fields are defined:

- Version:

The length is 4 bits. For IPv6, the field must be 6.

- Traffic Class:

The length is 8 bits. It indicates a type of service provided to the packet and is equal to the “TOS” in IPv4.

- Flow Label:

The length is 20 bits. This field is used to identify the packets of the same service flow. One node can be used as the source of several service flows. The flow label and source node IP address identify a service flow uniquely.

- Payload Length:

The length is 16 bits, including the byte length of the payload and the length of various IPv6 extension options (if any). In other words, it includes the length of an IPv6 packet except for the IPv6 header.

- Next Header:

This field indicates the protocol type in the header field following the IPv6 header. Similar to the IPv4 protocol field, the Next Header field can be used to indicate whether the upper layer protocol is TCP or UDP. It can also be used to indicate whether an extended IPv6 header exists.

- Hop Limit:

The length is 8 bits. When the device forwards the packet for one time, the value of this field will decrease by 1. When the value of this field is 0, this packet will be discarded. It is similar to the lifetime field in the IPv4 packet header.

- Source Address:

The length is 128 bits. It indicates the sender address of an IPv6 packet.

- Destination Address:

The length is 128 bits. It indicates the receiver address of an IPv6 packet.

At present, the following extended headers are defined in IPv6:

- Hop-by-Hop Options:

This extended header must immediately follow an IPv6 header. It contains the option data that must be checked by each node along the path.

- Routing Header (Routing (Type 0)):

This extended header indicates the nodes that a packet will go through before reaching the destination. It contains the addresses of various nodes that the packet goes through. The initial destination address of the IPv6 header is the first one of a series of addresses in the routing header, other than the final destination address of the packet. After receiving this packet, the node of this address will process the IPv6 header and the routing header, and send the packet to the second address in the routing header. This process continues until the packet reaches the final destination.

- Fragment:

This extended header is used to fragment the packets longer than the MTU of the path between the source node and destination node.

- Destination Options:

This extended header replaces the IPv4 option field. At present, the only defined destination option is an option to be filled with an integral multiple of 64 bits (8 bytes) when necessary. This extended header can be used to carry the information checked by the destination node.

- Upper-layer header:

It indicates the upper layer transmission protocol, such as TCP(6) and UDP(17).

Furthermore, the extended header of Authentication and Encapsulating Security Payload will be described in the IPSec section. At present, the IPv6 implemented by the device does not support IPSec.

IPv6 Path MTU Discovery

Similar to the path MTU discovery of IPv4, the path MTU discovery of IPv6 allows one host to discover and adjust the size of the MTU in the data transmission path.

Furthermore, when the data packet to be sent is larger than the MTU of the data transmission path, the host will fragment the packet by itself. This behavior makes it not necessary for the device to process the fragment, and thus save resources and improve the efficiency of the IPv6 network.

Caution

The minimum link MTU is 68 bytes in IPv4, indicating that the links along the path over which the packets are transmitted should support at least the link MTU of 68 bytes. The minimum link MTU is 1280 bytes in IPv6. It is strongly recommended that the link MTU of 1500 bytes should be used for the link in IPv6.

IPv6 Neighbor Discovery

The main functions of the IPv6 Neighbor Discovery Protocol include router discovery, prefix discovery, parameter discovery, address auto-configuration, address resolution (ARP), next-hop determination, neighbor unreachability detection, duplicate address detection, and redirection. Neighbor discovery defines 5 types of ICMP messages, which are router solicitation (ICMP type133), RA (ICMP type134), NS or ARP request (ICMP type135), neighbor advertisement or APR response (ICMP type136) and ICMP redirection message (ICMP type137).

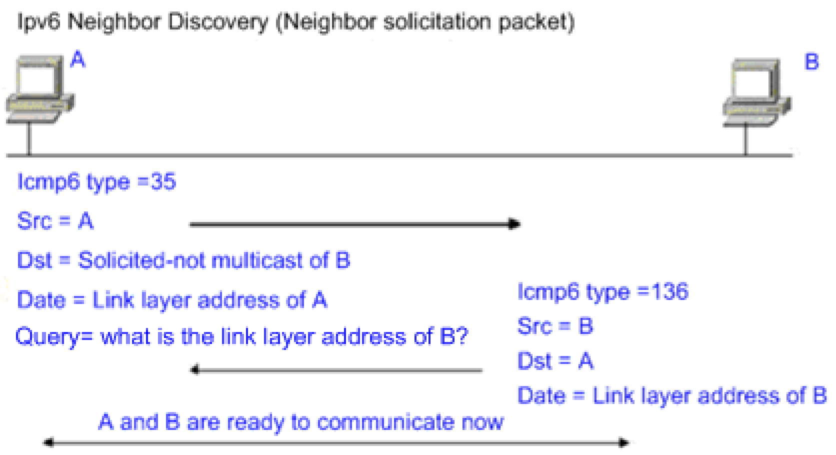
The following describes the neighbor discovery function in detail:

Address Resolution

A node must obtain the link layer address of another node before communicating with it. At this time, the node should send an NS message to the solicited multicast address, that is, the IPv6 address of the destination node. The NS message also contains the link layer address of itself. After receiving this NS message, the destination node responds with a message, referred to as neighbor advertisement (NA), with its link layer address. After receiving the response message, the source node can communicate with the destination node.

The following is the address resolution procedure:

Figure 9



Ipv6 Neighbor Discovery (Neighbor solicitation packet)
A
B
Icmp6 type =35
Src = A
Dst = Solicited-not multicast of B
Date = Link layer address of A
Query= what is the link layer address of B?
Icmp6 type =136
Src = B
Dst = A
Date = Link layer address of B
A and B are ready to communicate now

Neighbor Unreachability Detection

When the reachable time of a neighbor expires, neighbor unreachability detection is performed if an IPv6 unicast packet needs to be sent to this neighbor.

Neighbor unreachability detection and sending the IPv6 packet to the neighbor can be performed concurrently. During the detection, the device continues to forward the IPv6 packet to the neighbor.

Duplicate Address Detection

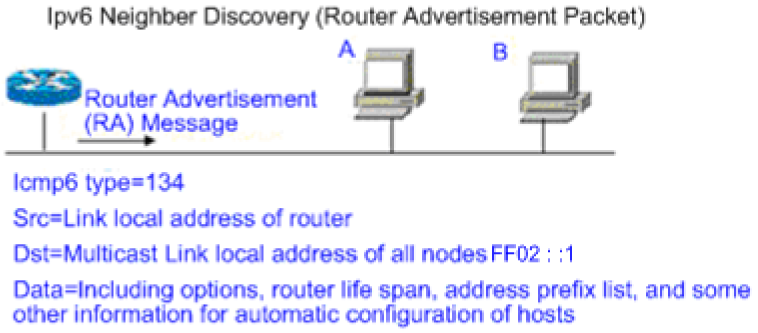
After an IPv6 address is configured for the host, duplicate address detection may be performed to know whether the IPv6 address is unique on the link, by sending an NS message with the source IPv6 address being an unspecified address.

Router, Prefix and Parameter Discovery

The router sends an RA to all the local nodes of the link periodically.

The following figure shows the process of sending the RA.

Figure 10



Ipv6 Neighbor Discovery (Router Advertisement Packet)
A
B
Router Advertisement
(RA) Message
Icmp6 type=134
Src=Link local address of router
Dst=Multicast Link local address of all nodes FF02 : :1
Data=Including options, router life span, address prefix list, and some other information for automatic configuration of hosts

In general, the RA contains the following contents:

- One or more IPv6 address prefixes used for the on-link determination or the stateless address auto-configuration.
- Effective period of the IPv6 address prefix.
- Host auto-configuration mode (stateful or stateless).

- Information for the default device (namely, the device determines whether it is used as the default device. If yes, it will announce the time to act as the default device).
- Other information for host configuration such as the hop limit, the MTU and the NS retransmission interval.

The RA is also used to respond to the RS message sent by the host. The RS message allows the host to obtain the auto-configuration information immediately without waiting for the device to send the RA. If there is no unicast address when the host is started, the RS message sent by the host will use the unspecified address (0:0:0:0:0:0:0:0) as the source address of the RS message. Otherwise, the existing unicast address is used as the source address, while the RS message uses the multicast address (FF02::2) of all devices on the local link as the destination address. The RA message, in response to the RS message, will use the source address of the RS message as the destination address (if the source address is the unspecified address, it will use the multicast address FF02::1) of all nodes on the local link.

The following parameters can be configured in the RA message.

Ra-interval: interval for sending the RA

Ra-lifetime: router lifetime, namely, whether the device acts as the default router of the local link and the time to act this role

Prefix: IPv6 address prefix of the local link, which can be used for the on-link determination or the stateless address auto-configuration, including the configuration of other parameters for the prefix

Rs-initerval: interval for sending the NS message

Reachabletime: time maintained after the neighbor is considered reachable

The above parameters are configured in the IPv6 interface properties.

⚠ Caution

1. No RA message is sent actively on the interface by default. To allow the device to send the RA message, you can use the **no ipv6 nd suppress-ra** command in interface configuration mode.
2. In order to enable normal stateless address auto-configuration of the node, the length of the prefix for the RA message should be 64 bits.

Redirection

After receiving the IPv6 packets, the router discovers an optimal next hop and sends an ICMP redirection message to notify the host of the optimal next hop. Next time the host sends the IPv6 packets to the optimal next hop directly.

Configuring IPv6

The following will describe the configuration of various functional modules of IPv6 respectively.

Configuring an IPv6 Address

This section describes how to configure an IPv6 address on an interface. No IPv6 address is configured by default.

Caution

Once an interface is created and its link state is UP, the system will automatically generate the link-local address for the interface. At present, IPv6 does not support anycast address.

For S57 and S76 series, the range of the length of the prefix of the interface IPv6 address is [0, 64] or [128, 128], because the range of the length of the routing prefix supported by the hardware forwarding table of the chip is [0, 64] or [128, 128]. For S86 and S96 series, the range of the length of the prefix of the interface IPv6 address is not limited, but the total number of IPv6 routes within the range [65, 127] of the length of the routing prefix supported by switches is 512.

To configure an IPv6 address, use the following commands.

Command	Function
Ruijie#**configure terminal**	Enters global configuration mode.
Ruijie(config)#**interface** *interface-id*	Enters interface configuration mode. Note that the **no switchport** command must be used to switch the layer-2 interface to the layer-3 interface.
Ruijie(config-if)#**ipv6 enable**	Enables the IPv6 protocol on an interface. If this command is not run, the system automatically enables the IPv6 protocol when you configure an IPv6 address for an interface.
Ruijie(config-if)#**ipv6 address** *ipv6-address/prefix-length* Ruijie(config-if)#**ipv6 address** *ipv6-prefix/prefix-length* [**eui-64**]	Configures an IPv6 unicast address for this interface. When the command includes the keyword **Eui-64**, only the prefix must be specified, and the interface ID is automatically generated in the EUI-64 format. The generated IPv6 address consists of the configured address prefix and the 64-bit interface ID. Note: Whether the keyword **eui-64** is used, it is necessary to enter the complete address format to delete an IPv6 address (prefix + interface ID or prefix length). When you configure an IPv6 address on an interface, the IPv6 protocol is automatically enabled on the interface. Even if you use **no ipv6 enable**, you cannot disable the IPv6 protocol.
Ruijie(config-if)#**end**	Returns to privileged EXEC mode.
Ruijie#show **ipv6 interface** *interface-id*	Displays the IPv6 interface information.
Ruijie#copy **running-config startup-config**	Saves the configuration.

To delete the configured IPv6 address, use the **no ipv6 address** *ipv6-prefix*I*prefix-length* **[eui-64]** command.

The following example configures an IPv6 address.

```
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if)# ipv6 enable
Ruijie(config-if)# ipv6 address fec0:0:0:1::1/64
Ruijie(config-if)# end
Ruijie(config-if)# show ipv6 interface GigabitEthernet 0/1
Interface GigabitEthernet 0/1 is Up, ifindex: 1
address(es):
Mac Address: 00:00:00:00:00:01
INET6: fe80::200:ff:fe00:1 , subnet is fe80::/64
```

```
INET6: fec0:0:0:1::1 , subnet is fec0:0:0:1::/64
Joined group address(es):
ff01:1::1
ff02:1::1
ff02:1::2
ff02:1::1:ff00:1
MTU is 1500 bytes
ICMP error messages limited to one every 100 milliseconds
ICMP redirects are enabled
ND DAD is enabled, number of DAD attempts: 1
ND reachable time is 30000 milliseconds
ND advertised reachable time is 0 milliseconds
ND retransmit interval is 1000 milliseconds
ND advertised retransmit interval is 0 milliseconds
ND router advertisements are sent every 200 seconds<160--240>
ND router advertisements live for 1800 seconds
```

Configuring ICMPv6 Redirection

This section describes how to configure the ICMPv6 redirection function on the interface. The redirection function of the IPv6 on the interface is enabled by default. The device needs to send a redirection message to the initiator during packet forwarding in the following cases:

- The destination address of the message is not a multicast address.
- The destination address of the message is not the device itself.
- The output interface of the next hop determined by the device for this message is the same as the interface that receives this message, namely, the next hop and the initiator are on the same link.
- The node identified by the source IP address of the packet is a neighbor of the local device. Namely, this node exists in the device’s neighbor table.

Caution

The device other than the host can generate the redirection message, and the device will not update its routing table when it receives the redirection message.

To enable redirection on the interface, use the following commands.

Command	Function
Ruijie#**configure terminal**	Enters global configuration mode.
Ruijie(config)#**interface** *interface-id*	Enters interface configuration mode. Note that the **no switchport** command must be used to switch the layer-2 interface to the layer-3 interface.
Ruijie(config-if)#**ipv6 redirects**	Enables the IPv6 redirection function.
Ruijie(config-if)#**end**	Returns to privileged EXEC mode.
Ruijie#**show ipv6 interface** *interface-id*	Displays the interface configuration information.
Ruijie#**copy running-config startup-config**	Saves the configuration.

To disable the redirection function, use the **no ipv6 redirects** command.

The example configures the redirection function.

```
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie (config-if)# ipv6 redirects
Ruijie (config-if)# end
Ruijie # show ipv6 interface GigabitEthernet 0/1
Interface GigabitEthernet 0/1 is Up, ifindex: 1
address(es):
Mac Address: 00:d0:f8:00:00:01
INET6: fe80::2d0:f8ff:fe00:1 , subnet is fe80::/64
INET6: fec0:0:0:1::1 , subnet is fec0:0:0:1::/64
Joined group address(es):
ff01:1::1
ff02:1::1
ff02:1::2
ff02:1::1:ff00:1
MTU is 1500 bytes
ICMP error messages limited to one every 10 milliseconds
ICMP redirects are enabled
ND DAD is enabled, number of DAD attempts: 1
ND reachable time is 30000 milliseconds
ND advertised reachable time is 0 milliseconds
ND retransmit interval is 1000 milliseconds
ND advertised retransmit interval is 0 milliseconds
ND router advertisements are sent every 200 seconds<160--240>
ND router advertisements live for 1800 seconds
```

Configuring a Static Neighbor

This section describes how to configure a static neighbor. No static neighbor is configured by default. In general, a neighbor learns and maintains its status by the Neighbor Discovery Protocol (NDP) dynamically. Moreover, you can configure the static neighbor manually.

To configure the static neighbor, use the following commands.

Command	Function
Ruijie#**configure terminal**	Enters global configuration mode.
Ruijie(config)#**ipv6 neighbor** *ipv6-address interface-id hardware-address*	Configure a static neighbor on the interface.
Ruijie(config)#**end**	Returns to privileged EXEC mode.
Ruijie#**show ipv6 neighbors**	View the neighbor list.
Ruijie#**copy running-config startup-config**	Saves the configuration.

To delete the specified neighbor, use the **no ipv6 neighbor** *ipv6-address interface-id* command.

The following example configures a static neighbor on the GigabitEthernet 0/1 interface.

```
Ruijie(config)# ipv6 neighbor fec0:0:0:1::100 GigabitEthernet 0/1 00d0.f811.1234
Ruijie (config)# end
```

```
Ruijie# show ipv6 neighbors verbose fec0:0:0:1::100
IPv6 Address       Linklayer Addr   Interface
fec0:0:0:1::100     00d0.f811.1234   GigabitEthernet 0/1
State: REACH/H Age: - asked: 0
```

Caution

When you configure a static neighbor, the configuration takes effect only when the neighbor prefix matches the interface. Specifically, the configured static neighbor prefix belongs to the network segment of an address configured for the interface, and does not conflict with the address. An invalid static neighbor is in the inactive state. Data sent to the destination is not sent to the MAC address specified by the static neighbor, but the MAC address is learned based on routes in dynamic learning mode. To view the validity status of a static neighbor, run the **show ipv6 neighbor static** command.

Configuring Duplicate Address Detection

This section describes how to configure duplicate address detection times. Duplicate address detection is mandatory to assign unicast addresses to interfaces. The purpose is to detect the uniqueness of an address. Duplicate address detection should be performed for addresses that are configured in manual configuration mode, stateless auto-configuration mode, and stateful auto-configuration mode. However, it is not necessary to perform duplicate address detection under the following two conditions:

- The management prohibits the duplicate address detection, namely, the number of the NS messages sent for the duplicate address detection is set to 0.
- Duplicate address detection cannot be performed for a configured anycast address.

Furthermore, if the duplicate address detection function is not disabled on the interface, the system will restart the duplicate address detection process for the configured address when the interface changes to the Up state from the Down state.

To configure the number of NS messages sent for duplicate address detection, use the following commands.

Command	Function
Ruijie#**configure terminal**	Enters global configuration mode.
Ruijie(config)#**interface** *interface-id*	Enters interface configuration mode. Note that the **no switchport** command must be used to switch the layer-2 interface to the layer-3 interface.
Ruijie(config-if)#**ipv6 nd dad attempts** *attempts*	Configures the number of NS messages sent for duplicate address detection. When it is set to 0, the duplicate address detection function is disabled on the interface.
Ruijie(config-if)#**end**	Returns to privileged EXEC mode.
Ruijie#**show ipv6 interface vlan** *1*	Displays the IPv6 information on the interface.
Ruijie#**copy running-config startup-config**	Saves the configuration.

To restore the default value, use the **no ipv6 nd dad attempts** command.

The following example configures the number of NS messages sent for duplicate address detection on the SVI1.

```
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if)# ipv6 nd dad attempts 3
Ruijie(config-if)# end
Ruijie# show ipv6 interface GigabitEthernet 0/1
Ruijie(config)# interface vlan 1
Ruijie(config-if)# ipv6 nd dad attempts 3
Ruijie(config-if)# end
Ruijie# show ipv6 interface vlan 1
Interface GigabitEthernet 0/1 is Up, ifindex: 1
address(es):
Mac Address: 00:d0:f8:00:00:01
INET6: fe80::2d0:f8ff:fe00:1 , subnet is fe80::/64
INET6: fec0:0:0:1::1 , subnet is fec0:0:0:1::/64
Joined group address(es):
ff01:1::1
ff02:1::1
ff02:1::2
ff02:1::1:ff00:1
MTU is 1500 bytes
ICMP error messages limited to one every 10 milliseconds
ICMP redirects are enabled
ND DAD is enabled, number of DAD attempts: 3
ND reachable time is 30000 milliseconds
ND advertised reachable time is 0 milliseconds
ND retransmit interval is 1000 milliseconds
ND advertised retransmit interval is 0 milliseconds
ND router advertisements are sent every 200 seconds<160--240>
ND router advertisements live for 1800 seconds
```

Configuring the IPv6 MTU

If an IPv6 packet exceeds the interface MTU size, the RGOS software splits the packet. For all devices in the same physical network segment, the IPv6 MTU of interconnected interfaces must be the same. The IPv6 MTU of interfaces automatically keeps consistent with the link MTU of interfaces.

Use the following commands to configure the IPv6 MTU.

Command	Function
Ruijie(config-if)# **ipv6 mtu** *bytes*	Configures the interface MTU value. The range is from 1,280 to 1,500.
Ruijie(config-if)# **no ipv6 mtu**	Restores the default MTU value.

Configuring Other Interface Parameters

The IPv6 parameters on an interface are divided into two parts. One is used to control the behavior of the device itself, and the other is used to control the contents of the RA sent by the device to determine what action should be taken by the host when the host receives this RA.

The following table describes these commands.

Command	**Function**
Ruijie#**configure terminal**	Enters global configuration mode.
Ruijie(config)#**interface** *interface-id*	Enters interface configuration mode. Note that the **no switchport** command must be used to switch the layer-2 interface to the layer-3 interface.
Ruijie(config-if)#**ipv6 enable**	Enables the IPv6 function.
Ruijie(config-if)#**ipv6 nd ns-interval** *milliseconds*	(Optional) Defines the retransmission interval of the NS message, in milliseconds. The default value is 1000 milliseconds.
Ruijie(config-if)#**ipv6 nd reachable-time** *milliseconds*	(Optional) Defines the time during which the neighbor is considered as reachable, in milliseconds. The default value is 30000 milliseconds.
Ruijie(config-if)# **ipv6 nd prefix** {*ipv6-prefix*/*prefix-length* | **default**} [[*valid-lifetime preferred-lifetime*] | [**at** *valid-date preferred-date*] | [**infinite** {**infinite** | *preferred-lifetime*}]] [**no-advertise**] | [[**off-link**] [**no-autoconfig**]]	(Optional) Sets the address prefix to be advertised in the RA message.
Ruijie(config-if)#**ipv6 nd ra-lifetime** *seconds*	(Optional) Sets the lifetime of the router in the RA message, namely, the time to act as the default device. The value 0 indicates that the device will not act as the default device of the directly-connected network. The default value is 1800 seconds.
Ruijie(config-if)#**ipv6 nd ra-interval** {*seconds* **min-max** *min_value max_value*}	(Optional) Sets the time interval for the device to send the RA message periodically, in seconds. The default value is 200 seconds. With **min-max** specified, the actual interval for sending the RA message is a random value between the minimum value and the maximum value. Without **min-max** specified, the actual interval for sending the RA message is the configured value multiplied by 1.2 or 0.8.
Ruijie(config-if)#**ipv6 nd managed-config-flag**	(Optional) Sets the **managed address configuration** flag bit of the RA message, and determines whether the host receiving the RA message will use the stateful auto-configuration to obtain the address. The flag bit is not configured for the RA message by default.
Ruijie(config-if)#**ipv6 nd other-config-flag**	(Optional) Sets the **other stateful configuration** flag bit of the RA message, and determines whether the host receiving the RA message will use the stateful auto-configuration to obtain information other than the address. The flag bit is not configured for the RA message by default.
Ruijie(config-if)#**ipv6 nd suppress-ra**	(Optional) Sets whether to suppress the RA message on this interface. The flag bit is not configured for the RA message by default.
Ruijie(config-if)#**end**	Returns to privileged EXEC mode.
Ruijie#**show ipv6 interface** [*interface-id*]	Displays the IPv6 information or the information of the RA sent by

Command	Function
[**ra-info**]	this interface.
Ruijie#**copy running-config startup-config**	(Optional) Saves the configuration.

To restore the default value, use the **no** commands of above commands. For details, see the *IPv6 Command Reference*.

Monitoring and Maintaining IPv6

Use the following commands to display some internal information of the IPv6 protocol, such as the IPv6 information, the neighbor table, and the routing table information of an interface.

Command	Function
show ipv6 interface [*interface-id*] [**ra-info**]	Displays the IPv6 information of the interface.
Show ipv6 neighbors [vrf *vrf-name*] [**verbose**] [*interface-id*] [*ipv6-address*]	Displays the neighbor information.
Show ipv6 route [vrf *vrf-name*] [**static** | **local | connected | bgp | rip | ospf | isis**]	Displays the information of the IPv6 routing table.

- Display the IPv6 information of an interface.

```
Ruijie# show ipv6 interface
interface GigabitEthernet 0/1 is Down, ifindex: 1
address(es):
Mac Address: 00:d0:f8:00:00:01
INET6: fe80::2d0:f8ff:fe00:1 , subnet is fe80::/64
INET6: fec0:1:1:1::1 , subnet is fec0:1:1:1::/64
Joined group address(es):
ff01:1::1
ff02:1::1
ff02:1::2
ff02:1::1:ff00:1
MTU is 1500 bytes
ICMP error messages limited to one every 10 milliseconds
ICMP redirects are enabled
ND DAD is enabled, number of DAD attempts: 1
ND reachable time is 30000 milliseconds
ND advertised reachable time is 0 milliseconds
ND retransmit interval is 1000 milliseconds
ND advertised retransmit interval is 0 milliseconds
ND router advertisements are sent every 200 seconds<160--240>
ND router advertisements live for 1800 seconds
```

- Display the information of the RA message to be sent on an interface.

```
Ruijie# show ipv6 interface ra-info
GigabitEthernet 0/1: DOWN
RA timer is stopped
waits: 0, initcount: 3
statistics: RA(out/in/inconsistent): 4/0/0, RS(input): 0

```

Configuring IPv6 Tunnels

Overview

IPv6 is designed to inherit and replace IPv4. However, the evolution from IPv4 to IPv6 is a gradual process. Therefore, it is inevitable that these two protocols coexist for a period before IPv6 completely replaces IPv4. At the beginning of this transition stage, IPv4 networks are still main networks. IPv6 networks are similar to isolated islands in IPv4 networks. The problems about transition can be divided into the following two types:

1) Communication among isolated IPv6 networks via IPv4 networks
2) Communication between IPv6 networks and IPv4 networks

This article discusses the tunnel technology that is used to solve problem 1. The solution to problem 2 is Network Address Translation-Protocol Translation (NAT-PT), which is not covered in this article.

The IPv6 tunnel technology encapsulates IPv6 packets in IPv4 packets. In this way, IPv6 packets can communicate via IPv4 networks. Therefore, with the IPv6 tunnel technology, isolated IPv6 networks can communicate with each other via existing IPv4 networks, avoiding any modification and upgrade to existing IPv4 networks. An IPv6 tunnel can be configured between area border routers (ABRs) or between an ABR and a host. However, all the nodes at the two ends of the tunnel must support the IPv4 and IPv6 protocol stacks. At present, the following tunnel technologies are supported.

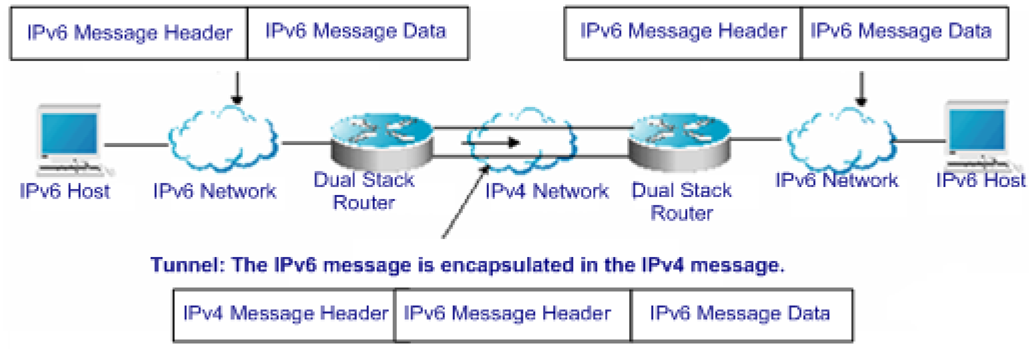
Tunnel Type	Reference
Manually Config Tunnel	RFC 2893
Automatic 6to4 Tunnel	RFC 3056
Intra-Site Automatic Tunnel Addressing Protocol(ISATAP)	draft-ietf-ngtrans-isatap-22

Caution

Interconnecting the isolated IPv6 networks through the IPv6 tunnel technology is not the ultimate IPv6 network architecture. Instead, it is a transitional technology.

The model using the tunnel technology is shown in the following figure:

Figure 11



The features of various tunnels are respectively described below.

Manually Configured IPv6 Tunnel

One manually configured tunnel is similar to one permanent link set up between two IPv6 domains via the IPv4 backbone network. It is applicable to the relatively fixed connections that have a higher requirement on security between two ABRs or between an ABR and a host.

On a tunnel interface, you must manually configure the IPv6 address, source IPv4 address (tunnel source) and destination IPv4 address (tunnel destination) of the tunnel. The nodes at the two ends of the tunnel must support the IPv6 and IPv4 protocol stacks. In practical applications, tunnels are always manually configured in pairs. You can think it as a point-to-point tunnel.

Configuring GRE Tunnel

A GRE tunnel allows a user to use a transport protocol (such as IP) to transmit network packets of any protocol. Our products support four types of GRE tunnels: IPv4 over IPv4, IPv6 over IPv4, IPv6 over IPv6, and IPv4 over IPv6.

On the tunnel interface, the IP address of the tunnel source and the IP address of the tunnel destination must be configured manually, and nodes at both ends of the tunnel must support IPv6 and IPv4 protocol stacks. The GRE tunnel is always configured simultaneously on two edge devices, and can be considered as a point-to-point tunnel.

Note

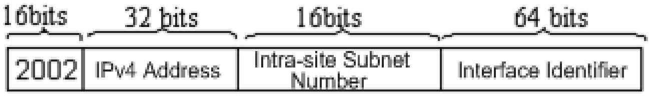
1. IPv4 over IPv6 GRE tunnel and IPv6 over IPv6 GRE tunnel are evaluation indicators.
2. IPv4 over IPv4 GRE is an evaluation indicator on the switch.
3. IPv6 over IPv4 GRE is an evaluation indicator on S5750 series switches.

Configuring Automatic 6to4 Tunnel

The automatic 6to4 tunnel technology allows isolated IPv6 networks to be interconnected via IPv4 networks. The difference between the automatic 6to4 tunnel and manually configured tunnel technologies is that the manual configured tunnel is a point-to-point tunnel, while a 6to4 tunnel is a point -to-multipoint tunnel.

The 6to4 tunnel uses an IPv4 network as a nonbroadcast multi-access (NBMA) link. Therefore, the devices of 6to4 need not be configured in pairs. The IPv4 address embedded in an IPv6 address will be used to look for the other end of the automatic tunnel. The 6to4 tunnel can be deemed as a point -to-multipoint tunnel. The automatic 6to4 tunnel can be configured on an ABR of one isolated IPv6 network. For each packet, it will automatically set up a tunnel to an ABR in another IPv6 network. The destination address of the tunnel is the IPv4 address of an ABR in the IPv6 network at the other end. The IPv4 address will be extracted from the destination IPv6 address of the packet. The destination IPv6 address begins with the prefix 2002::/16 in the following format.

Figure 12



IPv6 6to4 Address Format

The 6to4 address is an address for the automatic 6to4 tunnel technology. The IPv4 address embedded in it is usually the global IPv4 address of the egress of the ABR of the site. When the automatic tunnel is set up, the address is used as the destination IPv4 address for tunnel packet encapsulation. All the routers at the two ends of the 6ot4 tunnel must support the IPv6 and IPv4 protocol stacks. A 6to4 tunnel is usually configured between ABRs.

For example, if the global IPv4 address of the egress of the ABR of the site is 211.1.1.1 (D301:0101 in hexadecimal notation), a subnet number in the site is 1 and the interface identifier is 2e0:ddff:fee0:e0e1, then the corresponding 6to4 address can be denoted as follows:

2002: D301:0101:1: 2e0:ddff:fee0:e0e1

Caution

The IPv4 address embedded in the 6to4 address cannot be a private IPv4 address (i.e., the address of the network interface segment 10.0.0.0/8, 172.16.0.0/12 or 192.168.0.0/16) and must be the global IPv4 address.

Common application models of 6to4 tunnels:

- Simple application models

The simplest and most common application of 6to4 tunnels is used to interconnect multiple IPv6 sites. Each of the sites must have one connection to one of their shared IPv4 networks at least. This IPv4 network can be the Internet or a internal backbone network of an organization. The key is that each site must have a unique global IPv4 address. The 6to4 tunnel will use the address to form the IPv6 prefix of 6to4/48: 2002:IPV4 address/48.

- Hybrid application models

Based on the application described above, other 6to4 networks access the IPv6-only network through 6to4 relay devices at the edge. The router used to implement the function is called a 6to4 relay router.

Configuring ISATAP Automatic Tunnel

The Intra-site Automatic Tunnel Addressing Protocol (ISATAP) is a type of IPv6 tunnel technology by which an intra-site IPv6 architecture uses an IPv4 network as one nonbroadcast multi-access (NBMA) link layer, namely, using an IPv4 network as the virtual link layer of IPv6.

ISATAP is applicable to the case where the IPv6-only network inside a site is not ready for use yet and an IPv6 packet needs to be transferred internally in the site. For example, a few IPv6 hosts for test need to communicate with each other inside the site. By using an ISATAP tunnel, the IPv4/IPv6 dual stack hosts on a same virtual link can communicate with each other inside the site.

At the ISATAP site, the ISATAP device provides a standard router advertisement message, allowing the ISATAP host to be automatically configured inside the site. At the same time, the ISATAP device forwards the packets between an intra-site ISATAP host and an external IPv6 host.

The IPv6 address prefix used by ISATAP can be any legal 64-bit prefix for IPv6 unicast, including the global address prefix, link-local prefix and site-local prefix. The IPv4 address is placed as the last 32 bits of the IPv6 address, allowing a tunnel to be automatically set up.

ISATAP can be easily used with other transition technologies. Especially when used with the 6to4 tunnel technology, it can enable the dual-stack host of an intranet access an IPv6 backbone network very easily.

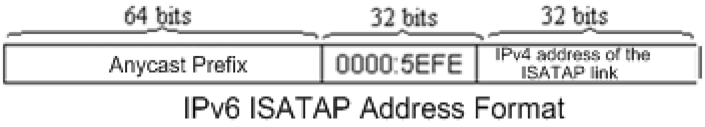
- ISATAP interface identifier

The unicast address used by ISATAP is in the form of a 64-bit IPv6 prefix plus a 64-bit interface identifier. The 64-bit interface identifier is generated in the revised EUI-64 address format. The value of the first 32 bits of the interface identifier is 0000:5EFE, an interface identifier of ISATAP.

- ISATAP address structure

An ISATAP address refers to a unicast address containing an ISATAP interface identifier in its interface identifier. An ISATAP address structure is shown in the following figure.

Figure 13



The above figure shows that the interface identifier contains an IPv4 address. The address is the IPv4 address of a dual-stack host and will be used when an automatic tunnel is automatically set up.

For example, the IPv6 prefix is 2001::/64 and the embedded IPv4 address is 192.168.1.1. In the ISATAP address, the IPv4 address is denoted as the hexadecimal numeral C0A8:0101. Therefore, its corresponding ISATAP address is as follows:

2001::0000:5EFE:C0A8:0101

Configuring 6RD Tunnel

If you want to configure a IPv6 rapid development (6RD) tunnel, configure the tunnel interface with both the source IPv4 address and destination IPv4 address. The host or device at the peer end of the tunnel should be configured in the same way.

Command	Description
Ruijie#**configure terminal**	Enters global configuration mode.

Ruijie(config)#**interface tunnel** *tunnel-number*	Configures a tunnel by specifying the tunnel number and enters interface configuration mode.
Ruijie(config-if-Tunnel id)#**tunnel mode ipv6ip 6rd**	Sets the tunnel type to 6RD tunnel,
Ruijie(config-if-Tunnel id)#**ipv6 enable**	Enables the IPv6 function on the interface. You can also enable the IPv6 function directly by configuring an IPv6 address.
Ruijie(config-if-Tunnel id)#**tunnel 6rd prefix** *ipv6-prefix* **/** *prefix-length*	Sets the 6RD prefix. If 6RD prefix is not configured, the 6RD tunnel cannot be up. If the prefix length is set to 0, it indicates that the prefix is deleted.
Ruijie(config-if-Tunnel id)#**tunnel 6rd ipv4 prefix-length** *length* **suffix-length** *length*	Sets the IPv4 prefix and suffix length for the 6RD domain. The valid range is from 0 to 31. The sum of the prefix and suffix length cannot be greater than 31. The default is 0.
Ruijie(config-if-Tunnel id)#**tunnel source** { *ipv4-address* | *interface-type interface-number* }	Sets the IPv4 source address of the tunnel or the referenced source interface number. The interface that is specified must be configured with an IPv4 address.
Ruijie(config-if-Tunnel id)#**tunnel 6rd br** *ipv4-address*	Sets the border relay (BR) IPv4 address for the 6RD customer edge (CE). This command is configured only on the 6RD CE. Configuring this command allows the 6RD router to disable security check on the tunnel packet containing this source address.
Ruijie(config-if-Tunnel id)#**exit**	Returns to privileged EXEC mode.
Ruijie(config)#**ipv6 route** *prefix::/prefix-length next-hop*	Configures the tunnel route.

The following example configures the 6RD tunnel on the device.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  Exit with CNTL/Z.
Ruijie(config)#interface Tunnel 100
Ruijie(config-if-Tunnel 100)#tunnel mode ipv6ip 6rd
Ruijie(config-if-Tunnel 100)#tunnel source 10.1.1.1
Ruijie(config-if-Tunnel 100)#tunnel 6rd prefix 2001:DA8::/32
Ruijie(config-if-Tunnel 100)#tunnel 6rd ipv4 prefix-length 16 suffix-length 0
Ruijie(config-if-Tunnel 100)#tunnel 6rd br 10.1.4.1
Ruijie(config-if-Tunnel 100)#ipv6 enable
Ruijie(config)#ipv6 address 2004::1/128
Ruijie(config)#ipv6 route 2001:da8::/32 Tunnel 100
Ruijie(config)#ipv6 route ::/0 Tunnel8 2001:DA8:401::1
Ruijie(config)#ipv6 route 2001:da8:101::/48 Null 0
```

Configuring 6RD Tunnel via DHCP Automatic Configuration

You can configure the 6RD parameter for the DHCP client via the DHCP option on the DHCP server. The 6RD parameter includes the generic IPv4 prefix and suffix length, 6RD prefix length, 6RD prefix, and IPv4 address of the 6RD BR for a given 6RD domain. If you want to create a 6RD tunnel for the DHCP client, you can configure the DHCP option 212 for the client to obtain the 6RD parameter. Use the following command in DHCP address pool configuration mode to configure the 6RD parameter available for the DHCP client.

Command	Function
Ruijie(dhcp-config)# **option 6rd ipv4masklen** <*mask-length*> **ipv6prefixlen** <*prefix-length*> **ipv6prefix** <*ipv6-prefix*> **br-addr** <*ipv4-address*>	Configures the 6RD parameter.
Use the following command to enable the DHCP 6RD client interface to obtain IP address.**Command**	**Function**
Ruijie(config-if-GigabitEthernet 0/0)#ip address dhcp 6rd	Enables the DHCP client to obtain the IP address.

The following example configures the 6RD parameter for the DHCP client on the DHCP server.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  Exit with CNTL/Z.
Ruijie(config)#ip dhcp pool 6rd
Ruijie(dhcp-config)#option 6rd ipv4masklen 16 ipv6prefixlen 32 ipv6prefix 2002:DA8:: br-addr
1.1.1.1
```

Configuring IPv6 Tunnels

Manually Configuring IPv6 Tunnels

This section describes how to configure tunnels manually.

To configure a tunnel manually, configure an IPv6 address on the tunnel interface and manually configure the IPv4 addresses of the source and destination of the tunnel. Then, configure the hosts or devices at the two ends of the tunnel to ensure that they support the dual stacks (the IPv6 and IPv4 protocol stacks).

Caution Do not configure tunnels manually with the same runnel source and tunnel destination.

Brief steps

```
config terminal
interface tunnel tunnel-num
tunnel mode ipv6ip
ipv6 enable
tunnel source {ip-address | type num}
tunnel destination ip-address
end
```

To configure an IPv6 tunnel manually, use the following commands in global configuration mode.

Command	Function
configure terminal	Enters global configuration mode.
interface tunnel *tunnel-num*	Specifies a tunnel interface number to create a tunnel interface and enters interface configuration mode.

Command	Function
tunnel mode **ipv6ip**	Sets the tunnel type to manually configured tunnel.
ipv6 enable	Enables the IPv6 function on the interface. You can also configure the IPv6 address to directly enable the IPv6 function on the interface.
tunnel source {*ip-address* | *type* *num*	Specifies the IPv4 source address or referenced source interface number of the tunnel. Note: If you specify an interface, the IPv4 address must have been configured on the interface.
tunnel destination *ip address*	Specifies the destination address of the tunnel.
end	Returns to privileged EXEC mode.
copy running-config startup-config	Saves the configuration information.

See the "Verifying and Monitoring IPv6 Tunnel Configuration" section to check the operation of the tunnel.

Configuring GRE Tunnels

This section describes how to configure GRE tunnels.

To configure a GRE tunnel, you need to manually configure the tunnel source IP address and tunnel destination IP address on the tunnel interface. The corresponding configurations must also be done on the peer host or device.

Caution

Do not configure a GRE tunnel with the same tunnel source IP address and tunnel destination IP address on the device.

Use the following commands to configure a GRE tunnel.

Command	Function
Ruijie# **configure terminal**	Enters global configuration mode.
Ruijie(config)# **interface tunnel** *tunnel-num*	Specifies the tunnel interface number to create a tunnel interface and enters interface configuration mode.
Ruijie(config-if-Tunnel id)# **tunnel mode** **gre** {**ip | ipv6**}	Sets the tunnel type to GRE tunnel, and specifies the carrier protocol as IPv4 or IPv6.
Ruijie(config-if-Tunnel id)# **tunnel source** {*ipv4-address* | *ipv6-address* | *interface-type* *interface-num* }	Specifies the IPv4 address of the tunnel source or source interface number referenced. If the interface is specified, the IPv4 address must have been configured on the interface.
Ruijie(config-if-Tunnel id)# **tunnel destination** *{ipv4-address* | *ipv6-address}*	Specifies the destination address of the tunnel. If the carrier protocol is IPv6, the IP address must be configured as the IPv6 address of the peer device.
Ruijie(config-if-Tunnel id)# **end**	Returns to privileged EXEC mode.
Ruijie# **copy running-config startup-config**	Saves the configuration information.

See the "Verifying and Monitoring IPv6 Tunnel Configuration" section to check the operation of the tunnel.

Caution

Because GRE features differ from device to device, the aforementioned commands may not be available on certain products.

Configuring 6to4 Tunnels

This section describes how to configure a 6to4 tunnel.

The destination address of a 6to4 tunnel is determined by the IPv4 address which is extracted from a 6to4 IPv6 address. The devices at the two ends of the 6to4 tunnel must support the dual stacks, namely, the IPv4 and IPv6 protocol stacks.

Caution

A device supports only one 6to4 tunnel. The encapsulation source address (IPv4 address) used by the 6to4 tunnel must be a globally routable address. Otherwise, the 6to4 tunnel will not work normally.

Brief steps

```
config terminal
interface tunnel tunnel-num
tunnel mode ipv6ip 6to4
ipv6 enable
tunnel source {ip-address | type num}
exit
ipv6 route 2002::/16 tunnel tunnel-number
end
```

To configure a 6to4 tunnel, use the following commands.

Command	Function
configure terminal	Enters global configuration mode.
interface tunnel *tunnel-num*	Specifies a tunnel interface number to create a tunnel interface and enters interface configuration mode.
tunnel mode ipv6ip 6to4	Sets the tunnel type to 6to4 tunnel.
ipv6 enable	Enables the IPv6 function of the interface. You can also configure the IPv6 address to directly enable the IPv6 function of the interface.
tunnel source {*ip-address* | *type num*	Specifies the encapsulation source address or referenced source interface number of the tunnel. Note: The IPv4 address must have been configured on the referenced interface. The used IPv4 address must be a globally routable address.
Exit	Returns to global configuration mode.

Command	Function
ipv6 route *2002::/16* **tunnel** *tunnel-number*	Configures a static route for the IPv6 6to4 prefix 2002::/16 and associates the output interface with the tunnel interface, i.e., the tunnel interface specified above.
End	Returns to privileged EXEC mode.
copy running-config startup-config	Saves the configuration information.

See the "Verifying and Monitoring IPv6 Tunnel Configuration" to check the operation of the tunnel.

Configuring ISATAP Tunnels

This section describes how to configure ISATAP tunnels.

On an ISATAP tunnel interface, the configuration of an ISATAP IPv6 address and the advertisement configuration of a prefix are the same as that of a common IPv6 interface. However, the address configured for an ISATAP tunnel interface must be a revised EUI-64 address. The reason is that the last 32 bits of the interface identifier in the IPv6 address are composed of the IPv4 address of the interface referenced by the tunnel source address. See the above sections for the information about ISATAP address formats.

Caution

A device supports multiple ISATAP tunnels. However, the source of each ISATAP tunnel must be different. Otherwise, there is no way to know which ISATAP tunnel a received ISATAP tunnel message belongs to.

Brief steps

```
config terminal
interface tunnel tunnel-num
tunnel mode ipv6ip isatap
ipv6 address ipv6-prefix/prefix-length eui-64
tunnel source interface-type num
no ipv6 nd suppress-ra
end
```

To configure an ISATAP tunnel, use the following commands.

Command	Function
configure terminal	Enters global configuration mode.
interface tunnel *tunnel-num*	Specifies a tunnel interface number to create a tunnel interface and enters interface configuration mode.
tunnel mode ipv6ip isatap	Sets the tunnel type to ISATAP tunnel.
ipv6 address **ipv6-prefix/prefix-length eui-64**	Configures the IPv6 ISATAP address. Be sure to use the **eui-64** keyword. In this way, the ISATAP address will be automatically generated. The address configured on an ISATAP interface must be an ISATAP address.

Command	Function
tunnel source type *num*	Specifies the source interface number referenced by the tunnel. On the referenced interface, the IPv4 address must have been configured.
no ipv6 nd suppress-ra	Sending router advertisement messages on an interface is disabled by default. You can use the command to enable the function, allowing the ISATAP host to be automatically configured.
End	Returns to privileged EXEC mode.
copy running-config startup-config	Saves the configuration information.

See the "Verifying and Monitoring IPv6 Tunnel Configuration" to check the operation of the tunnel.

Configuring the Tunnel to Support IPv6 Multicast

Currently, on the IPv6 network, both IPv6 unicast and multicast services need to be able to traverse the IPv4 network.

It is easy to configure IPv6 tunnel multicast. The tunnel interface can be configured in the same way as other common interfaces such as an SVI interface.

Caution

Multicast is supported only in the manually configured IPv6 tunnel. For tunnels of other types, multicast can be configured, but multicast data cannot be received or forwarded after the configuration.

For the manually configured IPv6 tunnel, if the tunnel is created based on an IPv6 tunnel of any type, multicast can be configured, but multicast data cannot be received or forwarded after the configuration.

When IPv6 multicast data traverses the IPv4 network, the MTU restrictions are the same as those for IPv6 unicast data.

Verifying and Monitoring IPv6 Tunnel Configuration

This section describes how to verify the configuration and operation of an IPv6 tunnel.

Brief steps

```
enable
show interface tunnel number
show ipv6 interface tunnel mumber
ping protocol destination
show ip route
show ipv6 route
```

To verify the configuration and operation of a tunnel, use the following commands.

Command	Function
show interface tunnel *tunnel-num*	Displays the information of a specified tunnel interface.

Command	Function
show ipv6 interface tunnel *tunnel-num*	Displays the IPv6 information of the tunnel interface.
ping protocol destination	Checks the basic connectivity of a network.
show ip route	Displays the IPv4 routing table.
show ipv6 route	Displays the IPv6 router table.

3) Display the information of a tunnel interface.

```
Ruijie# show interface tunnel 1
Tunnel 1 is up, line protocol is Up
Hardware is Tunnel, Encapsulation TUNNEL
Tunnel source 192.168.5.215  ,  destination 192.168.5.204
Tunnel protocol/transport IPv6/IP
Tunnel TTL is 9
Tunnel source do conformance check set
Tunnel source do ingress filter set
Tunnel destination do safety check not set
Tunnel disable receive packet not set
```

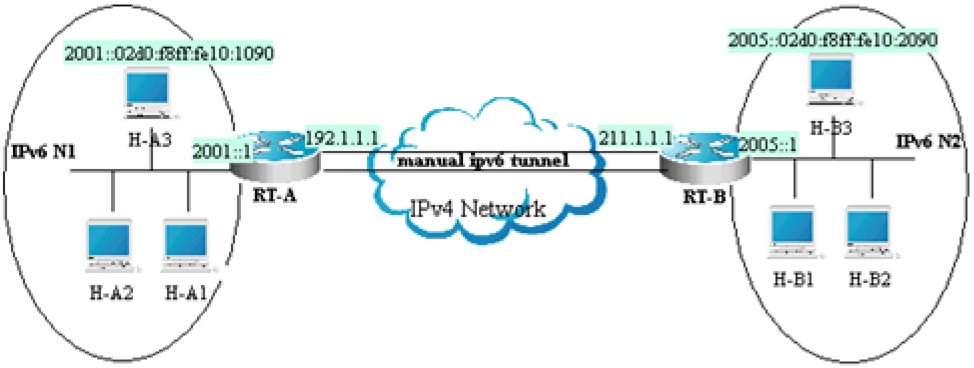
4) Display the IPv6 information of a tunnel interface.

```
Ruijie# show ipv6 interface tunnel 1
interface Tunnel 1 is Up, ifindex: 6354
address(es):
Mac Address: N/A
INET6: fe80::3d9a:1601 , subnet is fe80::/64
Joined group address(es):
ff02::2
ff01::1
ff02::1
ff02::1:ff9a:1601
INET6: 3ffe:4:0:1::1 , subnet is 3ffe:4:0:1::/64
Joined group address(es):
ff02::2
ff01::1
ff02::1
ff02::1:ff00:1
MTU is 1480 bytes
ICMP error messages limited to one every 100 milliseconds
ICMP redirects are enabled
ND DAD is enabled, number of DAD attempts: 1
ND reachable time is 30000 milliseconds
ND advertised reachable time is 0 milliseconds
ND retransmit interval is 1000 milliseconds
ND advertised retransmit interval is 0 milliseconds
ND router advertisements are sent every 200 seconds<240--160>
ND router advertisements live for 1800 seconds
```

IPv6 Tunnel Configuration Examples

Example of Configuring IPv6 Tunnels Manually

Figure 14



As shown in the above figure, IPv6 networks N1 and N2 are isolated by the IPv4 network. Now, the two networks are interconnected by configuring a tunnel manually. For example, the H-A3 host in N1 can access the H-B3 host in N2.

In the figure, RT-A and RT-B are routers that support the IPv4 and IPv6 protocol stacks. Tunnel configuration is performed on the ABRs (RT-A and RT-B) in N1 and N2. Note that the tunnel must be configured manually in pairs, that is, on RT-A and RT-B.

The following presents the tunnel configuration on routers:

Prerequisite: Assume that the routes of IPv4 are connected. In the following content, no more route configuration condition about IPv4 is listed.

RT-A:

#Connect the interfaces of the IPv4 network.

```
interface FastEthernet 2/1
no switchport
ip address 192.1.1.1 255.255.255.0
```

#Connect the interfaces of the IPv6 network.

```
interface FastEthernet 2/2
no switchport
ipv6 address 2001::1/64
no ipv6 nd suppress-ra  (optional)
```

#Configure the manual tunnel interface.

```
interface Tunnel 1
tunnel mode ipv6ip
ipv6 enable
tunnel source FastEthernet 2/1
tunnel destination 211.1.1.1
```

#Configure the route to the tunnel.

```
ipv6 route 2005::/64 tunnel 1
```

RT-B:

#Connect the interfaces of the IPv4 network.

```
interface FastEthernet 2/1
no switchport
ip address 211.1.1.1 255.255.255.0
```

# Connect the interfaces of the IPv6 network.

```
interface FastEthernet 2/2
no switchport
ipv6 address 2005::1/64
no ipv6 nd suppress-ra  (optional)
```

#Configure the manual tunnel interface.

```
interface Tunnel 1
tunnel mode ipv6ip
ipv6 enable
tunnel source FastEthernet 2/1
tunnel destination 192.1.1.1
```

#Configure the route to the tunnel.

```
ipv6 route 2001::/64 tunnel 1
```

Example of Manually Configuring IPv6 Tunnels to Support Multicast

Assume that the network topology is shown in Figure 4. On the basis of the previous example, the additional support to PIM SMv6 multicast is required. Detailed configurations related to multicast are shown below:

- RT-A

# Globally enable multicast.

```
ipv6 multicast-routing
```

# Enable PIM SMv6 on the interface.

```
interface Tunnel 1
IPv6 pim sparse-mode
```

- RT-B

# Globally enable multicast.

```
ipv6 multicast-routing
```

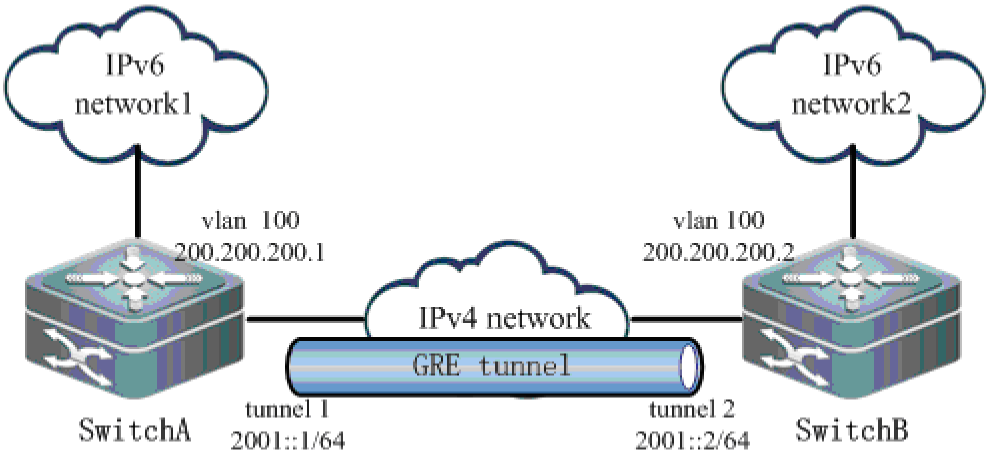
# Enable PIM SMv6 on the interface.

```
interface Tunnel 1
```

```
IPv6 pim sparse-mode
```

Example of Configuring IPv6 over IPv4 GRE Tunnels

Figure 15



As shown in Figure 15, two IPv6 networks, IPv6 network1 and IPv6 network2, need to be connected via a public IPv4 network to realize intercommunication. Layer-3 devices Switch A and Switch B supports both IPv4 and IPv6 stacks, and are interconnected via the IPv4 network. An IPv6 over IPv4 GRE tunnel needs to be created over this IPv4 network.

Assuming that IPv6 network1 is 2002::/64 and IPv6 network2 is 2003::/64, the configurations on Switch A and Switch B are shown below:

5) Configure Switch A.

# Configure interface vlan 100.

```
interface vlan 100
ip address 200.200.200.1 255.255.255.0
```

# Configure interface Tunnel 1.

```
interface Tunnel 1
 ipv6 address 2001::1/64
 tunnel mode gre ip
 tunnel source vlan 100
 tunnel destination 200.200.200.2
```

# Configure the route to pass through the tunnel interface to reach IPv6 network2.

```
ipv6 route 2003::/64 tunnel 1 2001::2
```

6) Configure Switch B.

# Configure interface vlan 100.

```
interface vlan 100
 ip address 200.200.200.2 255.255.255.0
```

# Configure interface Tunnel 1.

```
interface Tunnel1
 ipv6 address 2001::2/64
 tunnel mode gre ip
 tunnel source vlan 100
 tunnel destination 200.200.200.1
```

# Configure the route to pass through the tunnel interface to reach IPv6 network1.

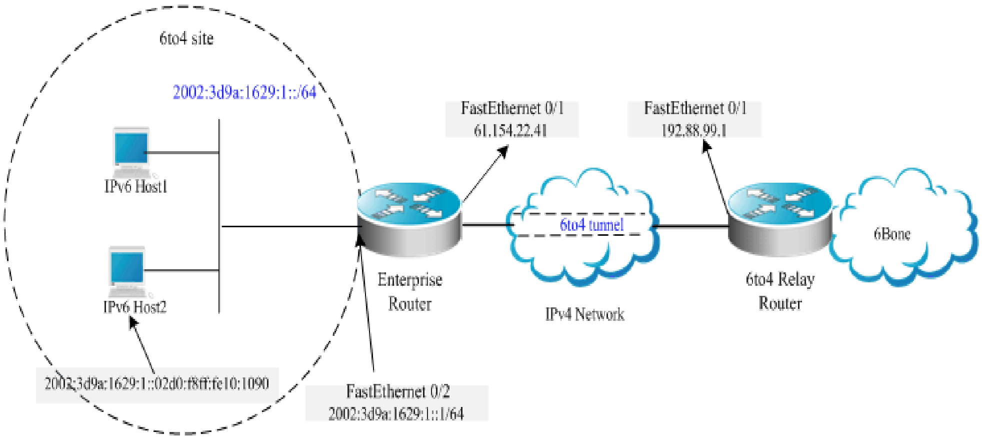
```
ipv6 route 2002::/64 tunnel 1 2001::1
```

7) View the operation of the tunnel, taking Switch A as an example.

```
show interface tunnel 1
Index(dec):3 (hex):3
Tunnel 1 is UP  , line protocol is UP
Hardware is  Tunnel
Interface address is: no ip address
  MTU 1496 bytes, BW 9 Kbit
  Encapsulation protocol is Tunnel, loopback not set
  Keepalive set (10 sec), retries 3
  Carrier delay is 2 sec
  RXload is 1 ,Txload is 1
  Tunnel source 200.200.200.1 (VLAN 100), destination 200.200.200.2
  Tunnel TOS 0x14,  Tunnel TTL 255
  Tunnel protocol/transport GRE/IP
   Key disabled, Sequencing disabled
   Checksumming of packets disabled
  Path MTU Discovery, ager 10 mins, min MTU 92, MTU 0, expires never
  Queueing strategy: FIFO
    Output queue 0/40, 0 drops;
    Input queue 0/75, 0 drops
  5 minutes input rate 0 bits/sec, 0 packets/sec
  5 minutes output rate 0 bits/sec, 0 packets/sec
    0 packets input, 0 bytes, 0 no buffer, 0 dropped
    Received 0 broadcasts, 0 runts, 0 giants
    0 input errors, 0 CRC, 0 frame, 0 overrun, 0 abort
    0 packets output, 0 bytes, 0 underruns , 0 dropped
    0 output errors, 0 collisions, 0 interface resets
```

Example of Configuring 6to4 Tunnels

Figure 16



As shown in the above figure, an IPv6 network (6to4 site) uses a 6to4 tunnel to access the IPv6 backbone network (6bone) via a 6to4 relay router.

As described above, the 6to4 tunnel technology is used to interconnect isolated IPv6 networks and the IPv6 backbone network can be accessed via the 6to4 relay router very easily. The 6to4 tunnel is an automatic tunnel and the IPv4 address embedded in the IPv6 address will be used to look for the other end of the automatic tunnel. Therefore, you need not configure the destination end for the 6to4 tunnel. Additionally, unlike a manual tunnel, the 6to4 tunnel need not be configured in pairs.

61.154.22.41 is 3d9a:1629 in hexadecimal notation.

192.88.99.1 is c058:6301 in hexadecimal notation.

⚠ Caution

When configuring a 6to4 tunnel on an ABR, be sure to use a globally routable IPv4 address. Otherwise, the 6to4 tunnel will not work normally.

The following is the configuration of the two routers in the figure (Assume that IPv4 routes are connected. Ignore the configuration of IPv4 routes.):

Enterprise router:

# Connect the interfaces of the IPv4 network.

```
interface FastEthernet 0/1
no switchport
ip address 61.154.22.41 255.255.255.128
```

# Connect the interfaces of the IPv6 network.

```
interface FastEthernet 0/2
no switchport
ipv6 address 2002:3d9a:1629:1::1/64
no ipv6 nd suppress-ra
```

# Configure the 6to4 tunnel interface.

```
interface Tunnel 1
tunnel mode ipv6ip 6to4
```

```
ipv6 enable
tunnel source FastEthernet 0/1
```

# Configure the route to the tunnel.

```
ipv6 route 2002::/16 Tunnel 1
```

# Configure the route to the 6to4 relay router to access 6bone.

```
ipv6 route ::/0 2002:c058:6301::1
```

ISP 6to4 relay router:

# Connect the interface of the IPv4 network.

```
interface FastEthernet 0/1
no switchport
ip address 192.88.99.1 255.255.255.0
```

# Configure the 6to4 tunnel interface.

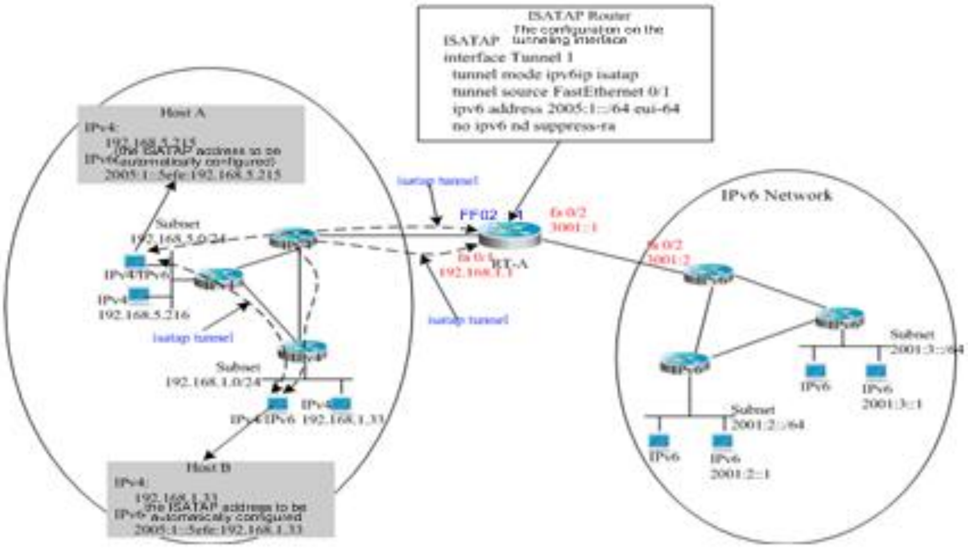
```
interface Tunnel 1
tunnel mode ipv6ip 6to4
ipv6 enable
tunnel source FastEthernet 0/1
```

# Configure the route to the tunnel.

```
ipv6 route 2002::/16 Tunnel 1
```

Example of Configuring ISATAP Tunnels

Figure 17



The above figure is one typical topology using an ISATAP tunnel. The ISATAP tunnel is used to communicate between isolated IPv4/IPv6 dual-stack hosts inside the IPv4 site. The ISATAP router has the two following functions inside the ISATAP site:

- Receive a router solicitation message from the ISATAP host inside the site and then respond with a router advertisement message for the ISATAP host inside the site to be automatically configured.
- Be responsible for the message forwarding function of the ISATAP host inside the site and the IPv6 host outside the site.

In the above figure, when Host A and Host B send the router solicitation message to the ISATAP router, the ISATAP router will respond with a router advertisement message. After receiving the message, the hosts will automatically perform configuration and generate their own ISATAP addresses respectively. Then, the IPv6 communication between Host A and Host B will be done via the ISATAP tunnel. When Host A or Host B need to communicate with the IPv6 host outside the site, Host A sends the message to the ISATAP router RT-A via the ISATAP tunnel and then RT-A forwards the message to the IPv6 network.

In the above figure, the ISATAP router (RT-A) is configured as follows:

# Connect the interfaces of the IPv4 network.

```
interface FastEthernet 0/1
no switchport
ip address 192.168.1.1 255.255.255.0
```

# Configure the ISATAP tunnel interface.

```
interface Tunnel 1
tunnel mode ipv6ip isatap
tunnel source FastEthernet 0/1
ipv6 address 2005:1::/64 eui-64
no ipv6 nd suppress-ra
```

# Connect the interfaces of the IPv6 network.

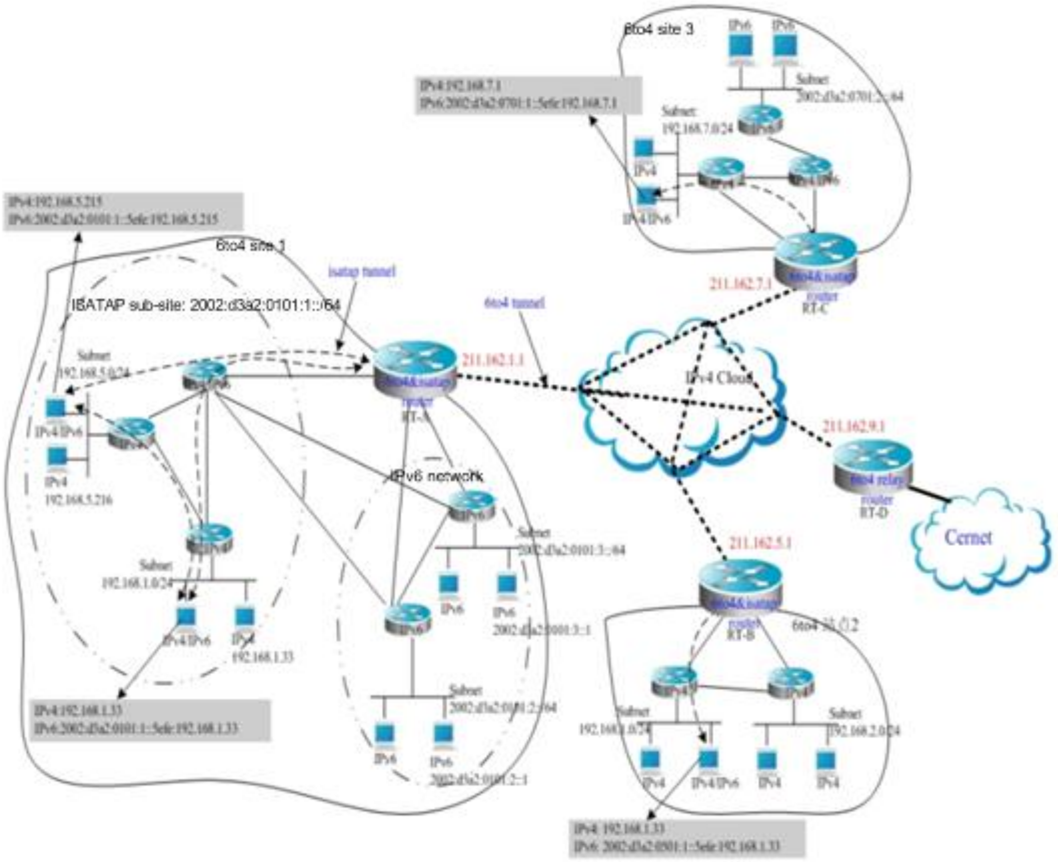
```
interface FastEthernet  0/2
no switchport
ipv6 address 3001::1/64
```

# Configure the route to the IPv6 network.

```
ipv6 route 2001::/64 3001::2
```

Example of Configuring ISATAP and 6to4 Tunnels

Figure 18



Note

The above figure shows a hybrid application of a 6to4 tunnel and an ISATAP tunnel. By using the 6to4 tunnel technology, various 6to4 sites are interconnected and the 6to4 sites access the Cernet network via the **6to4 relay router**. At the same time, by using the ISATAP tunnel technology inside the 6to4 sites, the IPv6 hosts isolated by IPv4 inside the sites perform IPv6 communication via the ISATAP tunnel.

Caution

In the above figure, the used global IP addresses including the address of the 6to4 relay router are only for convenience. When actually planning topologies, you should use a true global IP address and the address of the 6to4 relay. At present, many organizations provide the addresses of open and free 6to4 relay routers.

The configurations of ABRs at the 6to4 sites shown in the above figure are described respectively below. Note that only main related configurations are listed here.

RT-A:

# Connect the interfaces of the Internet.

```
interface GigabitEthernet 0/1
no switchport
ip address 211.162.1.1 255.255.255.0
```

# Connect the interfaces of the IPv4 network inside the site.

```
interface FastEthernet  0/1.
```

```
no switchport
ip address 192.168.0.1 255.255.255.0
```

# Configure the ISATAP tunnel interface.

```
interface Tunnel 1
tunnel mode ipv6ip isatap
tunnel source FastEthernet 0/1
ipv6 address 2002:d3a2:0101:1::/64 eui-64
no ipv6 nd suppress-ra
```

# Connect interface 1 of the IPv6 network.

```
interface FastEthernet 0/2
no switchport
2002:d3a2:0101:10::1/64
```

# Connect interface 2 of the IPv6 network.

```
interface FastEthernet  0/2
no switchport
2002:d3a2:0101:20::1/64
```

# Configure the 6to4 tunnel interface.

```
interface Tunnel 2
tunnel mode ipv6ip 6to4
ipv6 enable
tunnel source GigabitEthernet 0/1
```

# Configure the route to the 6to4 tunnel.

```
ipv6 route 2002::/16 Tunnel 2
```

# Configure the route to the 6to4 relay router RT-D to access the Cernet network.

```
ipv6 route ::/0 2002:d3a2::0901::1
```

RT-B:

# Connect the interfaces of the Internet.

```
interface GigabitEthernet 0/1
no switchport
ip address 211.162.5.1 255.255.255.0
```

# Connect interface 1 of the IPv4 network inside the site.

```
interface FastEthernet  0/1
no switchport
ip address 192.168.10.1 255.255.255.0
```

# Connect interface 2 of the IPv4 network inside the site.

```
interface FastEthernet  0/2
```

```
no switchport
ip address 192.168.20.1 255.255.255.0
```

# Configure the ISATAP tunnel interface.

```
tunnel mode ipv6ip isatap
tunnel source FastEthernet 0/1
ipv6 address 2002:d3a2:0501:1::/64 eui-64
no ipv6 nd suppress-ra
```

# Configure the 6to4 tunnel interface.

```
interface Tunnel 2
tunnel mode ipv6ip 6to4
ipv6 enable
tunnel source GigabitEthernet 0/1
```

# Configure the route to the 6to4 tunnel.

```
ipv6 route 2002::/16 Tunnel 2
```

# Configure the route to the 6to4 relay router RT-D to access the Cernet network.

```
ipv6 route ::/0 2002:d3a2::0901::1
```

RT-C:

# Connect the interfaces of the Internet.

```
interface GigabitEthernet 0/1
no switchport
ip address 211.162.7.1 255.255.255.0
```

# Connect the interfaces of the IPv4 network inside the site.

```
interface FastEthernet 0/1
no switchport
ip address 192.168.0.1 255.255.255.0
```

# Configure the ISATAP tunnel interface.

```
interface Tunnel 1
tunnel mode ipv6ip isatap
tunnel source FastEthernet 0/1
ipv6 address 2002:d3a2:0701:1::/64 eui-64
no ipv6 nd suppress-ra
```

# Connect the interfaces of the IPv6 network.

```
interface FastEthernet 0/2
no switchport
2002:d3a2:0701:10::1/64
```

# Configure the 6to4 tunnel interface.

```
interface Tunnel 2
tunnel mode ipv6ip 6to4
ipv6 enable
tunnel source GigabitEthernet 0/1
```

# Configure the route to the 6to4 tunnel.

```
ipv6 route 2002::/16 Tunnel 2
```

#Configure the route to the 6to4 relay router RT-D to access the Cernet network.

```
ipv6 route ::/0 2002:d3a2::0901::1
```

RT-D (6to4 relay):

# Connect the interfaces of the Internet.

```
interface GigabitEthernet 0/1
no switchport
ip address 211.162.9.1 255.255.255.0
```

# Connect the interfaces of the IPv6 network.

```
interface FastEthernet 0/1
no switchport
2001::1/64
no ipv6 nd suppress-ra
```

# Configure the 6to4 tunnel interface.

```
interface Tunnel 1
tunnel mode ipv6ip 6to4
ipv6 address 2002:d3a2::0901::1/64
tunnel source GigabitEthernet 0/1
```

#Configure the route to the 6to4 tunnel.

```
ipv6 route 2002::/16 Tunnel 1
```

Configuring NAT-PT

Overview

With the rapid development of the Internet, IPv4 becomes inadequate for the Internet, and IPv6 deployment has been on the agenda. To implement an IPv6 network, you are advised make the most of the existing network environment to build the next generation of the Internet to achieve smooth evolution and avoid excessive investment waste. As the Internet is currently based on IPv4 and unlikely to completely evolve to the IPv6 network within a short time, IPv6 and IPv4 networks will co-exist for quite some time.

That brings a challenge to maintain services and functions of the existing network and achieve transparent transmission between IPv4 and IPv6 networks at a low cost. Network Address Translation-Protocol Translation (NAT-PT) emerges in response to the communication between directly connected IPv6 and IPv4 networks.

Free communication between IPv6 and IPv4 networks can be ensured by using NAT-PT. Communication can be initiated by a host on either network. You can use NAT-PT to translate protocols and semantics without transforming or upgrading the host.

Basic Concepts

NAT for the IPv4 network is adopted and improved for IPv4-IPv6 address translation. It aims to establish and maintain address mappings.

PT is responsible for IPv4-IPv6 protocol translation. It builds new packets by replacing the IPv6 header with the IPv4 header or vice versa. Only certain types of the Internet Control Message Protocol version 4 (ICMPv4) and ICMPv6 packets can be translated because of their protocols, for example, translation between ICMPv4 and ICMPv6 request/response packets and translation between ICMPv4 and ICMPv6 destination-unreachable packets.

As a mode of dynamic address translation, Port Address Translation (PAT) is used for IPv6-IPv4 dynamic translation. Multiple IPv6 addresses can be mapped to the same IPv4 address differentiated by different ports to avoid IPv4 address depletion.

Working Principle

NAT-PT works on the border router between IPv6 and IPv4 networks. The NAT-PT module translates IP header addresses between IPv6 and IPv4 networks, and translates semantics of groups according to different protocols to achieve transparent transmission between IPv4 and IPv6 networks. NAT-PT can replace addresses statically or use an address pool containing global addresses. When a session passes through the border router, the border router takes an address from the address pool and assigns the address to the correct IPv4/IPv6 host. At the same time, to track the session to be translated, the session must pass though the same NAT-PT border router.

Protocols and Standards

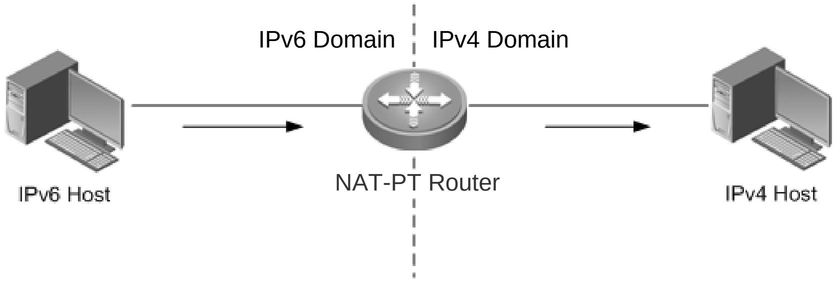
RFC2765: Stateless IP/ICMP Translation Algorithm (SIIT).

RFC2766: Network Address Translation - Protocol Translation (NAT-PT).

Applications

Scenario 1

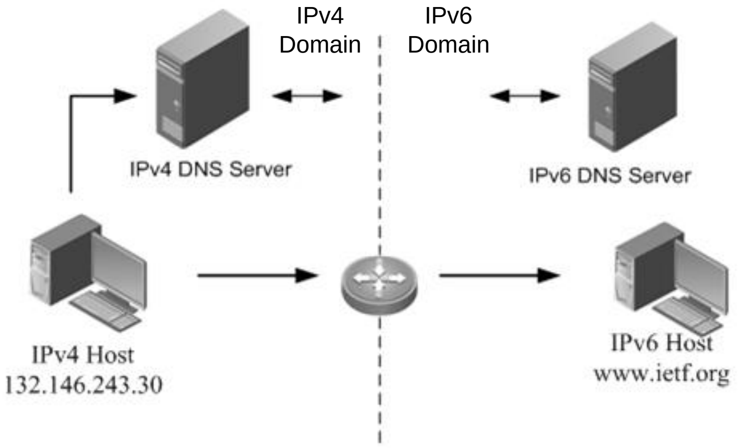
Figure 0–1 IP Address-based Access



In this scenario, NAT-PT aims at interworking between the IPv6 host and the IPv4 host to implement transparent transmission between IPv6 and IPv4 networks at a low cost without changing the topology or incurring extra expenses during packet transmission.

Scenario 2

Domain Name-based Access



In this scenario, as the IPv4 DNS packets and IPv6 DNS packets have different formats, the IPV6 DNS server cannot identify DNS requests from the IPv4 host and thereby cannot perform DNS resolution. NAT-PT is used to enable domain name-based access to the destination host, so that the IPv6 DNS server can respond to DNS requests from the IPv4 host and that domain name-based transparent transmission can be implemented between the IPv4 host and the IPv6 host.

Configuring NAT-PT

Defaults

Feature	Default Settings
NAT-PT	Disabled.
Maximum NAT-PT entry	100K

Feature	Default Settings
NAT-PT timeout	300 seconds
dns-timeout	300 seconds
finrst-timeout	60 seconds
icmp-timeout	90 seconds
syn-timeout	60 seconds
tcp-timeout	24 hours
udp-timeout	300 seconds

Configuring Static Source Address-based NAT-PT Mapping

Command	Description
Ruijie>**enable**	Enters privileged EXEC mode.
Ruijie#**configure terminal**	Enters global configuration mode.
Ruijie(config)#**ipv6 nat prefix***ipv6-prefix/prefix-length*	Assigns an IPv6 prefix as the global NAT-PT prefix.
Ruijie(config)#**interface** *interface-name interface-number*	Specifies an IPv6 interface and enters interface configuration mode.
Ruijie(config-if)#**ipv6 address** *ipv6-address/prefix-length*	Configures the IPv6 address of the interface.
Ruijie(config-if)#**ipv6 nat**	Enables NAT-PT for the interface.
Ruijie(config-if)#**exit**	Returns to global configuration mode.
Ruijie(config)#**interface** *interface-name interface-number*	Specifies an IPv4 interface and enters interface configuration mode.
Ruijie(config-if)#**ip address** *ip-address mask*	Configures the IPv4 address of the interface.
Ruijie(config-if)#**ipv6 nat**	Enables NAT-PT for the interface.
Ruijie(config-if)#**exit**	Returns to global configuration mode.
Ruijie(config)#**ipv6nat v6v4 source** *ipv6-address ipv4-address*	Configures the static IPv6-IPv4 address mapping.
Ruijie(config)#**ipv6 nat v4v6 source** *ipv4-address ipv6-address*	Configures the static IPv4-IPv6 address mapping.

Example: Configuring static source address-based NAT-PT mappings

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface fastethernet 0/1
Ruijie(config-if)#ipv6 nat
RouterB(config-if)#ipv6 address 2001::1/64
RouterB(config-if)#exit
RouterB(config)#ipv6 nat v4v6 source 8.0.0.2 2001:DA8:1::5
RouterB(config)#ipv6 nat v6v4 source 2001::18.0.0.5
```

Configuring Dynamic Source Address-based NAT-PT Mappings

Command	Description
Ruijie>**enable**	Enters privileged EXEC mode.
Ruijie#**configure terminal**	Enters global configuration mode.
Ruijie(config)#**ipv6 nat prefix***ipv6-prefix/prefix-length*	Assigns an IPv6 prefix as the global NAT-PT prefix.
Ruijie(config)#**interface** *interface-name interface-number*	Specifies an IPv6 interface and enters interface configuration mode.
Ruijie(config-if)#**ipv6 address** *ipv6-address/prefix-length*	Configures the IPv6 address of the interface.
Ruijie(config-if)#**ipv6 nat**	Enables NAT-PT for the interface.
Ruijie(config-if)#**exit**	Returns to global configuration mode.
Ruijie(config)#**interface** *interface-name interface-number*	Specifies an IPv4 interface and enters interface configuration mode.
Ruijie(config-if)#**ip address** *ip-address mask*	Configures the IPv4 address of the interface.
Ruijie(config-if)#**ipv6 nat**	Enables NAT-PT for the interface.
Ruijie(config-if)#**exit**	Returns to global configuration mode.
Ruijie(config)#**ipv6 nat v6v4 source list***access-list-name***pool***v4pool-name* or Ruijie(config)#**ipv6 nat v4v6 source list** *access-list-name***pool***v6pool-name*	Enables the dynamic IPv6-IPv4 or IPv4-IPv6 address mapping. Takes an address from *v4pool-name* (name of the IPv6 address pool) for translation to match the IPv6 Access Control List (ACL) entry **access-list-name**; or takes an address from *v6pool-name* (name of the IPv4 address pool) for translation to match the IPv4 ACL entry **access-list-name**.
Ruijie(config)#**ipv6 nat v6v4 pool** *v4pool-name start-ipv4 end-ipv4***prefix-length** *prefix-length* or Ruijie(config)#**ipv6 nat v4v6 pool***v6pool-namestart-ipv6 end-ipv6***prefix-length** *prefix-length*	Configures the IPv4 address pool with a specified prefix length or configures the IPv6 address pool with a specified prefix length.
Ruijie(config)#**ipv6 access-list** *access-list-name* or Ruijie(config)#**ip access-list**{ **standard** | **extended** } { *id* | *access-list-name* }	Configures IPv6 or IPv4 ACL Permit entries.

Example: Configuring dynamic source address-based NAT-PT mappings

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface fastethernet 0/1
Ruijie(config-if)#ipv6 nat
RouterB(config-if)#exit
RouterB(config)#ipv6 nat v6v4 source list v6_acl pool v4pool
RouterB(config)#ipv6 nat v6v4 pool v4pool 20.0.0.1 20.0.0.30 prefix-length 24
RouterB(config)#ipv6 nat v4v6 source 8.0.0.1 2001:DA8:1::5
RouterB(config)#ipv6 access-list v6_acl
RouterB(config-ipv6-acl)#permit ipv6 2001:DA8:2::/64 any
```

Monitoring

Command	Description
Ruijie#**clear ipv6 nat statistics**	Clears all NAT-PT statistics.
Ruijie#**clear ipv6 nat translations ***	Clears all records of NAT-PT.
Ruijie#**clear ipv6 nat translations icmp**	Clears all records of NAT-PT ICMP.
Ruijie#**clear ipv6 nat translations tcp**	Clears all records of NAT-PT Transmission Control Protocol (TCP).
Ruijie#**clear ipv6 nat translations udp**	Clears all records of NAT-PT User Datagram Protocol (UDP).
Ruijie#**debug ipv6 nat**	Displays NAT-PT debugging information.
Ruijie#**show ipv6 nat memory**	Displays NAT-PT memory information.
Ruijie#**show ipv6 nat pool**	Displays NAT-PT address pools.
Ruijie#**show ipv6 nat rule**	Displays translation rules.
Ruijie#**show ipv6 nat statistics**	Displays NAT-PT statistics.
Ruijie#**show ipv6 nat translations**	Displays records of NAT-PT.

Configuration Example

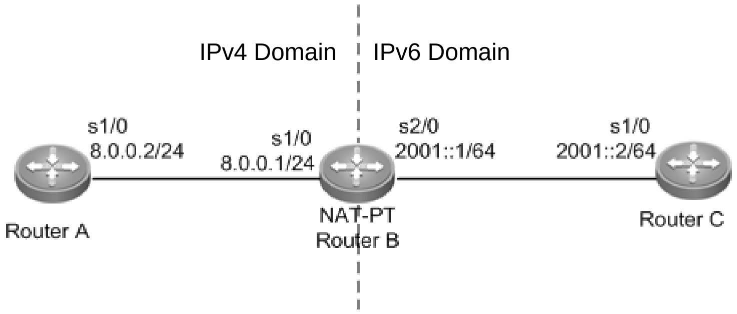
Static NAT-PT

Networking Requirements

Router C whose IPv6 address is 2001::2/64 wants to interwork with Router A whose IPv4 address is 8.0.0.2/24. For this purpose, you need to deploy Router B as an NAT-PT device between the IPv4 domain and the IPv6 domain and configure static IPv4 and IPv6 packet mappings on Router B to implement interworking between the IPv4 domain and the IPv6 domain.

Network Topology

Static NAT-PT Configuration



Configuration Tips

The following describes the Configuration Tips of configuration for static NAT-PT mappings:

- Configure an IPv4 address.
- Configure an IPv6 address.
- Configure the NAT-PT prefix and enable NAT-PT.
- Configure static IPv4 and IPv6 packet mappings.
- Configure the static route for IPv4 or IPv6.

Caution

When configuring the static source address-based mapping on Router C, you must avoid confliction between the mapped source IPv4 address and other addresses in the IPv4 domain to ensure a reachable route from Router A to the NAT-PT device (Router B).

Steps

- Configure the IP address of Router A in the IPv4 domain.

```
RouterA>enable
RouterA#configure terminal
RouterA(config)#interface s1/0
RouterA(config-if)#ip address 8.0.0.2 255.255.255.0
```

- Configure the IP address of Router C in the IPv6 domain.

```
RouterC>enable
RouterC#configure terminal
RouterC(config)#interface s1/0
RotuerC(config-if)#ipv6 enable
RouterC(config-if)#ipv6 address 2001::2/64
```

- Configure Router B.

```
RouterB>enable
RouterB#configure terminal
RouterB(config)#ipv6 nat prefix 2001:DA8:1::/96
RouterB(config)#interface s1/0
RouterB(config-if)#ip address 8.0.0.1 255.255.255.0
RouterB(config-if)#ipv6 nat
RouterB(config-if)#exit
RouterB(config)#interface s2/0
RouterB(config-if)#ipv6 enable
RouterB(config-if)#ipv6 nat
RouterB(config-if)#ipv6 address 2001::1/64
RouterB(config-if)#exit
RouterB(config)#ipv6 nat v4v6 source 8.0.0.2 2001:DA8:1::5
RouterB(config)#ipv6 nat v6v4 source 2001::2 8.0.0.5
```

- On Router C, configure a static route destined for the network segment matched to the NAT-PT prefix.

```
RouterC>enable
RouterC#configure terminal
RouterC(config)#ipv6 route 2001:DA8:1::/96 2001::1
```

Verification

```
Ruijie#show ipv6 nat translations

Prot   IPv4 source                    IPv6 source

       IPv4 destination               IPv6 destination

---    8.0.0.52001::2

       ---                            ---

---    ---                            ---

8.0.0.2                       2001:DA8:1::1

icmp   8.0.0.2,47             2001:DA8:1::5,47

8.0.0.5,47                    2001::2,47
```

Run the **ping 8.0.0.5** command on Router A to receive response packets.

```
Ruijie#ping 8.0.0.5

Sending 5, 100-byte ICMP Echoes to 8.0.0.5, timeout is 2 seconds:

< press Ctrl+C to break >

!!!!!

Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/10 ms
```

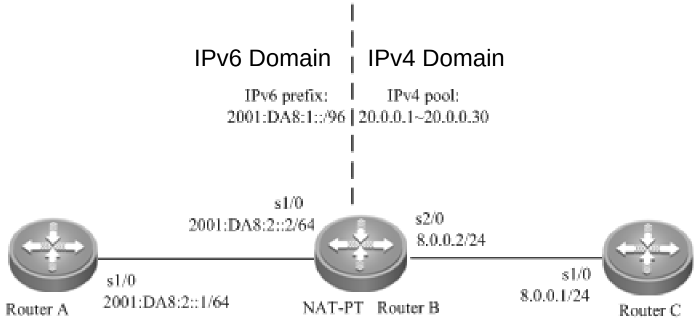
Dynamic NAT-PT

Networking Requirements

Router A whose IPv6 address is 2001:DA8:2::1 wants to access Router C whose IPv4 address is 8.0.0.1, but Router C is forbidden to access Router A. For this purpose, you need to deploy Router B between the IPv6 domain and the IPv4 domain for dynamic NAT-PT.

Network Topology

Dynamic NAT-PT configuration



Configuration Tips

The following describes the Configuration Tips of configuration for dynamic NAT-PT:

- Configure an IPv4 address.
- Configure an IPv6 address.
- Configure the NAT-PT prefix and enable NAT-PT.
- Configure dynamic address mapping in the IPv6 domain and static address mapping in the IPv4 domain.
- Configure the IPv4 address pool with a specified length.
- Configure IPv6 ACL Permit entries.

Steps

- Configure the IP address of Router C in the IPv4 domain.

```
RouterA>enable
RouterA#configure terminal
RouterA(config)#interface s1/0
RouterA(config-if)#ip address 8.0.0.1 255.255.255.0
```

- Configure Router B.

```
RouterB>enable
RouterB#configure terminal
RouterB(config)#ipv6 nat prefix 2001:DA8:1::/96
RouterB(config)#interface s1/0
RouterB(config-if)#ipv6 enable
RouterB(config-if)#ipv6 address 2001:DA8:2::2/64
RouterB(config-if)#ipv6 nat
RouterB(config-if)#exit
RouterB(config)#interface s2/0
RouterB(config-if)#ipv6 address 8.0.0.2 255.255.255.0
RouterB(config-if)#ipv6 nat
RouterB(config-if)#exit
RouterB(config)#ipv6 nat v6v4 source list v6_acl pool v4pool
RouterB(config)#ipv6 nat v6v4 pool v4pool 20.0.0.1 20.0.0.30 prefix-length 24
RouterB(config)#ipv6 nat v4v6 source 8.0.0.1 2001:DA8:1::5
RouterB(config)#ipv6 access-list v6_acl
RouterB(config-ipv6-acl)#permit ipv6 2001:DA8:2::/64 any
```

- Configure the IP address of Router A in the IPv6 domain.

```
RouterC>enable
RouterC#configer terminal
RouterC(config)#interface s1/0
RotuerC(config-if)#ipv6 enable
RouterC(config-if)#ipv6 address 2001:DA8:2::1/64
```

- On Router A, configure the static route destined for the network segment matched to the NAT-PT prefix.

```
RouterC>enable
RouterC#configure terminal
RouterC(config)#ipv6 route 2001:DA8:1::/96 2001:DA8:2::2
```

- On Router C, configure the static route destined for the network segment 20.0.0.0/24.

```
RouterC>enable
RouterC#configure terminal
RouterC(config)#ip route 20.0.0.0 255.255.255.08.0.0.2
```

Verification

```
Ruijie#show ipv6 nat translations
Prot  IPv4 source            IPv6 source
     IPv4 destination        IPv6 destination
---   8.0.0.12001:DA8:1::5
     ---                  ---
icmp  20.0.0.6,1024       2001:DA8:2::1,1024
8.0.0.1,10242001:DA8:1::5,1024
udp20.0.0.6,532001:DA8:2::1,53
8.0.0.1,13642001:DA8:1::5,1364
```

Run the **ping 2001:DA8:1::5** command on Router A to receive response packets from Router C.

```
Ruijie#ping 2001:DA8:1::5
Sending 5, 100-byte ICMP Echoes to 2001:DA8:1::5, timeout is 2 seconds:
< press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/10 ms
```

Configuring Stateful NAT64

Understanding Stateful NAT64

Overview

With the fast development of the Internet, IPv4 can no longer meet Internet requirements. Under this circumstance, IPv6 is about to be deployed. To support an IPv6 network, you must make full use of existing network resources to construct a next-generation Internet, thereby implementing smooth transition and avoiding excessive investment. The current Internet is based on IPv4 and cannot be transformed to the IPv6 network in a short time. Therefore, the IPv4 and IPv6 networks will coexist in a rather long time.

The coexistence, however, causes the following problems: how to keep current network services and functions at minimum cost; and how to implement transparent transmission between the IPv6 network and the IPv4 network. Network Address Translation 64 (NAT64, also called the IPv6-to-IPv4 address mapping), includes Stateful NAT64 and Stateless NAT64. Stateful NAT64 is mainly used when IPv6 network users initiate access requests to hosts/servers on the IPv4 network.

Basic Concepts

Stateful NAT64: Stateful IPv6-to-IPv4 network address translation protocol

Port Address Translation (PAT)

Network-Specific Prefix (NSP): Mainly used to check IPv6 destination addresses and IPv6 network addresses mapping to IPv4 host addresses.

Well-Known Prefix (WKP): Network prefix used by Stateful NAT64. It is used by default with the value of 64:ff9b::/96.

Working Principle

Stateful NAT64 provides a translation mechanism between IPv6 packets and IPv4 packets. This mechanism uses a Stateful NAT6 IPv6 prefix to implement translation from IPv4 host addresses to IPv6 addresses and takes NAT to implement translation from IPv6 host addresses to IPv4 addresses. Moreover, Statefull NAT64 performs protocol translation. NAT64 implements intercommunication between the pure IPv6 network and the IPv4 network.

Protocol Specification

RFC6052: IPv6 Addressing of IPv4/IPv6 Translators

RFC6144: Framework for IPv4/IPv6 Translation

RFC6145: IP/ICMP Translation Algorithm

RFC6146: Stateful NAT64: Network Address and Protocol Translation from IPv6 Clients to IPv4 Servers

Typical Application

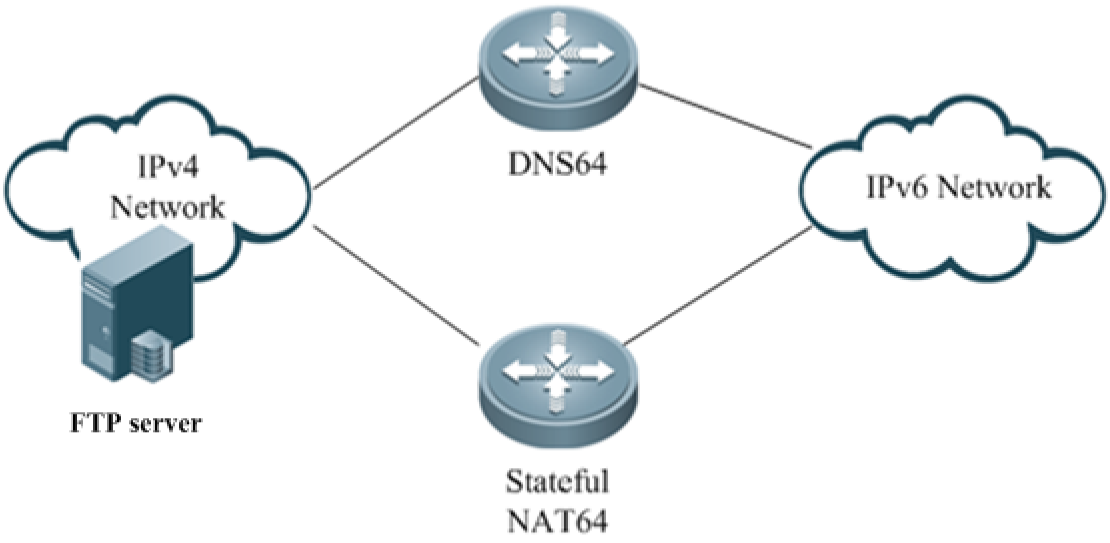


Figure 1-1 IPv6 Network Initiating a Session to IPv4 Network

Configuring Stateful NAT64

Default Configuration

Feature	Default setting
Stateful NAT64	Disabled
Default WKP	64:ff9b::/96

Configuring Static NAT64

Command	Function
Ruijie>**enable**	Enters privileged EXEC mode.
Ruijie#**configure terminal**	Enters global configuration mode.
Ruijie(config)#**ipv6 unicast-routing**	(Optional) Enables unicast routing, which is enabled by default.
Ruijie(config)#**interface** *interface-name interface-number*	Specifies an IPv6 network interface and enters interface configuration mode.
Ruijie(config-if)#**ipv6 enable**	Enables IPv6.
Ruijie(config-if)# **ipv6 address** *ipv6-address/prefix-length*	Configures the IPv6 address of the interface.
Ruijie(config-if)#**nat64 enable**	Enables NAT64 on the interface.
Ruijie(config-if)#**exit**	Exits interface configuration mode and returns to global configuration mode.
Ruijie(config)#**interface** *interface-name interface-number*	Specifies an IPv4 network interface and enters interface configuration mode.
Ruijie(config-if)#**ip address** *ip-address mask*	Configures the IPv4 address of the interface.
Ruijie(config-if)#**nat64 enable**	Enables NAT64 on the interface.

Ruijie(config-if)#**exit**	Exits interface configuration mode and returns to global configuration mode.
Ruijie(config)#**nat64 prefix stateful** *ipv6-address/prefix-length*	Allocates an IPv6 prefix as a global Stateful NAT64 prefix.
Ruijie(config)#**nat64 v6v4 static** *ipv6-address ipv4-address*	Configures NAT64 to map an IPv6 address to an IPv4 address in static mode.
Ruijie(config)#**end**	Exits global configuration mode and retunes to privileged mod.

The following example configures static Stateful NAT64.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface gigabitethernet 0/0/0
Ruijie(config-if)#ipv6 enable
Ruijie(config-if)#ipv6 address 2001:db8:1::1/96
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#interface gigabitethernet 1/2/0
Ruijie(config-if)#ip address 209.165.201.1 255.255.255.0
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#nat64 prefix stateful 2001:db8:0:1::/96
Ruijie(config)#nat64 v6v4 static 2001:db8:1::fffe 209.165.201.2
Ruijie(config)#end
```

Configuring Dynamic NAT64

Command	Function
Ruijie>**enable**	Enters privileged EXEC mode.
Ruijie**#configure terminal**	Enters global configuration mode.
Ruijie(config)#**ipv6 unicast-routing**	Enables unicast routing, which is enabled by default.
Ruijie(config)#**interface** *interface-name interface-number*	Specifies an IPv6 network interface and enters interface configuration mode.
Ruijie(config-if)#**ipv6 enable**	Enables IPv6.
Ruijie(config-if)# **ipv6 address** *ipv6-address/prefix-length*	Configures the IPv6 address of the interface.
Ruijie(config-if)#**nat64 enable**	Enables NAT64 on the interface.
Ruijie(config-if)#**exit**	Exits interface configuration mode and returns to global configuration mode.
Ruijie(config)#**interface** *interface-name interface-number*	Specifies an IPv4 network interface and enters interface configuration mode.
Ruijie(config-if)#**ip address** *ip-address mask*	Configures the IPv4 address of the interface.
Ruijie(config-if)#**nat64 enable**	Enables NAT64 on the interface.
Ruijie(config-if)#**exit**	Exits interface configuration mode and returns to global configuration mode.

Ruijie(config)#**ipv6 access-list** *access-list-name*	Configures an IPv6 ACL permit entry and enters IPv6 ACL mode.
Ruijie(config-ipv6-acl)#**permit ipv6** *ipv6-address* **any**	Filters IPv6 addresses based on ACL.
Ruijie(config-ipv6-acl)#**exit**	Exits interface configuration mode and returns to global configuration mode.
Ruijie(config)#**nat64 prefix stateful** *ipv6-address/prefix-length*	Allocates an IPv6 prefix as a global Stateful NAT64 prefix.
Ruijie(config)#**nat64 v4 pool** *pool-name start-ip-address end-ip-address*	Configures a NAT64 IPv4 address pool.
Ruijie(config)#**nat64 v6v4 list** *access-list-name* **pool** *pool-name*	Enables dynamic **NAT64.** *access-list-name* specifies an IPv6 ACL. The IPv6 addresses match the ACL are mapped to the addresses in *pool-name* address pool. *pool-name* specifies the name of an IPv4 address pool.
Ruijie(config)#**end**	Exits global configuration mode and returns to privileged EXEC mode.

The following example configures dynamic Stateful NAT64.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface gigabitethernet 0/0/0
Ruijie(config-if)#ipv6 enable
Ruijie(config-if)#ipv6 address 2001:db8:1::1/96
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#interface gigabitethernet 0/0/1
Ruijie(config-if)#ip address 209.165.201.24 255.255.255.0
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#ipv6 access-list nat64-acl
Ruijie(config-ipv6-acl)#permit ipv6 2001:db8:2::/96 any
Ruijie(config-ipv6-acl)#exit
Ruijie(config)#nat64 prefix stateful 2001:db8:1::/96
Ruijie(config)#nat64 v4 pool v4pool 209.165.201.1 209.165.201.254
Ruijie(config)#nat64 v6v4 list nat64-acl pool v4pool
Ruijie(config)#end
```

Configuring Dynamic PAT-Based NAT64

Command	Function
Ruijie>**enable**	Enters privileged EXEC mode.
Ruijie#**configure terminal**	Enters global configuration mode.
Ruijie(config)#**ipv6 unicast-routing**	(Optional) Enables unicast routing, which is enabled by default.

Ruijie(config)#**interface** *interface-name interface-number*	Specifies an IPv6 network interface and enters interface configuration mode.
Ruijie(config-if)#**ipv6 enable**	Enables IPv6.
Ruijie(config-if)# **ipv6 address** *ipv6-address/prefix-length*	Configures the IPv6 address of the interface.
Ruijie(config-if)#**nat64 enable**	Enables NAT64 on the interface.
Ruijie(config-if)#**exit**	Exits interface configuration mode and returns to global configuration mode.
Ruijie(config)#**interface** *interface-name interface-number*	Specifies an IPv4 network interface and enters interface configuration mode.
Ruijie(config-if)#**ip address** *ip-address mask*	Configures the IPv4 address of the interface.
Ruijie(config-if)#**nat64 enable**	Enables NAT64 on the interface.
Ruijie(config-if)#**exit**	Exits interface configuration mode and returns to global configuration mode.
Ruijie(config)#**ipv6 access-list** *access-list-name*	Configures an IPv6 ACL permit entry and enters IPv6 ACL mode.
Ruijie(config-ipv6-acl)#**permit ipv6** *ipv6-address* **any**	Filters IPv6 addresses based on ACL.
Ruijie(config-ipv6-acl)#**exit**	Exits interface configuration mode and returns to global configuration mode.
Ruijie(config)#**nat64 prefix stateful** *ipv6-address/prefix-length*	Allocates an IPv6 prefix as a global Stateful NAT64 prefix.
Ruijie(config)#**nat64 v4 pool** *pool-name start-ip-address end-ip-address*	Configures a NAT64 IPv4 address pool.
Ruijie(config)#**nat64 v6v4 list** *access-list-name* **pool** *pool-name* **overload**	Enables dynamic NAT64. *access-list-name* specifies an IPv6 ACL. The IPv6 addresses match the ACL are mapped to the addresses in *pool-name* address pool. *pool-name* specifies the name of an IPv4 address pool.
Ruijie(config)#**end**	Exits global configuration mode and returns to privileged EXEC mode.

The following example configures dynamic Stateful NAT64.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface gigabitethernet 0/0/0
Ruijie(config-if)#ipv6 enable
Ruijie(config-if)#ipv6 address 2001:db8:1::1/96
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#interface gigabitethernet 0/0/1
Ruijie(config-if)#ip address 209.165.201.24 255.255.255.0
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#ipv6 access-list nat64-acl
Ruijie(config-ipv6-acl)#permit ipv6 2001:db8:2::/96 any
Ruijie(config-ipv6-acl)#exit
Ruijie(config)#nat64 prefix stateful 2001:db8:0:1::/96
Ruijie(config)#nat64 v4 pool v4pool 209.165.201.1 209.165.201.254
Ruijie(config)#nat64 v6v4 list nat64-acl pool v4pool overload
Ruijie(config)#end
```

Configuring VRF-Based Stateful NAT64

Command	Function
Ruijie>**enable**	Enters privileged EXEC mode.
Ruijie**#configure terminal**	Enters global configuration mode.
Ruijie(config)#**ipv6 unicast-routing**	(Optional) Enables unicast routing, which is enabled by default.
Ruijie(config)#**vrf definition** *vrf-name*	Creates a multi-protocol VRF.
Ruijie(config-vrf)#**address-family ipv4**	Enables an IPv4 address family.
Ruijie(config-vrf-af)#**exit-address-family**	Exits a VRF address family.
Ruijie(config-vrf)#**address-family ipv6**	Enables an IPv6 address family.
Ruijie(config-vrf-af)#**exit-address-family**	Exits the VRF address family.
Ruijie(config-vrf)#**interface** *interface-name interface-number*	Specifies an IPv6 network interface and enters interface configuration mode.
Ruijie(config-if)#**vrf forwarding** *vrf-name*	Binds the multi-protocol VRF on the interface.
Ruijie(config-if)#**ipv6 enable**	Enables IPv6.
Ruijie(config-if)# **ipv6 address** *ipv6-address/prefix-length*	Configures the IPv6 address of the interface.
Ruijie(config-if)#**nat64 enable**	Enables NAT64 on the interface.
Ruijie(config-if)#**exit**	Exits interface configuration mode and returns to global configuration mode.
Ruijie(config)#**interface** *interface-name interface-number*	Specifies an IPv4 network interface and enters interface configuration mode.
Ruijie(config)#**vrf forwarding** *vrf-name*	Binds the multi-protocol VRF on the interface. The IPv4 and IPv6 protocol families of the multi-protocol VRF need to be enabled.
Ruijie(config-if)#**ip address** *ip-address mask*	Configures the IPv4 address of the interface.
Ruijie(config-if)#**nat64 enable**	Enables NAT64 on the interface.
Ruijie(config-if)#**exit**	Exits interface configuration mode and returns to global configuration mode.
Ruijie(config)#**ipv6 access-list** *access-list-name*	Configures an IPv6 ACL permit entry and enters IPv6 ACL mode.
Ruijie(config-ipv6-acl)#**permit ipv6** *ipv6-address* **any**	Filters IPv6 addresses based on ACL.
Ruijie(config-ipv6-acl)#**exit**	Exits interface configuration mode and returns to global configuration mode.
Ruijie(config)#**nat64 prefix stateful** *ipv6-address/prefix-length* [**vrf** *vrf-name*]	Allocates an IPv6 prefix to *vrf-name* as a Stateful NAT64 prefix.
Ruijie(config)#**nat64 v4 pool** *pool-name start-ip-address end-ip-address* [**vrf** *vrf-name*]	Configures a NAT64 IPv4 address pool for *vrf-name*.

Ruijie(config)#**nat64 v6v4 list** *access-list-name* **pool** *pool-name* [**vrf** *vrf-name*]	Enables dynamic NAT64. *access-list-name* specifies an IPv6 ACL. The IPv6 addresses match the ACL are mapped to the addresses in *pool-name* address pool. *pool-name* specifies the name of an IPv4 address pool. *vrf-name* specifies the name of the VRF.
Ruijie(config)#**ipv6 route vrf** *vrf-name ipv6-prefix/prefix-length interface next-hop*	Adds an IPv6 route. *vrf-name* specifies the name of the VRF; *ipv6-prefix* specifies an IPv6 prefix; *prefix-length* specifies the length of the IPv6 prefix; *interface* specifies an outbound interface; *next-hop* specifies a next-hop address.
Ruijie(config)#**ip route vrf** *vrf-name network mask interface next-hop*	Adds an IPv4 route. *vrf-name* specifies the name of VRF; *network* specifies a destination network segment; *mask* specifies a mask; *interface* specifies an outbound interface; *next-hop* specifies a next-hop address.
Ruijie(config)#**end**	Exits global configuration mode and returns to privileged EXEC mode.

The following example configures VRF-based dynamic Stateful NAT64.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#vrf definition vrf-name1
Ruijie(config-vrf)#address-family ipv4
Ruijie(config-vrf-af)#exit-address-family
Ruijie(config-vrf)#address-family ipv6
Ruijie(config-vrf-af)#exit-address-family
Ruijie(config-vrf)#interface gigabitethernet 0/0/0
Ruijie(config-if)#vrf forwarding vrf-name1
Ruijie(config-if)#ipv6 enable
Ruijie(config-if)#ipv6 address 2001:db8:1::1/96
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#interface gigabitethernet 0/0/1
Ruijie(config-if)#vrf forwarding vrf-name1
Ruijie(config-if)#ip address 209.165.201.24 255.255.255.0
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#ipv6 access-list nat64-acl
Ruijie(config-ipv6-acl)#permit ipv6 2001:db8:2::/96 any
Ruijie(config-ipv6-acl)#exit
Ruijie(config)#nat64 prefix stateful 2001:db8:0:1::/96 vrf vrf-name1
Ruijie(config)#nat64 v4 pool v4pool 209.165.201.1 209.165.201.254 vrf vrf-name1
Ruijie(config)#nat64 v6v4 list nat64-acl pool v4pool vrf vrf-name1
Ruijie(config)#ip route vrf vrf-name1 209.165.201.0 255.255.255.0 gigabitethernet 0/0/1
Ruijie(config)#ipv6 route vrf vrf-name1 2001:db8:0:1::D1A5:C918/120 gigabitethernet 0/0/0
Ruijie(config)#end
```

Monitoring and Maintaining Stateful NAT64

Command	Function
clear nat64 stateful statistics	Clears statistics about Stateful NAT64.
debug nat64 stateful {alg | control | event | memory | packet | pool | rule | translations}	Enables NAT64 debugging. Use the **no** form of this command to disable NAT64 debugging.
show nat64 stateful debug-buf	Displays the debugging buffer.
show nat64 mappings dynamic	Displays NAT64 dynamic mapping information.
show nat64 mappings static	Displays NAT64 static mapping information.
show nat64 prefix stateful [interfaces]	Displays all configured IPv6 prefixes of Stateful NAT64.
show nat64 services	Displays related NAT64 application layer gateway (ALG) information.
show nat64 stateful statistics	Displays statistics about Stateful NAT64.
show nat64 translations	Displays translation records of NAT64.

Configuration Examples

Static NAT64 Configuration Example

Networking Requirements

Host B on the IPv6 network can initiate a session to Host A on the IPv4 network and record the session entry. To meet the requirements, deploy a NAT64 device between the IPv6 network and the IPv4 network.

Networking Topology

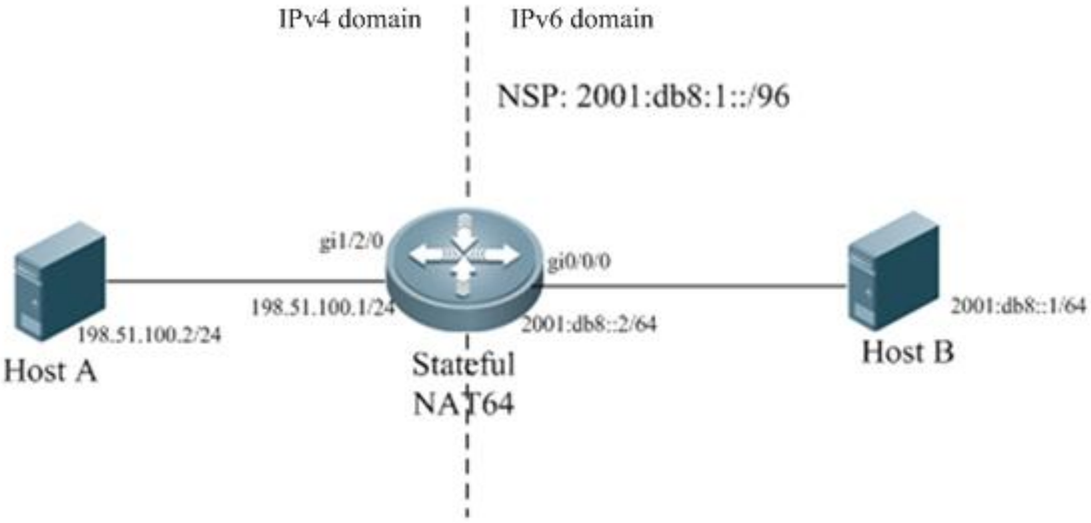

Figure 1-2 Topology of Static Stateful NAT64

Configuration Tips

- Configure the IPv6 address of an IPv6 network interface and enable NAT64 on the interface.
- Configure the IPv4 address of an IPv4 network interface and enable NAT64 on the interface.
- Configure a global NAT64 prefix.
- Configures static IPv6-to-IPv4 address translation.

Configuration Steps

1) Perform the following configurations on the Stateful NAT64 device.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface gigabitethernet 0/0/0
Ruijie(config-if)#ipv6 enable
Ruijie(config-if)#ipv6 address 2001:db8::2/64
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#interface gigabitethernet 1/2/0
Ruijie(config-if)#ip address 198.51.100.2 255.255.255.0
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#nat64 prefix stateful 2001:db8:1::/96
Ruijie(config)#nat64 v6v4 static 2001:db8::1 198.51.100.4
Ruijie(config)#end
```

2) On Host B

Configure the IPv6 address 2001:db8::1/64 on Host B and configure a static route to the prefix 2001:db8:0:1::/96.

3) On Host A

Configure the IP address 198.51.100.2/24 on Host A.

Verification

Run the **ping 2001:db8:1::c633:6401** command on Host B.

```
Ping statistics for 2001:db8:1::c633:6401:
   Packets: Sent = 3, Received = 3, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
Minimum = 0ms, Maximum = 0ms, Average = 0ms
Ruijie#show nat64 translations
Prot  IPv4 source           IPv6 source
     IPv4 destination        IPv6 destination
icmp  198.51.100.4,47       2001:db8::1 ,47
     198.51.100.1 ,47       2001:db8:1::c633:6401,47
```

Dynamic NAT64 Configuration Example

Networking Requirements

Host B, Host C or another host on the IPv6 network can initiate a session to Host A on the IPv4 network and record the session entry. To meet the requirements, deploy a NAT64 device between the IPv6 network and the IPv4 network. Dynamic NAT64 takes effect as long as the number of IPv6-domain hosts that initiate a session to Host A does not exceed the number of IPv4 addresses in the address pool.

Networking Topology

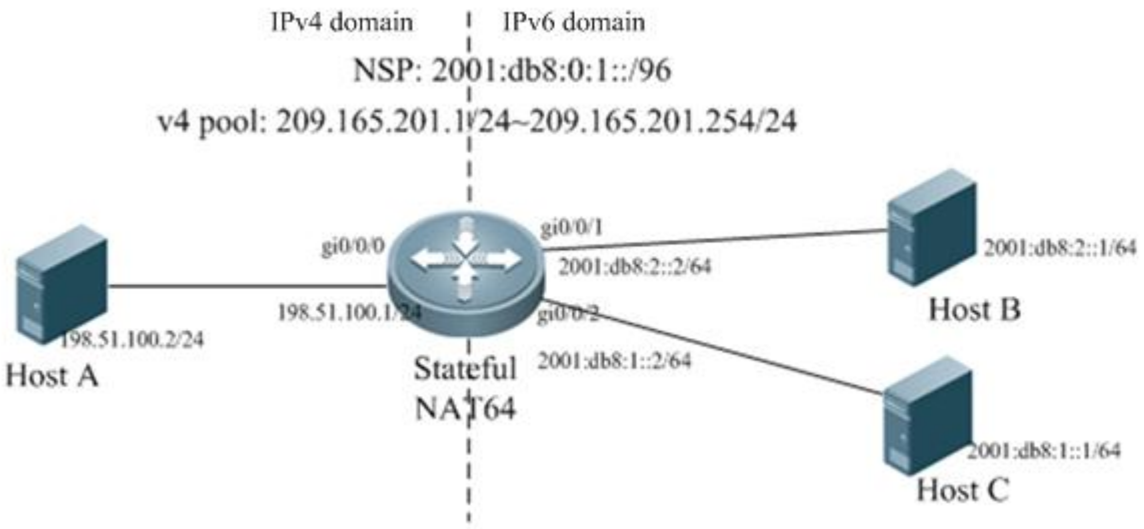

Figure 1-3 Topology of Dynamic Stateful NAT64

Configuration Tips

- Configure the IPv6 address of an IPv6 network interface and enable NAT64 on the interface.
- Configure the IPv4 address of an IPv4 network interface and enable NAT64 on the interface.
- Configure an ACL entry.
- Configure a global NAT64 prefix.
- Configures an IPv4 address pool.
- Configure a dynamic IPv6-to-IPv4 address translation list.

Configuration Steps

1) Perform the following configurations on the Stateful NAT64 device.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface gigabitethernet 0/0/1
Ruijie(config-if)#ipv6 enable
Ruijie(config-if)#ipv6 address 2001:db8:2::2/64
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#interface gigabitethernet 0/0/2
Ruijie(config-if)#ipv6 enable
Ruijie(config-if)#ipv6 address 2001db8:1::2/64
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#interface gigabitethernet 0/0/0
Ruijie(config-if)#ip address 198.51.100.1 255.255.255.0
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#ipv6 access-list v6_list1
Ruijie(config-ipv6-acl)#permit ipv6 any any
Ruijie(config-ipv6-acl)#exit
Ruijie(config)#nat64 prefix stateful 2001:db8:0:1::/96
Ruijie(config)#nat64 v4 pool v4_pool 209.165.201.1 209.165.201.254
Ruijie(config)#nat64 v6v4 list v6_list1 pool v4_pool
Ruijie(config)#end
```

2) On Host B

Configure the IPv6 address 2001:db8:2::1/64 on Host B and configure a static route to the prefix 2001:db8:0:1::/96.

3) On Host C

Configure the IPv6 address 2001:db8:1::1/64 on Host C and configure a static route to the prefix 2001:db8:0:1::/96.

4) On Host A

Configure the IP address 198.51.100.2/24 on Host A and configure a static route to the destination network segment 209.165.201.0/24.

Verification

Run the **ping 2001:db8:0:1::c633:6401** command on Host B.

```
Ping statistics for 2001:db8:0:1::c633:6401:
   Packets: Sent = 3, Received = 3, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
Minimum = 0ms, Maximum = 0ms, Average = 0ms
```

Run the **ping 2001:db8:0:1::c633:6401** command on Host C.

```
Ping statistics for 2001:db8:0:1::c633:6401:
   Packets: Sent = 3, Received = 3, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
Minimum = 0ms, Maximum = 0ms, Average = 0ms
Ruijie#show nat64 translations
Prot  IPv4 source           IPv6 source
     IPv4 destination        IPv6 destination
---   ----                 -----
```

```
icmp  209.165.201.1,47        2001:db8:2::1,47
     198.51.100.1 ,47       2001:db8:0:1::c633:6401,47
icmp  209.165.201.2,47        2001:db8:1::1,47
      198.51.100.1,47       2001:db8:0:1::c633:6401,47
```

Configuration Example of Dynamic PAT-Based NAT64

Networking Requirements

When the number of IPv6-domain hosts that initiate a session to Host A does not exceed the number of IPv4 addresses in the address pool, Host B or Host C on the IPv6 network can initiate a session to Host A on the IPv4 network and record the session entry. Otherwise, deploy a dynamic PAT-based NAT64 device between the IPv6 network and the IPv4 network, so that Host B or Host C can continue to access Host A.

Networking Topology

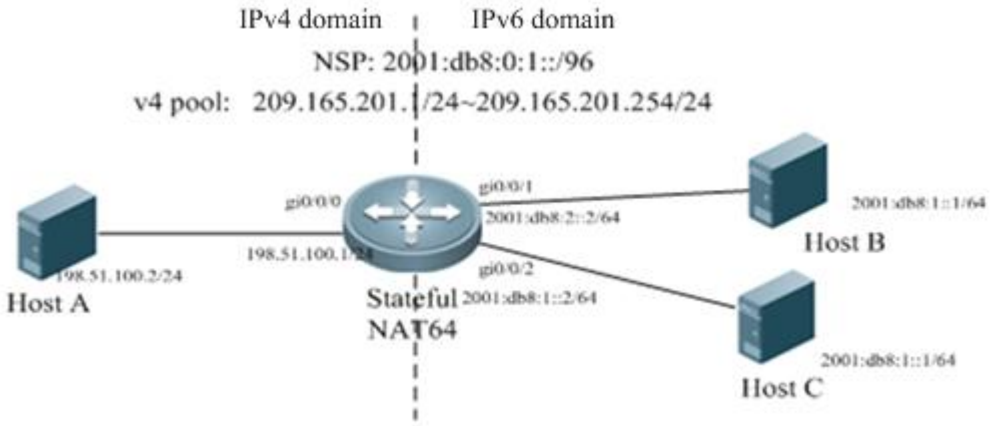

Figure 1-4 Topology of Dynamic PAT-Based NAT64

Configuration Tips

- Configure the IPv6 address of an IPv6 network interface and enable NAT64 on the interface.
- Configure the IPv4 address of an IPv4 network interface and enable NAT64 on the interface.
- Configure an ACL entry.
- Configure a global NAT64 prefix.
- Configures an IPv4 address pool.
- Configure a dynamic PAT-based IPv6-to-IPv4 address translation list.

Configuration Steps

1) Perform the following configurations on the Stateful NAT64 device.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface gigabitethernet 0/0/1
Ruijie(config-if)#ipv6 enable
Ruijie(config-if)#ipv6 address 2001:db8:2::2/64
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#interface gigabitethernet 0/0/2
Ruijie(config-if)#ipv6 enable
Ruijie(config-if)#ipv6 address 2001:db8:1::2/64
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#interface gigabitethernet 0/0/0
Ruijie(config-if)#ip address 198.51.100.1 255.255.255.0
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#ipv6 access-list v6_list1
Ruijie(config-ipv6-acl)#permit ipv6 any any
Ruijie(config-ipv6-acl)#exit
Ruijie(config)#nat64 prefix stateful 2001:db8:0:1::/96
Ruijie(config)#nat64 v4 pool v4_pool 209.165.201.1 209.165.201.254
Ruijie(config)#nat64 v6v4 list v6_list1 pool v4_pool overload
Ruijie(config)#end
```

2) On Host B

Configure the IPv6 address 2001:db8:2::1/64 on Host B and configure a static route to the prefix 2001:db8:0:1::/96.

3) On Host C

Configure the IPv6 address 2001:db8:1::1/64 on Host B and configure a static route to the prefix 2001:db8:0:1::/96.

4) On Host A

Configure the IPv address 198.51.100.2/24 on Host A and configure a static route to the destination network segment 209.165.201.0/24.

Verification

Run the **ping 2001:db8:0:1::c633:6401** command on Host B.

```
Ping statistics for 2001:db8:0:1::c633:6401:
    Packets: Sent = 3, Received = 3, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
Minimum = 0ms, Maximum = 0ms, Average = 0ms
```

Run the **ping 2001:db8:0:1::c633:6401** command on Host C.

```
Ping statistics for 2001:db8:0:1::c633:6401:
    Packets: Sent = 3, Received = 3, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
Minimum = 0ms, Maximum = 0ms, Average = 0ms
Ruijie#show nat64 translations
```

```
Prot  IPv4 source             IPv6 source
     IPv4 destination         IPv6 destination
---   ----                    -----
icmp  209.165.201.1,47         2001:db8:2::1 ,47
      198.51.100.1,47        2001:db8:0:1::c633:6401,47
icmp  209.165.201.1,1029        2001:db8:1::1, 1029
      198.51.100.1, 1029      2001:db8:0:1::c633:6401, 1029
```

Configuration Example of VRF-Based Stateful NAT64

Networking Requirements

Only hosts on the IPv6 network can initiate a session to Host A on the IPv4 network. Meanwhile, the router device can be divided into independently logical routers. To meet the requirements, deploy a VRF-based Stateful NAT64 device on the boundary between the IPv6 network and the IPv4 network, so that logical translation devices can communicate with each other.

Networking Topology

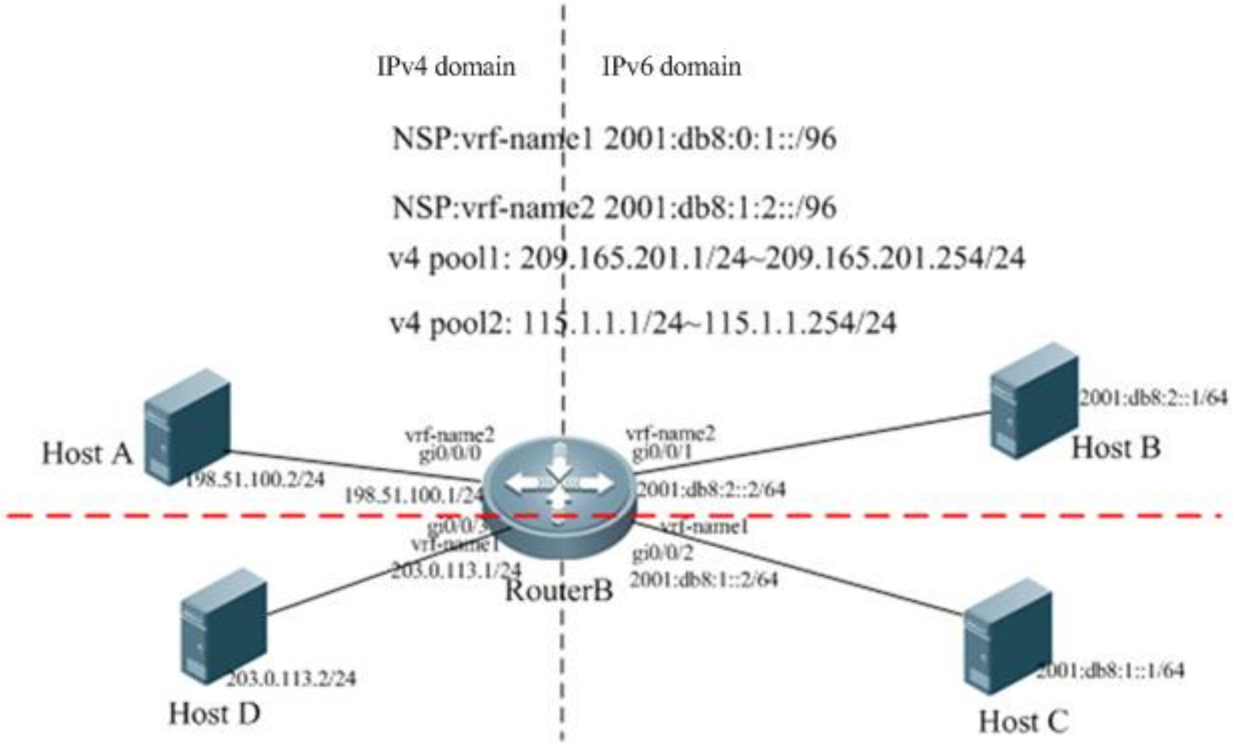

Figure 1-5 Topology of VRF-Based Stateful NAT64

Configuration Tips

- Create VRFs.
- Enable VRFs on interfaces.
- Configure the IPv6 address of an IPv6 network interface and enable NAT64 on the interface.

- Configure the IPv4 address of an IPv4 network interface and enable NAT64 on the interface.
- Configure a routing protocol.
- Configure an ACL.
- Configure global NAT64 prefixes for different VRFs.
- Configure IPv4 address pools for different VRFs.
- Configure dynamic IPv6-to-IPv4 translation access lists for different VRFs.

Configuration Steps

1) Perform the following configurations on Router B, which serves as the Stateful NAT64 device.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#vrf definition vrf-name1
Ruijie(config-vrf)#address-family ipv4
Ruijie(config-vrf-af)#exit-address-family
Ruijie(config-vrf)#address-family ipv6
Ruijie(config-vrf-af)#exit-address-family
Ruijie(config-vrf)#interface gigabitethernet 0/0/0
Ruijie(config-if)#vrf forwarding vrf-name1
Ruijie(config-if)#ip address 198.51.100.1 255.255.255.0
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#interface gigabitethernet 0/0/1
Ruijie(config-if)#vrf forwarding vrf-name1
Ruijie(config)#ipv6 enable
Ruijie(config-if)#ipv6 address 2001:db8:2::2/64
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#vrf definition vrf-name2
Ruijie(config-vrf)#address-family ipv4
Ruijie(config-vrf-af)#exit-address-family
Ruijie(config-vrf)#address-family ipv6
Ruijie(config-vrf-af)#exit-address-family
Ruijie(config-vrf)#interface gigabitethernet 0/0/3
Ruijie(config-if)#vrf forwarding vrf-name2
Ruijie(config-if)#ip address 203.0.113.2 255.255.255.0
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config-vrf)#interface gigabitethernet 0/0/2
Ruijie(config-if)#vrf forwarding vrf-name2
Ruijie(config-if)#ipv6 address 2001:db8:1::2/64
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#ipv6 access-list nat64-acl1
Ruijie(config-ipv6-acl)#permit ipv6 2001:db8:2::/64 any
Ruijie(config-ipv6-acl)#exit
Ruijie(config)#nat64 prefix stateful 2001:db8:0:1::/96 vrf vrf-name1
Ruijie(config)#nat64 v4 pool v4pool1 209.165.201.1 209.165.201.254
Ruijie(config)#nat64 v4 pool v4pool2 115.1.1.1 115.1.1.20
Ruijie(config)#nat64 v6v4 list nat64-acl1 pool v4pool1 vrf vrf-name1
Ruijie(config)#ipv6 access-list nat64-acl2
Ruijie(config-ipv6-acl)#permit ipv6 4001::/64 any
Ruijie(config-ipv6-acl)#exit
Ruijie(config)#nat64 prefix stateful 2001:db8:1:2::/96 vrf vrf-name2
Ruijie(config)#nat64 v6v4 list nat64-acl2 pool v4pool2 vrf vrf-name2
Ruijie(config)#ip route vrf vrf-name1 209.165.201.0 255.255.255.0 gi0/0/0
Ruijie(config)#ip route vrf vrf-name1 209.165.201.0 255.255.255.0 gi0/0/3
Ruijie(config)#ipv6 route vrf vrf-name1 2001:db8:0:1::/96 gi0/0/2
Ruijie(config)#ipv6 route vrf vrf-name1 2001:db8:0:1::/96 gi0/0/1
Ruijie(config)#ipv6 route vrf vrf-name2 2001:db8:1:2::/96 gi0/0/1
Ruijie(config)#ipv6 route vrf vrf-name2 2001:db8:1:2::/96 gi0/0/2
Ruijie(config)#ip route vrf vrf-name2 115.1.1.0 255.255.255.0 gi0/0/0
Ruijie(config)#ip route vrf vrf-name2 115.1.1.0 255.255.255.0 gi0/0/3
Ruijie(config)#end
```

2) On Host B

Configure the IPv6 address 2001:db8:2::1/64 on Host B and configure a static route to the prefix 2001:db8:0:1::/96.

3) On Host C

Configure the IPv6 address 2001:db8:1::1/64 on Host C and configure static routes to the prefixes 2001:db8:0:1::/96 and 2001:db8:1:2::/96.

4) On Host A

Configure the IP address 198.51.100.2/24 on Host A and configure a static route to the destination network segment 209.165.201.0/24.

5) On Host D

Configure the IPv6 address 203.0.113.2/24 on Host D and configure a static route to the destination network segment 209.165.201.0/24.

Verification

Run the **ping 2001:db8:0:1::c633:6401** command on Host B.

```
Ping statistics for 2001:db8:0:1::c633:6401:
   Packets: Sent = 3, Received = 3, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
Minimum = 0ms, Maximum = 0ms, Average = 0ms
```

Run the **ping 2001:db8:0:1::c633:6401** command on Host C.

```
Ping statistics for 2001:db8:0:1::c633:6401:
   Packets: Sent = 3, Received = 3, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
Minimum = 0ms, Maximum = 0ms, Average = 0ms
Ruijie#show nat64 translations
Prot  IPv4 source            IPv6 source
     IPv4 destination         IPv6 destination
---   ----                   -----
icmp  209.165.201.1,47        2001:db8:2::1 ,47
      198.51.100.1,47       2001:db8:0:1::c633:6401,47
icmp  209.165.201.2,1027      2001:db8:1::1 ,1027
     198.51.100.1 ,1027     2001:db8:0:1::c633:6401,1027
```

Configuration Example of ALG-Based Stateful NAT64

Networking Requirements

The various typical applications in address translation scenario on the pure IPv6 network or IPv4 network need not only address translation but also application-layer information transformation. For example, when IPv6 users on the IPv6 network initiate access requests to the IPv4 FTP server, the FTP ALG function needs to be added to the NAT64 device to meet application requirements. NAT64 can only translate addresses.

When some applications (such as DNS, VoIP, and multimedia applications) perform address family traversal, the corresponding protocols must ensure that the traversal function works well. NAT64 is only a transition technology and cannot meet all application requirements.

Networking Topology

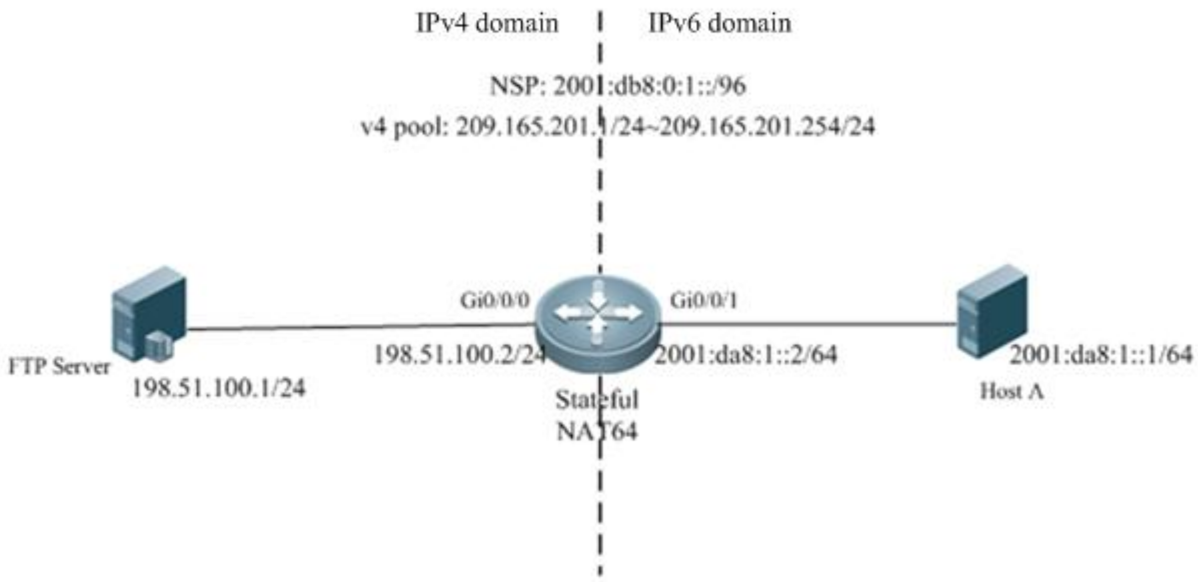

Figure 1-6 Topology of FTP ALG-Based Stateful NAT64

Configuration Tips

- Configure the IPv6 address of an IPv6 network interface and enable NAT64 on the interface.
- Configure the IPv4 address of an IPv4 network interface and enable NAT64 on the interface.
- Configure an ACL entry.
- Configure a global NAT64 prefix.
- Configures an IPv4 address pool.
- Configure a dynamic IPv6-to-IPv4 address translation list.
- Enable FTP ALG (enabled by default).

Configuration Steps

1) Perform the following configurations on the Stateful NAT64 device.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface gigabitethernet 0/0/1
Ruijie(config-if)#ipv6 enable
Ruijie(config-if)#ipv6 address 2001:da8:1::2/64
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#interface gigabitethernet 0/0/0
Ruijie(config-if)#ipv4 address 198.51.100.2 255.255.255.0
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#ipv6 access-list v6_list1
Ruijie(config-ipv6-acl)#permit ipv6 any any
Ruijie(config-ipv6-acl)#exit
Ruijie(config)#nat64 prefix stateful 2001:db8:0:1::/96
Ruijie(config)#nat64 v4 pool v4_pool 209.165.201.1 209.165.201.254
Ruijie(config)#nat64 v6v4 list v6_list1 pool v4_pool
Ruijie(config)#end
```

2) On Host A in the IPv6 domain

Configure the IP address 2001:da8:1::1/64 for Host A and configure a corresponding static route.

3) On the FTP server

Configure the IPv4 address as 198.51.100.1/24 and configure a static route to the destination network segment 209.165.201.0/24.

Verification

1) Run the **ping 2001:db8:0:1::c633:6401** command on Host A.

```
Ping statistics for 2001:db8:0:1::c633:6401:
   Packets: Sent = 3, Received = 3, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
```

```
Minimum = 0ms, Maximum = 0ms, Average = 0ms
```

2) Enter FTP mode.

Running the **put**, **get**, and **dir** commands can upload a file to the FTP server or download a file from it.

Configuring Stateless NAT64

Understanding Stateless NAT64

Overview

With the fast development of the Internet, IPv4 can no longer meet Internet requirements. Under this circumstance, IPv6 is about to be deployed. To support an IPv6 network, you must make full use of existing network resources to construct a next-generation Internet, thereby implementing smooth transition and avoiding excessive investment. The current Internet is based on IPv4 and cannot be transited to the IPv6 network in a short time. Therefore, the IPv4 and IPv6 networks will coexist in a rather long time.

The coexistence however, causes the following problems: how to keep current network services and functions at minimum cost; and how to implement transparent transmission between the IPv6 network and the IPv4 network. Network Address Translation 64 (NAT64, also called the IPv6-to-IPv4 network address translation protocol) includes Stateful NAT64 and Stateless NAT64. Stateless NAT64 is mainly used when IPv4 network users initiate access requests to hosts on the IPv6 network.

Basic Concepts

Stateless Network Address Translation 64 (Stateless NAT64): Stateless IPv6-to-IPv4 network address translation protocol. Stateless NAT64 provides a translation mechanism, which implements translation between IPv4 addresses and IPv6 addresses. The translation involves parsing the entire IPv6 header, obtaining related information and translating it into an IPv4 header or a completely converse translation process. Stateless NAT64 can translate the IP addresses of only some types of ICMPv4 and ICMPv6 packets due to the protocol features, such as translation between ICMPv4 request/response packets and ICMPv6 request/response packets and translation between unreachable ICMPv4 packets and unreachable ICMPv6 packets. Address translation for each packet relies on interface configurations. Stateless NAT64 does not maintain data flow statuses.

IPv4-translatable IPv6 address: IPv6 address after Stateless NAT64 that is allocated to an IPv6 host

☑ Stateless NAT64 can be used only when there are IPv4-translatable IPv6 addresses.

☑ Stateless NAT64 does not support multicast.

☑ Stateless NAT64 cannot be used by the application without a corresponding ALG.

☑ Stateless NAT64 cannot translate an IPv4 option, an IPv6 routing header in an IPv6 extension header, a hop-by-hop extension header, or a destination option header.

Working Principle

Stateless NAT64 works on the boundary device between the IPv6 network and the IPv4 network. The Stateless NAT64 module translates IP headers between the two networks and performs semantic translation for packets according to different protocols so as to implement transparent transmission between the two networks.

Protocol Specification

RFC6052: IPv6 Addressing of IPv4/IPv6 Translators

RFC6144: Framework for IPv4/IPv6 Translation

RFC6145: IP/ICMP Translation Algorithm

Typical Application

Application Scenario 1

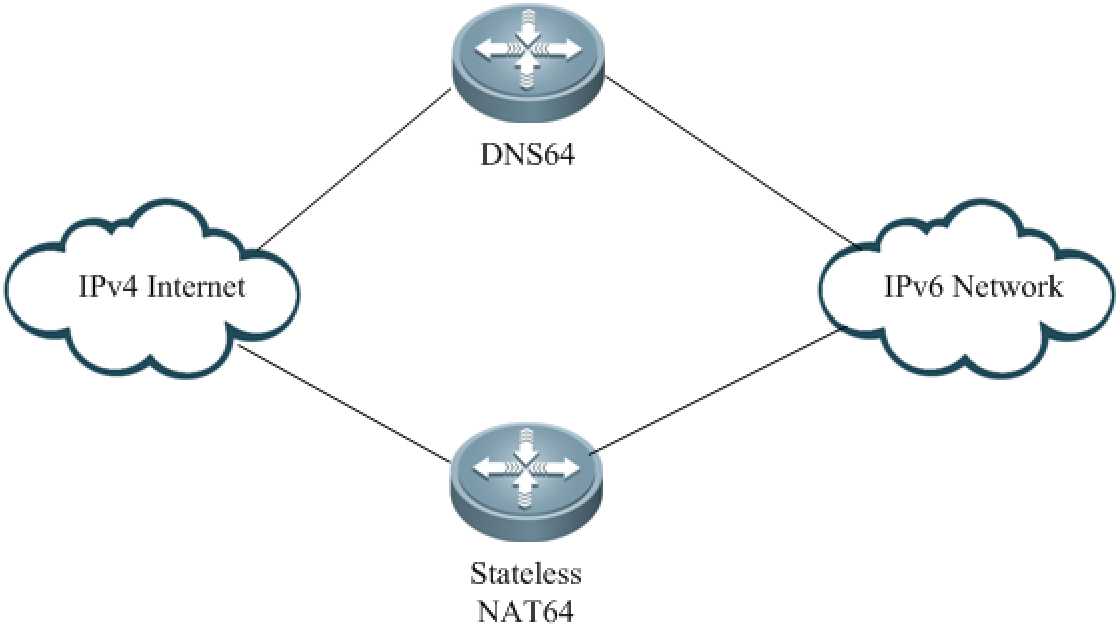

Figure 2-1 Interaction Between the IPv4 Internet and the IPv6 Network

This application scenario supports IPv4 network users to access IPv6 network resources.

Users of the IPv4 Internet can access IPv6 network resources in a specific scope.

This scenario has the following functions:

3) A new IPv6 content provider can provide resources for users both on the IPv6 network and the IPv4 Internet.

4) An IPv4 content provider that is transited to the pure IPv6 network can still provide resources for original IPv4 users and keep the connections with them.

This scenario has the following access modes:

- IP-based access
- Domain name-based access

Application Scenario 2

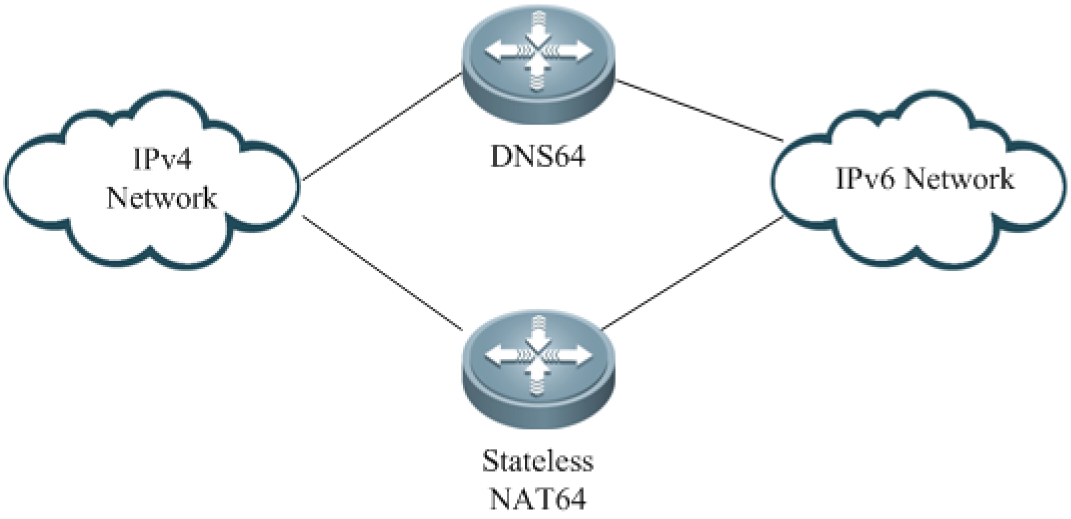

Figure 2-2 Interaction Between the IPv4 Network and the IPv6 Network

This application scenario mainly allows IPv4 network users to initiate access requests.

This scenario supports interaction between the IPv4 network and the IPv6 network, and mainly allows IPv4 network users to initiate access requests. The internal address can be a public address or a private address. The host addresses on the IPv6 network must be IPv4-translatable IPv6 addresses.

Configuring Stateless NAT64

Configuring Stateless NAT64

Command	Function
Ruijie>**enable**	Enters privileged EXEC mode.
Ruijie#**configure terminal**	Enters global configuration mode.
Ruijie(config)#**ipv6 unicast-routing**	(Optional) Enables unicast routing, which is enabled by default.
Ruijie(config)#**interface** *interface-name interface-number*	Specifies an IPv6 network interface and enters interface configuration mode.
Ruijie(config-if)#**ipv6 enable**	Enables IPv6.
Ruijie(config-if)# **ipv6 address** *ipv6-address/prefix-length*	Configures the IPv6 address of the interface.
Ruijie(config-if)#**nat64 enable**	Enables NAT64 on the interface.
Ruijie(config-if)#**exit**	Exits interface configuration mode and returns to global configuration mode.
Ruijie(config)#**interface** *interface-name interface-number*	Specifies an IPv4 network interface and enters interface configuration mode.
Ruijie(config-if)#**ip address** *ip-address mask*	Configures the IPv4 address of the interface.
Ruijie(config-if)#**nat64 enable**	Enables NAT64 on the interface.
Ruijie(config-if)#**exit**	Exits interface configuration mode and returns to global configuration mode.

Ruijie(config)#**nat64 prefix stateless** *ipv6-address/prefix-length*	Allocates an IPv6 prefix as a global Stateless NAT64 prefix.
Ruijie(config)#**nat64 route** *ipv4-prefix/length interface-name interface-number*	Configures a route which starts from an IPv4 network segment and is destined for a specific IPv6 interface. Running this command can configure a route with a specific prefix and the default route with the prefix 0.0.0.0/0 in a VRF.
Ruijie(config)#**ipv6 route** *ipv6-prefix/length interface-name interface-number nexthop-address*	Configures an IPv6 route, which is used to transmit the packets whose routes are changed to the destination IPv6 address.
Ruijie(config)#**end**	Exits global configuration mode and returns to privileged EXEC mode.

The following example configures Stateless NAT64.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface gigabitethernet 0/0
Ruijie(config-if)#ipv6 enable
Ruijie(config-if)#ipv6 address 2001:db8::1/96
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#interface gigabitethernet 0/1
Ruijie(config-if)#ip address 198.51.100.1 255.255.255.0
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#nat64 prefix stateless 2001:db8:0:1::/96
Ruijie(config)#nat64 route 203.0.113.0/24 gigabitethernet 0/0
Ruijie(config)#ipv6 route 2001:db8:0:1::/96 gigabitethernet 0/0 2001:db8::2
Ruijie(config)#ip route 0.0.0.0 0.0.0.0 198.51.100.2
Ruijie(config)#end
```

Configuring Multi-Prefix Stateless NAT64

Command	Function
Ruijie>**enable**	Enters privileged EXEC mode.
Ruijie**#configure terminal**	Enters global configuration mode.
Ruijie(config)#**ipv6 unicast-routing**	(Optional) Enables unicast routing, which is enabled by default.
Ruijie(config)#**interface** *interface-name interface-number*	Specifies an IPv6 network interface and enters interface configuration mode.
Ruijie(config-if)#**ipv6 enable**	Enables IPv6.
Ruijie(config-if)# **ipv6 address** *ipv6-address/prefix-length*	Configures the IPv6 address of the interface.
Ruijie(config-if)#**nat64 enable**	Enables NAT64 on the interface.

Ruijie(config-if)#**nat64 prefix stateless v6v4** *ipv6-address/prefix-length*	Configures the IPv6 prefix for Statelesss NAT64 (IPv6-to-IPv4 address translation) on an interface. The prefix must work with the global Stateless NAT64 prefix (v4v6). Otherwise, addresses cannot be translated.
Ruijie(config-if)#**exit**	Exits interface configuration mode and returns to global configuration mode.
Ruijie(config)#**interface** *interface-name interface-number*	Specifies an IPv4 network interface and enters interface configuration mode.
Ruijie(config-if)#**ip address** *ip-address mask*	Configures the IPv4 address of the interface.
Ruijie(config-if)#**nat64 enable**	Enables NAT64 on the interface.
Ruijie(config-if)#**exit**	Exits interface configuration mode and returns to global configuration mode.
Ruijie(config)#**nat64 prefix stateless v4v6** *ipv6-address/prefix-length*	Allocates an IPv6 prefix as a global Stateless NAT64 prefix. The prefix must work with the Stateless NAT64 prefix (v6v4). Otherwise, addresses cannot be translated.
Ruijie(config)#**nat64 route** *ipv4-prefix/length interface-name interface-number*	Configures a route which starts from an IPv4 network segment and is destined for a specific IPv6 interface. Running this command can configure a route with a specific prefix and the default route with the prefix 0.0.0.0/0 in a VRF.
Ruijie(config)#**ipv6 route** *ipv6-prefix/length interface-name interface-number*	Configures an IPv6 route, which is used to transmit the packets whose routes are changed to the destination IPv6 address.
Ruijie(config)#end	Exits global configuration mode and returns to privileged EXEC mode.

The following example configures multi-prefix Stateless NAT64.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface gigabitethernet 0/0
Ruijie(config-if)#ipv6 enable
Ruijie(config-if)#ipv6 address 2001:db8::1/96
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#nat64 prefix stateless v6v4 2001:db8:0:1::/96
Ruijie(config-if)#exit
Ruijie(config)#interface gigabitethernet 0/1
Ruijie(config-if)#ip address 198.51.100.1 255.255.255.0
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#nat64 prefix stateless v4v6 2001:db8:2::1/96
Ruijie(config)#nat64 route 203.0.113.0/24 gigabitethernet 0/0
Ruijie(config)#ipv6 route 2001:db8:0:1::/96 gigabitethernet 0/0 2001:db8::2
Ruijie(config)#ip route 0.0.0.0 0.0.0.0 198.51.100.2
Ruijie(config)#end
```

Configuring VRF-Based Stateless NAT64

Command	Function
Ruijie>**enable**	Enters privileged EXEC mode.
Ruijie**#configure terminal**	Enters global configuration mode.
Ruijie(config)#**ipv6 unicast-routing**	(Optional) Enables unicast routing, which is enabled by default.
Ruijie(config)#**interface** *interface-name interface-number*	Specifies an IPv6 network interface and enters interface configuration mode.
Ruijie(config-if)#**vrf forwarding vrf** *vrf-name*	Enables a VRF on an interface. The IPv4 and IPv6 protocol families of the VRF also need to be enabled.
Ruijie(config-if)#**ipv6 enable**	Enables IPv6.
Ruijie(config-if)# **ipv6 address** *ipv6-address/prefix-length*	Configures the IPv6 address of the interface.
Ruijie(config-if)#**nat64 enable**	Enables NAT64 on the interface.
Ruijie(config-if)#**exit**	Exits interface configuration mode and returns to global configuration mode.
Ruijie(config)#**interface** *interface-name interface-number*	Specifies an IPv4 network interface and enters interface configuration mode.
Ruijie(config-if)#**vrf forwarding vrf** *vrf-name*	Enables a VRF on an interface. The IPv4 and IPv6 protocol families of the VRF also need to be enabled.
Ruijie(config-if)#**ip address** *ip-address mask*	Configures the IPv4 address of the interface.
Ruijie(config-if)#**nat64 enable**	Enables NAT64 on the interface.
Ruijie(config-if)#**exit**	Exits interface configuration mode and returns to global configuration mode.
Ruijie(config)#**nat64 prefix stateless** *ipv6-address/prefix-length* **vrf** *vrf-name*	Configures Stateless NAT64 *ipv6-address/prefix-length* under *vrf-name*.
Ruijie(config)#**nat64 route** *ipv4-prefix/length interface-name interface-number* **vrf** *vrf-name*	Configures a route which starts from an IPv4 network segment and is destined for a specific IPv6 interface. Running this command can configure a route and the default route with the prefix 0.0.0.0/0 in a VRF.
Ruijie(config)#**ipv6 route** *ipv6-prefix/length interface-name interface-number*	Configures an IPv6 route, which is used to transmit the packets whose routes are changed to the destination IPv6 address.
Ruijie(config)#end	Exits global configuration mode and returns to privileged EXEC mode.

The following example configures VRF-based Stateless NAT64.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface gigabitethernet 0/0
Ruijie(config-if)# vrf forwarding 1
Ruijie(config-if)#ipv6 enable
Ruijie(config-if)#ipv6 address 2001:db8::1/96
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#interface gigabitethernet 0/1
Ruijie(config-if)# vrf forwarding 1
Ruijie(config-if)#ip address 198.51.100.1 255.255.255.0
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#nat64 prefix stateless 2001:db8:0:1::/96 vrf 1
Ruijie(config)#nat64 route 203.0.113.0/24 gigabitethernet 0/0 vrf 1
Ruijie(config)#ipv6 route vrf 1 2001:db8:0:1::/96 gigabitethernet 0/0 2001:db8::2
Ruijie(config)#ip route vrf 1 0.0.0.0 0.0.0.0 198.51.100.2
Ruijie(config)#end
```

Monitoring and Maintaining Stateless NAT64

Command	Function
clear nat64 stateless statistics	Clears statistics about Stateless NAT64.
debug nat64 stateless { **control** | **packet**]	Enables Stateless NAT64 debugging. Use the **no** form of this command to disable Stateless NAT64 debugging.
show nat64 stateless debug-buf	Displays the debugging buffer.
show nat64 prefix stateless [**interfaces**]	Displays all configured IPv6 prefixes of Stateless NAT64.
show nat64 stateless statistics	Displays statistics about Stateless NAT64.

Configuration Examples

Stateless NAT64 Configuration Example

Networking Requirements

Host A with the address 198.51.100.2/24 in the IPv4 domain can access Host B with the address 2001:db8:0:1::cb00:7101 in the IPv6 domain. To meet this requirement, deploy a NAT64 device (Router B) between the IPv4 domain and the IPv6 domain and configure a global IPv6 prefix for NAT64 on Router B to implement intercommunication between the two domains.

Networking Topology

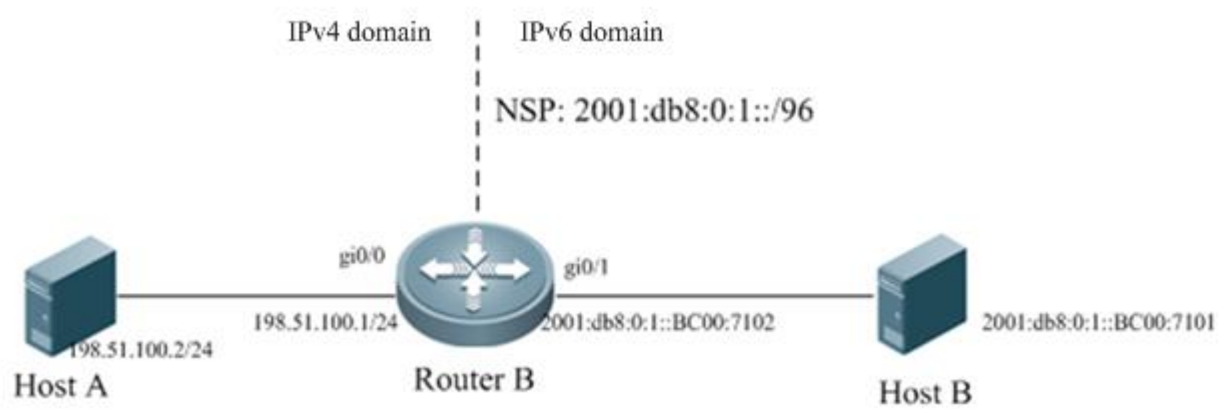

Figure 2-3 Topology of Stateless NAT64

Configuration Tips

Perform the following configurations on the Stateless NAT64 device:

- Configure the IPv6 address of an IPv6 network interface.
- Configure the IPv4 address of an IPv4 network interface.
- Configure a global NAT64 prefix and enable NAT64 on the interface.
- Configure a route which starts from the IPv4 network segment and is destined for the interface for NAT64.
- Configure a static route that is used to transmit translated packets to the IPv6 address.

Configuration Steps

5) Perform the following configurations on Router B, which serves as the Stateless NAT64 device.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)#interface gigabitethernet 0/1
Ruijie(config-if)#ipv6 enable
Ruijie(config-if)#ipv6 address 2001:db8:0:1::cb00:7102/96
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#interface gigabitethernet 0/0
Ruijie(config-if)#ip address 198.51.100.1 255.255.255.0
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#nat64 prefix stateless 2001:db8:0:1::/96
Ruijie(config)#nat64 route 203.0.113.0/24 gigabitethernet 0/1
Ruijie(config)#ipv6 route 2001:db8:0:1::/96 gigabitethernet 0/0 2001:db8:0:1::cb00:7101
Ruijie(config)#ip route 0.0.0.0 0.0.0.0 198.51.100.2
Ruijie(config)#end
```

6) On Host B

Configure the IPv6 address 2001:db8:0:1::cb00:7101/128 on Host B and configure a static route to the prefix 2001:db8:0:1::/96.

7) On Host A

Configure the IP address 198.51.100.2/24 on Host A and configure a static route to the destination network segment 203.0.113.0/24.

Verification

Run the **ping 203.0.113.1** command on Host A.

```
Ping statistics for 203.0.113.1:
   Packets: Sent = 3, Received = 3, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
Minimum = 0ms, Maximum = 0ms, Average = 0ms
Ruijie#sh nat64 stateless statistics
NAT64 Stateless Global stats:
   Created Packets translation (IPv4 -> IPv6): 0.
   Created Packets translation (IPv6 -> IPv4): 0.
   Packets droped in IPv4: 0.
   Packets droped in IPv6: 0.
NAT64 Stateless Interface stats:
   Gi0/1:
      Created Packets translation (IPv4 -> IPv6): 0.
      Created Packets translation (IPv6 -> IPv4): 0.
   Gi0/0:
      Created Packets translation (IPv4 -> IPv6): 0.
      Created Packets translation (IPv6 -> IPv4): 0.
```

Configuration Example of Multi-Prefix Stateless NAT64

Networking Requirements

Host A with the address 198.51.100.2/24 in the IPv4 domain can access Host B and Host C in different network segments of the IPv6 network. To meet this requirement, configure IPv6 prefixes on the IPv6 interfaces of different network segments on the Stateless NAT64 device (Router B).

Networking Topology

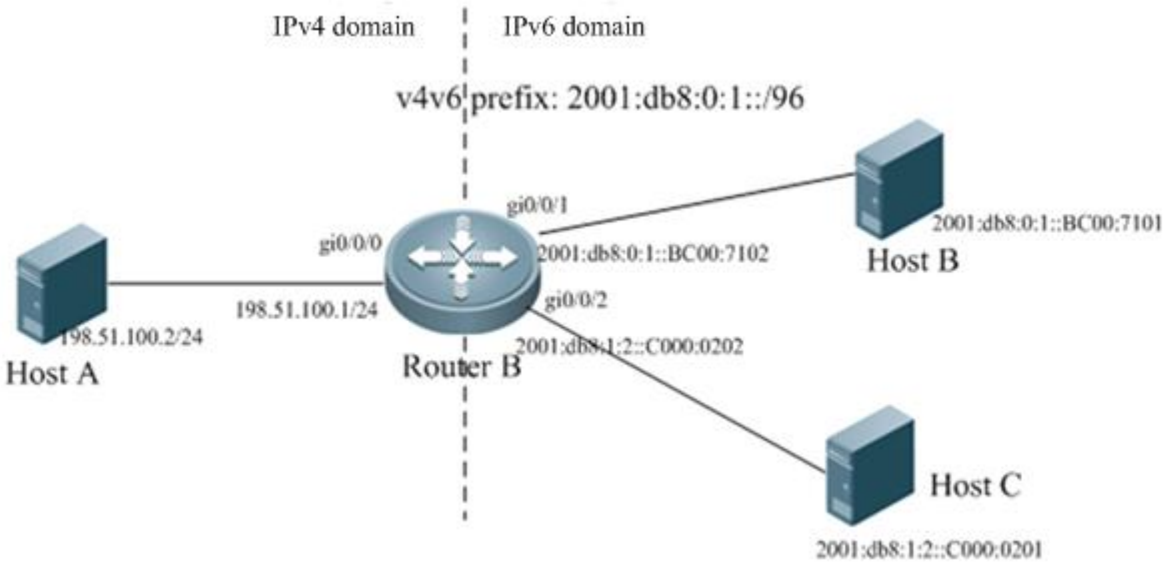

Figure 2-4 Multi-Prefix Stateless NAT64

Host A accesses Host B and Host C in two IPv6 network segments.

Configuration Tips

Perform the following configurations on the Stateless NAT64 device:

- Configure the IPv6 address of an IPv6 network interface, enable NAT64, and configure the Stateless NAT64 prefix (v6v4).
- Configure the IPv4 address of an IPv4 network interface and enable NAT64.
- Configure the Stateless NAT64 prefix (v4v6) in global mode.
- Configure a route which starts from an IPv4 network segment and is destined for the IPv6 interface for NAT64.
- Configure a static route that is used to transmit translated packets to the IPv6 address.

Configuration Steps

8) Perform the following configurations on Router B, which serves as the Stateless NAT64 device.

```
Ruijie#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Ruijie(config)# interface gigabitethernet 0/0/0
Ruijie(config-if)#ip address 198.51.100.1 255.255.255.0
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#exit
Ruijie(config)#interface gigabitethernet 0/0/1
Ruijie(config-if)#ipv6 enable
Ruijie(config-if)#ipv6 address 2001:db8:0:1::cb00:7102/96
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#nat64 prefix stateless v6v4 2011:db8:0:1::/96
Ruijie(config-if)#exit
Ruijie(config)#interface gigabitethernet 0/0/2
Ruijie(config-if)#ipv6 enable
Ruijie(config-if)#ipv6 address 2001:db8:1:2::C000:0202/96
Ruijie(config-if)#nat64 enable
Ruijie(config-if)#nat64 prefix stateless v6v4 2011:db8:1:2::/96
Ruijie(config-if)#exit
Ruijie(config)#nat64 prefix stateless v4v6 2011:db8:2::1/96
Ruijie(config)#nat64 route 203.0.113.0/24 gigabitethernet 0/0/1
Ruijie(config)#ipv6 route 2011:db8:0:1::/96 gigabitethernet 0/0/1 2001:db8:0:1::cb00:7101
Ruijie(config)#nat64 route 0.0.0.0/0 gigabitethernet 0/0/2
Ruijie(config)#ipv6 route 2011:db8:1:2::/96 gigabitethernet 0/0/2 2001:db8:1:2::C000:0201
Ruijie(config)#end
```

9) On Host B

Configure the IPv6 address 2001:db8:0:1::cb00:7101/128 on Host B and configure a static route to the prefix 2001:db8:0:1::/96.

10) On Host C

Configure the IPv6 address 2001:db8:0:1::c000:0201/128 on Host C and configure a static route to the prefix 2001:db8:1:2::/96.

11) On Host A

Configure the IPv6 address 198.51.100.2/24 on Host A and configure a static route to the destination network segment 203.0.113.0/24.

Verification

Run the **ping 203.0.113.1** command on Host A.

```
Ping statistics for 203.0.113.1:
   Packets: Sent = 3, Received = 3, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
Minimum = 0ms, Maximum = 0ms, Average = 0ms
```

Run the **ping 192.0.2.1** command on Host A.

```
Ping statistics for 192.0.2.1:
   Packets: Sent = 3, Received = 3, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
Minimum = 0ms, Maximum = 0ms, Average = 0ms
Ruijie#sh nat64 stateless statistics
NAT64 Stateless Global stats:
   Created Packets translation (IPv4 -> IPv6): 16.
   Created Packets translation (IPv6 -> IPv4): 31.
   Packets droped in IPv4: 0.
   Packets droped in IPv6: 0.
```

```
NAT64 Stateless Interface stats:
   Gi0/0/0:
      Created Packets translation (IPv4 -> IPv6): 16.
      Created Packets translation (IPv6 -> IPv4): 0.
   Gi0/0/1:
      Created Packets translation (IPv4 -> IPv6): 0.
      Created Packets translation (IPv6 -> IPv4): 19.
   Gi0/0/2:
      Created Packets translation (IPv4 -> IPv6): 0.
      Created Packets translation (IPv6 -> IPv4): 12.
```
